The question continues to be a matter of debate and based on their trial with 608 patients, Manes *et al* argue that high-risk patients may benefit from GM. They administered GM either before or after ERCP compared to a saline solution. The incidence of PEP was 9.4% in the placebo group, and significantly lower ( $P < 0.01$ ) in the GM groups regardless of the time GM was administered

(before ERCP 3.9%, after ERCP 3.4%)<sup>[33]</sup>.

The FDA does not approve GM and the use of GM is not recommended in published guidelines concerning the treatment of AP<sup>[4,2,34]</sup>. However, Japanese national guidelines recommend the use of protease inhibitors either applied intravenously or as CRAI<sup>[35]</sup> and GM is also approved in Italy where it is also used as prophylaxis against PEP<sup>[36]</sup>.

### Antioxidants

Oxidative stress most likely plays a major role in the early development of AP<sup>[37]</sup> and several experimental animal models show a beneficial effect of anti-oxidative drugs<sup>[38-44]</sup>. In humans depletion of antioxidants is observed in AP<sup>[45,46]</sup> correlating to the severity of the disease<sup>[47]</sup>.

Therapy with antioxidants administered intravenously has been investigated in a prospective double-blind placebo controlled randomized trial on patients with predicted severe AP but no effect on mortality could be demonstrated<sup>[48]</sup>. The prophylactic effect on the incidence of PEP was tested in two randomized prospective randomized trials with 256 and 106 patients, respectively. N-acetylcysteine (NAC) was administered before and after ERCP and both studies concluded that NAC was without any preventive effect<sup>[49,50]</sup>. Thus, there is no evidence for the use of NAC.

### NGL

NGL is a donor of nitrogen oxide (NO), which causes vasodilatation and reduces cardiac preload. The main indication for using NGL is angina pectoris<sup>[51]</sup>.

Experimental animal models have shown reduced pancreatic edema when administering NO as an infusion<sup>[52]</sup>, but until now no clinical randomized trials using NGL in the treatment of AP have been published. As prophylaxis prior to ERCP three prospective randomized trials have evaluated NGL. NO induces periampullary sphincter relaxation and dilation of the micro vascular vessels, which hypothetically improve pancreatic circulation and nutrition<sup>[53]</sup>.

Sudhindran *et al* observed in a study of 186 patients randomized to either NGL 2 mg sublingual 5 min prior to ERCP or placebo, an incidence of PEP in the NGL group of 8% compared to 18% ( $P < 0.05$ ) in the placebo group<sup>[54]</sup>. This finding was supported by Moreto *et al* who randomized 144 patients to either NGL as dermal patch or placebo, and found a significant reduction in the incidence of PEP (4% *vs* 16%,  $P < 0.05$ )<sup>[55]</sup>. Both studies have been criticized for having a surprisingly high incidence of PEP in the placebo groups<sup>[56]</sup>. In a recently published prospective randomized trial of 318 patients the overall incidence of PEP was 7.5% and no significant difference between the NGL group and the placebo group was revealed<sup>[57]</sup>.

NGL has the optimal qualities as a prophylactic agent as it is cheap and easy to administer. However further trials are needed to determine its potential use as prophylaxis against PEP.

### Corticosteroids

Corticosteroids are potent unspecific anti-inflammatory

drugs utilized in a variety of inflammatory diseases. Several case reports have suspected steroids of being the etiology to iatrogenic AP but a definitive relationship has not been established<sup>[58-60]</sup>.

In rat models of AP hydrocortisone has reduced mortality and blood cytokine levels<sup>[61,62]</sup>. No human trials using steroids as treatment of AP have been published and attempts to show a beneficial effect of steroids as prophylaxis against PEP in prospective placebo-controlled trials have so far been disappointing. In 1999 De Palma *et al* randomized 539 patients to either placebo ( $n = 266$ ) or hydrocortisone 100 mg ( $n = 273$ ) administered intravenously prior to ERCP. The total incidence of PEP was 5.3% ( $n = 28$ ) and no significant difference between the two groups could be demonstrated<sup>[63]</sup>. In a Polish trial published in 2001, 300 patients received oral prednisone 40 mg, allopurinol 200 mg or placebo 15 h and 3 h prior to ERCP. The total incidence of PEP was 10.7% and no significant difference among the three groups was displayed<sup>[64]</sup>. Sherman *et al* have confirmed these negative findings in an even larger prospective trial with 1115 patients<sup>[65]</sup>.

Although steroids have the potential to inhibit the inflammatory cascade there is no evidence for the use of neither hydrocortisone nor prednisone as prophylaxis against PEP.

### NSAID

NSAID have an analgesic as well as an anti-inflammatory effect. Most NSAID act as non-selective inhibitors of the enzyme COX which catalyses the formation of prostaglandins and thromboxane from arachidonic acid. NSAID are used for virtually every known inflammatory disease.

Salicylic acid and indomethacin have in isolated case reports been related to the development of AP<sup>[66-68]</sup> as has the selective cyclooxygenase (COX)-2 inhibitor celecoxib<sup>[69-72]</sup>.

Experimental animal models studying the effect of NSAID on AP have been contradictory and not revealed any effect on mortality<sup>[73-76]</sup>.

The only randomized human study on the therapeutic effect of NSAID on AP has been conducted by Ebbelhøj *et al* who included 30 patients randomized in two groups receiving either indomethacin suppositories 50 mg twice daily for 7 d or placebo. No difference in serum amylase or calcium was observed but patients in the indomethacin group demanded less opiate as analgesics during hospitalization. Mortality was not registered<sup>[77]</sup>.

Two studies testing the prophylactic effect of indomethacin given prior to ERCP to prevent PEP have been published. Montano *et al* included 117 patients, who received either indomethacin suppositories 100 mg or placebo 2 h prior to ERCP. The incidence of PEP was 2.5% and 6.8% respectively but the difference was not significantly different<sup>[78]</sup>. In a larger study from Iran 490 participants received 100 mg indomethacin suppositories or placebo and an incidence of PEP of 3.2% in the indomethacin group and 6.8% in the placebo group was observed. The difference was only borderline significant different ( $P = 0.06$ ) and a post hoc analysis showed

significant lower incidence of PEP in the subpopulation of patients who underwent pancreatography<sup>[79]</sup>. However this conclusion was hampered by the fact that the post hoc analysis was conducted on 10 subpopulations, which in general reduces the statistical power considerably<sup>[80]</sup>.

Another NSAID, diclofenac, has been investigated in a study including 220 patients receiving either diclofenac suppositories 100 mg or placebo immediately after ERCP. PEP occurred with lower frequency in the group receiving diclofenac compared to the placebo group (6% *vs* 15%,  $P < 0.05$ )<sup>[81]</sup>.

The overall impression from placebo-controlled trials suggests a beneficial effect of NSAID used as prophylaxis against PEP. Both diclofenac and indomethacin can be administered easily as suppositories and are inexpensive drugs. Still, placebo controlled randomized trials with a larger sample size are needed to verify this promising effect.

### IL-10

IL-10 is produced and released by the helper T cells and its primary effect is anti-inflammatory. Clinical observations have shown increased levels of IL-10 in the blood during AP but its role in the treatment of AP remains to be determined<sup>[82,83]</sup>. The effect of IL-10 on AP has been validated in two experimental studies which showed a reduced mortality<sup>[84,85]</sup>.

No human study on the therapeutic effect of IL-10 has been conducted but the prophylactic effect of IL-10 on PEP has been evaluated in two randomized studies. No significant difference among the IL-10 and placebo-treated group was observed in a study with 200 patients receiving either recombinant IL-10 (8 µg/kg) or placebo (9% *vs* 11%,  $P = 0.65$ )<sup>[86]</sup>. A second study randomized 137 patients to placebo or IL-10 (4 µg/kg or 20 µg/kg) administered 30 min prior to ERCP. Overall incidence of PEP was 14% and a significant difference in the incidence among the three groups was noted (24%, 10%, and 7%). However the incidence of PEP in the placebo was remarkable high<sup>[87]</sup>.

The results from these two published studies do not definitively support the use of IL-10 as prophylaxis against PEP.

### TNF-α

During AP the serum level of TNF-α is elevated<sup>[88,89]</sup>. The synthesis and release of TNF-α takes place in macrophages located in the pancreas. SAC may as well release TNF-α and do also express TNF-α receptors during AP<sup>[90-92]</sup>. A possible relationship between genetic polymorphism and severity of AP has been established<sup>[93]</sup>.

Blocking the TNF-α mediated inflammation with anti-TNF-α antibodies or pentoxifylline seems to have a beneficial effect on histology score and mortality in experimental animal models<sup>[94-98]</sup>.

No data on humans has hitherto been published apart from a single case-report concerning a patient with interstitial pancreatitis. In this case, a male patient with severe bloody diarrhea due to segmental Crohn's disease also showed signs of AP. Serum amylase was high and ultrasound and abdominal computer tomography (CT) scans revealed an edematous pancreas. Because of these

findings treatment with steroids and azathioprine was abandoned and instead a single infusion with infliximab 5 mg/kg was administered without complications. The patient's overall condition improved and serum amylase levels normalized<sup>[99]</sup>.

Thus experimental data suggest a potential role of specific TNF- $\alpha$  inhibition in the treatment of AP, but high risk of bacterial infection during AP is a matter of concern. Infliximab has been evaluated in alcoholic hepatitis, another condition associated with a high risk of bacterial infection. The administration of prednisolone 40 mg daily and infliximab 10 mg/kg at wk 0, 2 and 4 showed an increased mortality due to infection and the study was terminated prematurely by the monitoring committee<sup>[100]</sup>.

Hence clinical studies on AP must be carefully designed to evaluate the safety of infliximab or other specific TNF- $\alpha$  inhibitor.

### PAF

PAF was discovered in the 1970's and soon recognized to be an important inflammatory mediator<sup>[101]</sup>. Later studies with experimental pancreatitis revealed that PAF is released during AP<sup>[102]</sup> and induce AP when infused in arteries supplying the pancreas<sup>[103,104]</sup>. Experimental studies have shown a benefit from PAF inhibition with various antagonists on pancreatic edema and systemic inflammation as well as a decreased bacterial translocation<sup>[105-107]</sup>.

As a consequence of the promising results with experimental AP different clinical studies have evaluated the effect of PAF inhibition. The first trial consisted of 83 patients with AP receiving lexipafant ( $n = 42$ ) or placebo ( $n = 41$ ). Lexipafant was administered intravenously (60 mg/d for 3 d) and follow-up was assessed for 5 d by Organ Failure Score (OFS). The investigators reported a greater reduction in OFS in the lexipafant group (0.905 *vs* 0.341,  $P = 0.048$ ), but during the 5 d period mortality was unaffected<sup>[108]</sup>. These findings were confirmed in a second trial including only patients with severe AP. The participants received lexipafant ( $n = 27$ ), 100 mg/d for 5-7 d or placebo ( $n = 23$ ). In the treatment group a larger reduction in OFS was registered (1.42 *vs* 0.17,  $P = 0.003$ ). Overall mortality was 18% with no difference between the groups<sup>[109]</sup>. The last study was published in 2001 and involved 286 patients with severe AP. Lexipafant (100 mg/d,  $n = 148$ ) or placebo ( $n = 138$ ) was administered for 7 d. No positive effect could be shown neither on OFS nor mortality<sup>[110]</sup>. It has been argued that data on the effect of lexipafant on mortality from experimental AP were warranted before initiation of human trials and the sponsor's communication of the result has been questionable<sup>[111]</sup>. After the termination of the clinical trials the lack of effect on mortality in experimental AP was acknowledged<sup>[112]</sup>. Randomized trials on sepsis were also disappointing<sup>[113,114]</sup> and inhibition of PAF in the treatment of AP has thus been abandoned.

### Antibiotics

Antibiotics is used to prevent or treat infected necrosis in

the pancreas and does not have potential to change the pathobiologic course of AP. Infected necrosis in pancreas is a major clinical problem during AP which severely deteriorate the prognosis<sup>[115,116]</sup>. Hence, administration of antibiotics to prevent infection has been evaluated in several randomized trials.

Sainio *et al* randomized 60 patients with necrotizing pancreatitis. The inclusion criteria were C-reactive protein > 120 mg/L and pancreatic necrosis verified by an abdominal CT scan. The treated group received infusion of cefuroxim 1.5 g  $\times$  3 daily, while patients allocated to the control group only received antibiotics in case of clinical signs of infection. A significant higher mortality was registered in the control group compared to the cefuroxim group (23% *vs* 3%,  $P = 0.03$ )<sup>[117]</sup>.

Pederzoli *et al* randomized 74 patients with CT verified pancreatic necrosis to receive either imipenem or placebo but no effect on mortality was registered<sup>[118]</sup>. In another prospective randomized study with 90 patients Nordback *et al* administered imipenem intravenously 1.0 g  $\times$  3 daily and found a reduced incidence of multiorgan failure compared to the control group (28% *vs* 76%,  $P = 0.0003$ ) but no difference in mortality<sup>[119]</sup>.

The studies described above are open-label trials. In 2004 Isenmann *et al* published a controlled double-blind study of 114 patients with CT verified necrotizing AP. The inclusion criteria were C-reactive protein > 150 mg/L and/or CT-verified pancreas necrosis. Placebo was compared to a combination of ciprofloxacin and metronidazole and if any complications occurred the treatment was converted to open conventional treatment. No difference in mortality or incidence of pancreas necrosis could be shown<sup>[120]</sup>.

A Cochrane meta-analysis of 294 patients with CT-verified pancreas necrosis showed a reduced mortality in patients with necrotizing AP when beta-lactams and quinolones were administered intravenously as prophylaxis<sup>[121]</sup>.

The subject continues to be a matter of debate and recommendations from major clinical associations have different approaches to this issue<sup>[4,2,34]</sup>.

Studies on the effect of prophylactic antibiotics given prior to ERCP are limited. In a study by Raty *et al* with 315 patients cephtazidime was administered intravenously prior to ERCP compared with a control group. They found reduced incidence of PEP and cholangitis in the treatment group (3% *vs* 9%,  $P = 0.009$ )<sup>[122]</sup>. However the study was not placebo-controlled and routine administration of antibiotics prior to ERCP cannot be recommended until randomized placebo controlled studies confirm this finding.

### Probiotics

Intestinal permeability is increased during AP, which may facilitate translocation of bacteria from the intestinal lumen. Oral probiotics are living microorganisms that exert health benefits beyond those of inherent basic nutrition<sup>[123]</sup>.

Olah *et al* conducted two prospective placebo controlled double-blinded studies of the therapeutic effect of probiotics to AP. The studies were published in 2002

and 2007 including 45 and 62 patients with interstitial or severe AP. In the latter study reduced mortality in the probiotics groups was observed but the difference was not statistical significant<sup>[124,125]</sup>.

## CONCLUSION

As described in this review we only have limited evidence based pharmacological approaches when treating AP and none of these are curative. Several treatments including animal experimental studies have been tried in order to establish evidence for etiology based medical treatment (Tables 1 and 2). In Italy and Japan gabexate is used routinely with the aim to limit pancreatic auto-digestion, but as reported in this review there is no conclusive evidence for this approach.

Ocreotide may be considered as prophylaxis against PEP but high cost of this peptide hormone limits its potential in clinical practice. A much cheaper alternative is NSAID, which may be considered as prophylaxis against PEP.

Antibiotics are the drugs of choice when infection is evident. However, recommendations regarding the prevention of infected pancreatic necrosis are contradictory.

Various problems are encountered when designing clinical studies of AP. The low incidence of severe necrotizing AP constitutes a major problem, which demands multicenter studies. Another clinical challenge is the resemblance of AP to infection and before initialization of any experimental anti-inflammatory therapy bacterial infection must be refuted. This delays the start-up of the experimental protocol and causes bias as the patients in the meantime receive anti-bacterial treatment. A possible solution could be to administer antibiotics to all patients in combination with specific anti-inflammatory treatment or placebo.

In spite of these challenges the search for pharmacological treatment of AP must be sustained. As we present in this review experimental animal models support a potential effect of several anti-inflammatory drugs, which are candidates for randomized trials. The most interesting of these potential drugs is probably steroids, which are standard treatment of numerous inflammatory diseases but have never been investigated in the treatment of AP.

Because the outcome of the disease depends highly on the involvement of other organs, developing methods that inhibit the inflammatory signaling pathways presents a great potential. As new information regarding the inflammatory pathways continues to emerge from animal and clinical trials, specific treatment targeting these inflammatory processes should be considered. It is our opinion that animal models at this time support clinical trials with anti-TNF- $\alpha$  antibodies although a randomized trial must be designed not forgetting the safety issue.

### Abstract

Pancreatic cystic neoplasms are being increasingly recognized, even in the absence of symptoms, in large part, due to markedly improved imaging modalities such as magnetic resonance imaging (MRI)/magnetic resonance cholangio pancreatography (MRCP) and computer tomography (CT) scanning. During the past 2 decades, better imaging of these cystic lesions has resulted in definition of different types, including pancreatic intraductal papillary mucinous neoplasms (IPMN). While IPMN represent only a distinct minority of all pancreatic cancers, they appear to be a relatively frequent neoplastic form of pancreatic cystic neoplasm. Moreover, IPMN have a much better outcome and prognosis compared to pancreatic ductal adenocarcinomas. Therefore, recognition of this entity is exceedingly important for the clinician involved in diagnosis and further evaluation of a potentially curable form of pancreatic cancer.

### INTRODUCTION

Due to increasing precision of modern imaging modalities, particularly computer tomography (CT) scanning (with contrast enhancement) and magnetic resonance imaging (MRI)/magnetic resonance cholangio pancreatography (MRCP), pancreatic cystic lesions are commonly being detected. This has been reported in up to 25% of patients, particularly with increasing age<sup>[1,2]</sup>. From a pathological rather than imaging perspective, however, a cyst is formally defined as a fluid-filled and closed cavity with an epithelial lining. In the pancreas (as opposed to liver and spleen), cyst-like lesions have special significance as different neoplasms in the pancreas are true cysts, or alternatively, may appear cystic either from dilation of a tumor obstructed or stenosed pancreatic duct or from necrotic changes and degeneration within a solid neoplastic lesion, possibly from rapid tumor growth that outstrips its blood supply.

Most commonly, a pancreatic cystic lesion defined by imaging represents a pseudocyst, usually due to alcoholic pancreatitis. Pseudocysts are distributed evenly throughout the pancreas and have no evident risk of malignancy. In a pseudocyst, no epithelial lining is present. As such, the pathological criteria for a true cyst (despite its cystic imaging appearance) are not satisfied. Most other true cysts (with the exception of congenital pancreatic cysts) are neoplastic and, therefore, these represent a potentially significant clinical finding<sup>[3,4]</sup>. A number of different neoplastic cystic lesions in the pancreas have been identified and labeled as capitalized abbreviations (Table 1)<sup>[4]</sup>. As prognosis for each type of cystic neoplasm may differ, precise definition of any imaged cystic lesion, even if asymptomatic or incidentally detected, is crucial<sup>[5]</sup>.

### NEOPLASTIC PANCREATIC CYSTIC LESIONS

Most neoplastic cystic lesions of the pancreas occur in young or middle-aged females [serous cystadenoma (SCA), mucinous cystic neoplasia (MCN), and solid pseudo-papillary neoplasia (SPN)], however, intraductal papillary mucinous neoplasms (IPMN) are most often detected in elderly males (more so than females)<sup>[4]</sup>. Most cystic neoplasms are evenly distributed throughout the pancreas, however, the pancreatic head and uncinate process are

Table 1 Types of pancreatic cystic neoplasms

Types of pancreatic cystic neoplasms
Serous cystadenoma, or SCA
Mucinous cystic neoplasm, or MCN
Intraductal papillary mucinous neoplasm, or IPMN
Solid pseudopapillary neoplasm (with degeneration), or SPN
Cystic necrosis (endocrine tumor, ductal adenocarcinoma)

most common sites for IPMN while the body and tail are most common sites for MCN<sup>[4]</sup>. For most cystic types, malignant potential appears to be low, except for MCN and rapidly growing pancreatic ductal adenocarcinomas or even more rare endocrine neoplasms<sup>[4]</sup>. In contrast, most IPMN are slow growing and have low malignant potential, with a much better prognosis, especially if compared to pancreatic ductal adenocarcinoma<sup>[4]</sup>. Thus, their recognition is significant because an opportunity may be present at the time of recognition to resect surgically this type of pancreatic cystic neoplasm.

## INTRADUCTAL PAPILLARY MUCINOUS NEOPLASMS

IPMN appears to be quite a unique type of neoplasm, representing a broad spectrum of mucin-producing lesions of the exocrine pancreas classified as benign adenomas to invasive carcinoma. IPMN appear to arise from the epithelium of the main duct or its branches, often with variable duct dilation and IPMN are also believed by some to follow the so-called “adenoma-carcinoma” sequence. Neoplastic cells are most often papillary, although flat epithelium may also be defined.

IPMN of pancreas represents up to one-third of all pancreatic cystic neoplasms, but only about 1% of all pancreatic cancers<sup>[3,6]</sup>. Of particular note, IPMN also represents about 25% of all surgically resected pancreatic neoplasms, again likely emphasizing the critical significance of early recognition<sup>[6]</sup>. IPMN was first described by Ohhashi and colleagues in 1982 followed by a notation by the same group of a very prolonged survival (over a quarter century) of a case of IPMN<sup>[7]</sup>. The first series of North American patients were described only in 1990<sup>[8]</sup>. Since then, interest in this neoplasm appears to have increased exponentially as reflected in the annual number of publications in Medline from 1994 to 2006 related to IPMN noted elsewhere<sup>[6]</sup>. Interestingly, IPMN has also been documented to be multifocal and there is a higher occurrence rate of synchronous extrapancreatic malignancies (compared to pancreatic ductal adenocarcinoma)<sup>[9]</sup>. Finally, independent synchronous or metachronous pancreatic ductal adenocarcinomas<sup>[10]</sup> as well as endocrine tumors<sup>[11]</sup> with IPMN have also been described.

Based on anatomic involvement of the pancreatic duct, IPMN of the pancreas may predominantly involve the main pancreatic duct (“main duct type”), secondary ducts (“branch duct type”) or both (“mixed type”). Branch duct type IPMN are usually smaller, less papillary and

tend to occur in the periphery of the pancreatic head or in the distal pancreas. Malignant transformations occur less often in the branch duct type. Evidence suggests that asymptomatic branch duct IPMN less than 3 cm in size without mural nodules, thickened septa or high grade dysplasia have a relatively benign biological behavior and should be considered optimal candidates for surgical treatment<sup>[6]</sup>.

Diagnosis may be enhanced by MRCP combined with dynamic imaging since this improves localization, staging and, most important, the potential for surgical resectability. A contrast-enhanced CT scan may also yield added information regarding invasion, but also the relationship of the lesion to contiguous organs and vessels. Finally, endoscopic visualization of a patulous or so-called “fish-eye” papilla of Vater, especially at the time of ERCP may be helpful, if not pathognomonic. ERCP also permits an opportunity for added sampling of ductal content for cytology. Endoscopic ultrasonograph (EUS) may also provide added imaging information and permit fine needle aspiration biopsy although some concerns have been raised regarding the risk of seeding and dissemination of malignant cells<sup>[4]</sup>. Positron emission tomographic scanning may be helpful but its role needs to be better defined. Finally, serological studies including CA 19-9 and CEA may serve some value but it is limited since these are reported to be elevated in less than 20% of IPMN<sup>[4]</sup>. For pre-operative evaluation, all of these investigations may provide useful information, but are most important if surgical resection is being contemplated. Unfortunately, some patients are older with other concomitant health issues. In these, surgical treatment and resection may not lead to a significant positive long-term result and, as in these patients, even a more judicious approach to invasive evaluative investigations may be reasonable. If surgical excision is complete, recurrence may still occur, usually at a distant site, but this rate of recurrence is limited, and the overall 5-year survival rate has been reported to exceed 80% for noninvasive IPMN and approximately 50% for malignant invasive IPMN. Thus, accurate evaluation of IPMN is exceedingly important as a recent analysis<sup>[4]</sup> has suggested that this is one of the few surgically curable pancreatic neoplasms.

### Abstract

Proton Pump Inhibitors (PPI) are very effective in inhibiting acid secretion and are extensively used in many acid related diseases. They are also often used in patients with cirrhosis sometimes in the absence of a specific acid related disease, with the aim of preventing peptic complications in patients with variceal or hypertensive gastropathic bleeding receiving multidrug treatment. Contradicting reports support their use in cirrhosis and evidence of their efficacy in this condition is poor. Moreover there are convincing papers suggesting that acid secretion is reduced in patients with liver cirrhosis. With regard to *Helicobacter pylori* (*H. pylori*) infection, its prevalence in patients with cirrhosis is largely variable among different studies, and it seems that *H. pylori* eradication does not prevent gastro-duodenal ulcer formation and bleeding. With regard to the prevention and treatment of oesophageal complications after banding or sclerotherapy of oesophageal varices, there is little evidence for a protective role of PPI. Moreover, due to liver metabolism of PPI, the dose of most available PPIs should be reduced in cirrhotics. In conclusion, the use of this class of drugs seems more habit related than evidence-based eventually leading to an increase in health costs.

### INTRODUCTION

Proton Pump Inhibitors (PPI) are extensively used in different acid related diseases. Their efficacy in inhibiting acid secretion is well known<sup>[1-4]</sup>, and the use of this class of drugs has increased worldwide. They act through inhibition of the H<sup>+</sup>/K<sup>+</sup> ATPase of parietal cells producing the so called “inhibitory complex” and blocking HCl secretion<sup>[5]</sup>. They are metabolized in the liver by the CYP450 cytochrome<sup>[6]</sup>.

PPI are also often used in patients with liver cirrhosis sometimes in the absence of a specific acid related disease, with the aim of preventing peptic complications in patients with variceal or hypertensive gastropathic bleeding receiving multidrug treatment.

The aim of this editorial is to revise the efficacy and safety profile of PPI in patients with liver cirrhosis.

### GASTRIC ACID SECRETION AND LIVER CIRRHOSIS

The role of gastric secretion in cirrhosis is controversial. Some studies report reduced acid production<sup>[7-10]</sup> while others reported normal production<sup>[11-15]</sup>. The evaluation of 24-h acidity by gastric pH-metry in 49 patients with cirrhosis showed a marked hypoacidity in patients with cirrhosis compared to controls, mainly during the night hours<sup>[16]</sup>. This may depend on hemodynamic alterations consequent to portal hypertension and is supported by experimental studies showing reduced gastric acid secretion in animals with portal hypertension<sup>[17,18]</sup>. These observations rule out the relevance of gastric acid in the pathogenesis of ulcers in cirrhotics.

Gastrin, the gastric hormone whose secretion is regulated by intragastric pH, and that regulates the production of HCl and pepsin, is partially metabolized

**Table 1** Prevalence of peptic ulcer in patients with liver cirrhosis

Investigator	Number of patients	Gastric ulcer prevalence (%)
Siringo, 1995	324	4.6
Chen, 1996	245	20.8
Tsai, 1998	130	16.1
Kirk, 1980	163	14.7
Rabinovitz, 1990	216	7.8

by the liver and mainly by the kidneys. Gastrin is elevated in serum of patients with *Helicobacter pylori* (*H. pylori*) infection or atrophic gastritis. Few studies have evaluated gastrin levels in cirrhosis, and their contribution towards understanding the pathophysiology of gastric acid secretion is very limited. Avgerinos *et al*<sup>[19]</sup> evaluated the urinary gastrin output in patients with cirrhosis with and without hepato-renal syndrome. Serum gastrin levels were higher in cirrhotics compared to controls; and in cirrhotics with hepato-renal syndrome the difference was greater suggesting that impaired urinary gastrin secretion may contribute to their hypergastrinemia. The same results were found by Lo *et al*<sup>[11]</sup> who also showed a significantly lower maximal pepsin output in cirrhotics compared to controls.

Progastrin and gastrin serum levels have been reported to be significantly higher in patients with cirrhosis of any Child-Pugh class compared to controls while there are no differences between controls and patients with chronic hepatitis B or C<sup>[20]</sup>. Indeed, it is important to note that in this study, the prevalence of *H. pylori* infection in cirrhotic patients was 83% *versus* 50% in controls. Therefore, it is not clear whether the difference in progastrin and gastrin level was due to reduced liver metabolism, to *H. pylori* infection, or both. In summary, gastrin increase in patients with liver cirrhosis could be related to: (1) impaired hepatic gastrin catabolism; (2) impaired renal function, at least in those with HRS; (3) gastric mucosal alteration due to gastropathy-related cirrhosis.

## PEPTIC ULCERS AND LIVER CIRRHOSIS

Many authors reported an increased prevalence of peptic ulcers in patients with cirrhosis<sup>[21,22]</sup> and it was shown that cirrhotics have an increased risk of developing gastric or duodenal ulcers during an interval of one year compared to non cirrhotics<sup>[23]</sup>. The prevalence of peptic ulcers ranges between 4.6% and 21% in patients with cirrhosis<sup>[21,22,24-26,39]</sup> (Table 1). However, the pathogenesis of this finding is far from being elucidated and different factors have been proposed in relation to increased ulcer prevalence in patients with cirrhosis. Furthermore the prevalence of duodenal and gastric ulcers in patients with liver cirrhosis increases with disease progression<sup>[27]</sup> (Table 2). Several theories have been postulated. It has been demonstrated that the gastric mucosa in rats with portal hypertension is more susceptible to aggressive agents such as bile acids, aspirin and alcohol<sup>[28]</sup>. Some investigators have attributed to portal hypertension itself the increased risk of peptic ulcer<sup>[29]</sup>, nevertheless no

**Table 2** Gastric and duodenal ulcer in patients with liver cirrhosis according to the severity of portal hypertension (from Wu *et al* 1995)

	Controls (n = 60)		Compensated cirrhosis (n = 60)		Decompensated cirrhosis (n = 60)		P
	n	%	n	%	n	%	
Duodenal ulcer	2	3.3	10	16.7	8	13.3	0.046
Gastric ulcer	1	1.7	2	3.3	9	15.0	0.006
All ulcers	3	5.0	12	20.0	17	28.3	0.003

study has clarified the pathogenesis of peptic ulceration in cirrhosis.

## H PYLORI IN PATIENTS WITH LIVER CIRRHOSIS

The prevalence of *H. pylori* in patients with cirrhosis has been investigated in many epidemiological studies with values ranging from 27% to 89%<sup>[24,27,30-33]</sup>. This large variability may be due to the test used to evaluate *H. pylori* infection. In the study with the largest prevalence of *H. pylori* infection, values were obtained by titration of serum IgG, against *H. pylori*. The tests usually used for evaluating the presence of *H. pylori* should be revised since haemodynamic alterations in cirrhosis could impair the results of urea 13C BT, and hypergammaglobulinemia typical of cirrhosis, might produce a false positive test<sup>[34-38]</sup>. Italian studies generally and sometimes significantly showed a higher prevalence than in non cirrhotic patients, while studies from Taiwan failed to show a similar trend. When evaluating the prevalence of *H. pylori* infection in cirrhotics there seems to be no relationship between the aetiology of cirrhosis and the prevalence of *H. pylori* evaluated by determination of serum IgG<sup>[24]</sup>. The role of *H. pylori* in determining peptic ulceration in cirrhosis is controversial: some authors conclude that the increased risk of gastroduodenal ulcer is not related to *H. pylori* infection, whilst others conclude that peptic disease and non-ulcer dyspepsia are firmly linked to *H. pylori* infection<sup>[32,39-41]</sup>. A meta-analysis showed an increased risk of ulcers developing in patients with *H. pylori* infection and cirrhosis<sup>[42]</sup>.

If *H. pylori* infection were an etiopathological factor implicated in digestive bleeding in cirrhosis, eradication of infection would decrease the risk of ulcer recurrence. However a study aiming to investigate the role of *H. pylori* eradication in cirrhotics demonstrated a similar recurrence rate between cirrhotics with successful *H. pylori* eradication and those with active *H. pylori* infection<sup>[43]</sup>. In conclusion, the role of *H. pylori* infection in the occurrence of gastric or duodenal ulcers or in determining digestive bleeding in the setting of liver cirrhosis is still unclear.

## ESOPHAGEAL DISORDERS AND LIVER CIRRHOSIS

It has been postulated in the past, that gastro-esophageal reflux may contribute to oesophagitis and variceal

bleeding in cirrhotic patients<sup>[44]</sup>, and acid reflux could be exacerbated by the presence of ascites and water retention<sup>[45]</sup>. More recent papers do not confirm these hypotheses<sup>[46,47]</sup> and report a high incidence of gastro-esophageal reflux only in patients with alcoholic cirrhosis, though the presence of reflux did not correlate with disease severity or bleeding episodes<sup>[48]</sup>. Functional studies showed decreased lower esophageal sphincter function with low amplitude of primary peristalsis and acid clearance in patients with large varices<sup>[49-51]</sup>. These phenomenon could also be due to a mechanical effect of the presence of varices. In conclusion, it is unclear whether the presence of cirrhosis itself could predispose to the onset of gastro-esophageal reflux. It seems that the presence of varices is related to reflux episodes, although it is not clear whether these might contribute to bleeding from varices.

Another more studied point is the fact that endoscopic treatment for variceal bleeding or prevention of bleeding varices, may produce oesophageal motility dysfunction. Several studies evaluated the effect of endoscopic variceal sclerotherapy (EVS) on gastro-oesophageal reflux. Some authors suggest that endoscopic treatment produces an acute impairment of oesophageal motility which is partially restored after days or weeks<sup>[52-54]</sup>, others suggest that sclerotherapy produce a chemical esophagitis that impairs oesophageal motility and in turn may favour acid related reflux esophagitis<sup>[55]</sup>. It seems that endoscopic variceal ligation (EVL) is safer in terms of oesophageal dysmotility induction when compared to EVS<sup>[56-59]</sup>. The reason for this finding is unclear. Autoptical studies after EVS show the presence of obliteration of the submucosal vascular channels, fibrosis and oesophagitis<sup>[60]</sup> reflecting the necrosis induced by the sclerosing agent. The inflammation caused by EVS may justify motor dysfunctions and acid reflux. Avgerinos *et al*<sup>[61]</sup> showed that EVL produces a higher early increase in lower oesophageal sphincter pressure, and this might prevent gastro-oesophageal reflux.

Apart from the pathogenesis of motor dysfunction following EVS and EVL, these procedures are related to local complications such as oesophageal ulcerations, strictures and perforations<sup>[62,63]</sup>, although from this point of view, EVL seem to be safer than EVS<sup>[64,65]</sup>. Uncontrolled non randomized studies, showed that PPI may have a role in the prevention and healing of post-EVS ulcerations<sup>[66-69]</sup> although this was not confirmed by other authors<sup>[70]</sup>. With regard to post EVL ulcers, the incidence is between 2% to 5%<sup>[71,72]</sup>. Pantoprazole has been shown to reduce the size of ulcers in patients undergoing elective band ligation, but not the rate of occurrence or the symptoms<sup>[73]</sup>. Given the relatively benign nature of the intervention, the authors conclude that PPI treatment is advisable in patients undergoing elective EVL.

In summary, expert opinion based on evidence of scarce value, advise PPI use in cirrhotic patients undergoing endoscopic treatment for varices, especially when treatment is performed by EVS, to prevent gastro-esophageal reflux which may worsen the procedure related inflammation or ulceration.

## PPI SAFETY IN CIRRHOTIC PATIENTS

Acute hepatitis due to PPI use is described in the literature for most PPIs available on the market<sup>[74-79]</sup>. All PPIs are metabolized in the liver by cytochrome CYP450; two isoenzymes are involved in PPI metabolism (CYP2C19 and CYP3A4)<sup>[6]</sup>. CYP2C19 is the main metabolic pathway while CYP3A4 is activated only when the other enzyme is saturated<sup>[80]</sup>. Nevertheless, the affinity of each isoenzyme for different PPIs is different and rabeprazole is metabolized mainly by a non enzymatic pathway. There are two CYP2C19 phenotypes: extensive and poor metabolisers<sup>[81-83]</sup>. The poor phenotype is present in 2%-6% of Caucasians and 20% of the Asian population. Poor metabolisers have higher plasma levels of PPI, which could lead to higher efficacy but also to potential adverse events. The effects of these genotypes varies according to the specific PPI used and in general is greater when using omeprazole decreasing progressively to lansoprazole, esomeprazole, pantoprazole and finally rabeprazole<sup>[6,83]</sup>.

PPI are metabolized in the liver and secreted by the kidney. Renal impairment has minimal effect on PPI clearance, and therefore there is no need to reduce PPI dosage in patients with renal diseases<sup>[80,84]</sup>. This is not the case for liver impairment in which the Area under the Curve (AUC) of PPIs increases and their half-life becomes 4 h to 8 h greater<sup>[80]</sup> with increasing risk of accumulation. This effect was also seen with rabeprazole<sup>[85]</sup> although a dose reduction seems to be unnecessary with a 20 mg, once daily dose in patients with mild to moderate liver cirrhosis. When using other PPIs or rabeprazole at 40 mg/d dose, dose reduction in patients with cirrhosis is advisable.

## CONCLUSION

PPI drugs are extensively used in clinical practice in cirrhotic patients. Besides habit, the evidence that PPI are necessary in most indications is very weak. First of all, there is convincing evidence that acid secretion is reduced in patients with liver cirrhosis. This is mainly due to the presence of hypertensive gastropathy for which there is no evidence of any efficacy of PPI. With regard to *H. pylori* infection, its prevalence in patients with cirrhosis is largely variable among different studies, probably as a result of different diagnostic tests used. We believe that the condition of hypochloridemia of cirrhotics makes it more probable that its prevalence is lower than in the general population. Nevertheless, it seems that *H. pylori* eradication does not prevent from gastro-duodenal ulcer formation and bleeding.

It is probable that the main reason for PPI use in cirrhosis might be the prevention and treatment of oesophageal complications after banding or sclerotherapy of oesophageal varices. However even in this case evidence for a protective role of PPI are scarce. When using PPI in cirrhotic patients, the dose should be reduced in consideration of the increased half-life of these drugs in this group of patients. Dose adjustment does not seem necessary when using rabeprazole at a 20 mg, once daily

dose. The use of this class of drugs seems more habit-related than evidence-based, eventually leading to an increase in health costs.

## Abstract

Cholangiocarcinoma is a rare cancer originating from the neoplastic transformation of the epithelial cells (i.e. cholangiocytes) that line the biliary tract. The prognosis for patients with cholangiocarcinoma is grim due to lack of viable treatment options. The increase in world-wide incidence and mortality from cholangiocarcinoma highlights the importance of understanding the intracellular mechanisms that trigger the neoplastic transformation of cholangiocytes and the growth of biliary cancers. The purpose of the following review is to address what has been learned over the past decade concerning the molecular basis of cholangiocarcinogenesis. The material presented is divided into two sections: (1) mechanisms regulating neoplastic transformation of cholangiocytes; and (2) factors regulating cholangiocarcinoma growth. An understanding of the growth regulatory mechanisms of cholangiocarcinoma will lead to the identification of therapeutic targets for this devastating cancer.

## INTRODUCTION

Cholangiocytes are simple epithelial cells that line the intrahepatic biliary tract, which is a three-dimensional network of interconnecting ducts. The primary physiological function of cholangiocytes is the modification of bile of canalicular origin and drainage of bile from the liver<sup>[1]</sup>. In addition to their role in the modification of ductal bile, cholangiocytes also participate in the detoxification of xenobiotics<sup>[1]</sup>. In recent years, interest in the study of cholangiocytes has increased dramatically due to a rise in the incidence of cholestatic liver diseases and biliary tract cancers (i.e. cholangiocarcinoma) in patients worldwide<sup>[2-5]</sup>.

In diseases of the biliary tree (e.g. primary biliary cirrhosis (PBC), primary sclerosing cholangitis (PSC), liver allograft rejection and graft-versus-host disease), cholangiocytes are the primary target cells<sup>[1]</sup>. These cholangiopathies cause morbidity and mortality and are a major indication for liver transplantation<sup>[1]</sup>. In fact, these diseases contribute to 20% of the liver transplants in adults and 50% of those in pediatric patients<sup>[6]</sup>. Proliferation of cholangiocytes is critical for the maintenance of biliary mass and secretory function during the pathogenesis of chronic cholestatic liver diseases, such as primary biliary cirrhosis (PBC), and primary sclerosing cholangitis (PSC). Previous studies have demonstrated that proliferating cholangiocytes serve as a neuroendocrine compartment during liver disease pathogenesis and as such secrete and respond to a number of hormones and neuropeptides contributing to the autocrine and paracrine pathways that modulate liver inflammation and fibrosis, which are predicted to play key roles in cholangiocarcinogenesis<sup>[7]</sup>.

Cholangiocarcinomas are adenocarcinomas that arise from the neoplastic transformation of cholangiocytes. Cholangiocarcinoma occurs in approximately 2 per 100 000 people and account for approximately 13% of primary liver cancers<sup>[4]</sup>. Cholangiocarcinomas can be divided into three categories based upon anatomic location: (1) intrahepatic

cholangiocarcinoma, occurring in the bile ducts residing within the liver; (2) hilar cholangiocarcinoma, occurring at the confluence of the right and left hepatic ducts; and (3) distal extrahepatic bile duct cancers<sup>[8]</sup>. The prognosis for cholangiocarcinoma is grim due to lack of early diagnostic modalities and effective treatment paradigms. Cholangiocarcinomas are slow growing, metastasize late during the cancer's progression, and present with symptoms of cholestasis due to the blockage of the bile duct by tumor growth<sup>[8]</sup>. In most cases, the tumors are well advanced at the time of diagnosis, which results in limited treatment options<sup>[9]</sup>. Many of these tumors are too advanced to be removed surgically and chemotherapy and radiation therapy usually are not effective, which indicates the dire need to understand the mechanisms that activate the neoplastic transformation of cholangiocytes and control the growth of cholangiocarcinomas.

## RISK FACTORS FOR CHOLANGIOCARCINOMA

Several recent studies have shown that there is an increasing incidence of cholangiocarcinoma world-wide and in particular in Western countries, such as the United States, the United Kingdom, and Australia<sup>[4,10-12]</sup>. Although most patients do not have identifiable risk factors for the disease, several risk factors have been established for cholangiocarcinoma<sup>[13]</sup>. The list of risk factors includes: gallstones or gallbladder inflammation, chronic ulcerative colitis, chronic infection of liver flukes, *Clonorchis sinensis* and *Opisthorchis viverrini*, and primary sclerosing cholangitis (PSC)<sup>[14]</sup>. In addition, a recent study revealed several novel risk factors for intrahepatic cholangiocarcinoma<sup>[15]</sup>. Hepatitis C virus infection, non-alcoholic fatty liver disease, obesity and smoking are all associated with intrahepatic cholangiocarcinoma<sup>[15]</sup>. The majority of these risk factors have the common features of chronic liver inflammation, cholestasis, and increased cholangiocyte turnover<sup>[16,17]</sup>.

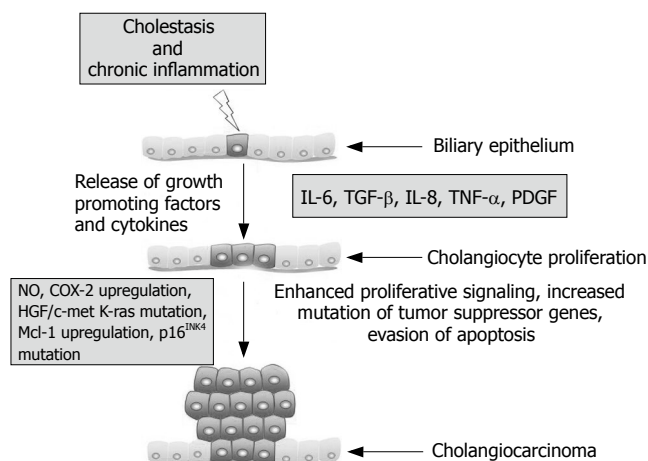

## MOLECULAR MECHANISMS CONTRIBUTING TO CHOLANGIOCARCINOGENESIS

A common and important contributor to the malignant transformation of cholangiocytes is chronic inflammation of the liver. This inflammation is often coupled with the injury of bile duct epithelium and obstruction of bile flow, which increases cholangiocyte turnover (i.e. dysregulation in the balance of cholangiocyte proliferation and apoptosis)<sup>[9,18]</sup>. Persistent inflammation is thought to promote carcinogenesis by causing DNA damage, activating tissue reparative proliferation, and by creating a local environment that is enriched with cytokines and other growth factors<sup>[19]</sup>. Thereby, chronic inflammation creates local environmental conditions that are primed for cells to develop autonomous proliferative signaling by constitutive activation of pro-proliferative intracellular signaling pathways and enhanced production of mitogenic

factors. Indeed recent studies have demonstrated that cholangiocytes release cytokines, such as interleukin 6 (IL-6), transforming growth factor- $\beta$  (TGF- $\beta$ ), IL-8, tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) and platelet-derived growth factor (PDGF). These factors can interact with cholangiocytes in an autocrine/paracrine fashion to regulate cholangiocyte intracellular signaling responses, which are thought to be altered during cholangiocarcinogenesis<sup>[20]</sup>.

Cytokines activate inducible nitric oxide synthase (iNOS) in cholangiocytes. This results in the generation of nitric oxide, which along with other reactive oxygen species, may alter DNA bases, result in direct DNA damage and trigger the downregulation of DNA repair mechanisms<sup>[18]</sup>. Nitric oxide can directly or through the formation of peroxynitrite species can lead to the deamination of guanine and DNA adduct formation thereby promoting DNA mutations<sup>[18,21]</sup>. The resultant DNA damage leads to an increased mutation rate and alteration of genes critical to cell proliferation control. Consistent with this line of thought, activating mutations and the overexpression of EGFR, erb-2, K-ras, BRAF and hepatocyte growth factor/c-met (HGF) have been reported for cholangiocarcinoma. In addition, the proto-oncogene c-erbB-2 is activated in patients with cholangiocarcinoma<sup>[22,23]</sup>. Mutations affecting the promoter of the tumor suppressor p16<sup>INK4a</sup> that result in loss of transcription occur in both PSC and PSC-associated cholangiocarcinoma<sup>[24]</sup>. Alterations of p53, APC, and DPC4 tumor suppressor genes by a combination of chromosomal deletion, mutation, or methylation; and infrequently microsatellite instability have also been linked to cholangiocarcinoma<sup>[25]</sup>. In addition to increased ability of cholangiocytes to escape from senescence, activation of iNOS promotes the upregulation of COX-2 in immortalized mouse cholangiocytes suggesting that COX-2 and COX-2 derived prostanoids might play a key role in cholangiocarcinogenesis<sup>[26,27]</sup>. COX-2 also upregulated the expression of Notch, which has been implicated in other cancer types<sup>[27]</sup>.

Cytokines, such as IL-6, appear to play an important role in cholangiocyte evasion of apoptosis. During the pathogenesis of cancer, the activation of evasion of apoptosis pathways helps to prevent cells with accumulating DNA damage from undergoing cell death pathways that normally eliminate such dysfunctional cells. Cholangiocarcinoma cells have been shown to secrete IL-6 and in an autocrine fashion IL-6 activates the pro-survival p38 mitogen activated protein kinase<sup>[28]</sup>. In fact, IL-6 upregulated the expression of myeloid cell leukemia-1 (Mcl-1) expression through STAT3 and AKT signaling pathways<sup>[29,30]</sup>. Mcl-1 is an anti-apoptotic protein in the Bcl-2 family of apoptotic proteins. Recently, the cellular expression of Mcl-1 has been shown to be controlled by the small endogenous RNA molecule, mir-29, which is down regulated in malignant cells consistent with Mcl-1 overexpression<sup>[31]</sup>. Enforced expression of mir-29 reduced Mcl-1 expression the malignant human cholangiocytes, KMCH<sup>[31]</sup>. Modulation of expression small endogenous RNAs such as mir-29 might represent a therapeutic paradigm for cholangiocarcinomas.

**Figure 1** Summary of key mechanisms regulating cholangiocarcinogenesis.

## FACTORS REGULATING CHOLANGIOCARCINOMA GROWTH

A number of recent studies have shown that the nervous system, neuropeptides and neuroendocrine hormones play a key role in the modulation of cholangiocarcinoma growth<sup>[32]</sup>. We have demonstrated that proliferating cholangiocytes serve as a neuroendocrine compartment during liver disease pathogenesis and as such secrete and respond to a number of hormones and neuropeptides contributing to the autocrine and paracrine pathways that modulate liver inflammation and fibrosis<sup>[7]</sup>. The sympathetic nervous system has been shown to have a role in the negative regulation of cholangiocarcinoma growth<sup>[33]</sup>. The cholangiocarcinoma cell lines, Mz-ChA-1 and TFK-1, express the  $\alpha_{2A}$ -,  $\alpha_{2B}$ -, and  $\alpha_{2C}$ -adrenergic receptor subtypes<sup>[33]</sup>. Stimulation of the  $\alpha_2$  receptors induced an upregulation of intracellular cAMP, which inhibited EGF-induced MAPK activity through an increase in Raf-1 and the sustained activation of B-raf, which resulted in the subsequent reduction of cholangiocarcinoma proliferation<sup>[33]</sup>. Although muscarinic acetylcholine receptor are expressed by cholangiocytes and play a role in regulating secretin-induced bile flow in rodents, the role of the parasympathetic nervous system has not been evaluated in cholangiocarcinoma and warrants consideration as a factor regulating cholangiocarcinoma growth<sup>[34,35]</sup>.

Other neuroendocrine hormones and neurotransmitters have also been shown to play a role in the regulation of cholangiocarcinoma growth. The cholangiocarcinoma cell lines, Mz-ChA-1, HuH-28 and TFK-1, express the gastrin/CCK-B receptor and gastrin inhibits the proliferation and induces the activation of apoptosis in these cholangiocarcinomas through the activation of  $Ca^{2+}$ -dependent PKC- $\alpha$  signaling. Most recently, Fava *et al* have shown that  $\gamma$ -aminobutyric acid (GABA) inhibits cholangiocarcinoma cell proliferation and migration<sup>[36]</sup>. This effect was also evident *in vivo* with GABA significantly decreasing the growth of cholangiocarcinoma tumor xenografts in nude mice<sup>[36]</sup>.

Female steroid hormones, such as estrogens, have also been shown to play a role in the promoting of

cholangiocarcinoma cell growth. 17- $\beta$  estradiol stimulated the proliferation of human cholangiocarcinoma cells *in vitro*, which was blocked by tamoxifen<sup>[37]</sup>. Alvaro *et al* have demonstrated that human intrahepatic cholangiocarcinomas express the receptors for both estrogens and insulin-like growth factor (IGF-1)<sup>[38]</sup>. Their study indicates that estrogens and IGF-1 coordinately regulate cholangiocarcinoma growth and apoptosis<sup>[38]</sup>.

Modulation of the endocannabinoid system is currently being targeted to develop possible therapeutic strategies for other cancer types. We recently demonstrated the novel finding that the two major endocannabinoids, anandamide and 2-arachidonylglycerol, have opposing actions on cholangiocarcinoma growth<sup>[39]</sup>. Interestingly, anandamide was found to be antiproliferative and to promote apoptosis, while, in contrast, 2-arachidonylglycerol stimulated cholangiocarcinoma cell growth<sup>[39]</sup>. Anandamide was shown to recruited Fas and Fas ligand into lipid rafts resulting in the activation of death receptor pathways and apoptosis in the cholangiocarcinoma cells<sup>[39]</sup>.

## CONCLUSION

Cholangiocarcinoma is a devastating neoplasm of the biliary tract that is increasing in incidence. While treatment options are limited, our knowledge base of the factors controlling cholangiocarcinogenesis and cholangiocarcinoma growth has greatly expanded in the past decade. These studies have clearly demonstrated that, during the course of chronic cholestasis and associated liver inflammation, a number of factors are released into the local environment that set into motion a series of events compound genomic damage leading to autonomous proliferation and escape from apoptosis (Figure 1). Several potential areas seem promising for the development of prevention and treatment strategies for cholangiocarcinoma. In particular, inhibition of the COX-2 pathway during PSC warrants further investigation. Also, modulation of cholangiocarcinoma growth by the regulating neural input or the endocannabinoid system might prove fruitful. Understanding the molecular mechanisms triggering biliary tract cancers will be key for the development of new treatments and diagnostic tools for cholangiocarcinoma.

## Abstract

Cholangiocarcinoma continues to be a challenging disease to treat. Systemic therapy is used in unresectable disease, disease progression after surgery, and in the palliative setting. Unfortunately, results of multiple phase II trials have rarely yielded positive results. As data on the molecular carcinogenesis of cholangiocarcinoma is developing, we are more able to understand the disease process and can use this understanding to create unique targeted therapies. We reviewed the role of c-Met/hepatocyte growth factor (HGF) in the development of cholangiocarcinoma. Furthermore, we explored the use of the c-Met guided cascade as a target to treat cholangiocarcinoma. We reviewed the current use and options for future development of c-Met agents to treat this disease.

## CHOLANGIOCARCINOMA

Cholangiocarcinoma continues to be a challenging

disease to treat. The only curative option remains surgical resection. Recent trends have allowed previously inoperable patients to undergo potentially curative surgery. Most recently, liver transplantation has been used in locally unresectable tumors with variable results<sup>[1-3]</sup>. Becker *et al*<sup>[4]</sup> reported outcome analysis for 280 patients treated at multiple centers over an 18-year period. Their data shows 5 and 10 years survivals of 74% and 38% respectively. Unfortunately, relatively few patients are diagnosed with limited stage disease that is amenable to surgical intervention (either resection or transplantation). Systemic therapy has been used in unresectable disease, disease progression after surgery, and in the palliative setting. Results of multiple phase II trials have rarely yielded positive results<sup>[5]</sup>. Average median survival remains less than one year and response rates are generally under 30%. Although the benefit is minimal, the most efficacious and clinically utilized chemotherapy regimens have been either gemcitabine or 5-fluorouracil (5FU)-based. Alberts *et al*<sup>[6]</sup> conducted a Phase II trial of gemcitabine, 5FU, and Leucovorin in advanced biliary disease. This study delivered 4 wk cycles of gemcitabine/5FU/Leucovorin on d 1, 8 and 15. The study enrolled carcinoma of the gallbladder and cholangiocarcinoma. For our scope, we will focus on their cholangiocarcinoma data. The study enrolled 28 patients with biliary cancer at multiple centers. Using the Response Evaluation Criteria in Solid Tumors (RECIST)<sup>[7]</sup> criteria two patients with biliary tract cancer achieved a partial response. The median time to disease progression was 4.6 mo and median survival was 9.9 mo. The primary endpoint of the study was successfully achieved, namely, to determine 6 mo survival. The overall data is fairly consistent with the previously reported data for single agent 5FU or gemcitabine. Although it is clear that 5FU and gemcitabine are active in cholangiocarcinoma, this study showed that the combination of the two most potent agents failed to produce a greater response rate or duration of response than either agent alone. This study and others like it increases suspicion that traditional chemotherapy is unlikely to make tangible progress in this devastating disease.

## MOLECULAR BIOLOGY OF CHOLANGIOCARCINOMA

Like many other malignancies, cholangiocarcinoma cells over-express epidermal growth factor receptors (EGFR)<sup>[8-10]</sup>. This observation led several investigators to postulate that Erlotinib (an oral inhibitor of EGFR/

**Figure 1** c-Met immunohistochemistry performed on: **A:** Normal liver; **B:** Cholangiocarcinoma; **C:** Early stage cholangiocarcinoma; **D:** Bile duct hyperplasia reproduced from Fazari (19) with permission.

HER1 tyrosine kinase) would show activity against cholangiocarcinoma. This interest intensified when activity was demonstrated against other malignancies such as lung<sup>[11]</sup> and pancreatic cancer<sup>[12]</sup>. Philip *et al.*<sup>[13]</sup> reported a Phase II trial in 42 patients with advanced biliary cancer. Using the Response Evaluation Criteria in Solid Tumors (RECIST) criteria three patients achieved a partial response (7%). Median time to disease progression was only 2.6 mo, and median overall survival was 7.5 mo. Interestingly, there was a certain subgroup (17%) that seemed to achieve prolonged (greater than 24 wk) disease stability. There did not appear to be a correlation between *EGFR/HER1* gene over-expression and response. This was not unexpected since *EGFR* mutations, *K-Ras* mutations, *p-AKT* levels, and proteomic signatures are also important predictors of erlotinib response and signal pathway dependence is difficult to predict from gene expression alone<sup>[11,14,15]</sup>. Although these results are promising, clinicians are left searching for better treatment options. Further advancement in the treatment of cholangiocarcinoma begins with a better understanding of the molecular mechanisms of carcinogenesis.

Data on the molecular carcinogenesis of cholangiocarcinoma is developing rapidly<sup>[16,17]</sup>. As in most cancers, multiple genes have been implicated in the molecular transformation of normally functioning tissue to malignant cells. These genetic changes cause a cascade of effects that include activation of oncogenes, inactivation of tumor suppressor genes, alterations in cell signaling, resistance to apoptosis, and direct induction of DNA damage. These genetic alterations affect all phases of the cell cycle and work in concert to transform bile secreting cells into an aggressive carcinoma. A detailed description of all of these mutations and their specific role in cholangiocarcinogenesis is beyond the scope of this publication. Here, we focus on the role of c-Met/hepatocyte growth factor (HGF) and its possible therapeutic implications. It has been reported that c-Met is over-expressed in more than half of biliary carcinomas<sup>[18]</sup>. As shown in Figure 1, Farazi *et al.*<sup>[19]</sup> demonstrated c-met over-expression in 80% of humanoid murine intrahepatic cholangiocarcinoma. Radaeva *et al.*<sup>[20]</sup> confirmed that cholangiocarcinoma expressed strong cell-surface immunoreactivity for c-Met. *c-Met* is a proto-oncogene located on chromosome 7q that codes for a tyrosine kinase growth factor receptor called HGF receptor<sup>[21]</sup>. HGF (also known as scatter factor) binds to c-Met and initiates autophosphorylation of an intracellular tyrosine kinase on the beta-subunit of the receptor. This activation allows the binding and ultimate activation of

**Figure 2** Schema of c-Met signaling pathways.

multiple signaling molecules such as Src, P13K, Gab1, SOS, Grb2, and MEK1/2 (Figure 2). The interaction of this multi-faceted activation system ultimately results in cellular alterations that contribute to carcinogenesis. It has been suggested in multiple studies that over-expression of c-Met is linked to cell invasion, angiogenesis, and tumor differentiation/proliferation<sup>[22-24]</sup> ([www.vai.org/met](http://www.vai.org/met)). Although the data is not conclusive, several researchers have suggested that c-Met behaves differently in intrahepatic and extrahepatic cholangiocarcinoma<sup>[25,26]</sup>. Leelawat *et al.*<sup>[27]</sup> demonstrated that stimulated over-expression of the *c-Met* gene in cholangiocarcinoma cells resulted in increased cell migration and invasion. Conversely, inhibition of *c-Met* expression decreased cellular phosphorylation and ultimately reduced cellular invasiveness. The presence of the *c-Met* oncogene and its unique cell signaling pathway provides one of many avenues by which specific cell targeting can be used to achieve better tumor control in cholangiocarcinoma<sup>[28]</sup>.

## C-MET THERAPIES

There are multiple focal points for interrupting c-Met activity with clinical compounds<sup>[29]</sup>. The earliest target in the cascade focuses on inhibition of the interaction

between HGF and the c-met receptor. Blocking the binding of the HGF to the transmembranous c-Met receptor works to halt c-Met signaling at the earliest point. Ultimately, c-Met fails to dimerize and tyrosine kinase activation does not occur. The alteration of this HGF/c-Met interaction can occur via multiple modalities including small interference RNAs (siRNA) which block c-Met expression, monoclonal antibodies against c-Met or HGF, and soluble c-Met fragment which can block HGF binding. Another target in the c-Met system is the direct tyrosine kinase inhibition. Similar to the tyrosine kinase inhibitors in chronicmyeloidleukemia (CML) and other tumors, designer compounds that are specific to the *c-Met* gene tyrosine kinase are administered. Although the interaction between HGF and the c-Met receptor is preserved, the cascade is halted by the selective binding of the inhibitor to the tyrosine kinase. Theoretically, all of these mechanisms would function to reduce cellular invasion, migration, angiogenesis, and ultimately, halt the process of carcinogenesis.

## C-MET THERAPIES FOR CHOLANGIOCARCINOMA

To date, only one study has reported c-Met targeted therapy in an animal model of cholangiocarcinoma<sup>[27]</sup>. This study showed that inhibition in c-Met expression or its downstream target MEK1/2 through specific targeted therapy is effective in halting disease progression *in vivo*. Inhibition was achieved through two molecular strategies. First, c-Met expression was altered through a *c-Met* specific small interfering RNA (siRNA) binding to the c-Met coded receptor. Second, siRNA specific binding to the *c-Met* downhill cascade product, MEK1/2, resulted in blunting of the cellular invasiveness of cholangiocarcinoma cells.

A number of c-Met and HGF antibody directed therapies receptor interaction have been shown biological activity in non-biliary cancer animal models<sup>[30,31]</sup> and human studies<sup>[32]</sup>. AMG102 is a fully human IgG2 monoclonal antibody against HGF. This compound has completed both preclinical trials and phase I dosing trials<sup>[33]</sup>. Although, the dose-escalating trials were performed on a variety of solid tumors, there is not current data on cholangiocarcinoma. A one-armed c-Met antibody has shown activity in preclinical studies<sup>[34]</sup>. Again, patients with cholangiocarcinoma have not been treated. Decoy met<sup>[35]</sup> is a soluble met receptor that interferes with HGF binding. It has been shown *in vivo* to have multiple anti-malignant properties including inhibiting angiogenesis, suppressing metastasis, and halting cellular proliferation. Decoy met functions to block the c-Met receptor as well as altering met dimerization. Decoy met has several properties that may make it more desirable than standard antibody directed therapies. For example, decoy met has a logarithmically greater affinity for the c-met receptor.

A series of c-Met tyrosine kinase inhibitors have been examined. XL880 is an oral c-Met tyrosine kinase inhibitor that is completing Phase I trials and beginning Phase II trials in humans. XL880 is a multi-kinase inhibitor that affects both the HGF/c-Met receptor family and the VEGF receptor family. The most common side effect

Table 1 Target sites of c-Met therapies

Target	Example	Current phase
HGF/c-met monoclonal antibody	AMG102 <sup>[33]</sup>	Phase II
Soluble c-met receptor	Decoy met <sup>[35]</sup>	Phase I
Tyrosine kinase inhibition	ARQ 197 <sup>[42]</sup>	Phase II
	XL880 <sup>[36,37]</sup>	Phase II
	PHA665752 <sup>[38]</sup>	Animal testing

of XL880 is hypertension. Although XL880-induced hypertension is very common, in phase I testing, it was manageable with anti-hypertensive medications<sup>[36]</sup>. XL880 is currently undergoing phase II clinical trials in a number of cancers. Early Phase II data on renal cell cancer has been positive<sup>[37]</sup>. It has shown activity in lung cancer (both small cell and non-small cell) xenografts in immunocompromised mice<sup>[38]</sup>. Additional tyrosine kinase inhibitors that are specific to the c-Met receptor have been developed<sup>[39-41]</sup>. ARQ 197 is a c-Met specific receptor tyrosine kinase inhibitor. This compound has completed Phase I dose escalation and has reached the recommended phase II dose. Partial responses and durable long term disease control have been achieved in several malignancies<sup>[42]</sup>. PHA665752 is a selective small molecule tyrosine kinase inhibitor of c-Met<sup>[38,43]</sup>. It has been shown to inhibit angiogenesis and induce apoptosis and cell cycle arrest. Interestingly, PHA665752 has been shown to have a cooperative effect when administered with rapamycin<sup>[43]</sup>. No current data on PHA665752 in humans is available.

## CLINICAL TRIALS WITH C-MET THERAPIES

There is scant data for any of the compounds in patients with cholangiocarcinomas (Table 1). The previously mentioned XL880 Phase I trial included 1 patient with cholangiocarcinoma. The slides presented at the 2007 ASCO meeting indicated that there was as 5 mo duration of response in Phase I testing. Unfortunately, the XL880 trial did not select for tumors over-expressing c-Met. Progress is rapidly being made through inhibition of the c-Met cascade. Hopefully, this will result in treatment advances in cholangiocarcinoma. Furthermore, other molecular mechanisms exist for using c-Met to target cellular death in cholangiocarcinoma. The possibility of using HGF or a monoclonal antibody to c-Met for immunotoxin construction should also be explored<sup>[45]</sup>. This would result in preferential introduction of deadly toxins into the cholangiocarcinoma cellular environment sparing normal cells (non c-Met expressing). As treatments directed against aggressive incurable cancers develop, their success will likely depend on their ability to deliver tumor selective, highly toxic treatments to carcinoma cells while sparing normal tissue. The c-Met cascade and others like it provide such an opportunity. Through these rapid developments, researchers, clinicians, and patients have hope of better treatments in the future.

### Abstract

Cholangiocarcinoma is a rare malignancy of the biliary tract. Key factors in determining therapeutic options include knowledge of tumor extent, anatomy and obtaining tissue diagnosis. Endoscopically, there are three modalities available to make the diagnosis of cholangiocarcinoma. These include endoscopic retrograde cholangiopancreatography, endoscopic ultrasound with fine needle aspiration and cholangioscopy. Management of cholangiocarcinoma endoscopically is typically confined to stent placement for palliative purposes or as a bridge to surgery. In this article, we will review the endoscopic techniques available for the diagnosis and management of cholangiocarcinoma.

### INTRODUCTION

Cholangiocarcinomas are rare malignancies involving the biliary tract. They can be divided into three anatomic groups: intrahepatic, perihilar, and distal extrahepatic. Perihilar tumors, also known as Klastkin tumors, involve the hepatic duct bifurcation. They are the most common, accounting for about 60%-80% of cholangiocarcinomas. Intrahepatic

tumors are least common<sup>[1]</sup>. The Bismuth classification is used to describe the biliary tract involvement and is helpful in planning surgical intervention. Type I tumors are found below the bifurcation of the left and right hepatic ducts. Type II tumors involve the bifurcation. Type IIIa and IIIb tumors occlude the common hepatic duct and either the right or left hepatic duct, respectively. Type IV tumors are multicentric, or they involve the bifurcation and both the right and left hepatic ducts (Figure 1). The incidence rates for cholangiocarcinomas vary depending on geographic location with the highest rates found in Southeast Asia. In the United States, between 4000 and 5000 cases are found annually. For unknown reason, the incidence of and mortality rates for intrahepatic cholangiocarcinomas have been increasing in recent years while the incidence of extrahepatic cholangiocarcinomas have been decreasing<sup>[2]</sup>. Accurate knowledge of tumor extent and anatomy as well as obtaining a tissue diagnosis is important in determining therapeutic options. In this article, we will review the endoscopic modalities available in the diagnosis and management of cholangiocarcinomas.

### DIAGNOSIS

The etiology of biliary strictures can often be difficult to establish. The differential diagnosis of biliary strictures is extensive and includes, but is not limited to, primary sclerosing cholangitis, gallbladder carcinoma, pancreatic carcinoma, intraductal papillary mucinous tumor, or benign biliary strictures from causes such as pancreatitis.

Cholangiocarcinomas often pose a diagnostic challenge due to difficulties in obtaining an adequate specimen for cytology. Tissue diagnosis is important in certain subgroups of patients such as those who are borderline surgical candidates, those with indeterminate strictures (e.g. patients with primary sclerosing cholangitis), or before chemotherapy and radiation therapy.

#### Magnetic resonance cholangiopancreatography

Magnetic resonance cholangiopancreatography (MRCP) can be a useful noninvasive adjunct to current techniques. It has the ability to define the proximal and distal extent of strictures as well as to evaluate for any intrahepatic mass lesion. One series evaluated the role of MRCP in patients with bile duct obstruction. Of 126 patients, 14 had bile duct malignancy. Of those 14, 12 patients were diagnosed by MRCP, with a sensitivity of 86% and specificity of 98%<sup>[3]</sup>. Another study by Rosch *et al*<sup>[4]</sup> had lower specificity for malignant obstructions. This study compared endoscopic retrograde cholangiopancreatography

**Figure 1** Classification of cholangiocarcinoma. **A:** The classification of cholangiocarcinoma can be based on anatomic location, intrahepatic, hilar or extrahepatic; **B:** Nonhilar lesions can be described as mass-like, periductal or intraductal; **C:** Bismuth classification for hilar lesions.

(ERCP), MRCP, computed tomography (CT) and endoscopic ultrasound (EUS) in the evaluation of biliary strictures. The specificity and sensitivity for MRCP to detect malignancy was 77% and 63%, respectively. Although MRCP provides the same imaging information as ERCP, many times ERCP is still required to provide a tissue diagnosis.

### ERCP

ERCP is useful in both the diagnosis and management of cholangiocarcinomas. It can delineate the anatomy of the biliary system and determine the extent of bile duct involvement which is important in determining resectability and surgical management (Figure 2). On cholangiography, the appearance of a stricture can suggest malignancy, but is not conclusive. Some characteristics suggestive of malignancy include a length greater than 10 mm, irregular margins, and an abrupt transition from normal duct to stricture, also known as shouldering<sup>[5]</sup>. Hilar strictures should also raise the suspicion for malignancy. Although, the appearance and location of a biliary stricture can suggest malignancy, tissue confirmation is usually needed in the majority of patients. Tissue for cytology may be obtained during ERCP by brushing, biopsy, bile aspiration or a combination of these. When necessary, therapeutic procedures can be performed, such as the placement of a biliary stent for treatment of obstructive jaundice.

Brush cytology has a high specificity of nearly 100%, but sensitivity is much lower, ranging from 18%-60% in most series<sup>[6,7]</sup>. The low sensitivity is likely related to low cellularity of these tumors and the desmoplastic reaction that is present.

Stricture manipulation by dilation theoretically should increase the availability of malignant cells for cytological examination. However, studies by deBellis *et al*<sup>[8]</sup> did not show a statistically significant difference in sensitivity before and after dilation. Patients underwent dilation with either a graduated dilating catheter or a dilating balloon. However, when the results of the pre- and post-dilation

**Figure 2** Hilar lesion causing bilateral strictures at the bifurcation of the left and right hepatic ducts with proximal dilation.

brushings were combined, the diagnostic yield increased from 35% to 44% ( $P = 0.001$ ). This indicates that repeated brushing, not necessarily the stricture manipulation, should increase the diagnostic yield.

Further studies compared different brush lengths and stiffness<sup>[6]</sup>. A standard cytology brush, 1.5 cm long with soft bristles, was compared to the Cytolong brush, 5 cm long with rigid bristles. Detection rates were not increased with usage of the longer cytology brush.

Advances in diagnostic methods have increased the diagnostic yield of brush cytology. Digital image analysis (DIA) is useful in specimens with limited cellularity as it looks at the DNA content of individual cells. DIA uses spectrophotometric methods to quantify DNA content, chromatin distribution, and nuclear morphology. Aneuploidy, or the presence of increased amounts of DNA, is quantitated and, if present, suggests malignancy. DIA increases the sensitivity of routine brush cytology from 18%-40%, but decreased the specificity from 98%-77%<sup>[9]</sup>.

Fluorescence *in-situ* hybridization (FISH) uses a commercial probe set to assess for polysomy of chromosomes 3, 7, 17, and 9p21. FISH increased the sensitivity from 15%-34%, and increased the specificity from 91%-98%<sup>[10]</sup>.

Of special note, when performing ERCP in patients with biliary strictures, there is a risk of cholangitis due to the injection of contrast and possible bacteria into an obstructed biliary system. Therefore, it is important to obtain adequate drainage across the biliary obstruction with placement of a stent to decrease this risk. In patients with a stent that had been previously placed, the removed biliary stent can be sent for cytology in order to increase diagnostic yield.

### EUS

Another modality that has become useful in diagnosing hilar cholangiocarcinomas is EUS with fine needle aspiration (FNA). CT or percutaneous ultrasound guided fine needle aspiration are not routinely used because these tumors are small and isoechoic to the liver, making them more difficult to assess. EUS has high-resolution imaging and can visualize lesions of 3 mm or greater. Although ERCP is the conventional test for evaluating biliary strictures, as we have discussed, the sensitivity remains low. In patients with ERCPs that are indeterminate or non-diagnostic for ma-

**Figure 3** A: Distal common bile duct lesion with proximal biliary dilation; B: Fine needle aspiration of common bile duct lesion; C: ERCP shows distal common bile duct stricture consistent with findings on EUS.

lignancy, EUS with fine needle aspiration is a useful tool (Figure 3).

EUS images, alone without FNA, are not reliable in evaluating hilar lesions. Criteria such as echotexture, size of mass, contour abnormalities, and the shape and borders of the stenosis do not reliably differentiate malignant from benign lesions. EUS also provides visualization of hilar, celiac axis and para-aortic lymph nodes to determine local and distant metastasis. Fine needle aspiration of these lymph nodes is the most accurate way to diagnose cholangiocarcinoma and also allows for staging. In addition, EUS can evaluate the pancreas for causes of biliary strictures such as pancreatic masses or changes of chronic pancreatitis.

In a study by Fritscher-Ravens *et al*<sup>[11]</sup>, patients with hilar strictures and inconclusive tissue diagnosis by ERCP, underwent EUS with fine needle aspiration. Of 44 patients, lesions at the hilum were noted in all the patients, and adequate material was obtained in 43 patients. Cytology revealed hilar cholangiocarcinoma in 59% of patients, with an accuracy of 91%, sensitivity of 89% and specificity of 100%. Accurate diagnosis changed the management in more than half of these patients that previously had non-diagnostic ERCPs.

In 2004, Eloubeidi *et al*<sup>[12]</sup> evaluated 28 patients in a prospective study to assess how EUS-FNA impacted patient management. Of the 28 patients, 3 were excluded because the lesion could not be identified by EUS. The sensitivity, specificity, and accuracy were 86%, 100%, and 88%, respectively, with numbers similar to the study by Fritscher-Ravens *et al*. A positive impact was made in 84% of patients. In 10 patients, surgery was prevented in patients with inoperable disease, 8 patients had surgery facilitated as they had unidentifiable cancer by other modalities, and 4 patients with benign disease avoided surgery. Prior studies have shown that 13%-24% of patients with suspected cholangiocarcinomas had benign disease at the time of surgery. By performing EUS with FNA in these patients with indeterminate strictures, surgical treatment could be tailored and appropriate management decisions be made.

A further modification of ultrasound technology allows the placement of a high frequency intraductal ultrasound probe (IDUS). Although several features such

as irregular wall thickening can be highly suggestive of malignancy, IDUS as yet has no associated capability for tissue acquisition.

### Peroral cholangioscopy and spyglass

During ERCP, miniature cholangioscopes can be used to directly visualize the bile ducts and any strictures or filling defects seen during ERCP. Directed tissue biopsies can also be obtained with miniature cholangioscopic biopsy forceps. Shah *et al*<sup>[13]</sup> in 2006 evaluated 62 patients with suspected pancreatic or biliary malignancy that had prior nondiagnostic studies. Cholangioscopy with either cholangioscopy-directed or assisted biopsies performed when applicable. Sixty-two patients underwent 72 examinations and 53 lesions were seen on cholangioscopy. Twenty-nine patients had either cholangioscopy-directed or assisted biopsies and 24 had both. Cholangiocarcinoma was identified in 14 patients. Two patients with intrahepatic cholangiocarcinomas were missed by cholangioscopy. In this study, the sensitivity and specificity for cholangioscopy to detect malignancy was 89% and 96%, respectively.

More recently, a single-operator peroral cholangio-pancreatography system known as Spyglass has been developed<sup>[14,15]</sup>. Older cholangioscopes were fragile, had limited tip deflection, and had limited ability to clean the lens and visual field. In addition, they required two endoscopists, one to operate the duodenoscope and another to operate the cholangioscope. With the Spyglass system, a single operator can control both scopes, there is 4-way deflected steering, and there are separate irrigation channels. A single operator system allows tight coordination of the duodenoscope and cholangioscope. Mastering the use of the system does require experience and advanced skills. The increased maneuverability of the Spyglass system allows for 4 quadrant biopsies. In bench stimulations, the Spyglass system had 100% success rates in obtaining target quadrant biopsies compared to 50% in conventional choledochoduodenoscopes. A feasibility study was performed with 35 patients, 22 of whom had indeterminate strictures. The procedure was successful in 91% of patients. Spyglass-directed biopsies were performed in 20 patients, and 19 had adequate tissue for examination. The preliminary sensitivity and specificity of Spyglass to detect malignancy were 71% and 100%, respectively. In this study, 2 patients

(6%) developed complications; one developed ascending cholangitis and the other intrahepatic abscess. Both patients recovered without sequelae. Currently, prospective multicenter clinical trials are ongoing.

## MANAGEMENT

Cholangiocarcinomas have a very poor prognosis with an average five-year survival of only 5%-10%. The only curative therapy for cholangiocarcinomas is surgical resection. If patients are not candidates for surgical resection, their median survival is 6.7-11.6 mo compared to 37.4-42.9 mo for patients who undergo surgical resection<sup>[16,17]</sup>. Distal cholangiocarcinomas have the highest resectability rates of about 91% while perihilar tumors have the lowest at 56%. Based on the experience at Johns Hopkins Hospital over 23 years, distal, intrahepatic, perihilar cholangiocarcinomas after resection have five-year survival rates of 28%, 44%, and 11%, respectively<sup>[18]</sup>.

Biliary decompression by placing a stent prior to surgery is a controversial issue. A biliary stent may make it difficult to assess the proximal extent of the tumor intraoperatively and may increase the risk of infections postoperatively. However, elevated bilirubin levels and liver dysfunction are factors that adversely affect postoperative morbidity. Indications for biliary stent placement preoperatively include cholangitis or prevention of cholangitis after a diagnostic ERCP is performed or if surgery is to be delayed for an extended amount of time<sup>[19,20]</sup>.

Only about 10%-20% of patients are candidates for surgery at the time of diagnosis secondary to advanced disease or overall poor medical health. In these patients with unresectable disease, the survival is very poor and there is rapid progression with biliary obstruction. Biliary decompression for palliative purposes can be accomplished surgically, radiologically or endoscopically.

### Unilateral versus bilateral stents

In order to provide palliation and relieve jaundice, only 25% of the liver needs to be adequately drained. Therefore, unilateral stents of either the left or the right system are typically sufficient. In a randomized controlled prospective trial, De Palma *et al*<sup>[21]</sup> evaluated 157 patients with malignant hilar biliary obstruction due to cholangiocarcinoma, gallbladder cancer or periportal metastatic lymphadenopathy. In patients with unilateral stenting, there was a higher success rate for stent insertion (89% *vs* 77%) and drainage (81% *vs* 73%) and, therefore, a lower early complication rate (19% *vs* 27%) when compared to bilateral stenting of both hepatic lobes. Early complications included cholangitis and stent occlusion. No differences were found in survival or procedure-related mortality.

In order to decrease the risk of cholangitis during an ERCP, it is important not to inject contrast above the level of a stricture unless adequate drainage can be ensured. Selective cannulization with a guidewire above the level of the stricture should be performed. Following that, the catheter should be passed above the stricture before injecting contrast. With the guidewire in place, a stent can be placed in the proper position ensuring that the contaminated segment will be properly drained (Figure 4).

**Figure 4** A: In this patient with a hilar mass, double stents were placed within the right and left hepatic systems to allow adequate drainage of contrast after cholangiogram was performed to decrease the risk of cholangitis; B: Endoscopic view of bilateral stents placed.

### Plastic versus metal stents

Both plastic and metal biliary stents are available. Numerous studies have compared plastic *versus* metal stents with regards to cost, complication rates, and survival<sup>[22-24]</sup>. There are no differences in survival with the use of either stents. Plastic stents have a higher risk of occlusion, with 30% occlusion rates after 3 mo and 70% after 6 mo<sup>[23]</sup>. In order to prevent problems with occlusion and cholangitis, they need to be exchanged every 3 mo. Metal stents have a longer patency of approximately 12 mo due to the fact that they have larger diameters compared to plastic stents (10 mm *vs* 3.8 mm). However, once placed they are very difficult to manipulate or remove. As far as cost effectiveness, the initial cost of a metal biliary stent is higher. However, with plastic stents, there are subsequent costs due to the need for repeat procedures for stent exchange and hospitalization for complications. Overall, there is no significant difference in the cost between metal and plastic stents. The decision to place a plastic *versus* metal stent should take into consideration the patients' overall health, expected length of survival, quality of life and local expertise. Often, a plastic stent is placed initially while further diagnostic workup is underway. Once the diagnosis is made and the patient has unresectable disease and a life expectancy of more than 6 mo, then the plastic stent can be replaced with a metal stent. Placement of a metal stent eliminates the need for repeated procedures and their associated risks.

## CONCLUSION

The diagnosis of cholangiocarcinomas is often challenging. Multiple endoscopic modalities are available to evaluate strictures or masses of indeterminate origin. ERCP with brush cytology using FISH or DIA technology along with EUS with FNA and cholangioscopy are available. Oftentimes, repeated procedures and a combination of these different techniques are necessary to achieve a tissue diagnosis. Having a cytologic diagnosis as well as knowing the stage of the disease plays an important role in decisions regarding management. Surgery is curative if the disease is detected at an early stage. When there is metastatic or advanced disease, endoscopic drainage plays a central role in providing palliation and improving quality of life. Placement of a unilateral stent is sufficient in providing adequate drainage and has lower morbidity than bilateral stents. In patients who require short-

term drainage, plastic stents are a good option. Because long term survival is so poor, metal stents should be considered if patients are not surgical candidates.

## INTRODUCTION

Cholangiocarcinoma is the second most common primary hepatic cancer. Despite advances in diagnostic techniques during the past decade, cholangiocarcinoma is usually encountered at an advanced stage. In this review, we

describe the classification, diagnosis, and initial management of cholangiocarcinoma with obstructive jaundice.

## CLASSIFICATION

Cholangiocarcinomas are epithelial neoplasms that originate from cholangiocytes and can occur at any level of the biliary tree. These lesions are broadly classified into intrahepatic cholangiocarcinoma, hilar cholangiocarcinoma, and distal extrahepatic bile duct tumors. Histologically, most cholangiocarcinomas (> 95%) are adenocarcinomas. They are pathologically classified into sclerosing, nodular, and papillary intraductal cancers<sup>[1]</sup>. A recent pathological classification applicable to both intrahepatic and extrahepatic cholangiocarcinomas divides these lesions into mass-forming (nodular), periductal-infiltrating (sclerosing), and intraductal-growing (papillary) cholangiocarcinomas<sup>[2]</sup>.

## DIAGNOSIS

### Laboratory data

Liver test abnormalities reflecting obstruction of the bile duct are usually observed. Strikingly elevated CA19-9 values in symptomatic patients usually signify advanced disease. Carcinoembryonic antigen (CEA) is also elevated in patients with cholangiocarcinoma, but is not diagnostic because of low sensitivity and specificity. Cholangitis and hepatolithiasis commonly lead to increased levels of tumor markers. Cholangiocarcinoma should not be diagnosed on the basis of laboratory data alone.

### Ultrasonography

Ultrasonography is the imaging technique of choice for the diagnosis of cholangiocarcinoma with obstructive jaundice. Visualization allows adequate diagnosis and staging in more than 90% of cases. The presence of dilated ducts without clear communications within a liver lobe indicates the extension of tumor into the segmental bile ducts. Ultrasonography is useful for evaluating the local extent of disease, but is of limited value for staging distant metastases. Intrahepatic cholangiocarcinomas may be identified as mass lesions, sometimes associated with bile duct dilatation proximal to the obstructing lesion. Tumor vascularity is an important characteristic that can be assessed by color Doppler ultrasonography. An abnormal pulsed Doppler signal obtained from the portal venous system due to severe narrowing or occlusion

strongly suggests major involvement and unresectable tumor. However, a normal pulsed Doppler signal does not exclude such involvement, if the tumor is contiguous with vessels showing interruption of the hyperechoic tumor-vessel interface<sup>[3,4]</sup>.

Endoscopic ultrasound (EUS) is useful for assessing the extent of disease and performing fine needle aspiration. Eloubeidi *et al*<sup>[5]</sup> reported that EUS-guided fine needle aspiration biopsy is useful for the diagnosis of suspected cholangiocarcinoma. The sensitivity, specificity, positive predictive value, negative predictive value, and accuracy were 86%, 100%, 100%, 57%, and 88%, respectively. EUS-guided fine needle aspiration of lymph nodes facilitates staging of disease in addition to visualization of the biliary tree<sup>[6]</sup>.

### Computed tomography (CT)

CT permits the identification of bile duct dilatation and assessment of the hepatic parenchyma and lymph nodes. However, the evaluation of horizontal spread by diagnostic imaging via the bile duct remains challenging in patients with cholangiocarcinoma, especially on conventional CT examination. Recently, the development of multidetector row CT scanners has permitted a reduction in the voxel size and facilitated rapid image reconstruction, enhancing the value of CT as an interactive diagnostic tool. Moreover, innovative methods for CT image reconstruction, including multiplanar reconstruction and three-dimensional images, were recently introduced for the visualization of biliary structures<sup>[7]</sup>. CT angiography has been demonstrated to be useful for the detection and assessment of vascular encasement<sup>[8-10]</sup>.

### Magnetic resonance imaging (MRI)

MRI with concurrent magnetic resonance cholangiopancreatography (MRCP) is the radiologic technique of choice for assessing the extent of disease<sup>[11,12]</sup>. The limitations of conventional imaging techniques have led to the increased use of MRCP, which is a noninvasive and highly accurate technique for the evaluation of patients with biliary obstruction. MRCP is optimally suited for the visualization of both intrahepatic and extrahepatic cholangiocarcinomas, which appear as hypointense lesions on T1-weighted images and hyperintense lesions on T2-weighted images. Images can be enhanced with the use of superparamagnetic iron or by delayed gadolinium enhancement<sup>[13,14]</sup>. The overall diagnostic accuracy for assessment of the level and cause of obstruction was 96.3% and 89.7%, respectively<sup>[12]</sup>. MR angiography can be used to evaluate vascular involvement<sup>[15]</sup>.

### Cholangiography

Before the development of MRCP, direct cholangiography was only technique for assessment of the biliary system. Direct cholangiography can be performed by either percutaneous transhepatic cholangiography or endoscopic retrograde cholangiography, and samples of the bile duct can be obtained<sup>[16,17]</sup>. Brushings are analyzed cytologically. In one study, the sensitivity, specificity, positive predictive value, negative predictive value, and accuracy of brush cytology were 75%, 100%, 100%, 12.5%, and 75.9%,

respectively. Biopsy specimens of the bile duct are examined histologically<sup>[18]</sup>. The diagnostic performance of transluminal forceps biopsy for malignant biliary obstructions was as follows: sensitivity, 78.4%; specificity, 100%; and accuracy, 79.2%<sup>[19]</sup>. Savader *et al*<sup>[20]</sup> compared the diagnostic accuracy of three different techniques for percutaneous transhepatic intraductal biopsy: brush cytology, clamshell forceps under choledochoscopic guidance, and clamshell forceps under fluoroscopic guidance. The choledochoscope-directed biopsy technique had the highest sensitivity and specificity among the three techniques, but was not significantly better than either the brush or fluoroscopic clamshell techniques ( $P > 0.10$ ). Multiple biopsies did not increase the overall sensitivity of intraductal biliary biopsy as a diagnostic technique. All three techniques were safe and easy to perform. In patients with malignant biliary obstruction, brush cytology was more sensitive for the diagnosis of cholangiocarcinoma than for the diagnosis of non-cholangiocarcinoma ( $P < 0.05$ ). The site of stenosis was unrelated to sensitivity and technical success ( $P > 0.05$ )<sup>[18,21]</sup>.

Rotational cine cholangiography is used to diagnose bile duct carcinoma. Rotational cine cholangiography is a reliable technique for detecting the confluence of the bile ducts, as well as for diagnosing the longitudinal extent of cancer spread along the bile duct wall<sup>[22]</sup>. Furukawa *et al*<sup>[23]</sup> evaluated the usefulness of three-dimensional cholangiography and rotating cine cholangiography for depicting the anatomy of the hilar bile duct and tumor extension, and for planning surgical procedures for hilar cholangiocarcinoma. Three-dimensional and cine cholangiography allowed accurate assessment of the biliary system in patients with hilar cholangiocarcinoma, facilitating the planning of surgery.

### Angiography

Angiography reveals the anatomy of the hepatic and biliary arteries. Angiography is a superb technique for the detection of vascular encasement. It is also useful for planning surgical procedures.

### Scintigraphy

**Technetium-99m galactosyl human serum albumin scintigraphy:** Technetium-99m-diethylenetriaminepentaacetic acid-galactosyl-human serum albumin (99mTc-GSA) is an analog ligand of asialoglycoprotein that binds specifically to asialoglycoprotein receptors (ASGP-R) residing in mammalian hepatocytes<sup>[24-26]</sup>. The hepatic uptake of 99mTc-GSA at 15 min or later reflects the receptor population or functional hepatocyte mass<sup>[27]</sup>.

Nanashima *et al*<sup>[28]</sup> studied the relation between morphological measurements of hepatic volume on CT and functional volume on 99mTc-GSA scintigraphy. There were no significant differences in the volume measurements between these two volumetric techniques. Volumetric measurement by 99mTc-GSA scintigraphy is useful for detecting changes in the functional volume of individual lobes of the liver and is a more dynamic method than the assessment of morphological changes on CT scanning.

We confirmed hemodynamic changes in the distribution of splenic venous flow in the liver, especially in the cirrhotic liver, and demonstrated the participation

of splenic venous flow in the regeneration or enlargement of the hepatic lobe by means of scintiphotosplenopography after percutaneous intrasplenic injection of  $^{99m}\text{Tc}$ -GSA. We concluded that splenic venous blood flow promotes liver fibrosis in the right lobe of the liver exposed to continuous damage, with gradually increasing flow into the left lobe, showing milder fibrosis<sup>[29]</sup>.

**Positron emission tomography (PET):** PET with  $^{18}\text{F}$ -fluorodeoxyglucose can be used to rule out metastatic disease, although the findings should be interpreted cautiously because of false positive results in inflammatory lesions; moreover a normal PET scan does not exclude cancer<sup>[30]</sup>.

## INITIAL MANAGEMENT

### Biliary drainage

In patients with obstructive jaundice who have cholangiocarcinoma, especially hilar cholangiocarcinoma, preoperative biliary drainage has been recommended to improve liver function before surgery and to reduce postoperative complications. Percutaneous transhepatic biliary drainage (PTBD) with multiple drains was previously the preferred method for the preoperative relief of obstructive jaundice. In patients with hilar cholangiocarcinoma, drainage is currently performed only for liver lobes that will remain after resection and for areas of segmental cholangitis. Endoscopic biliary drainage (EBD) is less invasive than PTBD. However, EBD has to be converted to PTBD in patients with segmental cholangitis, those requiring prolonged drainage, or those in whom the extent of longitudinal tumor extension is poorly defined<sup>[16]</sup>.

Kamiya *et al*<sup>[31]</sup> reported that impaired intestinal barrier function does not respond to external biliary drainage without bile replacement. Bile replacement during external biliary drainage can restore intestinal barrier function in patients with biliary obstruction, primarily by promoting the repair of physical damage to the intestinal mucosa. Koivukangas *et al*<sup>[32]</sup> reported that cell protein synthesis is disturbed earlier than cell dynamics in obstructive jaundice. Decreased baseline skin-collagen synthesis is partly restored by the resolution of jaundice<sup>[33]</sup>.

We previously reported that elevated serum collagen IV is a feature of malignant obstructive jaundice commonly associated with prolonged bilirubin clearance, and a useful indicator of clinical course, postoperative morbidity, and mortality in patients with malignant obstructive jaundice<sup>[34]</sup>.

The procedure of choice for biliary drainage before major hepatectomy in patients with obstructive jaundice remains controversial, i.e. selective biliary drainage of only the future remnant liver or total biliary drainage. Ishizawa *et al*<sup>[35]</sup> reported that selective biliary drainage is superior to total biliary drainage for promoting hypertrophy of the future remnant liver in patients undergoing portal vein embolization and for guaranteeing good liver function before major hepatectomy. Hochwald *et al*<sup>[36]</sup> showed that preoperative biliary stenting in proximal cholangiocarcinoma increases the incidence of contaminated bile and postoperative infectious complications. Cherqui *et al*<sup>[37]</sup> found that major liver resection without preoperative biliary drainage is

a safe procedure in most patients with obstructive jaundice. Recovery of hepatic synthetic function is identical to that of patients without jaundice. Transfusion requirements and the incidence of postoperative complications, especially bile leaks and subphrenic collections, are higher in jaundiced patients. Pitt *et al*<sup>[38]</sup> concluded that preoperative PTBD does not reduce operative risk but does increase hospital costs and, therefore, discouraged routine use. The indication for preoperative biliary stenting in patients with obstructive jaundice remains controversial.

### Portal vein embolization (PVE)

PVE before hepatectomy is designed to induce atrophy of the embolized lobe scheduled to be resected, while inducing compensatory hypertrophy of preserved lobe<sup>[39,40]</sup>. PVE with compensatory contralateral hypertrophy of the future liver remnant has been performed to enable extended hepatectomy (resection of  $\geq 5$  hepatic segments)<sup>[41,42]</sup>. We have reported on combined embolization of the hepatic artery and portal vein<sup>[43]</sup>.

### Biliary ablation

Selective biliary infusion of ethanol can be performed safely without serious complications, inducing lobar ablation with contralateral hypertrophy of the liver<sup>[44,45]</sup>.

### Operation

Surgical resection has been the mainstay of curative treatment for cholangiocarcinoma<sup>[46]</sup>. Major hepatectomy with systematic nodal dissection is associated with a good chance of prolonged survival in patients with carcinoma involving the hepatic hilus, including those with advanced disease<sup>[47,48]</sup>. Extended hemihepatectomy, with or without pancreatoduodenectomy, plus extrahepatic bile duct resection and regional lymphadenectomy has recently been recognized as the standard curative treatment for hilar bile duct cancer. Pancreatoduodenectomy is the choice of treatment for middle and distal bile duct cancer. Major hepatectomy with pancreatoduodenectomy (hepatopancreatoduodenectomy) has been performed in selected patients with widespread disease. Miyazaki *et al*<sup>[49,50]</sup> reported that parenchyma-preserving hepatectomy could result in curative resection and improve the outcomes of patients with hilar cholangiocarcinoma localized to the hepatic duct confluence who do not require vascular resection. Less-extensive procedures were also beneficial for less-advanced disease if the resection margins were free of tumor. Even with carefully selected treatment with curative intent, the 5-year survival of patients with cholangiocarcinoma ranges from 30% to 40%. A tumor-free surgical margin is the best predictor of survival. Several staging schemes have been proposed, but none correlates with resectability. Lymph node involvement is also a predictor of survival<sup>[48,51]</sup>.

### Adjuvant therapy

Neoadjuvant therapy with several types of treatment, including radiation, photodynamic therapy and chemotherapy, provides no clear benefit<sup>[52,53]</sup>.

### Palliative therapy

Previously, plastic endoprostheses were placed for the

palliative treatment of malignant biliary obstruction<sup>[54-57]</sup>. An expandable metal stent (EMS) is used to provide palliation in patients with malignant obstructive jaundice<sup>[58]</sup>. EMSs have been compared with plastic endoprotheses for the palliative treatment of malignant obstructive jaundice<sup>[59,60]</sup>. EMSs are inserted percutaneously<sup>[61-63]</sup> or endoscopically<sup>[59,64]</sup>.

Biliary stent placement combined with local tumor therapy, such as brachytherapy, extra-radiation therapy, or arterial infusion chemotherapy, can prolong the survival time of patients with malignant biliary obstruction<sup>[65-68]</sup>. Mezawa *et al*<sup>[69]</sup> developed a new PTBD tube coated with carboplatin.

Intrahepatic cholangiojejunostomy has been performed in patients with unresectable malignant biliary obstruction<sup>[70-72]</sup>. Endoscopic stenting for the management of this condition costs significantly less than surgical treatment<sup>[73]</sup>. Recently, EUS-guided hepaticogastrostomy has been performed<sup>[74]</sup>.

### Transplantation

Although early survival after transplantation for cholangiocarcinoma is excellent, high recurrence rates have generally discouraged liver replacement. Recent findings, however, have lead to a resurgence in orthotopic liver transplantation for unresectable, albeit locally contained cholangiocarcinoma. Becker *et al*<sup>[75]</sup> reported a series of 280 patients with cholangiocarcinoma who received orthotopic liver transplantation. After a median follow-up of 452 d, the survival rates at 1 and 5 years were 74% and 38%, respectively. Heimbach *et al*<sup>[76]</sup> reported on 56 patients who were treated for unresectable, stage I and II perihilar cholangiocarcinoma. Disease-free survival at 5 years was excellent (82%) in carefully selected patients who underwent neoadjuvant external-beam radiation therapy, transcatheter intrabiliary radiation, chemotherapy, and pretransplant-staging exploratory laparotomy. Neoadjuvant chemoradiotherapy with liver transplantation produces excellent results for selected patients with localized, regional node negative, hilar cholangiocarcinoma<sup>[76,77]</sup>.

## Abstract

**AIM:** To investigate transcriptional gene silencing induced by short hairpin RNAs (shRNAs) that target gene promoter regions of *RUNX3* gene, and whether shRNAs homologous to DNA sequences may serve as initiators for methylation.

**METHODS:** According to the principle of RNAi design, pSilencer3.1-H1-shRNA/*RUNX3* expression vector was constructed. The recombinant plasmid shRNA was transfected into human stomach carcinoma cell line SGC7901 with Lipofectamine 2000. Then, the positive cell clones were screened by G418. The mRNA and protein expression level of *RUNX3* in the stable transfected cell line SGC7901 were determined by RT-PCR, Western blotting and immunocytochemistry. Characteristics of the cell lines including SGC7901, pSilencer3.1-H1/SGC7901 and pSilencer3.1-H1-shRNA/*RUNX3*/SGC7901 were analyzed with growth curves, clone formation rate and cell-cycle distribution. The activated level of *RUNX3* was examined after treatment with the different density of 5'-aza-2'-deoxycytidine (5-Aza-CdR) by using semi-quantitative RT-PCR and Western blotting.

**RESULTS:** In the cell line SGC7901 transfected with pSilencer3.1-H1-shRNA/*RUNX3*, mRNA and protein

expression of the *RUNX3* gene was lost identified by RT-PCR, Western blotting and immunocytochemistry assay. The growth of pSilencer3.1-H1-shRNA/*RUNX3*/SGC7901 cells without expression of *RUNX3* was the fastest ( $P < 0.05$ ), its rate of clone formation was the highest ( $P < 0.01$ ), and the cell distribution in G<sub>0</sub>/G<sub>1</sub> and S/M phases was lowest and highest, respectively ( $P < 0.05$ ), compared with that of the transfected pSilencer3.1-H1 and non-transfected cells. Through RT-PCR and Western blot assay, inactivated *RUNX3* could not be reactivated by 5-Aza-CdR.

**CONCLUSION:** We found that, although shRNAs targeted to gene promoter regions of *RUNX3* could effectively induce transcriptional repression with chromatic changes characteristic of inactivation promoters, this was independent of DNA methylation, and the presence of RNA-dependent transcriptional silencing showed that RNA-directed DNA methylation might be an existing gene regulatory mechanism relative to the methylated in humans.

Investigation of transcriptional gene silencing and mechanism induced by shRNAs targeted to *RUNX3* *in vitro*. *World J Gastroenterol* 2008; 14(19): 3006-3014 Available from: URL: <http://www.wjgnet.com/1007-9327/14/3006.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.3006>

## INTRODUCTION

The human runt-related transcription factor 3 gene (*RUNX3*), a novel tumor suppressor, was originally cloned as *AML2* in human leukocythemia by Levanon in 1994 and is located on human chromosome 1p36.1<sup>[1]</sup>. *RUNX3* contains two promoters, p1 and p2, one at the beginning of exon 1 and the other in front of exon 2. The mRNA expression of *RUNX3* comes from transcription by p2, which has a high GC content due to a large conserved

CpG island around it and contains Sp1 sites and a CCAAT box without a TATA box. Recently, *RUNX3* has been considered to be a vital gene in the occurrence and development of gastric carcinoma<sup>[2]</sup>.

Multiple genes participate in the occurrence and development of gastric carcinoma, which is at the top list of malignant tumors in China. Deactivation of anti-oncogenes is more frequent than activation of proto-oncogenes in the gastric carcinogenesis process. Anti-oncogenes are devitalized by chromosomal absence, gene mutation, and aberrant CpG island hypermethylation of gene promoters. Moreover, the data have suggested that, due to transcription termination of *RUNX3* by aberrant CpG island hypermethylation at the promoter's 5'-terminal CpG island area, the active level of *RUNX3* decreased by 40% and 90%, respectively, in early and advanced gastric cancer. However, the inactivation mechanism of the aberrant CpG island hypermethylation is still unclear<sup>[3-6]</sup>.

The phenomenon by which small interference RNA molecules that target gene promoter regions can induce transcriptional gene silencing in a DNA cytosine methylation-dependent manner (RNA-directed DNA methylation, RdDM) was initially discovered by Wassenegger *et al* in 1994 in plants infected with epiviruses<sup>[7]</sup>. This suggested that RdDM might have an important role in the loss of expression of tumor suppressor genes, and *RUNX3*. We constructed a recombinant plasmid, which expressed short hairpin RNAs (shRNAs) complementary to the CpG island, including the promoter of the human *RUNX3* gene, to investigate transcriptional gene silencing and the mechanism mediated by shRNAs that target gene promoter regions of *RUNX3* in human stomach carcinoma cell lines.

## MATERIALS AND METHODS

### Design and synthesis of shRNAs

shRNAs that target the nucleotide sequence (GCCACTT-GATTCTGGAGGA) in the promoter of human *RUNX3* (NCBI, accession number AL023096) were designed by Ambion using restriction enzyme sites *Bam*H I and *Hind*III, and synthesized by Shanghai Biological Engineering Limited Company (China). The oligonucleotide sequence was as follows: 5'-GATCCGCCACTTGATTCTGGAGGATTCAGAGATCCTCCAGAATCAAGTGGCG GTTTTTTGGAAA-3' and 5'-AGCTTTTCCAAAAAACCGCCACTTGATTCTGGAGGATCTCTTGAATCCTCCAGAATCAAGTGGCG-3'.

### Construction of recombinant plasmid

The eukaryotic expression vector pSilencer3.1-H1 (Ambion), which was kindly provided by Doctor Lei XiaoYong (Institute of Pharmacologic Research, Nanhua University), was digested by *Bam*H I and *Hind*III restriction enzymes (MBI). The digested products, which were reclaimed using Gel-reclamation Kit (Omega), and the oligonucleotide sequence were ligated by T4 DNA ligase (MBI) at 4°C overnight to generate the recombinant pSilencer3.1-H1-shRNA/*RUNX3*. Then, the recombinant plasmid was validated by restriction enzymes digestion and sequencing.

### Cell line and cell culture

Human gastric cancer SGC-7901, MKN-28, SGC7901, MGC803 and BGC823 cell lines, which were first cultured by Academia Sinica (Shanghai, China), were purchased from the Central South University (Hunan, China). All cells were cultured with RPMI 1640 (Gibco) medium and supplemented with 100 mL/L calf serum (Sijiqing, Hangzhou, China) at 37°C in a humidified atmosphere containing 50 mL/L CO<sub>2</sub>.

### Transfection of plasmids

Fifty thousand SGC-7901 cells were seeded into each well in six-well plates and grown overnight. The medium was replaced with complete medium without fetal bovine serum (FBS). The recombinant pSilencer3.1-H1-shRNA/*RUNX3* and the empty pSilencer3.1-H1 were transfected into SGC7901 cells using Lipofectamine 2000 (Invitrogen) according to the manufacturer's instructions. The medium was replaced with a fresh medium of calf serum (150 mL/L) after 5 h transfection. Two days later, the transfected cells were selected by G418 (200 µg/mL) (Huamei Biotechnology Company, Beijing, China) until positive clones were discovered after 10 d. The cells were cultured and finally selected by G418 (100 µg/mL) for a further 10 d. Single clones were selected to build a stable transfected cell line.

### Chemical reagents

5'-Aza-2'-deoxycytidine (5-Aza-CdR), which is a DNA methyltransferase inhibitor, was purchased from Sigma (USA). It was diluted with PBS (pH 6.8), and finally prepared as 10 µmol/L mother liquor by filtrated sterilization. The mother liquor was stored at -70°C.

### Total RNA extraction and cDNA preparation

Total RNA was extracted from each sample using the Total RNA Extract Kit (Omega) following the manufacturer's instructions. The concentration of RNA was measured by spectrophotometry. Total RNA was reverse-transcribed to cDNA with reverse transcriptase (RT) reagents (Promega) according to the manufacturer's protocol. Briefly, the RT reaction was carried out in a final volume of 20 µL that contained 4 µL 25 mmol/L MgCl<sub>2</sub>, 2 µL 10 × RT buffer, 2 µL 10 mmol/L dNTP mixed liquor, 1 µL RNase inhibitor, 1 µL Oligo (dT) 15 primers, 15 U AMV retroviralase, 8.37 µL water free from enzyme, and 2 µL total RNA. The mixture was incubated at 70°C for 10 min and 42°C for 60 min, and RT was inactivated by heating at 95°C for 5 min, followed by incubation at 4°C for 5 min.

### Determination of growth curve

SGC-7901, pSilencer3.1-H1/SGC7901 and pSilencer3.1-H1-shRNA/*RUNX3*/SGC7901 cells were suspended in RPMI1640 medium and seeded in a 24-well plate at a density of  $2.0 \times 10^4$  cells/well. Culture medium was changed every 2 d. The number of cells was counted consecutively for 8 d. Each experiment was done in triplicate.

### Colony formation

Single cells were mixed with the semi-solid agar (3 g/L) with growth medium and plated on a basal agar layer

(6 g/L) in three six-well plates. The cells were cultured at 37°C in a humidified atmosphere that contained 50 mL/L CO<sub>2</sub> for 10 d. Then, colonies that contained > 100 cells in soft agar were counted under an inverted microscope and the rate of colony formation was calculated by the mean percentage of colonies.

#### Flow cytometry (FCM) with propidium iodide (PI) staining

The cells were passaged at a density of  $5.0 \times 10^5$ /mL. After 4 h, they were treated with serum-free medium for 12 h, followed by treatment with medium that contained calf serum (100 mL/L) for 24 h. Cells were collected by trypsinization and prepared as a single cell suspension by mechanical blowing with PBS, washed with cold PBS twice, and fixed with 700 mL/L alcohol at 4°C for 24 h. Fixed cells were washed with PBS and stained with PI (50 µg/mL in PBS) for 30 min at room temperature in the dark. DNA content in PI-stained cells was detected by FCM.

#### Primers and real-time RT-PCR

As shown in Table 1, specific primers for *RUNX3* and *β-actin* genes were designed based on sequence data from the GenBank database. The primers were purchased from Shanghai Biological Engineering. Conditions for all PCRs were optimized on Cycler iQ (Bio-Rad, USA) and the optimum annealing temperature was 55°C. The following cycler running protocol was used: denaturation (95°C, 2 min), amplification and quantification repeated 35 times (94°C for 30 s, 55°C for 30 s, and 72°C for 1 min). In addition, a non-template control (ddH<sub>2</sub>O control) was analyzed for each template. All samples were amplified simultaneously in triplicate.

#### Western blot analysis

Cells were collected, washed three times with PBS, lysed in cell lysate that contained 0.1 mol/L NaCl, 0.01 mol/L Tris-HCl (pH 7.6), 0.001 mol/L EDTA (pH 8.0), 1 µg/mL aprotinin and 100 µg/mL PMSF, and then centrifuged at  $13000 \times g$  for 10 min at 4°C. The extracted protein sample (50 µg total protein/lane) was added to the same volume of sample buffer and subjected to denaturation at 100°C for 10 min. The samples were electrophoresed on 100 g/L SDS PAGE at 28 mA for 30 min until they reached the bottom of the spacer gel, separated on the separation gel at 120 V for 1.5 h, and finally transferred onto PVDF membrane at 105 mA for 3.5 h at 4°C. The PVDF membrane was treated with TBST that contained 50 g/L skimmed milk at room temperature for 2 h, followed by incubation with the primary antibody *RUNX3* (1:100 dilution) (Boaosen Biotechnology Company, Beijing China; bs-0378R) at 37°C for 2 h or 4°C overnight. After being washed with TBST for 30 min, the corresponding secondary antibody (1:2000 dilution) (Zhongshan Jinqiao Biotechnology Company, Beijing, China) was added and incubated at room temperature for 1 h. The membrane was then washed three times for 15 min each with TBST. Fluorescence was produced from solution A and B that contained a chemiluminescence generator. Both *RUNX3* and *β-actin* protein expression were quantitatively estimated by densitometric scanning performed with Imaginer 2200. *RUNX3* protein concentration was

Table 1 Sequence of primers and amplified length of genes

Gene	Sequence	Amplified length (bp)
<i>RUNX3</i>	5'-GAGTTTCACCCTGACCA TCACTGTG-3' 5'-GCCCCATCACTGGTCTTGAAGGTTGT-3'	870
<i>β-actin</i>	5'-CTACAATGAGCTGCGTGTGC-3' 5'-AGGAGGACTTCTTCGAT-3'	500

normalized to *β-actin* level and expressed as a densitometric ratio.

#### Immunohistochemistry

Cells were seeded on the axenic cover glass in six-well plates at  $1 \times 10^5$  cells/well, and were grown overnight. The cover glasses with adhered cells were washed three times with PBS, and fixed in 95% alcohol for 10 min. After being rinsed three times in PBS, the endogenous peroxidase activity was suppressed by 30 mg/L hydrogen peroxide for 15 min, followed by rinsing three times in PBS. Antigen repair was performed by immersing the sections in 10 mmol/L sodium citrate buffer (pH 6.0) and heating for 15 min in a microwave oven. Non-specific binding was blocked by incubation with 30 mL/L bovine serum albumin (BSA) for 40 min. The cells were treated for 16 h with goat anti-human polyclonal IgG antibodies of *RUNX3* (Boaosen Biotechnology Company; bs-0378R) at 37°C for 2 h or 4°C overnight, according to the manufacturer's recommended concentration (1:200 dilution). PBS was used as a negative control. After washing three times in PBS, the cover glasses were treated with biotinylated rabbit anti-goat immunoglobulin (Zhongshan Jinqiao Biotechnology Company) for 1 h at room temperature and then by horseradish peroxidase-streptavidin complex (Man Xin Biotechnology Company, Huzhou, China) for 30 min. The cover glasses were then washed three times in PBS and incubated in DAB for 2 min. Next, the cover glasses were rinsed gently with distilled water and counterstained with hematoxylin for 30 s, and dehydrated in alcohol prior to mounting. Images were collected by Olympus DD70 BX51 (Olympus, Japan) and analyzed by IMAGE-PRO plus 4.1 software (Media Cybernetics, USA). Eight visual fields in each section were randomly selected and the mean value of relative OD was measured and calculated by taking the OD of background as 1. The extent of immunohistochemical staining was categorized as positive (1-1.5) and strongly positive (> 1.5).

#### Statistical analysis

Experimental data in each group were expressed as mean ± SD. Analysis of variance (ANOVA) was performed with the Statistical Package for the Social Sciences (SPSS 13.0) for Windows by using one way ANOVA and pairwise comparison with Student's *t* test. *P* < 0.05 was considered statistically significantly.

## RESULTS

#### *RUNX3* protein expression in human gastric carcinoma cell lines

Western blot analysis showed that the relative densities

**Figure 1** RUNX3 expression in the gastric cancer cells detected by Western blot. 1: Positive control: Normal gastric tissue; 2: MKN-28 cells; 3: SGC-7901 cells; 4: MGC-803 cells; 5: BGC-823 cells.

of RUNX3 protein bands of normal gastric mucosa, well-differentiated gastric carcinoma cell line MKN-28, moderately differentiated gastric carcinoma cell line SGC7901, poorly differentiated gastric carcinoma cell lines MGC803 and BGC823 were:  $1.279 \pm 0.105$ ,  $0.003 \pm 0.001$ ,  $1.057 \pm 0.610$ ,  $0.857 \pm 0.212$ ,  $0.477 \pm 0.321$  respectively (Figure 1). The moderately differentiated gastric carcinoma cell lines SGC7901 was selected for further experiments.

#### Identification of the recombinant plasmids

The recombinant eukaryotic expressing vector-pSilencer3.1-H1-shRNA/RUNX3 was cut by the double restriction enzyme *Bam*HI and *Hind*III. Then the enzyme products were electrophoresis using the agar gel (27 g/L). And the objective fragment 65 bp was obtained (Figure 2).

#### mRNA and protein expression of RUNX3 in transfected SGC-7901 cells

In SGC-7901, pSilencer3.1-H1/SGC7901 and pSilencer3.1-H1-shRNA/RUNX3/SGC790 cells, RT-PCR showed that the relative densities of RUNX3 mRNA bands were  $1.116 \pm 0.217$ ,  $1.057 \pm 0.187$  and  $0.002 \pm 0.001$ , respectively (Figure 3), and Western blot analysis indicated that the relative densities of RUNX3 protein bands were  $0.812 \pm 0.091$ ,  $0.786 \pm 0.103$  and  $0.021 \pm 0.002$ , respectively (Figure 4). Immunocytochemistry disclosed that RUNX3 protein was located in the endochylema and the nucleus, and loss of expression of RUNX3 in SGC790 cells transfected with recombinant plasmid-pSilencer3.1-H1-shRNA/RUNX3 (Figure 5).

#### Effect of RUNX3 on proliferation of SGC-7901 cell line

The growth curves showed that the pSilencer3.1-H1-shRNA/RUNX3/SGC7901 cells grew more quickly than the control cells, SGC7901 and pSilencer3.1-H1/SGC7901 cells ( $P < 0.05$ , Figure 6), but that the rate of cell growth

**Figure 2** Identification of recombinant by restrict endonucleases digestion. M: DNA Ladder; 1: pSilencer3.1-H1/SGC7901; 2: pSilencer3.1-H1-shRNA/RUNX3/SGC-7901; 3: pSilencer3.1-H1-shRNA/RUNX3/SGC7901 cut with *Bam*HI/*Hind*III.

**Figure 3** RUNX3 expression in the three groups of cells detected by RT-PCR. M: DL2000 marker; 1: SGC7901 cells; 2: pSilencer3.1-H1/SGC7901 cells; 3: pSilencer3.1-H1-shRNA/RUNX3/SGC7901 cells.

**Figure 4** RUNX3 expression detected by Western blot. 1: SGC7901 cells; 2: pSilencer3.1-H1/c SGC7901 cells; 3: pSilencer3.1-H1-shRNA/RUNX3/SGC7901 cells.

was similar in the two control groups. The results of the soft-agar colony-formation experiment indicated that a significant increase in the colony-formation rate in the pSilencer3.1-H1-shRNA/RUNX3/SGC790 cells ( $17.4 \pm 0.31\%$ ) was found compared with that in the control SGC-79011 ( $9.9 \pm 0.3\%$ ) and pSilencer3.1-H1/SGC7901 ( $9.7 \pm 0.6\%$ ) cells ( $P < 0.01$ , Figure 7). The colony-formation rates of the two control cells were similar. FCM with PI staining suggested that the proportion of cells in  $G_0/G_1$  and S phases in pSilencer3.1-H1-shRNA/RUNX3/SGC7901 cells significantly decreased and increased, respectively ( $P < 0.05$ , Figure 8 and Table 2), compared with the control cells.

**Figure 5** RUNX3 expression in SGC7901 cells by immunohistochemistry ( $\times 400$ ). **A:** SGC7901 cells, the protein of RUNX3 expressed and located in the endochylema and the nucleus in the SGC7901 cell without transfection; **B:** pSilencer3.1-H1/SGC7901 cells, the protein of RUNX3 expressed and located in the endochylema and the nucleus in the SGC7901 cell with the plasmid DNA of pSilencer3.1-H1; **C:** pSilencer3.1-H1-shRNA/RUNX3/SGC7901 cells, the protein of RUNX3 lost expression in the SGC7901 cells transfected with the recombinant plasmid-pSilencer 3.1-H1-shRNA/RUNX3.

**Figure 6** The growth effect of SGC7901 cell by silencing *RUNX3* ( $^aP < 0.05$ ).

### Expression of *RUNX3* in transfected cells treated with 5-Aza-CdR

The pSilencer3.1-H1-shRNA/*RUNX3*/SGC7901 cells ( $1 \times 10^6/100$  mL) were treated with  $5 \times 10^{-6}$  mol/L and  $1 \times 10^{-5}$  mol/L 5-Aza-CdR. Cells were collected after 3 d treatment. The cells treated with  $5 \times 10^{-6}$  mol/L 5-Aza-CdR were named experimental group 1, and those treated with  $1 \times 10^{-5}$  mol/L 5-Aza-CdR were experimental group 2.

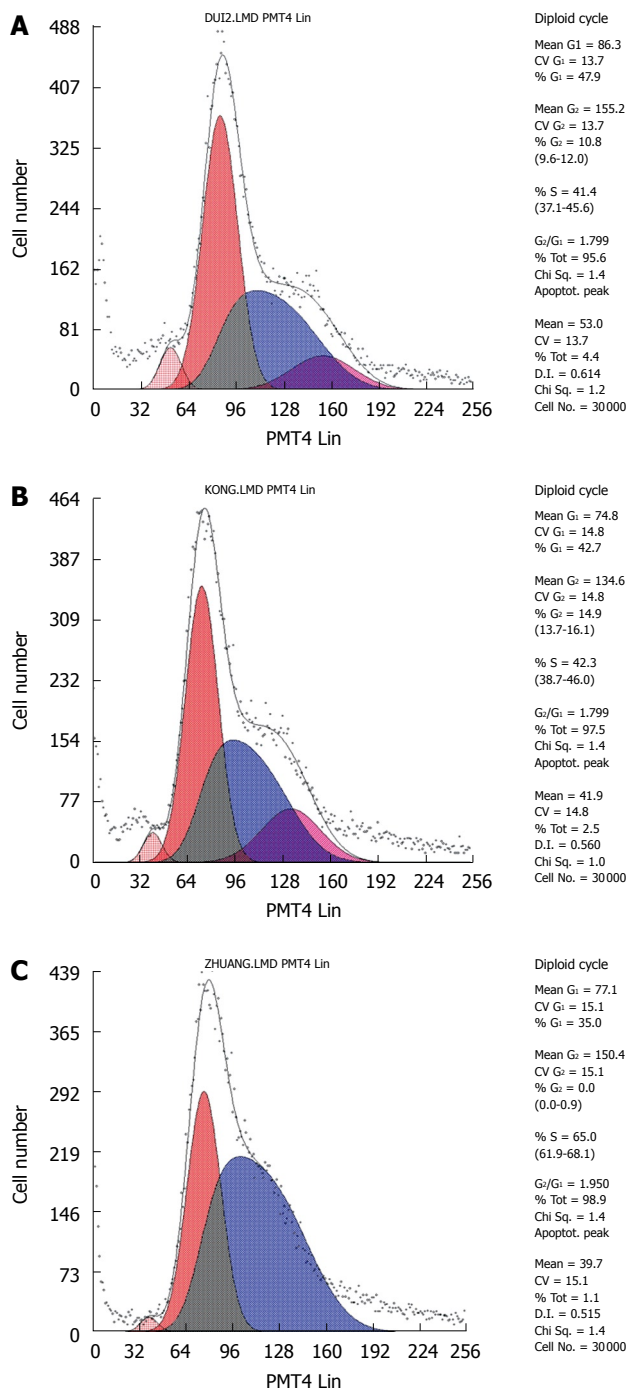

**Figure 7** The colony formation assay of SGC7901 in the soft agar ( $\times 100$ ). **A:** SGC7901 cells, the cloning efficiency was  $9.9\% \pm 0.3\%$  in the SGC7901 cell without transfection; **B:** pSilencer3.1-H1/SGC7901 cells, the cloning efficiency was  $9.7\% \pm 0.6\%$  in the SGC7901 cell with the plasmid DNA of pSilencer3.1-H1; **C:** pSilencer3.1-H1-shRNA/*RUNX3*/SGC7901 cells, the cloning efficiency was  $17.4\% \pm 0.31\%$  in the SGC7901 cells transfected with the recombinant plasmid-pSilencer3.1-H1-shRNA/*RUNX3*. A significant increase of the colony formation rate in the pSilencer3.1-H1-shRNA/*RUNX3*/SGC7901 cells was discovered compared with the controls-the SGC7901 cells and pSilencer3.1-H1/SGC7901 cells ( $P < 0.01$ ).

**Table 2** Cell cycle distribution of three groups by FCM ( $n = 3$ , mean  $\pm$  SD, %)

Groups	G <sub>0</sub> /G <sub>1</sub>	S	G <sub>2</sub> /M

pSilencer3.1-H1-shRNA/SGC7901	40.3 $\pm$ 2.0	49.3 $\pm$ 0.9	8.1 $\pm$ 0.3
pSilencer3.1-H1-shRNA/ <i>RUNX3</i> /SGC7901	37.2 $\pm$ 1.9	60.5 $\pm$ 0.8	7.3 $\pm$ 0.9

RT-PCR showed that the relative densities of *RUNX3* mRNA bands were  $0.861 \pm 0.167$ ,  $0.004 \pm 0.001$ ,  $0.002 \pm 0.001$  and  $0.002 \pm 0.001$ , respectively (Figure 9), and Western blot analysis that the band densities of *RUNX3* were  $1.013 \pm 0.138$ ,  $0.003 \pm 0.001$ ,  $0.002 \pm 0.001$  and  $0.005 \pm 0.001$ , respectively (Figure 10).

**Figure 8** The cell cycle analysis by FCM. **A:** SGC790 cells, the cell proportions of G<sub>0</sub>/G<sub>1</sub> and S stages were  $43.2\% \pm 1.2\%$  and  $47.7\% \pm 1.1\%$  in the SGC7901 cell without transfection, respectively; **B:** pSilencer3.1-H1/SGC7901 cells, the cell proportions of G<sub>0</sub>/G<sub>1</sub> and S stages were  $40.3\% \pm 2.0\%$  and  $49.3\% \pm 0.9\%$  in the SGC7901 cell with the plasmid DNA of pSilencer3.1-H1 respectively; **C:** pSilencer3.1-shRNA/RUNX3/SGC7901 cells, the cell proportions of G<sub>0</sub>/G<sub>1</sub> and S stages were  $37.2\% \pm 1.9\%$  and  $60.5\% \pm 0.8\%$  in the SGC790 cells transfected with the recombinant plasmid-pSilencer3.1-H1-shRNA/RUNX3 respectively. Compared with that of G<sub>0</sub>/G<sub>1</sub> and S stages of two controls, the cell proportions of G<sub>0</sub>/G<sub>1</sub> and S stages in the pSilencer3.1-H1-shRNA/RUNX3/SGC7901 cells decreased and increased obviously, respectively ( $P < 0.05$ ).

## DISCUSSION

In the occurrence and development of gastric carcinoma, the mechanism of abnormal silencing of anti-oncogenes mediated by epigenomics in the un-first-class structure

levels of nucleotide sequence such as DNA methylation and histone modification, is still unclear. Many researchers have assumed that aberrant CpG island hypermethylation of the promoters of anti-oncogenes exists frequently in tumors. However, it is still not known how the aberrant CpG island hypermethylation takes place. Recently, the phenomenon by which siRNA molecules that target gene promoter regions can induce transcriptional gene silencing in a DNA cytosine methylation-dependent manner has attracted much attention.

siRNA can induce post-transcriptional gene silencing through RNA-RNA binding and transcriptional gene silencing through RNA-DNA binding. Transcriptional gene silencing refers to siRNA molecules that hinder production of mRNA from DNA before gene transcription, by

modifying chromosomal DNA and histones. It include three patterns; RNA-directed DNA methylation, RNA-directed heterochromatinization and RNA-directed DNA ablation<sup>[8-10]</sup>. The idea of RNA-directed DNA methylation was obtained from a propagation study in *Arabidopsis thaliana*<sup>[11]</sup>. It is not known whether a similar mechanism exists in mammalian systems.

Some elements, such as the required constituents of RNA-directed DNA methylation in plants, have been discovered in mammals. They contain three DNA methyltransferases (DNMT) 1, which play a role in maintaining methyltransferases. DNMT3A and DNMT3B can be let in the new methylated sites. The two processes including the methylated maintenance and repeated methylation might exist to affect genome DNA in mammals as in plants<sup>[12]</sup>. DNMT3A and DNMT3B have been observed to participate in the orientation of siRNA that target gene promoters<sup>[13]</sup>. As to human HeLa cells, the percentage of the mature-type miR-21 located in the cytoplasm and the nucleus were 80% and 20%, respectively. After transfection with fluorescently-labeled siRNA/miR-21, the fluorescence which siRNA/miR-21 binds the complementary sequences was observed in the cytoplasm and the nucleus. A identical consequence has appeared in cells transfected with fluorescently-labeled siRNA/let-7a<sup>[14]</sup>.

Some previous investigations have reported that siRNA molecules that target gene promoter regions can induce transcriptional gene silencing and DNA cytosine methylation around the promoter region. In the study by Morris *et al*, elongation factor 1  $\alpha$  (EF1 $\alpha$ ) was knocked down by the promoter-directed siRNA in HEK293 cells by transfection. After treatment with 5-Aza-CdR (4  $\mu$ mol/L) and trichostatin A (TSA, 0.05 mmol/L), deactivation of EF1 $\alpha$  was reversed and detected through nuclear run-on assays and RT-PCR. According to the above data, the transcriptional silencing of EF1 $\alpha$  might be associated with DNA methylation of the targeted sequence<sup>[15]</sup>. According to research by Castanotto *et al*, shRNAs, molecules homologous to DNA sequences in the promoter and early transcribed regions of RASSF1, can direct the partial gene silencing and low levels of *de novo* DNA methylation. They used a methylation-specific polymerase chain reaction (MSP) and bisulfite sequencing in HeLa cells<sup>[16]</sup>. Moreover, Weinberg's investigation showed that transcriptional silencing and DNA methylation of EF1 $\alpha$  can be directed by antisense interference alone in human 293T cells transfected with EF1 $\alpha$  siRNA. This targets the promoter of it using the peptide MPG, which transports siRNAs to the nucleus. This silencing is accompanied by increased methylation level in histone 3 lysine 9 (H3K9) and histone 3 lysine 27 (H3K27). Furthermore, siRNAs EF52 is associated with the transient expression of Flag-tagged DNMT3A, the targeted EF1 $\alpha$  promoter, and trimethylated H3K27<sup>[17]</sup>. Previous studies have indicated that, in mammalian cells, the unique RNA endonuclease Dicer, which cuts long dsRNA to form siRNA, is situated in the cytoplasm<sup>[18-20]</sup>. RNA-induced silencing complex (RISC), which binds to siRNAs in the cell-substance, may gain access to the nucleus when caryotheca vanishes during cell division, or it may be transported into the nucleus, as in

plants. Furthermore, siRNA can integrate the homologous DNA sequences (promoters) and induce transcriptional gene silencing in a DNA cytosine methylation-dependent manner<sup>[11,21]</sup>.

We confirmed that aberrant CpG island hypermethylation of the promoter of RUNX3 is a critical pathway to cause down-regulation or loss of expression of the gene. How may the pathway be connected with the mechanism of RNA-directed DNA methylation? In our experiment, on the basis of the principle of RNAi design, pSilencer3.1-H1-shRNA/RUNX3 expression vector was constructed, and transfected in SGC7901 cells by liposomes. RT-PCR, western blot and immunocytochemistry showed that mRNA and protein expression of RUNX3 were absent in the stable cell line SGC7901 transfected with the recombinant plasmid. Moreover, compared with those transfected with pSilencer3.1-H1 and non-transfected cells, cells transfected with pSilencer3.1-H1-shRNA/RUNX3 grew most quickly. Both the clone number and size were largest following soft-agar colony-formation assay ( $P < 0.01$ ) and the number of cells in G<sub>0</sub>/G<sub>1</sub> and S/M phases was lowest and highest following FCM ( $P < 0.05$ ). The above results indicated that, through RNA-dependent transcriptional silencing (RdTS), knockdown of the gene at the transcriptional stage was feasible and effective. After loss of expression of RUNX3 protein, the proliferation rate of SGC7901 cells increased. These results, like the previous description<sup>[3-6]</sup>, suggested that RUNX3, a putative tumor suppressor, might have an important role in stomach tumorigenesis. However, after the deal with the different density of 5-Aza-CdR, which may reactivate anti-oncogenes silenced by *de novo* methylation, inactivated RUNX3 was not reactivated, as shown by RT-PCR and the silenced. The phenomenon was different from the RdDM described in plants. At the same time, similar results have been reported. In two human glioblastoma cell lines, U-87 and U-118, siRNA homologous to the promoter region of *huntingtin* gene can repress transcriptional expression of the target gene. However, no CpG methylation has been observed on the target sequences by bisulfite-mediated genomic sequencing<sup>[21,22]</sup>. In the research of Ting *et al*, the human colorectal cancer cells, HCT116, were transfected with two 21-nucleotide-long dsRNAs (dsCDH1-1 and dsCDH1-2). The two sequences were homologous to the CpG island of the endogenous gene promoter of *CDH1* but did not overlap any known transcribed sequences. The findings suggested that promoter-targeting dsRNAs could effectively silence *CDH1* transcription, which results in a net decrease in mRNA and protein production, as demonstrated by RT-PCR and Western blot. Absence of DNA methylation at the targeted sequences was reviewed by MSP and bisulfite sequencing. Transfection of the human breast cancer cells, MCF-7, used a silencing strategy virtually identical to that above for *CDH1*. The transcriptional silencing without DNA methylation was reviewed and the results were identical<sup>[23]</sup>.

What accounts for these opposing results? We believe the answer may lie in the types of DNA methylation assays performed. In the work by Morris *et al*, the DNA methylation data remain to be verified because DNA

methylation was not as extensive, and there was indirect evidence for 5-Aza-CdR and TSA, a histone-deacetylase inhibitor. Co-administration alleviating the silencing was difficult to interpret as the reason of the *EF1 $\alpha$*  silencing. In other investigations, MSP distinguishes between non-methylated and methylated alleles by using two sets of primers to amplify either non-methylated or methylated sequences after bisulfite treatment, which specifically converts non-methylated cytosines to uracils. The shortcoming of MSP analysis is that it examines a few CpG sites in the sequences that are recognized by the primers, and the design of primers is very difficult. Mismatch sequencing was used to verify the overall target region by unbiased primers that did not contain CpG dinucleotides to amplify the bisulfite-converted promoter region. Due to the existence of incomplete mismatch conversions, unconverted cytosine residues in both CpG and CpG contexts remained as cytosine and created a false negative result. Furthermore, the PCR primers that were used previously to obtain the initial mismatch sequencing template that contains CpG sites may bias the amplification step and produce problematic mismatch sequencing results<sup>[5]</sup>. Such non-conversions may partly explain the different results in the mismatch sequencing. In the current study, the level of DNA methylation was testified preliminary and indirect. The finding that inactivation of *RUNX3* was not reactivated with 5-Aza-CdR could not confirm sufficiently that the transcriptional silencing of *RUNX3* was independent of DNA methylation. Therefore, further study is needed.

Taken together, the presence of RdTS indicated that RdDM might be an existing gene regulatory mechanism relevant to methylation in humans, even though we are currently unable to verify this. A recent study has shown that, in *A. thaliana*, RdDM is studied in the progeny of plants being silenced, and DNA methylation may still be involved in a prolonged silencing event in human cells<sup>[24]</sup>. Therefore, further experiments, which include a thorough examination of the long-term and full-scale outcomes of RdTS, are needed to research RNA-directed DNA methylation in mammalian systems.

## COMMENTS

### Background

Aberrant CpG island hypermethylation of the promoter of *RUNX3*, a tumor suppressor, is associated with its transcriptional silencing and the loss of gene functions in stomach cancer. However, the mechanism of the aberrant CpG island hypermethylation is still unclear.

### Research frontiers

In plants, siRNA molecules that target gene promoter regions can induce transcriptional gene silencing in a DNA cytosine methylation-dependent manner (RdDM). Whether a similar mechanism exists in mammalian systems is a vital and controversial issue. Recently, the RdDM theory on gene regulation has attracted close attention from researchers and has become a highlight in tumor studies.

### Innovations and breakthroughs

This article focuses on the relationship between siRNA molecules and aberrant CpG island hypermethylation in the promoter domain of *RUNX3*, through the RNA interference principle and gene transfection technology in human gastric cancer cell lines.

### Applications

*RUNX3* is an important anti-oncogene. Its mechanism of methylation may contribute to the study of the etiology of gastric cancer, and offer a theoretical basis for gene therapy of gastric cancer

### Terminology

RNA interference is an evolutionarily conserved mechanism of gene silencing. It can affect transcriptional gene silencing induced by siRNA that target gene promoter regions in a DNA cytosine methylation-dependent manner.

### Peer review

This is a good study in which the authors demonstrated that, shRNAs that targeted gene promoter regions of *RUNX3* could effectively induce transcriptional repression with chromatic changes characteristic of inaction promoters, but it was independent of DNA methylation. The study was well designed and the results are convincing.

## Abstract

**AIM:** To investigate the malignant potential of hepatic stem cells derived from the bone marrow stromal cells (BMSCs) in a mouse model of chemical hepatocarcinogenesis.

**METHODS:** BMSCs from male BALB/c mice were harvested and cultured, then transplanted into female syngenic BALB/c mice *via* portal vein. Hepato-carcinogenesis was induced by 6 mo of treatment with diethylnitrosamine (DEN). Six months later, the liver was removed from each treated mouse and evaluated by immunohistochemistry and fluorescence *in situ* hybridization (FISH).

**RESULTS:** Twenty-six percent of recipient mice survived and developed multiple hepatocellular carcinomas (HCCs). Immunohistochemically, HCC expressed placental form of glutathione-S-transferase (GST-P) and  $\alpha$ -fetoprotein, but did not express cytokeratin 19. Y chromosome positive hepatocytes were detected by fluorescent *in situ* hybridization (FISH) in the liver of mice treated with DEN after BMSCs transplantation while no such hepatocytes were identified in the liver of mice not treated with DEN. No HCC was positive for the Y chromosome by FISH.

**CONCLUSION:** Hepatic stem cells derived from the bone marrow stromal cells have a low malignant potential in our mouse model of chemical hepatocarcinogenesis.

## INTRODUCTION

Hepatocellular carcinoma (HCC) is the fifth most common cancer in the world<sup>[1]</sup>. Hepatitis B or C virus can induce chronic hepatitis and potentially result in liver cirrhosis and HCC, and these viral infections are frequently seen among HCC patients<sup>[2]</sup>. However, there is no clear evidence as to which cell is directly involved in the development of HCCs<sup>[3-5]</sup>. Two cell lineages have been considered as candidates: the first is hepatic stem cell, and the second is mature hepatocyte.

Oval cells are small, oval shaped epithelial cells identified as hepatic stem cells in the adult liver only following severe, repetitive liver injury<sup>[6]</sup>. There are increasing evidences that oval cells are the cellular targets for transformation in the development of HCC<sup>[7-8]</sup>. Oval cells might give rise to HCC as a result of the arrest of stem cell maturation<sup>[9]</sup>. Previous studies indicated that bone marrow cells can differentiate into oval cells in rodents and that a similar process could possibly take place in humans<sup>[10,11]</sup>. The incidence of plasticity has been shown to be very variable, from extremely rare to a range from 20% to 40%<sup>[12,13]</sup>. Although there is still controversy about which part of bone marrow cells can differentiate into hepatocytes, the present study clearly shows that transplanted bone marrow cells may help restore the hepatic degenerative diseases and reduce CCl<sub>4</sub>-induced liver fibrosis<sup>[14]</sup>. Some studies readily demonstrated bone marrow stromal cells (BMSCs) differentiated into hepatocyte-like cells in culture

after HGF treatment *in vitro*<sup>[15]</sup>. Therefore, BMSCs could be a valuable strategy for future replacement therapy of damaged or malfunctioned hepatocytes, because getting autologous BMSCs is easier than obtaining other tissue-specific stem cells. However, the safety and efficacy of hepatic stem cells derived from bone marrow cells should be adequately confirmed before any such therapies are tested in humans.

Our aim was to study the malignant potential of hepatic stem cells derived from BMSCs *in vivo*. To identify hepatic stem cells, BMSCs of male mice were transplanted into recipient female mice. After BMSCs transplantation, HCC was induced in the recipients by chemical hepatocarcinogenic compounds and the presence of the Y chromosome was evaluated in HCC.

## MATERIALS AND METHODS

### Animals

Six to eight week old BALB/c mice were purchased from the Animal Breeding Center of Sun Yat-Sen University (Guangzhou, China). Mice were bred and maintained in an air-conditioned animal house with specific pathogen-free conditions, using an alternate 12 h cycle of daylight and darkness, and unlimited access to chow and water. All animal experiments were performed in accordance with the guidelines of the Animal Care and Use Committee of Sun Yat-Sen University.

### Isolation and culture of bone marrow stromal cells (BMSCs)

BMSCs were harvested from bone marrow of the femurs and tibias of male mice by inserting a 21-gauge needle into the shaft of the bone and flushing it with DMEM medium supplemented with heparin<sup>[16]</sup>. The cell suspension was centrifuged over a Ficoll step gradient (density 1.077 g/mL) (Sigma, St. Louis, MO) at 1500 r/min for 10 min. The interface fraction was then collected and cultured in DMEM medium, supplemented with 10% fetal bovine serum, 2 mmol/L L-glutamine, 100 U/mL penicillin, and 100 µg/mL streptomycin. Isolated cells were grown at 37°C and 5% CO<sub>2</sub> for 3 d. After removing the suspended cells, the adherent BMSCs were grown to 90% confluence and used between passages 3 and 4. After serum starvation for 4 h, BMSCs were treated with human recombinant HGF (Sigma-Aldrich, USA) at a concentration of 50 µg/L. Cultures were maintained by media exchange every 3 d. On d 21, all cells were detached for the next experiment.

The above detached cells were coated on the glass slides and fixed with 4% paraformaldehyde for 10 min at room temperature, followed by methanol for 2 min at -20°C, and permeabilized with 0.1% Triton X-100 for 10 min. Slides were blocked for 30 min using blocking and diluent solution, then incubated with rabbit anti- $\alpha$ -fetoprotein antibody or goat anti-albumin antibody at 4°C overnight. The cells were reincubated sequentially for 30 min with FITC-conjugated secondary antibody or PE-conjugated secondary antibody. The slides were counterstained with 4',6-diamidino-2-phenylindole (DAPI, Sigma) before mounting and observed under fluorescence microscope.

### Transplantation of BMSCs

BMSCs were harvested after cultured for passages 3 or 4 and suspended in DMEM medium supplemented with penicillin/streptomycin. BMSCs were washed twice in DMEM medium before intraportal injection. Cell viability (> 95%) was measured by trypan blue dye exclusion.

Anesthesia was performed with ether and partial hepatectomy used the standard method for two-thirds resection<sup>[17]</sup>. Briefly, after ligation of the pedicle and resection of the two largest lobes (median and left), the remaining liver was composed of the caudate and epiploic lobes. BMSCs were injected into the female liver *via* the superior mesenteric vein using insulin syringes after hepatectomy<sup>[18]</sup>. A total of 10<sup>6</sup> cells were injected per mouse.

### Diethylnitrosamine(DEN)-induced hepatocarcinogenesis

After partial hepatectomy and BMSCs injection, mice were allowed to recover for one week. Thereafter, DEN (Sigma) was continuously administered for 12 wk through drinking water at a final concentration of 100 µg/L to induce hepatocarcinogenesis<sup>[3]</sup>.

Sixty female BALB/c mice were randomly assigned to three groups. Ten mice in the normal control group were given BMSCs and non-supplemented drinking water. Twenty-five mice in the model group were continuously administered DEN in the drinking water. Twenty-five mice in the experimental group received BMSCs and DEN. The animals were sacrificed at 6 mo after the carcinogen regimen and the livers were fixed in 10% formalin for 24 h and embedded with paraffin. Routine histology was performed with haematoxylin-eosin staining. Serial sections were cut from liver samples with the macroscopically visible liver tumors and the right lobe for pathologic examination.

### Liver histopathology

To identify characteristics of tumors in the liver after BMSCs transplantation and DNE administration, placental form of glutathione-S-transferase (GST-P),  $\alpha$ -fetoprotein, and cytokeratin 19 were assayed immunohistochemically for these tumor nodules as previously described<sup>[19]</sup>. Briefly, after being deparaffinized with xylene, quenched with hydrogen peroxide and blocked with normal serum, the liver tissue sections were incubated for 1 h with rabbit anti- $\alpha$ -fetoprotein polyclonal antibody (dilution 1:100; Santa Cruz, USA), goat anti-cytokeratin 19 monoclonal antibody (dilution 1:100; Santa Cruz), or goat anti-GST-P polyclonal antibody (dilution 1:1000; Stressgen, Canada). FITC-conjugated secondary antibody or PE-conjugated secondary antibody was added. Counterstaining of nuclei was performed with DAPI for fluorescence staining.

### Fluorescent in situ hybridization (FISH)

Because BMSCs transplantation was performed from male donor mice to female recipient mice, the transplanted bone marrow derived cells could be recognized in the recipient by the presence of the Y chromosome in the nucleus. Therefore, FISH for the mouse Y chromosome was conducted to detect the transplanted bone marrow derived cells according to the Cambio protocol (<http://www.cambio.com>).

**Figure 1** Immunofluorescence of  $\alpha$ -fetoprotein and albumin in bone marrow stromal cells, with or without treatment of HGF in culture ( $\times 400$ ). **A:**  $\alpha$ -fetoprotein expression was negative in the absence of HGF; **B:** Albumin expression was negative in the absence of HGF; **C:**  $\alpha$ -fetoprotein expression localized at the cytoplasm in hepatocyte-like BMSCs; **D:** Albumin expression localized at the cytoplasm in hepatocyte-like BMSCs.

cambio.co.uk/). Paraffin-embedded slides were deparaffinized by baking in an oven overnight at  $37^{\circ}\text{C}$  and cleared in xylene three times for 10 min each; and they were then dehydrated and air-dried. Sections were incubated in 1 mol/L sodium thiocyanate for 10 min at  $80^{\circ}\text{C}$ , washed in PBS, and digested in pepsin (0.4% w/v) in 0.1 mol/L HCl at  $37^{\circ}\text{C}$  for 10 min. The protease was quenched in glycine (0.2% v/w) in  $2 \times$  PBS, post-fixed in paraformaldehyde (4% w/v) in PBS, dehydrated through graded alcohols and air-dried. A fluorescein isothiocyanate (FITC)-labeled Y-chromosome paint (Cambio, Cambridge, UK) was added to the sections, sealed under glass with rubber cement, heated to  $80^{\circ}\text{C}$  for 10 min, and incubated overnight at  $37^{\circ}\text{C}$ . The slides were washed in formamide (50% w/v)/ $2 \times$  saline sodium citrate (SSC) at  $37^{\circ}\text{C}$ , washed with  $2 \times$  SSC and  $4 \times$  SSC/Tween-20 (0.05% w/v) at  $37^{\circ}\text{C}$ . The slides were rinsed in  $0.5 \times$  SSC at  $37^{\circ}\text{C}$ . FITC amplification kit (Cambio) was used to amplify fluorescence signal. The slides were counterstained with DAPI before mounting and observed under confocal microscope (Zeiss, German).

### Statistical analysis

Data were presented as mean  $\pm$  SD. Significant differences were determined using ANOVA in SPSS10.0.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Differentiation of BMSCs into hepatocytes in vitro

To confirm the differentiation of BMSCs into hepatocytes, we selected cultural BMSCs with or without treatment of HGF for 21 d in culture and examined the expression of  $\alpha$ -fetoprotein and albumin by immunofluorescence. We found that

cultural BMSCs without treatment of HGF could not express  $\alpha$ -fetoprotein and albumin (Figure 1A and B), while differentiated hepatocyte-like BMSCs with treatment of HGF expressed  $\alpha$ -fetoprotein and albumin (Figure 1C and D).

### Survival rate

We evaluated the survival rate of mice that underwent BMSCs transplantation and/or DEN treatment. All mice that underwent BMSCs transplantation were still alive at the end of the study. Thirteen (26.0%) of 50 mice induced with DEN survived at the end of the 6-month study period, including six mice in the model group and seven in the experimental group. The survival rates were similar between the model group and the experimental group ( $P > 0.05$ ).

### Tumor development in the livers of recipient mice

All of the survived recipient mice developed multiple HCCs. Thirteen mice developed HCCs including six mice in the model group and seven mice in the experiment group. These tumors were evenly distributed among the liver lobes of mice. The average sizes of hepatic tumors were not different between the two groups ( $4.8 \pm 1.5$  mm vs  $4.4 \pm 1.1$  mm;  $P > 0.05$ ).

HE stained sections of these tumors confirmed to be HCCs (Figure 2A) expressed GST-P and  $\alpha$ -fetoprotein (Figure 2B and C), but not Cytokeratin 19 (Figure 2D). No other types of liver tumors, such as hepatoblastoma or cholangiocellular carcinoma, were noted in our experiment.

### Repopulation and carcinogenesis of transplanted BMSCs

To follow the repopulation and differentiation of BMSCs, we transplanted male BMSCs into the liver of normal and

**Figure 2** Histopathological analysis of the tumors in the liver serial sections of recipient mice after 6 mo of DEN treatment ( $\times 400$ ). **A:** HCC nodules development at 6 mo stained with haematoxylin-eosin; **B:** HCC expressing GST-P appeared as red fluorescence by immunofluorescence; **C:** HCC expressing  $\alpha$ -fetoprotein appeared as green fluorescence by immunofluorescence; **D:** HCC was negative for cytokeratin 19 by immunofluorescence.

**Figure 3** Repopulation and carcinogenesis of male bone marrow-derived cells in female recipient liver tissues by FISH for Y chromosome ( $\times 400$ ). **A:** normal male liver, positive Y-chromosome signals appeared as green dots in the nuclei stained with DAPI, a chromosomal marker that appears as blue fluorescence; **B:** Six months after BMSCs transplantation and DEN treatment, some of hepatocyte nuclei were positive for the Y chromosome in the liver of female recipients; **C:** Six months after BMSCs transplantation without DEN treatment, none of hepatocyte nuclei was positive for Y chromosome in the liver of female recipients; **D:** HCC was negative for Y chromosome in nucleus.

DEN-treated female mice. FISH was performed to detect Y chromosome in the female recipients. A positive FISH signal was detected in the nucleus which was confirmed

by counterstaining with DAPI. In male mouse liver, which served as positive control, most of the cells stained positive for Y-chromosome with fluorescein signal in the nuclei (Figure 3A).

We found that male BMSCs infused *via* portal vein into female syngeneic mouse liver could engraft and differentiate into hepatocytes after induction with DEN using FISH for Y chromosome. Six months after BMSCs transplantation and DEN challenge, FISH revealed that 15% of hepatocyte nuclei were positive for the Y chromosome in the liver of female recipients (Figure 3B). In addition, no nucleus showed two or more signals. However, donor-derived cells were not detected when BMSCs were transplanted to normal recipients without DEN treatment (Figure 3C). Moreover, no HCC was positive for the Y chromosome by FISH (Figure 3D).

## DISCUSSION

The liver is classified as a conditionally renewing tissue and hepatocytes proliferate quiescently and hepatic stem cells are not needed under normal circumstances. Oval cells reside within or adjacent to the canals of Hering and comprise a quiescent compartment of dormant stem cells in adult livers<sup>[6]</sup>. They can be activated to proliferate and differentiate into hepatocytes or bile duct epithelial cells when there is severe hepatic liver damage and coexistent impaired hepatocyte regeneration.

Accumulated evidence indicates that bone marrow cells can differentiate into specific cell types<sup>[20]</sup>. It has been reported that 30%-50% liver regeneration with bone marrow-derived cells in the FAH mouse model offers a selective proliferative advantage in the transplanted cells<sup>[21]</sup>. Bone marrow-derived hepatocytes may originate from the

mesenchymal compartment, rather than the hematopoietic compartment<sup>[22]</sup>. However, other data demonstrate that bone marrow-derived hepatocyte is only a possible but rare event, even in the presence of very strong selection pressure<sup>[23]</sup>. Several reports have demonstrated that cell fusion is the principal source of bone marrow-derived hepatocytes<sup>[24]</sup>, and bone marrow-derived hepatocytes are primarily of mature myelomonocytic cells which fuse spontaneously with host hepatocytes producing functional liver repopulation<sup>[14]</sup>.

The identity of the specific cell types that differentiate to express hepatocyte characteristics remains undetermined. BMSCs comprise marrow stromal stem cells, sharing characteristics with other multi-potent stem cells such as neural stem cells and hematopoietic stem cells, because they possess the capability of self-renewal and progeny differentiation potentials<sup>[25]</sup>. Our study demonstrates that cultured BMSCs differentiated hepatocyte-like cells which expressed  $\alpha$ -fetoprotein and albumin with the treatment of HGF *in vitro*. After BMSCs transplantation, Y chromosome positive cells appeared only in mice treated with DEN and not in mice who did not receive DEN. These results suggest that in our model, BMSCs can differentiate into hepatocytes under limited conditions. Bone marrow-derived hepatic stem cells seem not to be required for normal hepatocyte substitution. Indeed, in the present study, we found that in positive hepatocytes, no nucleus had two or more Y chromosomes by FISH. This finding indicates that transdifferentiation, rather than cell fusion, was the main process in our model.

DEN is a DNA alkylating agent that is rapidly metabolized to reactive metabolites. These metabolites interact with DNA to form various DNA adducts, leading to genetic alterations<sup>[26]</sup>. GST-P is a highly expressed cytoplasmic protein during early and late steps of carcinogenesis and GST-P sensitivity is higher than that of other enzymes for the detection of malignant transformation<sup>[27]</sup>. Seventy percent of HCCs were stained positively for  $\alpha$ -fetoprotein in clinical cases. In our study, chronic exposure to DEN caused multiple HCCs. These HCCs express GST-P and  $\alpha$ -fetoprotein, but not cytokeratin 19 which was expressed in cholangiocellular carcinoma.

In this study, we focused our interest on the original cell lineage of carcinogenesis. There are two major nonexclusive hypotheses of the cellular origin of cancer: from stem cells due to maturation arrest or from dedifferentiation of mature cells. Debate has centered on whether hepatocytes are responsible for HCCs through dedifferentiation, or whether oval cells are the prime target for malignant changes after a differential "block"<sup>[3,5]</sup>. Oval cells are possibly involved in hepatocarcinogenesis based on the followings: (1) massive existence of oval cells in an animal rodent hepatocarcinogenic model<sup>[28]</sup>; (2) development of HCC after transformation of oval cells<sup>[8]</sup>; and (3) occurrence of mixed hepatocellular and cholangiocarcinomatous tumors (oval cell exhibits bipotential developmental ability)<sup>[29]</sup>. However, the relationship between oval cells and cancer is only circumstantial. In this study, no HCC was positive for Y chromosome after long-term carcinogenic induction. However, as all hepatic stem cells might not be labeled by our method as mentioned above, we cannot completely exclude the stem cell theory. Although

our results may be limited to BMSCs transplanted mice treated with DEN, we can state that the malignant potential of the hepatic stem cell derived from bone marrow seems to be low. Further studies are needed to clarify the precise interaction of bone marrow cells with hepatic regeneration and carcinogenesis using other animal models or human studies.

In conclusion, our study demonstrates that cultured BMSCs could differentiate hepatocyte-like cells with HGF treatment *in vitro*. BMSCs can differentiate into hepatocytes in our model. Hepatic stem cells derived from bone marrow stromal cells are not cellular origin of hepatocellular carcinomas in the DEN model of carcinogenesis. Bone marrow cells may potentially be used in cell based replacement therapy or gene delivery systems. Under these circumstances, our results indicate that hepatic stem cell therapy derived from bone marrow is safe.

## COMMENTS

### Background

Bone marrow stromal cells can differentiate into hepatic stem cells in rodents and in humans. Bone marrow stromal cells could be a valuable strategy for future replacement therapy of damaged or malfunctioned hepatocytes, because getting autologous bone marrow cells is easier than obtaining other tissue-specific stem cells. However, the safety and efficacy of hepatic stem cells derived from bone marrow stromal cells should be adequately confirmed before any such therapies are tested in humans.

### Research frontiers

There are two major nonexclusive hypotheses of the cellular origin of cancer: from stem cells due to maturation arrest or from dedifferentiation of mature cells. Debate has centered on whether hepatocytes are responsible for hepatocellular carcinoma (HCC) through a process of dedifferentiation, or whether oval cells are the prime target for malignant changes after a differential "block". There are increasing evidences that oval cells are the cellular targets for transformation in the development of HCC. Accumulating evidences indicate that bone marrow cells can differentiate into specific cell types. It has been reported that 30%-50% liver regeneration with bone marrow-derived cells in the FAH mouse model offers a selective proliferative advantage in the transplanted cells. Bone marrow-derived hepatocytes may originate from the mesenchymal compartment, rather than the hematopoietic compartment.

### Innovations and breakthroughs

This study demonstrates that cultured bone marrow stromal cells could differentiate hepatocyte-like cells *in vitro*. Bone marrow stromal cells can differentiate into hepatocytes. Hepatic stem cells derived from bone marrow stromal cells are not cellular origin of hepatocellular carcinomas in a mouse model of carcinogenesis. Bone marrow cells may potentially be used in cell based replacement therapy or gene delivery systems. The results in this study indicate that hepatic stem cell therapy derived from bone marrow is safe.

### Applications

Bone marrow stromal cells might be applicable for future replacement therapy of damaged or malfunctioned hepatocytes.

### Peer review

This paper is interesting and the study appears well conducted. The conclusions, although of a limited scope given the design of the study, are in agreement with the results.

## Abstract

**AIM:** To compare the costs and effectiveness of no screening and no eradication therapy, the population-based *Helicobacter pylori* (*H. pylori*) serology screening with eradication therapy and  $^{13}\text{C}$ -Urea breath test (UBT) with eradication therapy.

**METHODS:** A Markov model simulation was carried out in all 237900 Chinese males with age between 35 and 44 from the perspective of the public healthcare provider in Singapore. The main outcome measures were the costs, number of gastric cancer cases prevented, life years saved, and quality-adjusted life years (QALYs) gained from screening age to death. The uncertainty surrounding the cost-effectiveness ratio was addressed by one-way sensitivity analyses.

**RESULTS:** Compared to no screening, the incremental cost-effectiveness ratio (ICER) was \$16166 per life year saved or \$13571 per QALY gained for the serology screening, and \$38792 per life year saved and \$32525 per QALY gained for the UBT. The ICER was \$477079 per life year saved or \$390337 per QALY gained for the UBT compared to the serology screening. The cost-effectiveness of serology screening over the UBT was robust to most parameters in the model.

**CONCLUSION:** The population-based serology

## INTRODUCTION

Gastric cancer is the second leading cause of cancer death worldwide, which leads to a substantial burden of morbidity, mortality, and health care costs<sup>[1,2]</sup>. *H. pylori* infection has been recognized as an important risk factor for cancer of gastric body and antrum (distal cancers)<sup>[3,4]</sup>. Approximately 50% of the world population has been affected by *H. pylori*<sup>[5]</sup>. Although less than 1% of the infected will develop cancer, population-based *H. pylori* screening in high-risk population has been proposed as a cost-effective strategy in the long term in Western countries<sup>[6-8]</sup>.

The East Asian countries such as China and Japan have the highest incidence of distal gastric cancer, which is twice as common in males as in females<sup>[1]</sup>. *H. pylori* infection was also found to be strongly linked to increased risk of gastric cancer in ethnic Chinese and Japanese<sup>[9]</sup>. Early detection and eradication of *H. pylori* infection might be a useful way to reduce the risk of gastric cancer in Asian populations where prevalence of *H. pylori* infection and gastric cancer are significantly higher than in the West<sup>[1]</sup>. However, it is unknown whether it is cost-effective to implement population-based *H. pylori* screening

in high-risk Asian populations. Moreover, two widely used screening programs demonstrated good sensitivity and specificity in detection of *H pylori* infection in Chinese<sup>[10,11]</sup>, therefore the question arises which screening program is more cost effective?

This study was aimed to evaluate the clinical and economic effects associated with no screening, population-based *H pylori* serology screening, and population-based <sup>13</sup>C-Urea breath test (UBT) in Singapore Chinese males using a Markov model.

## MATERIALS AND METHODS

### Model structure

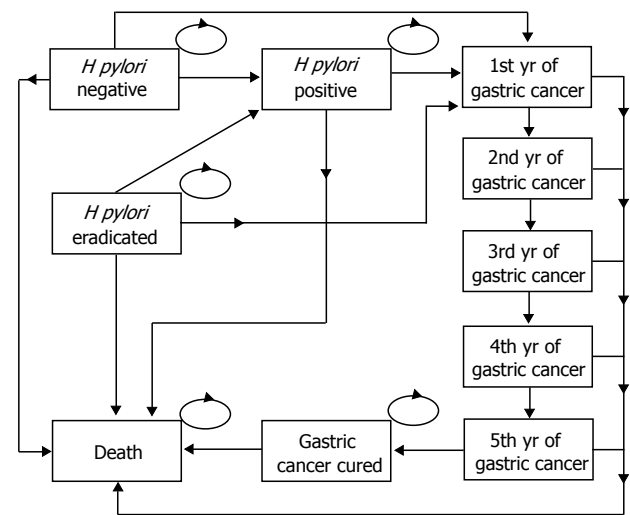

The decision analytical model compared three strategies: strategy 1, no screening and no eradication therapy; strategy 2, single serology screening for *H pylori* and treating those tested positive with eradication therapy; and strategy 3, single screening for *H pylori* using the UBT and treating those tested positive with the same eradication therapy as used in strategy 2. After the screening and treatment, both costs and outcomes of the strategies were evaluated using a Markov model (Figure 1)<sup>[12,13]</sup>, which, from the public healthcare provider's perspective, estimated the costs, number of gastric cancer cases prevented, life years saved, and quality-adjusted life years (QALYs) gained from screening age to death (either died of gastric cancer or other causes, or achieved full life expectancy<sup>[14]</sup>). The distribution of people in the Markov states before the simulation started (i.e. cycle 0) was determined by the sensitivity and specificity of the screening strategies and prevalence of *H pylori* infection. The transition probabilities and corresponding plausible ranges in the model were obtained from a critical review of the published literature on target population where available (Table 1). Probabilities were converted from available rates using the formula recommended<sup>[13]</sup>.

### Sensitivity analyses

One-way sensitivity analyses were conducted by altering individual variables within the aforementioned ranges. Based on the one-way sensitivity analyses, we additionally performed the best-case and the worst-case analyses, which included the most optimistic and pessimistic values for selected key variables.

### Incidence and prevalence rates

We evaluated all Singapore Chinese males aged from 35 to 44 as the prevalence of *H pylori* infection at this age group increased substantially compared to the younger age<sup>[10,15]</sup>. Age-specific *H pylori* infection rate, gastric cancer incidence, and mortality were applied when the cohort aged in the model<sup>[10,16,17]</sup>. The relative risk in developing gastric cancer in *H pylori* infected persons compared to the uninfected was obtained from published literature<sup>[3,18]</sup>. Proportion of gastric cancer death among deaths from all causes was derived from local reports<sup>[17]</sup>. The 1- to 5-year survival rates were estimated from a large prospective cohort study in Chinese<sup>[19]</sup>. Persons who survived for more

**Figure 1** Markov model schematic. *H pylori* eradicated referred to the state of persons with positive screening test and the infection was successfully eradicated by the triple therapy.

than 5 years after diagnosis of gastric cancer were assumed to be cured and therefore achieved full life expectancy as the 5-year survival rate adequately reflected the curative success of gastric cancer treatment<sup>[7,20]</sup>.

### Screening and eradication therapy

The screening strategies included 1 single serology screening by using enzyme-linked immunosorbent assay (ELISA) with a sensitivity and specificity of 93% and 79%, respectively (strategy 2)<sup>[10]</sup> and 1 single UBT using simple gas chromatograph-mass selective detector with a sensitivity and specificity of 97.9% and 95.8%, respectively (strategy 3)<sup>[11]</sup>. In both strategies, persons with positive test for *H pylori* (including both true and false positive) were treated with a triple therapy (i.e. rabeprazole 20 mg, amoxicillin 1000 mg, clarithromycin 500 mg, all twice a day for 4 d) with an eradication rate of 91%<sup>[21,22]</sup>. This regimen was specifically chosen because it is safe and effective with less resistance rate in patients and is recommended by the Asia-Pacific consensus conference<sup>[23-25]</sup>. Persons who stopped the triple therapy due to side effects or did not comply with the regimen were considered as treatment failure and thus remained infected. Persons who remained infected despite attempts at eradication had life expectancies and other outcomes identical to the infected who did not undergo treatment. The reinfection rate of the persons whose infection had been successfully eradicated was assumed to be identical to the persons who had never been infected (i.e. 1% annually in the base-case analysis)<sup>[6,26]</sup>. Once the reinfection occurred, an individual's gastric cancer risk was considered the same as that of an untreated, infected person of the same age.

An underlying assumption of the present study is that eradication of *H pylori* infection can reduce only the certain level of excess risk of distal gastric cancer (60% of all gastric cancers)<sup>[4,27]</sup>. We conservatively assumed that persons cured of *H pylori* infection will

Table 1 Parameter estimates in the base-case analysis

Input variable	Base-case analysis	Range	Ref.
Incidence and prevalence rates			
Age-specific prevalence of <i>H pylori</i> (%)	20.0-43.3	-	[10]
Age-specific prevalence of gastric cancer per 100 000	3-342	-	[17]

Triple therapy: Rabeprazole 20 mg, amoxicillin 1000 mg, and clarithromycin 500 mg, twice a day for 4 d. <sup>1</sup>All costs were estimated from the records of local public hospitals.

have 30% of excess risk reduction compared to those *H pylori* infected persons in the base-case analysis, while a wide range of excess risk reduction from 10% to 100% was tested in one-way sensitivity analysis.

## Costs

The present study was done from the public healthcare provider's perspective. Thus, the model included direct medical costs of serology screening, the UBT, and triple therapy. Adverse effects associated with the triple therapy that necessitated medical intervention were also included (Table 1). Annual direct medical costs associated with treatment of gastric cancer were estimated at the average level across different stages of the cancer<sup>[28]</sup>. Nonmedical direct costs and indirect costs were not included. The costs were accrued from the time of screening until death. All costs were reported in 2006 US dollars and annually discounted at 3% in all analyses<sup>[29]</sup>.

## Effectiveness

Three health outcomes evaluated in this model included number of gastric cancer cases prevented, life years saved,

and QALYs gained. All outcomes were also annually discounted at 3% in the base-case analysis<sup>[29]</sup>.

## Incremental cost-effectiveness ratio (ICER)

ICER was expressed as US dollars per life year saved and US dollars per QALY gained, which were calculated for the two screening strategies compared to no screening strategy, as well as the UBT compared to the serology screening. The cost-effectiveness threshold was estimated at \$28 000 per QALY gained in local context, which was derived from the conventional threshold of \$50 000 per QALY gained used in the United States by comparing the gross national income per capita between the United States and Singapore<sup>[28,30]</sup>.

## RESULTS

There were a total of 237 900 Chinese males aged between 35 and 44 in Singapore<sup>[31]</sup>. In the base-case scenario, compared to no screening and no eradication therapy, strategy 2 that implemented the serology screening on all cohort members with treatment for those with positive test

**Table 2** Incremental cost-effectiveness ratios of screening strategies at age 40 yr (compared to no screening strategy unless stated)

US\$/QALY	Base-case		Best-case <sup>1</sup>		Worst-case <sup>1</sup>	
	Serology	UBT	Serology	UBT	Serology	UBT
ICER per life year saved	16166	38792 477079 <sup>2</sup>	Dominant	Dominant Dominant <sup>2</sup>	389728	640000 5645449 <sup>2</sup>
ICER per QALY gained	13571	32525 390337 <sup>2</sup>	Dominant	Dominant Dominant <sup>2</sup>	324773	560000 Dominated <sup>2</sup>

ICER: Incremental cost-effectiveness ratio; QALY: Quality-adjusted life year; UBT: <sup>13</sup>C-Urea breath test. <sup>1</sup>Variables modified in best and worst-case analyses were, gastric cancer risk reduction by eradication (100% and 10%, respectively), relative risk (12 and 2), cost of annual gastric cancer treatment (\$59000 and \$328), cost of the serology screening (\$10 and \$50), cost of the UBT (\$60 and \$100), and annual discount rate (0% and 7%); <sup>2</sup>The ICER was calculated by comparing the UBT with the serology screening.

cost \$9.8 million, which saved 523 life years or gained 623 QALYs by preventing 272 gastric cancer cases. Strategy 3 that implemented the UBT on this cohort with treatment for those with positive test cost \$23.0 million, which saved 550 life years or gained 656 QALYs by preventing 281 gastric cancer cases. A total of 875 and 847 persons were screened for each case of gastric cancer prevented in strategy 2 and 3, respectively. The serology screening avoided \$1.4 million of discounted expenditures on treatment of gastric cancer, while the UBT avoided \$1.5 million. The ICER were \$16166 per life year saved and \$13571 per QALY gained for the serology screening, and \$38792 per life year saved and \$32525 per QALY gained for the UBT (Table 2). When compared to serology screening, the ICER was \$477079 per life year saved or \$390337 per QALY gained for the UBT.

In the one-way sensitivity analyses, the level of excess gastric cancer risk reduction attributable to *H pylori* eradication varied from 10% to 100%<sup>[6,7]</sup>. Using a \$28000 per QALY gained as a threshold, the serology screening would be cost-effective if *H pylori* eradication reduced more than 15% of excess gastric cancer risk. In contrast, the UBT could be cost-effective only when the excess gastric cancer risk was reduced by 35% or more (Figure 2A).

The ICER was sensitive to age at which population-based screening was carried out as shown in Figure 3. When screening age was more than 32 years, the ICER was less than \$28000 per QALY gained for the serology screening. The UBT appeared cost-effective when the screening age was more than 45 years (Figure 2B).

Relative risk of gastric cancer for *H pylori* infected population had a significant impact on the ICER. When *H pylori* eradication was assumed to reduce 30% of excess gastric cancer risk (as in the base-case analysis), the serology screening appeared cost-effective over the full range of the relative risk (i.e. from 2 to 12). In contrast, the UBT appeared cost-effective only with the relative risk above 5 (Figure 2C).

Cost of annual gastric cancer treatment imposed a substantial impact on the cost-effectiveness of the strategies. For both strategies, the cost had an approximately linear relation with the ICER that decreased dramatically with the increase in annual cost of the cancer treatment (Figure 2D). When the annual cost was \$30075, the one-time expenditure on serology screening and treatment of those with positive test would be fully offset by the savings in preventing gastric

cancers (Figure 2D). Cost of the serology screening and the UBT also had a moderate impact on the ICER. Each \$5 increment in cost of the serology screening and the UBT augmented the ICER by \$2000 and \$1800, respectively (data not shown).

The ICER was also sensitive to the annual discount rate. With the increase in the annual discount rate, the ICER appeared less favorable for both strategies.

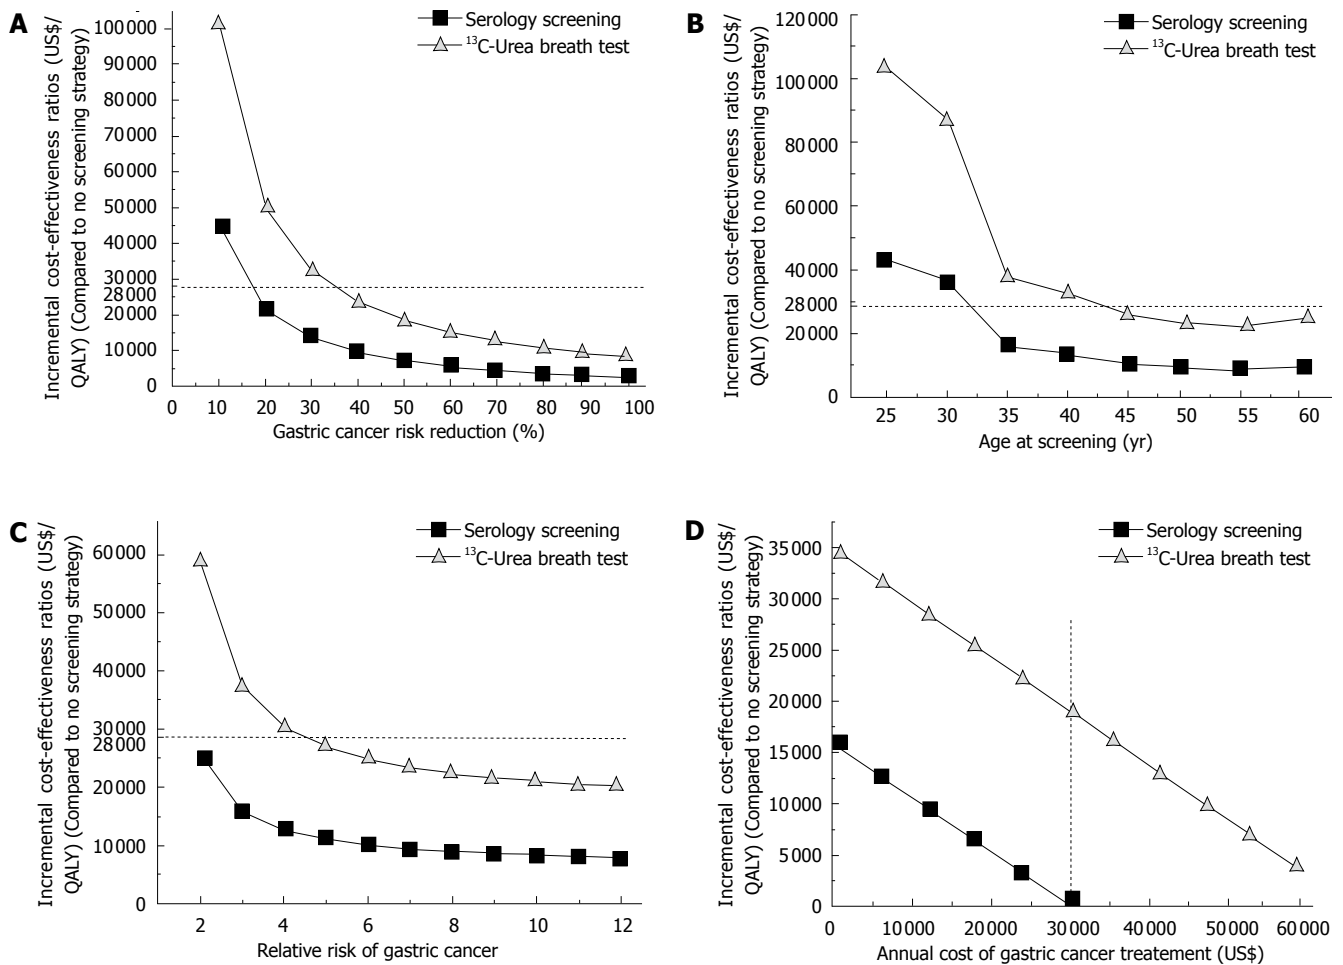

Other variables had little impact on the cost-effectiveness within the ranges listed in Table 1, which included sensitivity and specificity of the serology screening and the UBT, effectiveness of *H pylori* eradication, probability and costs of adverse effects related to eradication therapy necessitating medical intervention, and utilities of each health state.

In all these sensitivity analyses, the ICER was extremely less favorable for the UBT compared to the serology screening.

In the best-case and worst-case analyses, the most critical variables, including level of excess gastric cancer risk reduction, relative risk of gastric cancer in *H pylori* infected population, annual cost of gastric cancer treatment, cost of the serology screening and the UBT, and annual discount rate, were simultaneously varied. Both strategies achieved more health benefits (i.e. life years gained or QALYs) at a lower cost compared to no screening, and the UBT also received more health benefit at a lower cost compared to the serology screening in the best-case scenario (i.e. dominant) (Table 2). In contrast, the ICER was more than \$300000 for all comparisons in the worse-case scenario. The UBT achieved the same gaining in QALYs but at an extra cost of \$11290897 compared to the serology screening in the worst case analysis (Table 2).

## DISCUSSION

The present study modeled the life-time cost and effectiveness associated with population-based *H pylori* screening and treatment for those with positive test in Chinese males. Compared to no screening and no eradication therapy strategy, the serology screening was cost-effective, while the UBT was not cost-effective based on the threshold of \$28000 per QALY gained. The UBT gained very little extra health benefits in terms of either

**Figure 2** A: Sensitivity analysis on excess gastric cancer risk reduction attributable to *H pylori* eradication; B: Sensitivity analysis on age at time of screening; C: Sensitivity analysis on relative risk of gastric cancer in *H pylori* infected people with 30% gastric cancer risk reduction attributable to eradication; D: Sensitivity analysis on annual cost of gastric cancer treatment.

life years saved or QALYs gained but at a substantially higher cost compared to the serology screening. This suggests that the population-based serology screening for *H pylori* infection be adopted in this specific population, especially under the circumstances that the cost of gastric cancer treatment keeps arising due to the advances in new technologies. Also with this model, future clinical advances on the efficacy of *H pylori* eradication in prevention of gastric cancer can be easily translated into the cost-effectiveness ratio, which is now playing an increasingly important role in informing medical decision making.

The serology screening was found to be cost-effective in the present study, which is similar to the published studies using the similar model to estimate the economic and clinical effects of *H pylori* screening<sup>[6,7]</sup>. Nevertheless, the model used in the present study had several improvements which are worth noting. First, we have a health state to identify the persons who were *H pylori* positive and successfully eradicated by the triple therapy (i.e. '*H pylori* eradicated' in Figure 1). This is a health state in the Markov model which can allow for successful capturing of the economic and health benefits resulted from the screening strategies. Second, in line with the important assumption that the persons who survived more than 5 years after diagnosis of gastric

cancer were assumed to be cured<sup>[7,20]</sup>, we used five tunnel states, instead of a single gastric cancer health state, to represent the status for each of the first five years since diagnosed with gastric cancer. The mortalities for these tunnel states were different from each other based on the epidemiological evidence<sup>[19]</sup>. This refinement may better simulate the real progress of gastric cancer and thus obtain more accurate estimations in cost and effectiveness. Third, this model is life-time estimation and every person remained in the model until death. Thus some parameters are time-sensitive including *H pylori* incidence, gastric cancer incidence, and mortality (Table 1). Instead of fixed point estimates, age-specific estimates may be more appropriate and accurate to reflect the changes in these important parameters with the aging of the cohort in the model.

Besides, some differences between these two studies and the present study are notable. The cost and effectiveness of the screening strategies essentially stemmed from the actual number of gastric cancer cases prevented by the strategies. Therefore, given the certain level of excess gastric cancer risk reduction by the eradication, cost of gastric cancer treatment and relative risk of gastric cancer in *H pylori* infected persons are deemed to have a very important and significant impact on

Figure 3 Sensitivity analysis on annual discount rate.

the estimated ICER. The screening strategies would save more money if the cost needed to treat a gastric cancer case increased and prevent more gastric cancer cases if relative risk of gastric cancer in *H pylori* infected persons increased. Furthermore, the economic and health benefits of prevention of gastric cancer cases may only occur in the future rather than in the present, which highlights the important role of discount rate used: the larger the discount rate used the less the benefits obtained (Figure 3). However, these parameters were not examined in some previous study<sup>[6]</sup>, or only little impact of these parameters was reported<sup>[7]</sup>.

The cost-effectiveness of the serology screening over the UBT study was robust to most of the parameters through the one-way sensitivity analyses. Nevertheless, some findings are worth attention. As shown in Figure 3, the screening strategies would be more cost-effective if the starting age increased, which might be explicitly explained by the fact that both *H pylori* infection rate and gastric cancer incidence would increase with age. However, a recent large randomized controlled trial in Chinese revealed that persons with precancerous lesions (gastric atrophy, intestinal metaplasia, and dysplasia) significantly reduced the efficacy of *H pylori* eradication in prevention of gastric cancer compared to those without the lesions<sup>[32]</sup>. As the precancerous lesions increased significantly with age in Chinese<sup>[33]</sup>, this could be important evidence to support the younger screening age. Thus, we suggested that the optimal screening age could be 35 years where there would be a substantial improvement on the ICER compared to younger age but only slight improvement compared to older age. Otherwise, if an older screening age was chosen, despite the increase in *H pylori* infection rate and gastric cancer incidence, the level of excess gastric cancer risk reduction (i.e. the efficacy of the eradication) would remain at the far lower end of the spectrum, favoring no screening against the serology screening (Figure 2).

Prevention of gastric cancer will save the medical expenditures for treatment of cancer and increase the life years and QALYs. However, this health benefit could be associated with additional medical expenditures (even the expenditures on daily living for extended life years)

incurred during the extended life years, which will not occur in case of premature death. As including this cost component remains controversial, we did not take it into consideration in the present study. We also acknowledged that some parameters used in the model (e.g. survival rate of gastric cancer) were not available for Chinese males in Singapore, which may limit the accuracy of point estimates for cost and effectiveness. Finally, the threshold for ICER used in the present study was estimated from the US threshold using the ratio of gross national income between two countries, which is relative arbitrary and warrants further empirical local studies on this important topic.

In summary, the population-based serology screening for *H pylori* infection was more cost-effective than the UBT in prevention of gastric cancer in Singapore Chinese males.

## COMMENTS

### Background

*H pylori* infection has been recognized as an important risk factor for gastric cancer. Screening for *H pylori* has been proposed as a cost-effective strategy in prevention of gastric cancer.

### Research frontiers

A number of screening strategies are currently available. However, it is unknown which screening strategy is more cost-effective in high-risk populations, especially in Asian populations.

### Innovations and breakthroughs

A separate health state was used to identify the persons who were *H pylori* positive and successfully eradicated by the triple therapy. This state can allow for successful capturing of the economic and health benefits resulted from the screening strategies. Five tunnel states, instead of a single gastric cancer health state, were used in line with the important assumption that the persons who survived more than 5 years after diagnosis of gastric cancer were assumed to be cured.

### Applications

The findings in this study will be useful and important for decision makers to efficiently allocate scarce health resources for population-based *H pylori* screening.

### Peer review

The authors studied a clinically relevant issue. The manuscript is well written and is worth of publication in the Journal as is. This study has a substantial element of novelty. There is no data in literature concerning cost-effectiveness of serology-based screening strategy, particularly in countries with high prevalence of the infection, where the gastric cancer is a problem of special importance.

### Abstract

**AIM:** To evaluate the accuracy of endoscopic ultrasound (EUS), EUS-fine needle aspiration (FNA) in evaluating mediastinal lymphadenopathy.

**METHODS:** Only EUS and EUS-FNA studies confirmed by surgery or with appropriate follow-up were selected. Articles were searched in Medline, Pubmed, and Cochrane control trial registry. Only studies from which a 2 × 2 table could be constructed for true positive, false negative, false positive and true negative values were included. Two reviewers independently searched and extracted data. The differences were resolved by mutual agreement. Meta-analysis for the accuracy of EUS was analyzed by calculating pooled estimates of sensitivity, specificity, likelihood ratios, and diagnostic odds ratios. Pooling was conducted by both Mantel-Haenszel method (fixed effects model) and DerSimonian Laird method (random effects model). The heterogeneity of studies was tested using Cochran's Q test based upon inverse variance weights.

**RESULTS:** Data was extracted from 76 studies ( $n = 9310$ ) which met the inclusion criteria. Of these, 44 studies used EUS alone and 32 studies used EUS-FNA. FNA improved the sensitivity of EUS from 84.7% (95% CI: 82.9-86.4) to 88.0% (95% CI: 85.8-90.0). With FNA, the specificity of EUS improved from 84.6% (95% CI: 83.2-85.9) to 96.4% (95% CI: 95.3-97.4). The  $P$  for

chi-squared heterogeneity for all the pooled accuracy estimates was  $> 0.10$ .

**CONCLUSION:** EUS is highly sensitive and specific for the evaluation of mediastinal lymphadenopathy and FNA substantially improves this. EUS with FNA should be the diagnostic test of choice for evaluating mediastinal lymphadenopathy.

### INTRODUCTION

Management of patients with mediastinal lymphadenopathy depends on the etiology of lymphadenopathy. Differentiating inflammatory from neoplastic processes in the mediastinal lymph nodes is not only important from the treatment standpoint, but also vital in predicting survival. Multiple diagnostic modalities are available to evaluate mediastinal lymphadenopathy. Computer tomography (CT) of the chest does not clearly image the aortopulmonary, subcarinal, and paraesophageal areas due to the lowering of image resolution because of the movement and partial volume effect of pulmonary vessels, aortic arch, and left atrium<sup>[1]</sup>. Also, for lesions smaller than 1 cm, the sensitivity of CT is low<sup>[2-5]</sup>, and the size-based criteria to diagnose metastatic involvement of the lymph nodes have lower accuracy<sup>[6]</sup>. Therefore, other methods were introduced, including transbronchial biopsy, CT-guided transthoracic fine-needle aspiration (FNA), mediastinoscopy, or thoracoscopic biopsy.

In the transbronchial technique, the FNA needle

is advanced blindly, reducing the yield of diagnosing subcarinal and paraesophageal nodes to approximately 50%<sup>[7,8]</sup>. Due to the potential danger of inadvertent vascular puncture, transthoracic biopsy is avoided when the mass is close to major vessels. This procedure is also associated with significant complications, including bleeding and pneumothorax in up to 25%-35% of cases<sup>[9,10]</sup>. Extended cervical mediastinoscopy or anterior mediastinoscopy can be used to access level 5 (aortopulmonary window) mediastinal nodes, which is not inspected by the standard methods<sup>[11-13]</sup>. Extended cervical mediastinoscopy has a sensitivity of 83% in examining the paraaortic and subaortic lymph node chains, but the subcarinal group is inaccessible<sup>[11]</sup>. Thoracoscopy can visualize the inferior mediastinum effectively, but it is limited only to accessing the level of major bronchi, leaving the superior mediastinum non-visualized<sup>[14]</sup>. Both procedures are invasive, require hospitalization and general anesthesia, and both have limitations.

With the introduction of endoscopic ultrasonography (EUS), it is now possible to visualize not only the gastrointestinal tract but also surrounding structures. However, EUS is limited in its ability to distinguish an inflammatory/reactive process from a malignancy, particularly within lymph nodes<sup>[15,16]</sup>. The accuracy of EUS in diagnosing mediastinal lymphadenopathy has been varied<sup>[17-21]</sup>. FNA during EUS may be performed safely in a short outpatient procedure setting without general anesthesia. It is not clear to what extent, if any, FNA adds in improving the accuracy of EUS to diagnose mediastinal lymphadenopathy<sup>[22-25]</sup>.

The goal of this meta-analysis was to evaluate the accuracy of EUS alone and EUS with FNA in correctly diagnosing mediastinal lymphadenopathy. Due to multiple studies scattered in the literature and no published meta-analysis in this area, this meta-analysis was performed in an attempt to answer this essential clinical question. This meta-analysis and systematic review was written in accordance with the proposal for reporting by the QUOROM (Quality of Reporting of Meta-analyses) statement<sup>[26]</sup>. Since this manuscript looks at diagnostic accuracy of a test, the study design for this meta-analysis and systematic review conformed to the guidelines of Standards for Reporting of Diagnostic Accuracy (STARD) initiative<sup>[27]</sup>.

## MATERIALS AND METHODS

### Study selection criteria

Only EUS-FNA studies confirmed by surgery or appropriate follow-up were selected. From this pool, only studies from which a 2 × 2 table could be constructed for true positive, false negative, false positive and true negative values were included.

### Data collection and extraction

Articles were searched in Medline, Pubmed, Ovid journals, Cumulative Index for Nursing & Allied Health Literature, ACP journal club, DARE, International Pharmaceutical Abstracts, old Medline, Medline non-indexed citations, OVID Healthstar, and Cochrane Control Trial Registry.

The search terms used were endoscopic ultrasound, EUS, ultrasound, mediastinal lymphadenopathy, nodal invasion, fine needle aspiration, FNA, staging, surgery, sensitivity, specificity, positive predictive value, and negative predictive value. 2 × 2 tables were constructed with the data extracted from each study. To give validity to the data, two authors (SP and JR) independently searched and extracted the data into an abstraction form. Any differences were resolved by mutual agreement.

### Quality of studies

Clinical trial with a control arm can be assessed for the quality of the study. A number of criteria have been used to assess this quality of a study (e.g. randomization, selection bias of the arms in the study, concealment of allocation, and blinding of outcome)<sup>[28,29]</sup>. There is no consensus on how to assess studies without a control arm. Hence, these criteria do not apply to studies without a control arm<sup>[29]</sup>. Therefore, for this meta-analysis and systematic review, studies were selected based on completeness of data and inclusion criteria.

### Statistical analysis

Meta-analysis for the accuracy of EUS in diagnosing the etiology of mediastinal lymphadenopathy was performed by calculating pooled estimates of sensitivity, specificity, likelihood ratios, and diagnostic odds ratios. EUS studies were grouped into time periods to standardize the change in EUS technology and EUS criteria for lymph node involvement<sup>[30]</sup>. These time periods were 1988 to 1994, 1995 to 1999, and 2000 to 2006. Pooling was conducted using both Mantel-Haenszel method (fixed effects model) and DerSimonian Laird method (random effects model). The confidence intervals were calculated using the F distribution method<sup>[31]</sup>. The width of the point estimates in the Forrest plots indicates the assigned weight to that study. For 0 value cells, a 0.5 was added as described by Cox<sup>[32]</sup>. The heterogeneity of the sensitivities and specificities was tested by applying the likelihood ratio test<sup>[33]</sup>. The heterogeneity of likelihood ratios and diagnostic odds ratios were tested using Cochran's *Q* test based upon inverse variance weights<sup>[34]</sup>. Heterogeneity among studies was also tested by using summary receiver operating characteristic (SROC) curves. SROC curves were used to calculate the area under the curve (AUC). The effect of publication and selection bias on the summary estimates was tested by Harbord-Egger bias indicator<sup>[35]</sup> and Begg-Mazumdar indicator<sup>[36]</sup>. Also, funnel plots were constructed to evaluate potential publication bias using the standard error and diagnostic odds ratio<sup>[37,38]</sup>.

## RESULTS

The initial search using the search terms identified 4310 reference articles. Among these, 460 relevant articles were selected and reviewed by two authors independently. Data was extracted from 76 studies (*n* = 9310) which met the inclusion criteria. Of these, 44 studies used EUS alone<sup>[17,18,39-80]</sup> and 32 studies used EUS-FNA<sup>[19-25,81-107]</sup>. Figure 1 shows the search results. Table 1 shows the characteristics for EUS studies without FNA and Table 2

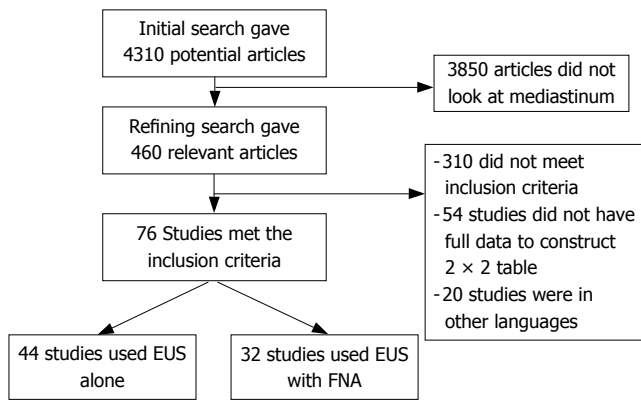

Figure 1 The search results.

76 selected studies were published as full-text articles in peer review journals. The pooled estimates given are estimates calculated by the fixed effect model.

### Accuracy of EUS with and without FNA

Pooled sensitivity to diagnose the cause for mediastinal lymphadenopathy was 84.7% (95% CI: 82.9-86.4) for

depicts characteristics of EUS studies with FNA. All the

**Figure 2** Forrest plots. **A:** Sensitivity of EUS alone in diagnosing mediastinal lymphadenopathy; **B:** Sensitivity of EUS-FNA in diagnosing mediastinal lymphadenopathy.

EUS alone *versus* 88.0% (95% CI: 85.8-90.0) for EUS with FNA. The Forrest plot showing the sensitivity of EUS with and without FNA in various studies is shown in Figure 2A and B, respectively. EUS without FNA had a pooled specificity of 84.6% (95% CI: 83.2-85.9) and with FNA was 96.4% (95% CI: 95.3-97.4). Forrest plots showing specificity from various studies with and without FNA is depicted in Figure 3A and B, respectively.

The pooled positive likelihood ratio of EUS without FNA was 3.3 (95% CI: 2.6-4.3) and with FNA was 11.2 (95% CI: 5.9-21.2). The pooled negative likelihood ratio was 0.24 (95% CI: 0.1-0.3) for EUS without FNA and 0.13 (95% CI: 0.1-0.2) for EUS with FNA. The diagnostic odds ratio, the odds of having nodal metastasis in positive as compared to negative EUS studies, was 19.1 (95% CI: 12.7-28.5) for EUS without FNA and 106.9 (95% CI: 54.4-210.3) for EUS with FNA. Figure 4 shows a Forrest plot of various studies with FNA and their DOR. All the pooled estimates calculated by random effect models were similar to the estimates of fixed effect model.

SROC curves for EUS without FNA showed an area under the curve (AUC) of 0.91. EUS with FNA showed

an AUC of 0.97. Figure 5 shows the SROC curve. The *P* for Chi-squared heterogeneity for all the pooled accuracy estimates was  $> 0.10$ . Table 3 shows the accuracy estimates of EUS alone and EUS-FNA.

### Effect of technology over time

To standardize the criteria for lymph node involvement and change in technology, the studies were grouped into three time periods<sup>[30]</sup>. These time periods were 1988 to 1994, 1995 to 1999, and 2000 to 2006. During these time periods, the number of studies that met the inclusion criteria for EUS alone were 17, 17, and 10, respectively. Studies that met inclusion criteria for EUS-FNA were 4, 10, and 18, respectively. For the most recent time period, EUS alone had a sensitivity of 81.6% (95% CI: 77.8-85.1) and specificity of 82.4% (95% CI: 78.2-86.1). During the same time period, EUS-FNA had a sensitivity of 91.7% (95% CI: 89.3-93.7) and specificity of 96.8% (95% CI: 94.9-98.2). All pooled estimates during the three time periods are given in Table 4. The *P* for chi-squared heterogeneity for all the pooled accuracy estimates was  $> 0.1$ .

Figure 3 Forrest plots. A: Specificity of EUS alone in diagnosing mediastinal lymphadenopathy. B: Specificity of EUS-FNA alone in diagnosing mediastinal lymphadenopathy.

# Bias estimates

The bias calculations using Harbord-Egger bias indicator gave a value of 1.08 (95% CI: -0.79-2.95,  $P = 0.29$ ) for EUS studies without FNA and 2.02 (95% CI: 0.29-3.74,  $P = 0.04$ ) for studies with FNA. The Begg-Mazumdar indicator for bias gave a Kendall's tau  $b$  value of 0.13 ( $P = 0.36$ ) for studies without FNA and -0.19 ( $P = 0.07$ ) for studies with FNA. The funnel plots for the studies without and with FNA are shown in Figure 6A and B.

# DISCUSSION

Diagnosing the correct etiology for mediastinal lymphadenopathy helps direct precise therapy and prognosis. Thoracoscopic procedures for tissue biopsy carry a risk of complications in 25%-35% of cases<sup>[9,10]</sup>. The advantage of EUS is the ability to perform FNA during the procedure for tissue diagnosis. The procedure is, in comparison with other alternative options, safe, less invasive, and does not require general anesthesia or hospitalization<sup>[107]</sup>. The complication rate is extremely low (0.5%-2.3%) with several studies reporting no complications<sup>[48,77,83,107]</sup>. Modalities using FNA, such as transbronchial, computed

tomography, or thoracoscopic procedure, cannot be used for the entire mediastinum<sup>[2-13]</sup>. EUS has the ability to image the aortopulmonary window, the subcarinal nodes, inferior mediastinum, and entire posterior part of the mediastinum.

This meta-analysis and systematic review was written in accordance with the proposal for reporting by the QUOROM (Quality of Reporting of Meta-analyses) statement<sup>[7]</sup>. This meta-analysis and systematic review shows that the pooled sensitivity of EUS for mediastinal lymphadenopathy is high and use of FNA during the procedure, further increases such sensitivity. The pooled specificity for diagnosing mediastinal lymphadenopathy is also high with substantial improvement if FNA is performed during the procedure (from 84.6% to 96.4%). Diagnostic odds ratio is defined as the odds of having a positive test in patients with true anatomic disease when compared to patients who do not have the disease. EUS has a very high diagnostic odds ratio for mediastinal lymphadenopathy. For example, if EUS indicates mediastinal lymphadenopathy and if FNA is performed on the enlarged nodes, the patient has odds of 106 times to have the correct etiology for lymph node enlargement. If EUS shows mediastinal lymphadenopathy, then the nodes

**Figure 4** Forrest plot showing diagnostic odds ratio of EUS-FNA in identifying mediastinal lymphadenopathy.

**Figure 5** SROC for EUS to diagnose mediastinal lymphadenopathy.

should be biopsied by FNA to improve the diagnostic accuracy.

The positive likelihood ratio measures how well a test identifies a disease state. The higher the positive likelihood ratio, the better the test performs in identifying the correct disease state. The negative likelihood ratio of the same test measures how well the test performs in excluding a disease state. The lower the negative likelihood ratio, the better the test performs in excluding a disease. For mediastinal lymphadenopathy, EUS has a high positive likelihood ratio and low negative likelihood ratio. This indicates that EUS performs better in diagnosing and excluding mediastinal lymphadenopathy. For mediastinal lymphadenopathy, all the pooled accuracy estimates of EUS are higher if FNA

**Table 3** Pooled diagnostic accuracy estimates of EUS alone and EUS-FNA

	EUS	EUS-FNA
Studies	44	32
Pooled sensitivity	84.7% (82.9-86.4)	88.0% (85.8-90.0)
Pooled specificity	84.6% (83.2-85.9)	96.4% (95.3-97.4)
Positive likelihood ratio	3.3 (2.6-4.3)	11.2 (5.9-21.2)
Negative likelihood ratio	0.24 (0.1-0.3)	0.13 (0.1-0.2)
Diagnostic odds ratio	19.1 (12.7-28.5)	106.9 (54.4-210.3)
Area under the curve	0.91	0.97

is performed during the procedure. Also, these pooled estimates give a baseline for future study comparisons.

The EUS studies with FNA were grouped into time periods and analyzed to standardize the criteria and the technology of EUS over the past two decades. Over the last two decades, the sensitivity and specificity of EUS with FNA has substantially improved.

Due to the possibility of different studies using slightly different criteria for diagnosis, heterogeneity among the studies was tested by drawing SROC curves and finding the AUC. An AUC of 1 for any test indicates that the test is excellent. SROC curves for EUS showed that the value for AUC was very close to 1, indicating that EUS is an excellent test to diagnose mediastinal lymphadenopathy. Publication bias and selection bias may affect the summary estimates. Studies with statistically significant results tend to be published and cited. Smaller studies may show larger treatment effects due to fewer case-mix differences (e.g. patients with only early or late disease) than larger trials. This bias can be estimated by bias indicators and construction of

**Figure 6** Funnel plots. **A:** Bias assessment for EUS studies without FNA in examining mediastinal lymphadenopathy; **B:** Bias assessment for EUS-FNA studies in examining mediastinal lymphadenopathy.

**Table 4** Pooled diagnostic accuracy estimates of EUS alone and EUS-FNA for different time periods with 95% CI

Time period	No. of studies	Pooled sensitivity	Pooled specificity	Pooled LR+ 1	Pooled LR-2	Pooled DOR3
EUS without FNA						
1988 to 1994	17	88.0% (85.4-90.2)	85.2% (83.4-86.9)	3.6 (2.4-5.4)	0.2 (0.1-0.3)	27.5 (14.5-52.4)
1995 to 1999	17	82.6% (78.8-85.9)	84.4% (81.6-86.9)	3.0 (2.0-4.5)	0.3 (0.2-0.4)	14.8 (7.5-29.3)
2000 to 2005	10	81.6% (77.8-85.1)	82.4% (78.2-86.1)	3.4 (2.2-5.3)	0.3 (0.2-0.4)	14.9 (6.7-33.1)
EUS-FNA						
1988 to 1994	4	71.8% (63.9-78.9)	96.8% (94.9-98.1)	15.5 (2.4-101.2)	0.3 (0.1-0.6)	61.8 (10.5-63.8)
1995 to 1999	10	88.9% (83.5-93.0)	94.7% (90.7-97.3)	8.1 (2.8-23.3)	0.1 (0.1-0.2)	57.0 (20.7-57.1)
2000 to 2005	18	91.7% (89.3-93.7)	96.8% (94.9-98.2)	12.5 (5.2-29.8)	0.1 (0.1-0.2)	17.7 (5.0-62.8)

<sup>1</sup>LR+: Positive likelihood ratio; <sup>2</sup>LR-: Negative likelihood ratio; <sup>3</sup>DOR: Diagnostic odds ratio.

funnel plots. Bias among studies can affect the shape of the funnel plot. In this meta-analysis and systematic review, bias calculations using Harbord-Egger indicator<sup>[36]</sup> and Begg-Mazumdar indicator<sup>[37]</sup> showed no statistically significant bias for EUS studies without FNA. Furthermore, funnel plot analyses showed no significant bias for EUS without FNA and EUS-FNA studies (Figure 6B).

In conclusion, EUS has high sensitivity and specificity to evaluate mediastinal lymphadenopathy. This meta-analysis demonstrates that FNA substantially improves the specificity of EUS in evaluating mediastinal lymphadenopathy. EUS with FNA should be the diagnostic test of choice for evaluating mediastinal lymphadenopathy.

Received: October 23, 2007 Revised: March 25, 2008

### Abstract

**AIM:** To investigate the therapeutic efficacy of short-term, multiple daily dosing of intravenous interferon (IFN) in patients with hepatitis B e antigen (HBeAg)-positive chronic hepatitis B.

**METHODS:** IFN- $\beta$  was intravenously administered at a total dose of 102 million international units (MIU) over a period of 28 d in 26 patients positive for HBeAg and HBV-DNA. IFN-beta was administered at doses of 2 MIU and 1 MIU on d 1, 3 MIU twice daily from d 2 to d 7, and 1 MIU thrice daily from d 8 to d 28. Patients were followed up for 24 wk after the end of treatment.

**RESULTS:** Six months after the end of the treatment, loss of HBV-DNA occurred in 13 (50.0%) of the 26 patients, loss of HBeAg in 9 (34.6%), development of anti-HBe in 10 (38.5%), HBeAg seroconversion in 8 (30.8%), and normalization of alanine aminotransferase (ALT) levels in 11 (42.0%).

**CONCLUSION:** This 4-wk long IFN- $\beta$  therapy, which was much shorter than conventional therapy lasting 12 wk or even more than 1 year, produced therapeutic effects similar to those achieved by IFN- $\alpha$  or pegylated-IFN- $\alpha$  (peg-IFN). Fewer adverse effects, greater efficacy, and a shorter treatment period led to an improvement in patients' quality of life. IFN- $\beta$  is administered intravenously, whereas IFN- $\alpha$  is administered intramuscularly or subcutaneously. Because both interferons are known to bind to an identical receptor and exert antiviral effects through intracellular signal transduction, the excellent results of IFN- $\beta$  found in this study may be attributed to the multiple doses allowed by the intravenous route.

**Hepatitis B virus; Interferon beta; Multiple daily dosing; Short-term treatment; Intravenous injection**

### INTRODUCTION

The increasing prevalence of chronic hepatitis caused by hepatitis B or C virus infection represents a concern in many regions worldwide. Interferons (IFN) are widely used in the treatment of the disease. With the recent launch of lamivudine, adefovir, and entecavir, the number of treatment options for chronic hepatitis B has increased. Treatment with these oral nucleoside analogues has serious drawbacks, such as the development of resistant HBV strains<sup>[1,2]</sup> and the need for years of treatment<sup>[3,4]</sup> or even a lifetime therapy. Thus, a large number of patients still require IFN therapy, which is effective in a relatively short period of time. Recently, however, in some patients, the treatment with IFN is often prolonged up to 24-48 wk to improve efficacy<sup>[5-7]</sup>. IFN- $\alpha$  is administered intramuscularly or subcutaneously and may be associated with such adverse effects as fatigue, insomnia, anorexia, and alopecia<sup>[7,8]</sup>. These effects presumably result from prolonged elevation of blood IFN levels. Prolonged exposure to higher levels of the circulating drug may produce a greater therapeutic effect while inducing greater adverse effects<sup>[9,10]</sup>. Treatment for a higher therapeutic effect without consideration of the burden on patients is not a good therapeutic strategy.

In Japan, IFN preparations for the treatment of hepatitis B include IFN- $\alpha$  for intramuscular or subcutaneous administration and IFN- $\beta$  for intravenous administration<sup>[11]</sup>. Both IFN- $\alpha$  and IFN- $\beta$  bind to the an identical IFN receptor and induce PKR and other antiviral proteins via intracellular signal transduction systems represented by JAK/STAT<sup>[12]</sup>. Because of the intravenous route, the blood concentration of IFN- $\beta$  reaches its peak immediately after infusion and then decreases

rapidly<sup>[13]</sup>. Decrease or loss of efficacy by receptor down-regulation<sup>[14-16]</sup> and adverse effects with IFN therapy are less likely to occur because blood level of IFN- $\beta$  does not maintain after signal transduction *via* the IFN receptor. The receptor function is maintained, and thus frequent dosing of IFN- $\beta$  is likely to produce greater efficacy. Indeed, in patients with hepatitis C, we found that IFN- $\beta$  in divided doses administered in the morning and evening was more effective than that administered once daily at the same total dose<sup>[17]</sup>.

For the development of short-term IFN therapy for hepatitis B, in the present study we investigated a 4-wk, multiple daily dosing of intravenous IFN- $\beta$ , a new regimen that produced therapeutic effects similar to those achieved by 24-wk or 1-year treatment with IFN- $\alpha$ .

## MATERIALS AND METHODS

### Patients

Among Japanese adult patients with chronic hepatitis B who were positive for HBeAg and HBV-DNA and presented at our hospital from 1996 to 2002, 26 patients were enrolled in this open-label study. The study was conducted in accordance with the Declaration of Helsinki, and the patients consented to the experimental treatment of hepatitis B. Inclusion criteria were: age of 20 years or older, blood HBeAg positivity, blood HBV-DNA positivity, and persistent abnormal elevation of ALT levels. Exclusion criteria included: coinfection with hepatitis C virus or HIV, presence of hepatocellular carcinoma, symptoms caused by decompensated cirrhosis, alcoholic, autoimmune, drug-induced, or other non-viral liver disorders, and hypersensitivity to IFN- $\beta$ . Any herbal medicines were discontinued during the treatment with IFN- $\beta$ .

### Treatment methods

Human fibroblast-derived natural IFN- $\beta$  (FERON<sup>®</sup>, Toray Industries Inc., Japan) was used; 1 to 3 MIU was dissolved in 100 mL of 5% glucose or isotonic saline solution for injection and infused intravenously for about 10 minutes. The dosing schedule comprised 2 MIU in the morning and 1 MIU in the evening (twice daily) at d 1 of treatment, 3 MIU in the morning and evening (twice daily) from d 2 through d 7, and 1 MIU each in the morning, in the afternoon, and at bedtime (thrice daily) from d 8 to d 28, with a total dose of 102 MIU administered over a treatment period of 28 d. Patients were followed up for 24 wk after the end of the IFN- $\beta$  therapy.

### Laboratory methods

Blood samples were collected immediately before the start of treatment, weekly during the treatment, and monthly during the follow-up period. Biochemical and hematological tests were performed each time. HBsAg was measured by reversed passive hemagglutination (R-PHA), anti-HBs was measured by passive hemagglutination (PHA), HBeAg and anti-HBe were measured by radioimmunoassay (RIA). HBV-DNA polymerase activity was measured by radioassay. Serum HBV-DNA was

measured by branched DNA probe assay (Chiron Corp, USA) with a detection sensitivity of 0.70 megaequivalents (Meq) per milliliter. Anti-hepatitis C virus antibodies were measured by enzyme immunoassay (EIA). In addition, 2',5'-oligoadenylate synthetase (2-5AS), an indicator of IFN activity, was quantitatively measured by RIA.

### Statistical analysis

Values are given as either mean  $\pm$  SD or median and range. For comparison, Student's *t*-test or the Chi-square test were used. Statistical tests were two-sided, and a *P* value of less than 0.05 was considered as statistically significant.

## RESULTS

### Patient population

Clinical characteristics of the 26 patients with HBeAg positive chronic hepatitis B at beginning of the treatment are shown in Table 1. All patients received a total dose of 102 MIU of IFN- $\beta$  over a period of 28 d, and none of them dropped out because of adverse effects or other reasons.

### Clinical outcomes

Six months after the end of IFN administration, loss of HBV-DNA occurred in 13 (50.0%) patients, loss of HBeAg in 9 (34.6%), loss of HBV-DNA and HBeAg in 9 (34.6%), development of anti-HBe in 10 (38.5%), and HBe seroconversion in 8 (30.8%). The last parameter is a measure of the therapeutic effect, defined by the loss of HBeAg and the subsequent development of anti-HBe. ALT levels normalized in 11 (42.0%) of the 26 patients. The percentage of patients, which became negative for HBV-DNA, HBeAg, and the change in ALT levels during/after the treatment are shown in Table 2 and Figure 1, respectively.

### Baseline HBV DNA polymerase activity and virological response

Patients were stratified according to baseline DNA polymerase activity (less than 1000 cpm *vs* 1000 cpm or more), and virological responses were recorded. Among 15 patients with an activity lower than 1000 cpm, 11 (73.3%) had a complete virological response, and 4 (26.7%) had no response. Among the 11 patients with an activity of 1000 cpm or more, 2 (18.2%) had a complete virological response, and 9 (81.8%) had no response.

### 2-5AS

Figure 2 shows the change in 2-5AS levels. The level of 2-5AS at baseline was  $114.8 \pm 102.1$  (mean  $\pm$  SD). The levels at wk 1, 2, and at the end of treatment were  $389.9 \pm 205.3$ ,  $333.3 \pm 133.4$ , and  $344.3 \pm 181.2$ , respectively.

### Adverse effects

No patients discontinued treatment because of adverse effects, with a treatment completion rate of 100%. Fever was mild because antipyretic loxoprofen sodium was administered before intravenous infusion to suppress IFN-

Table 1 Clinical characteristics at the beginning of the treatment

Characteristics	Baseline

Table 2 Response rate in patients with HBeAg positive chronic hepatitis B by interferon-β treatment (%)

	wk 1	wk 2	End of the treatment	6 mo after treatment
HBV-DNA negative	5/26 (19.2)	5/26 (19.2)	10/26 (38.5)	13/26 (50.0)
HBeAg and HBV-DNA negative			4/26 (15.4)	9/26 (34.6)

Figure 1 Change in ALT levels during treatment with interferon-β and during the follow-up.

Figure 2 Change in 2'5'AS levels during treatment.

induced fever. During treatment with IFN, no patients experienced depression. There was no proteinuria, severe thrombocytopenia or leukopenia (as shown in Figure 3).

## DISCUSSION

Approximately 10 years ago, the IFN therapy for chronic hepatitis B was administered for up to 4 wk in Japan. However, a 24-wk regimen has been recently used because

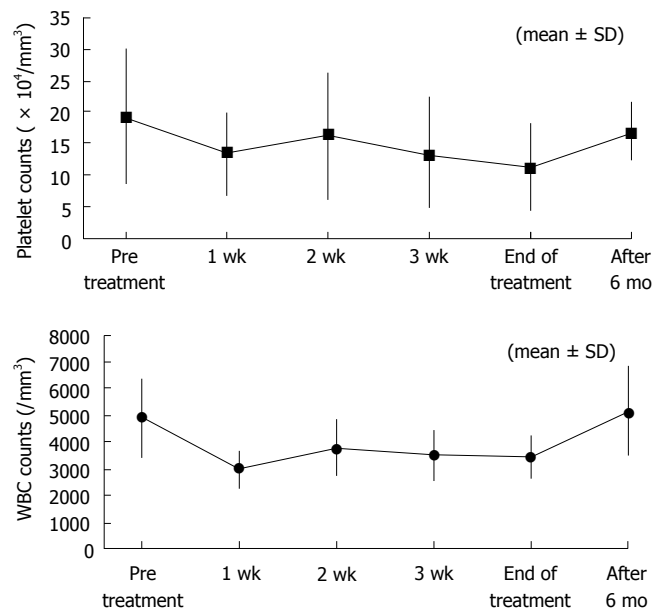

Figure 3 Changes in platelet and WBC counts.

Table 3 Comparison of response rates in patients with HBeAg positive chronic hepatitis B at 6 mo after the treatment (%)

	INF-β (iv) 4 wk	INF-α (sc or im) 12-24 wk	Lamivudine 1 yr	Adefovir dipivoxil 48 wk	Pegylated interferon-α 48 wk
Loss of serum HBV DNA	50	37	44	21	32
Loss of HBeAg	35	33	17-32	24	34
HBeAg seroconversion	31	Difference of 18	16-18	12	32
Loss of HBsAg		8	< 1	0	3

Histological improvement			49-56	53	38
Durability of the response		80-90	50-80		82

a longer treatment seems to improve the efficacy. In the present study, we used a short-term, intravenous therapy of 4 wk, which seems to be against the recent recommendations for long-term regimens. However, 4-wk multiple daily dosing of intravenous IFN-β used in our study produced therapeutic effects similar to those achieved by 12-wk or 24-wk IFN-α or 48-wk peg-IFN-α, which are indicated by the American Association for the Study of Liver Diseases<sup>[18,19]</sup>. The HBe seroconversion rate with IFN-β in this study was 31%, which was higher than the reported 12-18% with IFN-α<sup>[18,20]</sup>, lamivudine<sup>[18,21-23]</sup>, or adefovir<sup>[19,24]</sup>, and which was almost equal to that achieved by a 48-wk therapy with peg-IFN-α<sup>[25]</sup> (Table 3). In the United States, the distribution of HBV genotypes was reported as genotypes A (33%), B (21%), C (34%), D (9%), E (1%), F (1%), and G (1%)<sup>[26]</sup>. Given that the majority (about 80%) of Japanese patients infected with HBV has IFN-resistant genotype C<sup>[27]</sup>, the multiple daily dosing of intravenous IFN-β used in this study appears to be a beneficial treatment.

**Figure 4** Typical pattern of clinical course with transient increase in ALT level after treatment with interferon- $\beta$ .

Our results suggest that HBV DNA polymerase activity at baseline before the treatment may be used to predict the therapeutic effect of IFN to some degree. Multiple daily dosing of IFN- $\beta$  may be the regimen of first-line choice in patients with baseline HBV DNA polymerase activity less than 1000 cpm because 73.3% of those patients had a complete virological response. We believe that the direct antiviral effect of IFN on HBV is enough to achieve a complete response in those patients, whereas an appropriate host immune response are also needed in patients with a polymerase activity of 1000 cpm or more indicating rapid proliferation of HBV. A typical example is shown in Figure 4. The patient had an HBV DNA polymerase activity of 1338 cpm and an HBV-DNA level of 710 Meq/mL before the IFN therapy. After the end of IFN- $\beta$  administration, an increase in HBV-DNA and subsequent rapid increase in ALT levels (so-called Schub) occurred, followed by the loss of HBeAg, HBV-DNA, and DNA polymerase, normalization of ALT levels, and development of anti-HB. The rapid increase in ALT levels probably resulted from the host's immune response to the rapid increase in the HBV proliferation following the regimen and the subsequent rapid elimination of infected hepatocytes in an appropriate manner.

Our dosing regimen had a good safety profile with a low incidence of mild adverse effects and no serious adverse effects. This may be attributed to lower daily doses of 3 MIU from d 8 onward and a short treatment period of 1 mo. Although platelet and leukocyte counts decreased at wk 1 compared with baseline levels, the counts remained unchanged thereafter until the end of treatment and almost returned to baseline levels after completion of therapy. Our previous experience suggested that thrombocytopenia and proteinuria should be closely monitored during treatment with IFN- $\beta$  at doses of 3 MIU twice daily. However, cytopenia did not worsen because of switching to 1 MIU thrice daily from d 8. The levels of 2-5AS in blood (mean  $\pm$  SD) at baseline and wk 1, 2, and 4 of treatment were  $133.9 \pm 122.2$ ,  $445.0 \pm 209.7$ ,  $335.0 \pm 139.9$ , and  $387.8 \pm 200.7$ , respectively, and

remained elevated during treatment, suggesting that the dose regimen produced a potent and durable antiviral effect despite a modest cytopenia.

In general, the pharmacokinetics of an intravenously administered drug are characterized by a higher blood elimination rate, higher peak blood concentration, and greater tissue distribution than an intramuscularly administered drug, and these are also true of IFN. Different types of IFN formulations are available for therapy, and human fibroblast IFN- $\beta$  is applicable to intravenous administration for the treatment of hepatitis in Japan.

We chose intravenous administration and multiple daily dosing because of the following three reasons. First, intravenously administered IFN- $\beta$  is rapidly eliminated from the blood and below the detection limit shortly after administration<sup>[13]</sup>. Compared with intramuscularly or subcutaneously administered IFN- $\alpha$ , IFN- $\beta$  accumulates to a lesser degree and is likely to have less adverse effects<sup>[28]</sup>. Second, blood concentrations of IFN administered intravenously in multiple daily doses fluctuate with high blood levels and rapid elimination rates. Accordingly, this regimen is likely to avoid persistently elevated blood IFN levels and resultant downregulation of the IFN receptor<sup>[14-16]</sup>, which is likely to occur after intramuscular or subcutaneous administration. The avoidance of the receptor downregulation allows effective binding of IFN and its receptor, and triggers the host defense mechanisms a few times a day to eliminate the virus. Third, the drug administered intravenously is more extensively distributed into organs than that administered intramuscularly. For elimination of HBV present in hepatocytes, intravenous dosing is considered as an effective route of administration, which allows extensive delivery of IFN to the liver. When IFN- $\alpha$ , which was induced by treating human leukocytes with the Sendai virus, was administered intravenously or intramuscularly to rats, IFN- $\alpha$  was detectable in the liver at 10 and 30 min but not at 1 h after intravenous administration whereas IFN levels remained below the detection limit for 4 h in rats receiving an intramuscular administration<sup>[29]</sup>. In patients with hepatitis, a transient increase in ALT levels is often observed after intravenous administration of IFN<sup>[30]</sup>. Because IFN distributes in the liver at high concentrations after intravenous administration, extensive loss of infected hepatocytes may occur, resulting in an increase in ALT levels.

When IFN or any other cytokine that exerts a pharmacological effect *via* receptor binding is administered, it is important to choose an appropriate route of administration that ensures effective delivery of the drug to the target-cells. An ideal pharmacokinetic profile should include a rapid increase to effective blood concentrations and a rapid elimination after receptor binding to avoid downregulation of the receptor. We believe that intravenous IFN therapy can also be used effectively for the treatment of other diseases including cancer, infection with HIV, and SARS. However, intravenous IFN is now available only in Japan. For further promotion of research on the establishment of intravenous IFN therapy as a convenient, general way of treating these diseases,

intravenous IFN should preferably be available in other countries.

Oral nucleoside analogues, such as lamivudine, adefovir, and entecavir, have a potent effect in suppressing hepatitis B virus; however, most patients relapse and become positive for the virus after discontinuation of treatment. Thus, these drugs should be taken for a few years or the rest of patients' lives. These agents also cause problems including development of resistant strains and fetotoxicity, which discourages physicians from administering these agents in pregnant, parturient, and nursing women. Meanwhile, IFN therapy tends to continue for more than 6 months, and increased adverse effects associated with prolonged therapy have become a significant problem. In Japan, both physicians and patients have great difficulty coping with these problems and they are waiting for new effective treatments that ensure improvement in the quality of life for patients.

Short-term treatment with multiple daily dosing of IFN- $\beta$  used in the present pilot study has fewer adverse effects, good therapeutic effects, and reproducibility to some degree. Further studies and randomized clinical trials are required to confirm our promising results.

## COMMENTS

### Background

Hepatitis B virus (HBV) is a major cause of liver disease worldwide, ranging from acute and chronic hepatitis to cirrhosis and hepatocellular carcinoma. Therefore, in order to improve the hepatitis and cirrhosis, and decrease the risk of hepatocellular carcinoma on the patients of chronic hepatitis B, it is extremely important to achieve sustained suppression of HBV replication, normalize serum alanine aminotransferase (ALT) level, and induce seroconversion by therapies. Recently, interferon (IFN)- $\alpha$  (conventional and pegylated) with or without nucleoside analogues or nucleoside analogues only are used for therapy. However, available therapies are suboptimal.

### Research frontiers

Therapies using IFN- $\alpha$  and/or nucleotide analogues are needed a long period to treat. Furthermore, those therapies are associated with some side effects. So, the authors tried to establish the new therapeutic protocol using IFN- $\beta$ , because IFN- $\beta$  belongs to type I IFN family like IFN- $\alpha$  and there were some reports that indicated the treatment of IFN- $\beta$  twice a day was more effective than that of IFN- $\alpha$  or IFN- $\beta$  once a day in chronic hepatitis C patients.

### Innovations and breakthroughs

In this study, the author's have evaluated the efficacy of a short term (4 wk), multiple daily dosing therapeutic protocol using IFN- $\beta$  for chronic hepatitis B patients. As a result, the therapeutic efficacy of that regimen is similar to that of PEG-IFN- $\alpha$  treatment for 24 wk or 1 year. Furthermore, the side effects of IFN- $\beta$  treatment in this study were less than those of PEG-IFN- $\alpha$  or IFN- $\alpha$  treatment for 24 wk or 1 year. Therefore, this treatment method of IFN- $\beta$  few times a day is more effective than standard therapeutic protocols on chronic hepatitis B patients for the first time.

### Applications

In the present pilot study, the authors indicated that the treatment protocol of IFN- $\beta$  in this study could improve a rate of side effects compare with the standard IFN- $\alpha$  or PEG-IFN- $\alpha$  treatment protocol without loss of therapeutic effects. Further studies and randomized clinical trials are required to confirm the indication of short term therapy for chronic hepatitis B.

### Terminology

It has reported that the treatment of IFN- $\beta$  twice a day is more effective than that of IFN- $\alpha$  or IFN- $\beta$  once a day in chronic hepatitis C patients. However, there is

no investigation that described the efficacy of treatment of IFN- $\beta$  twice a day on chronic hepatitis B patients.

### Peer review

The authors may want to provide end-of-treatment data as well, in addition to the SVR data that they have provided. Overall, I feel this is a novel approach that needs wider consideration.

FA responses differed significantly from those for the other two groups ( $P < 0.01$ ).

**CONCLUSION:** Despite the small number of cases studied, the higher reactivity to FAs in Group I compared to Groups II and III adds new information, and suggests the presence of a possible alteration in intestinal epithelial function.

### Abstract

**AIM:** To compare the response to skin prick tests (SPTs) to food antigens (FAs) and inhalant allergens (IAs) in patients with two subtypes of irritable bowel syndrome (IBS) and healthy controls.

**METHODS:** We compared the results of SPTs for IAs and FAs in 87 volunteers divided into three groups: diarrhea predominant IBS (D-IBS) Group I ( $n = 19$ ), constipation predominant IBS (C-IBS) Group II ( $n = 17$ ), and normal controls Group III ( $n = 51$ ).

**RESULTS:** Of the 285 tests (171 for FAs and 114 for IAs) performed in Group I we obtained 45 (26.3%) positive responses for FA and 23 (20.1%) for IA. Of the 153 tests for FA in Group II, we obtained 66 (20.1%) positive responses, and of the 102 tests for IA, we obtained 20 (19.6%) positive responses. Of the 459 tests for FA performed in Group III, we obtained 39 (8.4%) positive responses, and of the 306 for IA, we obtained 52 (16.9%) positive responses. The numbers of positive responses were not significantly different between the three groups, but in the D-IBS group, the number of SPT

### INTRODUCTION

Irritable bowel syndrome (IBS) is an extremely common disorder that affects about one in every 5-10 persons. Estimates of prevalence range from 9% to 22% depending upon population group studied<sup>[1-7]</sup>.

The exact pathophysiology of IBS remains unknown, although various mechanisms including gastrointestinal dysmotility and visceral hypersensitivity have been well studied in IBS<sup>[8-10]</sup>. Recent interest has also been directed to the possible participation of the mucosa in the pathophysiology of IBS<sup>[11-13]</sup>. Inflammatory mediators cause intestinal dysfunction and a consequent increase in permeability<sup>[14-17]</sup>. However the role and interaction of inflammatory mediators with IBS remains to be determined<sup>[17]</sup>.

IBS is defined by symptomatic criteria rather than biological markers. No diagnostic tests are available, clinical subtypes of IBS are based on the predominant symptom:

IBS diarrhea predominant (D-IBS), IBS constipation predominant (C-IBS), and mixed (m-IBS), and treatment is selected based on the predominant symptom<sup>[3,18,19]</sup>.

Clinically, the frequency of IBS is associated with psychological stress, food intolerance (adverse reaction to a specific food or ingredient that is not immune mediated or associated with psychological phenomena), intestinal infections, and even previous abdominal surgery<sup>[3,7,12,20-25]</sup>.

Dunlop *et al.*<sup>[16]</sup> have reported that patients with sub-type D-IBS (pos-infectious and non-infectious origin) have a more pronounced permeability increase in the proximal intestine compared with controls and those with C-IBS. Another aspect of that study was the detection of a significant correlation between atopy and increased intestinal permeability, which suggests that at least a subset of IBS patients may have a systemic immunological disorder. Other studies have reported a correlation between asthma, food allergy and IBS<sup>[26-29]</sup>, but the role of allergic reactions in the pathophysiology of IBS remains controversial<sup>[7,13,27,29-31]</sup>.

We have previously observed that volunteers with a diagnosis of IBS have reported higher cutaneous reactivity to food antigens than to inhalant allergens, when compared to patients with functional dyspepsia and normal controls<sup>[30]</sup>. The association between food hypersensitivity and IBS symptoms is still open to question<sup>[7,17,20,22-25]</sup>. New information is useful for a better understanding of the relationship between increased intestinal permeability, mucosal barrier defects, and intestinal inflammation in IBS patients.

The aim of this study was to compare the response to skin prick tests (SPTs) with food and inhalant antigens in two subtypes of IBS and healthy controls.

## MATERIALS AND METHODS

We studied the response to SPTs with inhalant and food extracts<sup>[32]</sup> in 87 volunteers, 36 patients with IBS (evaluated by a pre-designed questionnaire based on the Rome III criteria<sup>[18]</sup> for functional gastrointestinal diseases), and 51 normal volunteers (school employees and medical students at Antonio Pedro University Hospital). They were evaluated between September 2006 and January 2007. The volunteers were first evaluated in outpatient clinics for functional gastrointestinal diseases at Antonio Pedro University Hospital. Subjects completed a questionnaire which included Rome III criteria for IBS, and were submitted to a clinical evaluation that included a careful history (age, duration of symptoms, psychosocial factors, alarm symptoms, personal history of atopy, family history of gastrointestinal disease), examination, and stool examination for ova and parasites (Brazil is an endemic area for parasitic infections). The inclusion criteria were age > 18 years old and a diagnosis of IBS, or volunteers from the general population. The exclusion criteria were clinical suspicion or diagnosis of organic disease of the gastrointestinal tract (including positives stool examination for ova and parasites) at least 12 mo prior to the study after clinical evaluation.

The subjects were divided into three groups. D-IBS,

Group I ( $n = 19$ ; 14 female, five male; mean age 32.6 years), with IBS ROMA III Criteria for recurrent abdominal discomfort or pain at least 3 d per month in the last 3 mo, associated with two or more of the following: (1) improvement with defecation; (2) onset associated with a change in stool frequency; or (3) onset associated with a change in stool form (appearance). C-IBS, Group II ( $n = 17$  subjects; 12 female, five male; mean age 31.8 years. Controls, Group III ( $n = 51$  subjects; 31 female, 20 male; mean age 26.3 years) without previous or current significant gastrointestinal symptoms. The three groups, after informed consent (approved by the local Ethical Committee: number CAAE 009025800007) were submitted to SPTs with nine food extracts (ovalbumin, egg yolk, nuts, peanuts, wheat flour, cow's milk, soya, crustaceans and chocolate), and six inhalant extracts (*Dermatophagoides* spp., *Blomia tropicalis*, air dust, *Dermatophagoides pteronissimus*, house dust and *Dermatophagoides farinaceus*)<sup>[14]</sup>.

The contents of glycerinated food extracts (1:20), the positive control substance, histamine, and the negative control substance, saline, were commercially available (M Queiroz Laboratory, Rio de Janeiro, Brazil). They were applied by the prick technique (percutaneous) puncture through the standardized punter (discarded after use to avoid cross reaction), which allowed allergen absorption at multiple points in the skin. The test reading, done at the 20 min after the beginning were made by the measures of the wheel diameter eliciting by the test, obtained in millimeters. A wheal that was 3 mm greater than that of the negative control was considered positive. Anything less was considered negative<sup>[14]</sup>.

## Statistical analysis

Data were analyzed using Pearson's  $\chi^2$  test.  $P < 0.05$  was considered significant.

## RESULTS

A total of 1305 SPTs (783 for the FAs and 522 for the IAs) (nine FAs and six IAs for each volunteer) were accomplished in the three groups. In the D-IBS Group I, we obtained 45 positive responses for food extracts, which corresponded to 26.3% of the 171 tests performed and 23 positive responses for IAs, which corresponded to 20.1% of the 114 tests performed. In the C-IBS Group II, we obtained 21 positives responses (13.7% of the 153 tests) for FAs and 20 positive responses (19.6%) for IAs. In the control Group III, 39 (8.4%) positive responses were obtained in 459 tests performed for FAs, and 52 (16.9%) for IAs.

The positive responses were not concentrated in one or two subjects, but dispersed throughout the populations examined. The numbers of positive responses to SPT for each antigen did not differ significantly between the three groups ( $P > 0.05$ ).

Nine (52.9%) C-IBS and 11 (57.8%) D-IBS patients reported intolerance to several foods, but we did not find any correlation between positive SPTs and specific food intolerance in these subjects. Ten (58.8%) C-IBS and 12 (63.1%) D-IBS patients reported a personal history of

**Table 1** Personal history of allergies and food intolerance, and SPT response to FAs and IAs in IBS patients and normal controls (%)

	D-IBS ( <i>n</i> = 19)	C-IBS ( <i>n</i> = 17)	Without gastrointestinal symptoms ( <i>n</i> = 51)
Reported food intolerance	11 (57.8)	9 (52.9)	3 (5.8)
Personal history of allergies	12 (63.1)	10 (58.8)	26 (50.9)
No. of tests for FAs	171	153	459
Positive SPT for FAs	45 (26.3) <sup>b</sup>	21 (13.7)	39 (8.4)
No. of tests for IAs	114	102	306
Positive SPT for IAs	23 (20.1)	20 (19.6)	52 (16.9)

Papule 3 mm larger than the negative control was considered to be a positive response. <sup>b</sup>*P* < 0.01 compared to the other groups ( $\chi^2$ ).

allergies. Three (5.8%) volunteers without gastrointestinal symptoms reported food intolerance and 26 (50.9%) had a personal history of allergies. A personal history of allergies and the number of positive SPTs to IAs did not differ significantly between the three groups (*P* > 0.05). However, the number of positive SPTs to FAs in the D-IBS group differed significantly from that in the other two groups (*P* < 0.01) (Table 1).

## DISCUSSION

In the present study, we observed that patients with a diagnosis of D-IBS had higher cutaneous reactivity to FAs than to IAs, when compared with those with C-IBS and healthy controls. An association between IBS and sensitivity to several foods was identified in two groups, but the SPT response was not specific for any type of food. None of the volunteers with IBS reported intolerance to an isolated food, and positive SPT responses also were not correlated significantly with a history of intolerance to a specific food. A positive SPT response for a specific food was not associated with the crises of IBS in any of the patients in Groups I and II.

IBS is a common disorder worldwide, but its exact pathophysiology remains unknown<sup>[3]</sup>. Various mechanisms, including gastrointestinal dysmotility and visceral hypersensitivity, have been extensively studied in IBS<sup>[6-10]</sup>, but recent interest has also been associated with, or directed to the possible participation of the intestinal mucosa in the pathophysiology of IBS<sup>[11-13,17]</sup>. Several lines of evidence suggest that IBS may be associated with inflammation in the ileal or colonic mucosa, and at least in a subset of patients with IBS, the mucosal immune system seems to be activated<sup>[11,15-17]</sup>. Mucosal inflammation and immune system activation in IBS can be caused by many factors, including gastrointestinal infections, changes in the resident microflora, bile salts and FAs<sup>[15-17]</sup>.

FAs can activate the mucosal system when there is disruption of the gut barrier<sup>[31,33-36]</sup>. It is hypothesized that mucosal immune activation by FAs may contribute to the development of food allergy and IBS<sup>[9,11,13,15-17,21,25]</sup>. Clinically, the role of food-intolerance-induced symptoms in IBS frequently contrasts with that in food allergy<sup>[20,22-25,29,37-42]</sup>, and dietary elimination may be associated with symptom improvement<sup>[31]</sup>. However, the interaction of food with

the gastrointestinal system is not completely understood<sup>[13,17,20,22,23,25,29,33-37,39]</sup>.

Our results demonstrate that patients with IBS symptoms have non-specific intolerance to foods, probably associated with generalized hypersensitivity. The lack of specificity suggests that people with IBS symptoms, associated or not with food intolerance, have difficulties with food in general and specific foods may not be involved in the pathogenesis of this condition. In agreement with other studies, we suspect that IBS causes food sensitivity rather than vice-versa<sup>[3,22,37,38,41]</sup>.

The mechanisms underlying these inflammatory responses are unclear, but recent studies have suggested that an alteration in the mucosal barrier function and a consequent increase in intestinal permeability are the basis for the increased inflammation in IBS<sup>[14-17]</sup>. Dunlop *et al*<sup>[16]</sup> have reported that patients with D-IBS have a pronounced permeability increase in the proximal intestine compared with controls, and those without a history of infection onset have a more severe defect. The increase in intestinal permeability could conceivably activate the release of neurotransmitters that stimulate afferent neurons<sup>[13]</sup>.

Scientific evidence of the functional interface between the immune and sensory motor systems of the gut and respiratory systems has been reported<sup>[34,35,39]</sup>. Recent studies have reported that the prevalence of asthma and respiratory bronchial hyper-responsiveness are more common in IBS patients than in controls, and have suggested that at least a subset of IBS patients may have a systemic immunological disorder<sup>[27,28]</sup>. We have previously noticed that IBS patients have greater cutaneous reactivity to FAs than to IAs, when compared to patients with functional dyspepsia or normal controls. An association between IBS and sensitivity to multiple foods and non-specific response to SPTs has also been identified<sup>[30,42]</sup>.

In the current study, the presence of diarrhea in IBS was a significant contributor to the greater cutaneous reactivity response to FAs. No patients with IBS, with or without diarrhea, presented with gastrointestinal infections over the 12 mo that preceded the study, including positive stool examination for ova and parasites. We did not find a significant association between personal history of allergies, IBS sub-type, food intolerance and SPT response. The discrepancies between the response to SPTs to FAs and IAs in the two subtypes of patients with IBS suggest disruption of the gut barrier in patients with D-IBS. Our findings are in agreement with other studies<sup>[13,16,17,37,38,41]</sup>.

We conclude that the lack of specificity to food SPT response and the greater cutaneous reactivity to FAs than to IAs may be associated with altered epithelial function and increase in intestinal permeability in D-IBS. Further studies are needed to clarify the potential pathogenic mechanisms underlying the association between IBS and allergy, and to determine if IBS is one or several disorders.

## COMMENTS

### Background

Irritable bowel syndrome (IBS) symptoms are frequently associated with the reporting of many food sensitivities. The role of food-intolerance-induced symptoms in IBS frequently contrasts with that in food allergy, but the pathogenesis

of this association is not completely understood. Food antigens (FAs) can activate the mucosal system when there is disruption of the gut barrier. The report of a significant correlation among atopy and increased intestinal permeability suggests that at least a subset of IBS patients may have a systemic immunological disorder.

### Research frontiers

New information is useful for a better understanding of the relationship between increased intestinal permeability, mucosal barrier defects, and intestinal inflammation in IBS patients. Studies are needed to clarify the potential pathogenic mechanisms underlying the association between IBS and allergy, and to determine if IBS is one or several disorders.

### Innovations and breakthroughs

The results of skin prick tests (SPTs) for IAs and FAs in two sub-types of IBS patients were compared. They confirmed a functional interface between the immune and sensory motor systems in the gut and suggest that in D-IBS, the epithelial function (intestinal permeability) in particular can be altered. Few studies regarding the subject are available in literature. This study provides valuable information about clinical and epidemiological aspects of IBS in Brazil.

### Applications

The underlying cause of the pathophysiological changes encountered in IBS remains unclear. In clinical practice, the type and severity of symptoms determines the treatment of IBS. Our results add new information in answer to the question. Is IBS one or several disorders? Future clinical investigations will be useful for a better understanding of the results obtained here.

### Peer review

The article gives a clear delineation of the research background and provides important data about pathophysiological changes in IBS. The references are appropriate and updated.

## Abstract

**AIM:** To investigate injuries of anatomy variants of hepatic duct confluence during hepatobiliary surgery and their impact on morbidity and mortality of these procedures. An algorithmic approach for the management of these injuries is proposed.

**METHODS:** During a 6-year period 234 patients who had undergone major hepatobiliary surgery were retrospectively reviewed in order to study postoperative bile leakage. Diagnostic workup included endoscopic and magnetic retrograde cholangiopancreatography (E/MRCP), scintigraphy and fistulography.

**RESULTS:** Thirty (12.8%) patients who developed postoperative bile leaks were identified. Endoscopic stenting and percutaneous drainage were successful in 23 patients with bile leaks from the liver cut surface. In the rest seven patients with injuries of hepatic duct confluence, biliary variations were recognized and a stepwise therapeutic approach was considered. Conservative management was successful only in 2 patients. Volume of the liver remnant and functional liver reserve as well as local sepsis were used as criteria for either resection of the corresponding liver segment or construction of a biliary-enteric anastomosis. Two deaths occurred in this group of patients with hepatic duct confluence variants (mortality rate 28.5%).

**CONCLUSION:** Management of major biliary fistulae

that are disconnected from the mainstream of the biliary tree and related to injury of variants of the hepatic duct confluence is extremely challenging. These patients have a grave prognosis and an early surgical procedure has to be considered.

## INTRODUCTION

Dissection of the biliary tract constitutes the most crucial step in liver resections and every effort should aim to secure integrity and normal bile flow of the liver remnant. However, up to 40% of the patients are lacking the conventional biliary branching pattern and are more often exposed to sectorial bile duct transection during liver resection<sup>[1]</sup>.

The most frequent biliary variants are found in the right liver. The right posterior sectorial duct (RPSD) and the right anterior sectorial duct (RASD) may be joining the left hepatic duct (LHD), the common hepatic duct (CHD) or even the cystic duct<sup>[2-10]</sup>. Although biliary complications in liver resections occur approximately in 10%, they are responsible for one third of the postoperative mortality<sup>[11,12]</sup>. Fortunately, the majority is amenable to non surgical treatment, but when reoperation is necessitated mortality rate may reach up to 70%<sup>[13,14]</sup>. This high

mortality rate is due to the fact that accurate diagnosis is delayed and surgical treatment is influenced by the ongoing intra-abdominal septic process. Our study aims to present our experience in managing injuries of hepatic duct confluence variants proposing an algorithmic approach.

## MATERIALS AND METHODS

During a 6-year period (Jan, 2001-Dec, 2006) 234 patients who underwent major hepatobiliary surgery were retrospectively reviewed, in order to evaluate postoperative biliary complications due to anatomic variations of hepatic duct confluence. The hepatectomy procedures performed included segmentectomy, lobectomy and extended lobectomy (trisegmentectomy). Our technique of hepatectomy has been described previously<sup>[15]</sup>, using the Pringle maneuver, vascular outflow obstruction and sharp parenchymal dissection. For major hepatectomies (lobectomy-extended lobectomy) hilar dissection was performed to divide the correspondent vessels<sup>[16]</sup>. The diagnosis of a biliary complication was based upon the presence of a persistent bile leakage *via* the drain, the surgical incision, or the development of an intra-abdominal biloma confirmed by imaging studies. In our department, we do not perform routine preoperative imaging studies of the biliary tree anatomy. Postoperative diagnostic imaging studies included endoscopic retrograde and magnetic resonance cholangiopancreatography (ERCP-MRCP) and occasionally scintigraphy (Tc99m-HIDA) or fistulography.

Thirty patients (12.8%) who developed postoperative bile leaks were identified and conservative treatment (endoscopic stenting and percutaneous drainage) resolved the problem in 23 patients. In the remaining 7 patients, a biliary variant injury of hepatic duct confluence was diagnosed. One of these seven patients underwent an initial laparoscopic cholecystectomy and was also included in this group.

Clinical characteristics, type of operation performed, type of biliary variant, treatment and outcome of these patients with variant injuries are presented in Table 1. Classification of bile duct injuries was based on that used for hepatic duct confluence by Ayuso *et al*<sup>[17]</sup>. Treatment involved a conservative (percutaneous drainage of bilomas and perihepatic abscesses, antibiotics, *etc*) and a surgical (liver resection, biliary-enteric anastomosis) approach. Timing of surgical intervention was based upon criteria of non-responsiveness to external drainage and/or persistence of intra-abdominal sepsis. The type of procedure was based upon the estimated volume of the liver remnant and the functional reserve of the liver (Child-Pugh classification) and intraoperative factors (local inflammatory process, aberrant bile duct features, *etc*).

## RESULTS

Injuries of variants of the hepatic duct confluence were retrospectively found in 7 patients (three males and four females) with an age range from 36 to 76 years old. Six patients had undergone initially major liver resections (2 for hydatid cyst and 4 for carcinoma) and in one patient a laparoscopic cholecystectomy was performed. All

patients developed a major biliary fistula postoperatively that was disconnected from the mainstream of the biliary tree. According to the classification and imaging workup previously mentioned, 1 type C, 3 type D, 2 type E and 1 type F injuries were recognized. This simply means that the most common injury involved the right posterior sectorial duct (RPSD) in four patients (cases 1, 2, 6 and 7), while injuries of the right anterior sectorial duct (RASD) were recognized in two patients (cases 3 and 4; Figure 1). In one patient (case 5), during an extended right lobectomy, the sectorial bile duct draining liver segment I, joining separately the common bile duct (type E injury), was transected with a consequent biliary fistula (Figure 2).

All patients were initially treated conservatively, but only two (cases 3 and 4) had an uneventful outcome with resolution of the bile leak 2 mo and 4 mo, respectively, after the initial operation. One patient (case 2) refused surgical therapy and died from septic shock. The remaining four patients were approached surgically; two underwent a delayed biliary-enteric (B-E) anastomosis (cases 1 and 7) while the other two had a resection of the compromised liver segments (cases 5 and 6).

In case 1, 14 mo after the initial procedure (left lateral sectionectomy) exploratory laparotomy revealed a complex situation; liver segment's IV duct was found transected and draining in the abdomen and the RPSD was ligated near its junction with the LHD. Resection of segment IV and B-E anastomosis of the dilated RPSD with a Roux-en-Y intestinal loop were carried out and the patient had an uneventful postoperative course. In contrast, the delayed B-E anastomosis in case 7, performed 10 mo after the initial procedure (laparoscopic cholecystectomy), failed and resection of liver segments VI & VII was carried out. Unfortunately, the postoperative course was complicated by overwhelming sepsis due to accidental injury of the duodenum and the patient died.

The last 2 patients (cases 5 and 6) underwent liver resections of the compromised liver segments, 6 mo and 8 mo, respectively, after initial operation with an uneventful postoperative course. An algorithmic approach for these injuries is depicted in Figure 3.

Overall, hospital stay ranged from 20-150 d (mean, 63 d) and the mortality rate in this group of patients with injuries of variants of the hepatic duct confluence was 28.5% (2/7).

## DISCUSSION

Prevailing strategy in hepatobiliary surgery should always be the ascertainment of the integrity of normal bile flow from the liver remnant; otherwise, life-threatening complications may occur. Biliary complications in hepatobiliary surgery vary between 3%-15% and share a significant portion of the postoperative morbidity and mortality<sup>[11-14,18]</sup>. The cause of biliary leakage is usually due to unsutured collateral biliary branches of the cut surface and a non-surgical treatment settles the problem in the majority of the patients<sup>[19]</sup>. However, aberrant biliary anatomy is frequently encountered during hepatobiliary surgery and represents a totally different problem from that aforementioned.

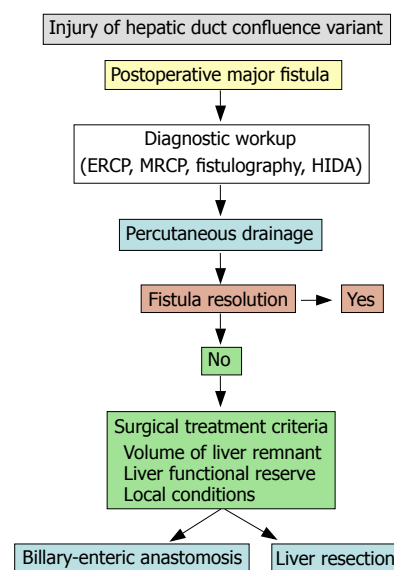

Table 1 Characteristics of patients with injury of aberrant bile ducts

No	Sex	Age	Initial operation	Biliary variant injury <sup>1</sup>	Treatment	Outcome
1	F	51	Left lateral sectionectomy (Hydatid cyst)	RPSD (type D)	Resection of segment IV and biliary-enteric (B-E) anastomosis	Uneventful
2	F	76	Left Hepatectomy (CHD carcinoma)	RPSD (type C)	Denied liver resection	Died
3	M	65	Left hepatectomy (Liver carcinoma)	RASD (type D)	Conservative (external drainage)	Resolved after 2 mo
4	M	71	Left hepatectomy (Liver carcinoma)	RASD (type D)	Conservative (external drainage)	Resolved after 4 mo
5	M	51	Right extended lobectomy (cholangiocarcinoma)	Segment's I duct (type E)	Resection of segment I	Uneventful
6	F	49	Resection of segment V (Hydatid cyst)	RPSD (type E)	Liver resection (VI, VII)	Uneventful
7	F	36	Laparoscopic cholecystectomy	RPSD (type F)	1. B-E anastomosis failed 2. Liver resection (VI, VII)	Died

<sup>1</sup>Types of biliary variants<sup>[17]</sup>: Type A: Right hepatic duct (RHD) joins the left hepatic duct (LHD); Type B: Triple confluence of right posterior sectorial duct (RPSD) and right anterior sectorial duct (RASD) and LHD; Type C: RASD or the RPSD joins the common bile duct (CBD); Type D: RASD or RPSD joins separately the LHD; Type E: Absence of confluence; sectorial ducts join separately at the common hepatic duct (CHD); Type F: RPSD joins the cystic duct.

**Figure 1** A: Retrograde cholangiogram demonstrating the left hepatic duct and its confluence with the right anterior sectorial duct (arrow, case 7); B: Fistulogram via the drain tube resulted in a retrograde cholangiogram through the transected right posterior sectorial duct (black arrow). Presence of a nasobiliary tube (white arrow) draining the left hepatic duct (case 7).

**Figure 3** An algorithmic approach for the management of patients with injuries of hepatic duct confluence variants.

**Figure 2** A: HIDA scan demonstrating bile leakage after right extended hepatectomy (case 5); B: Stentogram with intact hepatico-jejunal anastomosis in the same patient (case 5).

Preoperative assessment of biliary anatomy and possible variations in order to prevent intraoperative injury is currently performed by means of three dimensional helical computed tomography cholangiography<sup>[20-23]</sup> and various magnetic resonance imaging techniques<sup>[24-27]</sup>. If a biliary variant is assumed to be injured intraoperatively, the surgeon should perform an intraoperative cholangiography through the injured bile duct in order to estimate the type and extent of injury. In case of a disconnected from the biliary tree sectorial bile duct the decision of the surgical approach should be based on criteria of the volume of the liver remnant and liver functional reserve in case of additional hepatectomy; otherwise a Roux-en-Y biliary-enteric anastomosis must be carried out in order to drain bile to the gut.

Several efforts have been made in order to reduce or manage postoperative bile leaks. A randomized trial using an intraoperative leakage test, injecting isotonic sodium chloride solution *via* the cystic duct had no advantage on reducing postoperative bile leak<sup>[28]</sup>, while the application of a fibrin glue sealant on the cut surface of the liver seems not to be justified<sup>[29]</sup>. A case report describing infusion

of pure ethanol in an injured sectorial duct resulting in atrophy of the corresponding liver segment and cessation of postoperative bile leak seems to be a minimally invasive approach to this devastating complication needing, however, further evaluation<sup>[30]</sup>. Postoperative persistent major biliary fistula that has been attributed from diagnostic workup to an injury of a variant of the hepatic duct confluence is initially treated conservatively by means of percutaneous drainage and management of ensuing sepsis usually in a critical care environment. This approach was effective in two of our seven patients and the bile leak resolved 2 mo and 4 mo after initial operation.

Unfortunately, conservative treatment may not settle the problem and ongoing intra-abdominal sepsis fuelled by the major bile leak is associated with high morbidity and mortality. Despite adequate biliary drainage and critical care support, surgical treatment should be instituted in order to manage this problem. A planned approach based upon patient's general status, volume of future liver remnant and liver functional reserve, type and extent of injury and the volume of the corresponding liver segment draining through the injured sectorial bile duct are crucial for decision making. Surgical treatment includes either a resection of the corresponding liver segment or a biliary-enteric anastomosis with a Roux-en-Y limb. In our series, two patients underwent a biliary-enteric anastomosis, which was not successful in one of them and resection of the corresponding liver segment was additionally carried out. Resection of the liver segment, drained by the injured sectorial bile duct, was carried out successfully in two more patients. Therefore, in the case of injury of a variant of the hepatic duct confluence an algorithmic approach is proposed and depicted schematically in Figure 3.

In conclusion, variants of hepatic duct confluence are frequently involved and injured during major hepatic surgery and seriously complicate postoperatively all patients due to delay of diagnosis and ongoing intra-abdominal sepsis. Preoperative imaging of the biliary branching pattern (ERCP, MRCP) remains the only way to recognize and address properly the problem posed by the variant of biliary anatomy. MRCP offers a reliable and non-invasive visualization of the biliary tree in a manner for the surgical approach to be planned and adapted to prevent an injury of a variant of the hepatic duct confluence. However, if this occurs, conservative treatment is the initial approach in managing these patients. Failure to resolve the problem conservatively leads to a planned re-operation which includes either a biliary-enteric anastomosis or a resection of the corresponding to the injury liver segment.

## COMMENTS

### Background

Hepatobiliary surgery is frequently encountered with variations in biliary anatomy. Injuries of variants of the hepatic duct confluence add significant morbidity and mortality after liver resections, due to the development of major bile leakage and ensuing septic sequelae.

### Research frontiers

Preoperative evaluation of anatomical variants seems to be critical in avoiding inadvertent injury. Conservative treatment by means of minimally invasive techniques of injuries of variants of hilar biliary anatomy requires further

evaluation. Surgical treatment is still debatable whether to resect the compromised liver segment or to restore bile drainage to the gut by performing a biliary-enteric anastomosis.

### Innovations and breakthroughs

The proposal of an algorithmic approach to manage postoperatively the injuries of the variants of hepatic duct confluence.

### Applications

The implications of this study are for further evaluation of newer conservative therapeutic techniques and/or decision-making regarding surgical management.

### Peer review

The author's proposed an algorithm to manage the injury of the biliary tract after hepatobiliary surgery. Their recommendation is of clinical value for the patients who may have biliary anomaly. However, it is most important for avoiding bile duct injuries during hepatic resection to evaluate accurate anatomy of bile duct preoperatively.

Wang SM, Zhu J, Pan LF, Liu YK. Inhibitory effect of dimeric  $\beta$  peptide on the recurrence and metastasis of hepatocellular carcinoma *in vitro* and in mice. *World J Gastroenterol* 2008; 14(19): 3054-3058 Available from: URL: <http://www.wjgnet.com/1007-9327/14/3054.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.3054>

## Abstract

**AIM:** To block the adhesion of tumor cells to the extracellular matrix, and prevent tumor metastasis and recurrence, the dimer of the  $\beta$  peptide (DLYYLMDSLMSMKGDLYYLMDSLMSMK,  $\beta 2$ ) was designed and synthesized and its anti-adhesion and anti-invasion effects on hepatocellular carcinoma cells were assessed. Additionally, its influence on the metastasis and recurrence of mouse hepatocellular carcinoma was measured.

**METHODS:** The anti-adhesion effect of  $\beta 2$  on the highly metastatic hepatocellular carcinoma cell line HCCLM6 cells and fibronectin (FN) was assayed by the MTT assay. The inhibition of invasion of HCCLM6 cells by  $\beta 2$  was observed using a Transwell (modified Boyden chamber) and matrigel. Using the hepatocellular carcinoma metastasis model and LCI-D20 nude mice, the influence of  $\beta 2$  on the metastasis and recurrence of hepatocellular carcinoma after early resection was investigated.

**RESULTS:** HCCLM6 cells co-incubated with 100  $\mu\text{mol/L}$ , 50  $\mu\text{mol/L}$ , 20  $\mu\text{mol/L}$  or 10  $\mu\text{mol/L}$   $\beta 2$  for 3 h showed an obvious decrease in adhesion to FN. The adhesion inhibition ratios were 11.8%, 21.7%, 29.6% and 48.7%, respectively. Additionally, HCCLM6 cells cultured with 100  $\mu\text{mol/L}$   $\beta 2$  had a dramatic decrease in cell invasion.  $\beta 2$  was also observed to inhibit the incisional edge recurrence and the distant metastasis of nude mice hepatocellular carcinoma after early resection ( $P < 0.05$ ).

**CONCLUSION:** The  $\beta 2$  peptide can specifically block the adhesion and invasion of HCCLM6 cells, and can inhibit HCC recurrence and metastasis of LCI-D20 model pos-

## INTRODUCTION

Despite significant advances in the treatment of human hepatocellular carcinoma (HCC) and the prevention of postoperative metastasis, the 5-year postoperative recurrence rate of HCC is still very high<sup>[1,2]</sup>. Many efforts have been made to develop a more efficient treatment to inhibit and prevent tumor metastasis, as the recurrence and metastasis of HCC is still a large problem in clinical practice. It is well known that the metastatic process is very complex, including tumor cells dissociating from the primary locus, invading the surrounding tissue, entering and extravasating from the circulation, and growing in distant organs<sup>[3,4]</sup>. During this process, cell adhesion is one of the most important events<sup>[5]</sup>. Many studies have been focused on the synthesized anti-adhesion peptides<sup>[6-8]</sup>. However, the application of these short peptides is limited due to their short half-life and high dosage required. To prolong the peptide's half-life, the polymer and a derivative of synthesized peptides were designed<sup>[9-11]</sup>. The anti-tumor metastasis effect of the repeat sequence of synthesized peptides was stronger than that of non-repeat peptides<sup>[12,13]</sup>.

Integrins are a family of adhesion molecules located on cells and in the extracellular matrix. The expression level of integrins is related closely to a cell's migration ability<sup>[14,15]</sup>. The anti-adhesion peptide  $\beta$  (DLYYLMDSLMSMK,  $\beta 1$ ) was designed by Liu *et al*<sup>[16]</sup>, according to the conserved sequence of the integrin  $\alpha$  and  $\beta$  unit. This peptide can block the

interaction between tumor cells and the extracellular matrix and can also inhibit intrahepatic and pulmonary metastases after carcinosectomy in a nude mouse model with human HCC of high metastatic potential (LCI-D20)<sup>[17-21]</sup>. On the basis of these studies, here we have designed and synthesized the dimeric peptide  $\beta$  ( $\beta$ 2). The effects of  $\beta$ 2 on the adhesion of human liver cancer cell line HCCLM6 cells to fibronectin (FN), the invasion of HCCLM6 cells to reconstituted basement membrane, as well as liver cancer recurrence and metastasis after hepatectomy in a nude mouse model were investigated.

## MATERIALS AND METHODS

### Cell culture

The highly metastatic hepatocellular carcinoma cell line HCCLM6, initially established and preserved by the Liver Cancer Institute, Fudan University, was cultured in Dulbecco's modified eagle's medium (DMEM, Gibco, UK), supplemented with 10% fetal bovine serum, 100 U/mL penicillin and grown at 37°C under an atmosphere of 5% CO<sub>2</sub>. The medium was replenished every three days to maintain cell growth.

### Coating the 96 well high bind microplate with FN

Ten  $\mu$ g/mL FN (Sigma, USA) solution (containing 10  $\mu$ g/mL FN, 20 mmol/L Tris-Cl, pH 7.4, 150 mmol/L NaCl, 1 mmol/L MgCl<sub>2</sub>, 1 mmol/L CaCl<sub>2</sub>, 1 mmol/L MnCl<sub>2</sub>) was added to a 96-well high bind microplate (Corning, USA) (100  $\mu$ L per well), and allowed to incubate at 4°C overnight. The plate was then incubated with blocking buffer (10 mmol/L Hepes, pH 7.4, 140 mmol/L NaCl, 5.4 mmol/L KCl, 5.56 mmol/L glucose, 3% BSA, 1 mmol/L MgCl<sub>2</sub>, 2 mmol/L CaCl<sub>2</sub>, 1 mmol/L MnCl<sub>2</sub>) at 37°C for 2 h and air dried for further use.

### Cell adhesion assay

$\beta$ 2 peptide was designed in our laboratory using the sequence DLYYLMDSLYSMKGGDLYYLMDSLYS MK. The peptide was synthesized by Shanghai Sangon Bioengineering Company. 100  $\mu$ L of a HCCLM6 suspension ( $2 \times 10^5$ /mL) was plated in each well of an FN coated 96-well high bind microplate. 100  $\mu$ L DMEM medium containing  $\beta$ 2 at a concentration of 200  $\mu$ mol/L, 100  $\mu$ mol/L, 40  $\mu$ mol/L or 20  $\mu$ mol/L was added to the cells concomitantly. The same volume of cell culture medium in place of  $\beta$ 2 was added to the control group. 200  $\mu$ L of cell culture medium only was added in the plate for the blank group. The assay was conducted in quintuplicate for each sample. After incubation for 3 h at 37°C, under an atmosphere of 5% CO<sub>2</sub>, the unattached cells were gently washed away with HANKS buffer. The attached cell number in each well was measured by MTT. The inhibition rate of  $\beta$ 2 on cell adhesion to FN was calculated with the following equation: Cell adhesion inhibitory rate = (average OD of control well-average OD of  $\beta$ 2-treated well)/(average OD of control well-average OD of blank well)  $\times$  100%

### MTT assay

The number of attached cells in each well was examined by

the MTT assay, as previously described<sup>[22]</sup>, and quantified by a micro-titer plate reader (Amersham, USA). Briefly, after incubation for 3 h at 37°C in 5% CO<sub>2</sub>, the unattached cells were removed by gentle washing with HANKS buffer. 100  $\mu$ L DMEM and 20  $\mu$ L MTT (5 mg/mL) (Sigma, USA) were added to each well. After incubation at 37°C for 4 h, the medium was discarded. 200  $\mu$ L of 0.04 mol/L hydrochloric acid in isopropanol was added to each well. The amount of MTT formazan product, which reflects the number of cells adhering to FN, was determined by measuring absorbance with a microplate reader at a test wavelength of 570 nm and a reference wavelength of 630 nm.

### Invasion assay

Invasion assays were performed as described previously<sup>[23]</sup>. Briefly, the upper portion of Transwell chambers (Corning, USA) were coated with 75  $\mu$ L of Matrigel (BD, USA) diluted 1:10 in serum-free DMEM and incubated at 37°C for 2 h. The supernatants of HCCLM6 cells containing DMEM with 10% FCS were harvested after the cells had grown to confluence, and after adding FN at a final concentration of 5  $\mu$ g/mL, resulting in conditioned medium. The trypsinized cells were harvested and diluted to a  $2 \times 10^6$ /mL cell suspension with serum-free DMEM. 100  $\mu$ L of the cell suspension and 100  $\mu$ L of 200  $\mu$ mol/L  $\beta$ 2 peptides in serum-free DMEM or serum-free DMEM only as a control were added in the upper chambers. Concurrently, 600  $\mu$ L of conditioned medium was added to the bottom chamber of the Transwell plate. After incubation at 37°C for 48 h under a 5% CO<sub>2</sub> atmosphere, the non-invading cells and the gel were gently removed from the upper chamber with cotton-tipped swabs. Cells were rinsed with PBS, and the cells on the filters were fixed with Formaldehyde and stained in Giemsa staining solution for 30 min. The number of invaded cells on the filters was counted in 5 randomly selected high-powered ( $\times$  200) fields per filter under a microscope (Leica, Switzerland). Invasion inhibitory rate was expressed as the following equation: Invasion inhibitory rate = [1 - (invaded cell number in  $\beta$ 2 chamber/invaded cell number in control chamber)]  $\times$  100%.

### Animal model and treatment

Twelve 5-wk-old male nude mice (BALB/cA) weighing 17-20 g were obtained from the Shanghai Institute of Materia Medica, Chinese Academy of Sciences. The nude mouse model of human hepatocellular carcinoma with high metastatic potential (LCI-D20), which was established in Zhongshan Hospital Liver Cancer Institute, Fudan University, was used in this study. A tumor block of LCI-D20 nude mice human liver cancer metastasis model was implanted into the left lobe of the nude mouse liver as described previously<sup>[24]</sup>. Briefly, a left upper abdominal transverse incision was made under anesthesia; the left lobe of the liver was exposed and a part of the liver surface was mechanically injured with scissors. Next, a tumor block of 0.2 cm  $\times$  0.2 cm  $\times$  0.2 cm was fixed within the liver tissue. After the operation, mice were kept in laminar-flow cabinets under specific-pathogen-free conditions and given free access to mouse chow. Liver cancer early resection

**Table 1** The inhibitory effects of  $\beta 2$  on the invasion ability of HCCLM6 cells ( $n = 5$ )

Group	Mean of invaded cell (SD)	Invasion inhibitory rate (%)
Control group	19.30 (9.3)	-
$\beta 2$ group	12.20 (6.2)	36.80%

**Table 2** Liver cancer recurrences in incisional margins in nude mouse models after early resection

Group	Number of mice tested	Mean weight of recurrent lesion (g) (SD)	Number of mice with recurrent lesion
Control group	6	2.31 (0.64)	6

<sup>a</sup> $P < 0.05$  vs control group.

was performed 0.2 cm from the edge of the cancer at day 10 after implantation, prior to metastasis. At day 1 after resection, the animals were subcutaneously administrated 100  $\mu$ L of 1 mg/mL of  $\beta 2$  or NS as a control every other day for 10 doses. Mice were harvested at day 55 postimplantation, and lungs were fixed in 10% formalin, embedded in paraffin, cut into 5  $\mu$ m slides and metastatic nodes were observed and counted under a microscope. If recurrence of the incisional margin of cancer was found, the lesion would be resected and weighed.

All of the animal experiments were conducted in strict accordance with the National Institute of Health Guide for the Care and Use of Laboratory Animals.

### Statistical analysis

All data were entered into Excel spreadsheets (Excel, Microsoft, Seattle, USA). We used the SAS program (SAS Institute Inc., Cary, NC, USA) for statistical analysis. Comparisons for dimensional outcomes employed the Student's *t*-test, or the Mann Whitney *U* test when the data were not normally distributed. Values of  $P < 0.05$  in a two-tailed fashion were considered to be statistically significant.

## RESULTS

### The inhibitory effect of $\beta 2$ on the adhesion of HCCLM6 cells to FN

The inhibitory effect of  $\beta 2$  on the adhesion of HCCLM6 cells to FN is shown in Figure 1. HCCLM6 cells co-incubated with 100  $\mu$ mol/L, 50  $\mu$ mol/L, 20  $\mu$ mol/L and 10  $\mu$ mol/L  $\beta 2$  for 3 h led to an obvious decrease in cellular adhesion. The adhesion inhibition ratios were 11.8%, 21.7%, 29.6% and 48.7%, respectively. This observation indicates that  $\beta 2$  is able to inhibit the adhesion of HCCLM6 cells to FN, and thus  $\beta 2$  might obstruct the invasion of HCC cells to paratumor liver parenchyma.

### The inhibitory effect of $\beta 2$ on the invasion ability of HCCLM6 cells

After incubation with 100  $\mu$ mol/L  $\beta 2$ , the number of invaded HCCLM6 cells was decreased. The inhibitory rate

**Figure 1** The inhibitory effect of  $\beta 2$  on the adhesion of HCCLM6 cells to fibronectin ( $n = 5$ ).

was 36.8% (Table 1). Thus,  $\beta 2$  might block HCC cells from invading the surrounding tissue and entering and extravasating from the circulation *in vivo*.

### The influence of $\beta 2$ on the intrahepatic recurrence of the LCI-D20 model after early resection

On the 10th d post-tumor-implantation, LCI-D20 tumors were resected, and  $\beta 2$  or the same volume of saline was subcutaneously injected. On day 55, mice were sacrificed to check for intrahepatic recurrence. The recurrent tumor was located around the incisional margins. Compared with the control group, the weight of the intrahepatic recurrent tumor of the  $\beta 2$  group was markedly decreased and statistically significant. There were 4 (4/6) mice with intrahepatic recurrent tumor in the  $\beta 2$  group, while there were 6 (6/6) mice with an intrahepatic recurrent tumor in the control group (Figure 1 and Table 2). These results indicate that  $\beta 2$  have inhibitory effects on tumor recurrence in the incisional margin.

### The inhibitory effects of $\beta 2$ on metastasis of liver cancer in nude mouse models after early resection

On the 55th day after tumor implantation, the number of metastatic nodes was calculated under a microscope. The result showed that there were fewer metastatic nodes in the  $\beta 2$  treatment group compared to the control group, and there was a statistical difference between the  $\beta 2$  group and the control group. Furthermore, all of the 6 mice in the control group (6/6) had metastatic nodes, but only 4 (4/6) mice had metastatic nodes in the  $\beta 2$  group. These results indicate that  $\beta 2$  have a significant preventive and therapeutic effect on the metastasis of liver cancer (Table 3).

## DISCUSSION

The adhesion molecules on the surface of both tumor cells and endothelial cells are associated with tumor metastasis and recurrence. Blocking the interaction between tumor cell adhesion molecules and their ligands is a major target in the prevention of cancer metastasis<sup>[25,26]</sup>. Many studies have focused on the synthesized anti-adhesion peptides<sup>[27,28]</sup>. One such peptide is RGD<sup>[29,30]</sup>, derived from the common conserved sequence of the main matrix

**Table 3** The lung metastasis in liver cancer nude mouse models after early resection

	Number ( <i>n</i> )	The total number of metastatic nodes in lung	The number of mice with lung metastatic nodes
Control group	6	30	4
β2 group	6	11 <sup>a</sup>	2

<sup>a</sup>*P* < 0.05 *vs* control group.

proteins such as fibronectin, collagen and fibrinogen. A second peptide is YIGSR<sup>[31]</sup>, which originated from the basement membrane protein laminin. The third peptide is EILDV<sup>[32]</sup>, which stemmed from the core sequence of fibronectin. The application of these short peptides was limited due to their short half-life, the ease with which they are degraded and the requirement for a high dosage. To prolong the peptides' half-life, the polymer and derivative of synthesized peptides were designed. The anti-tumor metastatic effect of repeat sequence of synthesized peptides was stronger compared to non-repeat peptides. The more times the sequence is repeated, the stronger the anti-metastasis effect is.

FN is an important cell adhesion molecule in the extracellular matrix. It mediates cell adhesion and migration, and plays a significant role in tumor invasion and metastasis. Assaying FN adhesion to tumor cells is a method commonly used for studying tumor cell metastasis. In this study, the extracellular matrix was simulated by coating cell culture plates with FN, after which the inhibitory effects of β2 peptide on FN adhesion to liver cancer cells were investigated. The results demonstrated that after co-culturing the peptides with HCCLM6 cells for 3 h, a distinct and specific inhibitory effect of β2 peptide on FN adhesion to tumor cells was observed.

Tumor cells must penetrate the basement membrane for at least three times during metastasis; i.e. dislodging from the original site, entering blood circulation, and migrating from blood flow into remote sites. Matrigel, used as a basement membrane matrix, is produced from mouse Engelbreth-Holm-Swarm sarcoma rich in extracellular matrix protein. The artificial basement membrane is plated on a Millipore filter in Transwell culture chambers, and forms a membrane structure similar to natural basement membrane. Invasive, metastatic tumor cells can penetrate the membrane under the induction of chemotactics, simulating tumor cells' invasion of the basement membrane *in vivo*. The results indicated that β2 exerted significant inhibitory effects on the invasion of HCCLM6 cells.

Metastasis and recurrence of liver cancer is a major determinant for the prognosis and long-term survival of liver cancer patients. Polypeptide therapy is a newly developed treatment for tumors<sup>[31]</sup>, but its clinical application is restricted by the degradation of these peptides. β peptides can inhibit the metastasis and recurrence of human liver cancer in nude mouse models after early excision, and can also block the recurrence of cancer at the incisional margins.

The β peptide blocked tumor cell adhesion to FN through two possible mechanisms. First, the β peptide took up the integrin binding site competently through

binding to the RGD sequence of the matrix protein. Next, the β peptide also interacted with integrin because the β peptide was designed according to the conserved sequence of the integrin α and β unit.

Taken together, these cell and animal studies demonstrated that the β2 peptide can prevent and treat liver cancer adhesion and metastasis and recurrence. Therefore, the β peptide is worthy of further investigation, as it is a potential drug for blocking tumor metastasis and recurrence.

## COMMENTS

### Background

Despite significant advances in the treatment of human hepatocellular carcinoma (HCC), metastasis and recurrence remain the main obstacles for HCC patients gaining a better outcome and long-term survival. It is well known that during the metastatic process, cell adhesion is one of the most important events. The adhesion molecules on the surface of both tumor cells and endothelial cells are associated with tumor metastasis and recurrence. So, blocking the interaction between tumor cell adhesion molecules and their ligands has become a major target in prevention cancer metastasis.

### Research frontiers

To prevent tumor metastasis and recurrence through inhibiting the adhesion of tumor cells, many studies have focused on the synthesized anti-adhesion peptides such as RGD, YIGSR and EILDV. These peptides are derived from the common conserved sequence of the main matrix proteins such as fibronectin, collagen, fibrinogen and laminin. Liu *et al* designed a new anti-adhesion peptide β (DLYYLMDSLYSYMK, β1) according to the conserved sequence of the α and β unit of integrins. These peptides can inhibit the adhesion of tumor cells and cancer metastasis and recurrence. But their application is limited due to the short half-life and high dosage required.

### Innovations and breakthroughs

On the basis of Liu's study, to prolong the peptide's half-life, the dimer of β peptide (DLYYLMDSLYSYMKGGDLYYLMDSLYSYMK, β2) was designed and synthesized and the anti-adhesion and anti-invasion effect of it on hepatocellular carcinoma cells, as well as its influence to the metastasis and recurrence of mouse hepatocellular carcinoma were measured. The result showed that β2 can inhibit the adhesion of HCCLM6 cells to FN in dose-effect manner. And the number of invaded HCCLM6 cells was decreased when incubated together with 100 μmol/L β2. Compared with the control group, the weight of the intrahepatic recurrent tumor and the number of metastatic nodes in lung of the β2 group were markedly decreased.

### Applications

β2 might obstruct the invasion of HCC cells to paratumor liver parenchyma and block HCC cells from invading the surrounding tissue and entering and extravasating from the circulation *in vivo*. In addition, β2 have inhibitory effects on tumor recurrence in the incisional margin and a significant preventive and therapeutic effect on the metastasis of liver cancer. Taken together, these cell and animal studies demonstrated that the β2 peptide can prevent and treat liver cancer adhesion, metastasis and recurrence.

### Peer review

On the basis of previous work, the β2 peptide (DLYYLMDSLYSYMKGGDLYYLMDSLYSYMK, β2) was designed and synthesized. After co-culturing with HCCLM6 cells for 3 h, a distinct and specific inhibitory effect of β2 peptide on FN adhesion to tumor cells was observed. And also β2 showed significant inhibitory effects on the invasion of HCCLM6 cells. Furthermore, β2 peptides can inhibit the metastasis and recurrence of human liver cancer in nude mouse models after early excision, and can also block the recurrence of cancer at the incisional margins. These results indicate that β2 have a significant preventive and therapeutic effect on the metastasis of liver cancer.

### Abstract

**AIM:** To investigate the role of hepatitis B virus (HBV) replication in the development of hepatocellular carcinoma (HCC), a nested case-control study was performed to study the relationship between HBV DNA level and risk of HCC.

**METHODS:** One hundred and seventy cases of HCC and 276 control subjects free of HCC and cirrhosis were selected for this study. Serum HBV DNA level was measured using fluorescein quantitative polymerase chain reaction at study entry and the last visit.

**RESULTS:** In a binary unconditional logistic regression analysis adjusted for age, cigarette smoking, alcohol consumption and family history of chronic liver diseases, the adjusted odds ratios (95% confidence intervals) of HCC in patients with increasing HBV DNA level were 2.834 (1.237-6.492), 48.403 (14.392-162.789), 42.252 (14.784-120.750), and 14.819 (6.992-31.411) for HBV DNA levels  $\geq 10^4$  to  $< 10^5$ ;  $\geq 10^5$  to  $< 10^6$ ;  $\geq 10^6$  to  $< 10^7$ ;  $\geq 10^7$  copies/mL, respectively. Forty-six HCC cases were selected to compare the serums viral loads of HBV DNA at study entry with those at the last visit. The HBV DNA levels measured at the two time points did not differ significantly.

### INTRODUCTION

Chronic hepatitis B virus (HBV) infection is still a worldwide health problem<sup>[1]</sup>, with approximate 400 million patients persistently infected<sup>[2,3]</sup>. Although most of the HBV carriers are asymptomatic, about one-third (25%-40%) die from cirrhotic complications or hepatocellular carcinoma (HCC)<sup>[4]</sup>. The relative risk of HBV carriers for the development of HCC is up to 200:1, which is one of the highest relative risks known for a human malignancy<sup>[5]</sup>. Due to the high incidence of recurrence and secondary primary tumor, the survival rate of HCC after any treatment is still low<sup>[6]</sup>. Therefore, looking for the predictive factors for HCC in patients with chronic Hepatitis B will have a profound impact on the prevention and treatment of chronic HBV infection.

The precise mechanisms by which chronic Hepatitis B leads to HCC are not clearly understood. Viral, host (sex, age and genetic susceptibility) and environmental factors may play interactive roles in hepatocarcinogenesis<sup>[7-12]</sup>. Recent studies have indicated that serum level of HBV DNA may be a risk factor for HCC<sup>[13-16]</sup>. Tang *et al*<sup>[17]</sup> have previously reported that adult HBV carriers who maintain high-titer serum HBV DNA are at higher risk for development of HCC. In Taiwan, a 12-year follow-up study of 4841 men who were Hepatitis B surface antigen

(HBsAg) positive has demonstrated that the risk of HCC is 2.7-10.7-fold higher in patients with baseline HBV DNA levels of  $4.0 \log_{10}$  copies/mL to  $\geq 6.0 \log_{10}$  copies/mL<sup>[18]</sup>. However, it is important to study different endemic regions to verify the relationship between active HBV replication and development of HCC, because there is a geographic distribution of HBV genotypes. In particular, the data are largely lacking in mainland of China, where chronic HBV infection is highly endemic and accounts for half of the chronic hepatitis B in the world.

The township of Qidong, at the mouth of the Yangtze River, is one of the highest endemic regions for chronic HBV infection and HCC in China<sup>[19]</sup>. Between October 1996 and February 2006, we followed a total of 2387 HBsAg-positive adult residents in Qidong city. The aims of this study were to determine whether chronic HBV carriers who maintain high serum HBV DNA level are at higher risk for development of HCC in Chinese patients with chronic Hepatitis B.

## MATERIALS AND METHODS

### Study population

In October 1996, about 18000 male residents between the ages of 20 and 65 yr living in 17 townships in Qidong county, China were invited to participate in a prospective study. All of those invited were tested for serum HBsAg, alanine aminotransferase (ALT) and  $\alpha$ -fetoprotein (AFP). A total of 2387 participants who were seropositive for HBsAg and confirmed to be free of HCC by AFP level and abdominal ultrasonography were followed up with abdominal ultrasonography and serological tests including ALT, AFP, HBV serological markers (HBsAg) and anti-Hepatitis C virus (HCV) antibody until February 2006. Each study participant provided informed written consent and a structured questionnaire on sociodemographic characteristics, habits of alcohol and tobacco consumption and family histories. A serum specimen was collected from each participant at every interview. All of the serum samples were stored at  $-30^{\circ}\text{C}$  before analysis. This study was approved by the research ethics committee at Zhongshan Hospital, Fudan University, Shanghai, China.

### Laboratory testing

Serum HBsAg and anti-HCV antibody were tested by commercially available enzyme immunoassay kits (Shanghai Kehua Bio-engineering Co. Ltd., China). Serum ALT level was determined by ultraviolet-lactate dehydrogenase (UV-LDH) method and serum AFP level was determined by ELISA (Shanghai Kehua Bio-engineering Co. Ltd.).

### Fluorescein quantitative polymerase chain reaction (FQ-PCR)

The serum HBV DNA levels were determined using the FQ-PCR detection system (Taqmen; Roche USA), according to the manufacturer's instructions. HBV DNA was extracted using the commercial Kit (Shanghai Shenyong Biotech Company) from 50  $\mu\text{L}$  serum. The PCR reaction was carried out as follows:  $37^{\circ}\text{C}$  for 120 s,  $94^{\circ}\text{C}$  for 180 s, followed by 40 cycles of  $94^{\circ}\text{C}$  for 10 s,  $55^{\circ}\text{C}$  for 30 s and

$72^{\circ}\text{C}$  for 40 s. The lower limit of detection of this assay was 500 copies/mL with a linear range of up to  $10^8$  copies/mL.

### Statistical analysis

The  $\chi^2$  test was used to compare baseline characteristics between patients and controls subjects. Wilcoxon signed ranks test has been used to compare the constancy of the viral replication at two time points. For statistical comparisons, a value of 500 copies/mL was assigned, the detection limit of the assay, to samples that had undetectable levels of HBV DNA. Samples of the two groups were divided into six subgroups, according to the level of serum HBV DNA expressed as the logarithmic equivalent (LGE) per milliliter, subgroup 1 ( $< 500$  copies/mL, undetectable), subgroup 2 ( $2.69 \log_{10}$  to  $3.99 \log_{10}$  copies/mL), subgroup 3 ( $4.0 \log_{10}$  to  $4.99 \log_{10}$  copies/mL), subgroup 4 ( $5.0 \log_{10}$  to  $5.99 \log_{10}$  copies/mL), subgroup 5 ( $6.0 \log_{10}$  to  $6.99 \log_{10}$  copies/mL), and subgroup 6 ( $\geq 7.0 \log_{10}$  copies/mL). Binary unconditional logistic regression analysis was used to evaluate relative risks. Potential confounders including age, cigarette smoking, alcohol consumption and family history of chronic liver diseases were adjusted. SPSS 13.0 for Windows was used for all statistical analyses.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Demographic characteristic of HCC and control patients

No participants had any clinical evidence of HCC at study entry. By December 31, 2004, 243 participants died of HCC. The data were obtained from medical records and searches of computer files of death certification and cancer registry systems. To ensure complete ascertainment, we also contacted relatives by mail to identify cases. HCC was diagnosed on the basis of either surgical biopsy or an elevated serum AFP level ( $\geq 400$  ng/mL), combined with at least one positive image on sonography, computed tomography and/or magnetic resonance imaging. Seventy-three patients diagnosed with HCC within the first two years of our study probably had subclinical HCC at study entry, and were therefore, excluded from the analysis, which left 170 cases of HCC. The paired serum samples were available only in 46 cases, both at study entry and at the time of HCC, for determining the change in serum HBV DNA level over time. Two hundred and seventy-six subjects with chronic Hepatitis B infection and normal ALT level at each follow-up, and free of evidence of cirrhosis or HCC, were selected as controls.

At baseline, there were no significant differences in age, cigarette smoking and alcohol consumption between HCC and control patients, while the family histories of HBV-associated chronic liver diseases were significantly different between the two groups. 85/170 (50%) of cases had a family history, while only 92/276 (33.3%) of control subjects had (Table 1).

### Baseline serum HBV DNA level in HCC patients and controls

186/276 (67.4%) samples of control subjects had undetectable levels of serum HBV DNA. Compared with those with undetectable levels of serum HBV DNA, the adjusted odds ratios of HCC for subjects with increasing

Table 2 Association between HBV DNA level at study entry and subsequent risk of HCC *n* (%)

HBV DNA level (log <sub>10</sub> copies/ mL)	HCC patients ( <i>n</i> = 170)	Control patients ( <i>n</i> = 276)	Adjusted odds ratio (95% CI)
1 undetectable	44 (25.9)	186 (67.4)	1.000 (reference)
2 (2.69-3.99)	5 (2.9)	46 (16.7)	0.465 (0.172-1.259)
3 (4.00-4.99)	12 (7.1)	19 (6.9)	2.834 (1.237-6.492)
4 (5.00-5.99)	30 (17.6)	4 (1.4)	48.403 (14.392-162.789)
5 (6.00-6.99)	38 (22.4)	5 (1.8)	42.252 (14.784-120.750)
6 (≥ 7.00)	41 (24.1)	16 (5.8)	14.819 (6.992-31.411)

Adjusted for age at enrollment (continuous variable), cigarette smoking, alcohol consumption and family history of chronic liver diseases.

HBV DNA level were 0.465 (95% CI 0.172-1.259), 2.834 (1.237-6.492), 48.403 (14.392-162.789), 42.252 (14.784-120.750), and 14.819 (6.992-31.411). The analysis has been adjusted for age, cigarette smoking, alcohol consumption and family history of chronic liver diseases. The risk of HCC was increased with increasing HBV viral load in 4.0 log<sub>10</sub> to 7.0 log<sub>10</sub> copies/mL (Table 2).

### Change of serum HBV DNA level over time

All the control subjects in our study were followed up for 10 years with persistently normal ALT level, and had no history of interferon- $\alpha$  or nucleoside analogue therapy. HBV DNA levels were compared between entry and last visit in asymptomatic HBV carriers (controls). There was a statistically significant difference in serum HBV DNA level at the two time points (Table 3). For the 46 patients for whom the serum samples were collected both at study entry and at or after the time of HCC diagnosis, the time interval between collection of the two samples ranged from 24 to 94 mo. The log HBV DNA levels measured at the two time points did not have a statistically significant difference.

## DISCUSSION

Family history of liver carcinoma is one of the main risk

Table 3 Comparison of serum levels of HBV DNA at study entry and at last visit in asymptomatic HBV carriers (controls) *n* (%)

HBV DNA level (log <sub>10</sub> copies/mL)	At study entry ( <i>n</i> = 276)	At last visit ( <i>n</i> = 276)	<i>Z</i>	<i>P</i> value
1 undetectable	186 (67.4)	221 (80.1)	-4.904	<i>P</i> < 0.01
2 (2.69-3.99)	46 (16.7)	30 (10.9)		
3 (4.00-4.99)	19 (6.9)	9 (3.3)		
4 (5.00-5.99)	4 (1.4)	6 (2.2)		
5 (6.00-6.99)	5 (1.8)	3 (1.1)		
6 (≥ 7.00)	16 (5.8)	7 (2.5)		

factors for HCC, especially in the Chinese population<sup>[20-22]</sup>. In our study, 85/170 (50%) of cases had a family history of HBV-associated chronic liver diseases. However, only 92/276 (33.3%) of control subjects did.

In China, HBV DNA levels > 5.0 log<sub>10</sub> copies/mL have been considered clinically significant, and are suggested by clinical practice guidelines for making a decision on antiviral therapy in chronic carriers of Hepatitis B. The guidelines are supported by the findings of a meta-analysis of 26 trials of statistical significance and consistent correlations between viral load and histological grading, and biochemical and serological response<sup>[23]</sup>. However, the relationship between different levels, especially lower levels, of HBV DNA and risk of HCC remains uncertain.

During the past 10 years, longitudinal studies have been used to evaluate HBV DNA level as risk factors of HCC in HBV carriers. A significant biological gradient of HCC risk by serum HBV DNA level from 4.0 log<sub>10</sub> to 7.0 log<sub>10</sub> copies/mL was observed in our cohort. Similar to previous results<sup>[24]</sup>, the HCC risk started to increase significantly at a serum HBV DNA level of 4.0 log<sub>10</sub> copies/mL, which is much lower than the level of 5.0 log<sub>10</sub> copies/mL suggested by clinical practice guidelines for making decisions on antiviral therapy in carriers of chronic Hepatitis B. Viral loads < 4.0 log<sub>10</sub> copies/mL have been thought to be characteristic of an inactive carrier state and a much lower risk of HCC. Moreover, it is important to know that compared to viral loads between 5.0 log<sub>10</sub> and 7.0 log<sub>10</sub> copies/mL, patients with HBV DNA levels > 7.0 log<sub>10</sub> copies/mL were at lower risk of developing HCC. Chronic HBV carriers with mid-high viral loads (4.0 log<sub>10</sub> to 7.0 log<sub>10</sub> copies/mL) tended to be in the phase of immune clearance, while the majority of those with viral load levels of 7.0 log<sub>10</sub> copies/mL were immunotolerant and at lower risk of HCC. Our findings are partly consistent with studies in different areas. In Japan, Ohata *et al.*<sup>[25]</sup> have investigated the risk factors for HCC in 73 patients with HBV-associated liver disease. A high viral load of HBV DNA, together with age and histological fibrosis, were found to be linked to the occurrence of HCC. Yang *et al.*<sup>[26]</sup> have reported that HCC risk increased with the increasing HBV viral load above 7.5 log<sub>10</sub> copies/mL. They have also found that HCC risk is associated with Hepatitis B e antigen (HBeAg) positivity among HBsAg-positive men in Taiwan. Based on these results, the serum level of HBV DNA may be used as a prominent risk predictor for HCC, independent of age, histological

fibrosis and HBeAg status.

To the best of our knowledge, there have been few studies on longitudinal stability of HBV DNA level in HBV carriers over time in mainland China. In the 276 control subjects in our study, all the HBV DNA levels in samples at the last visit were compared with those collected at study entry. 186/276 (67.4%) samples of control subjects had undetectable levels of serum HBV DNA at study entry, while 221/276 (80.1%) samples had undetectable levels of serum HBV DNA at the last visit. During a follow-up period of 10 years, the HBV DNA levels of those asymptomatic carriers tended to decrease. Forty-six case patients were selected whose serum samples were collected both at study entry and after the time of HCC diagnosis. Compared with serum HBV DNA levels at study entry, viral load after HCC onset remained at high levels. This implied that for chronic HBV carriers free of antiviral therapy, HCC was preceded by persistently high replication activity of HBV and viral levels did not decline with progression of HCC.

It is generally agreed that antiviral treatment is suitable in patients with active HBV replication ( $\geq 5.0 \log_{10}$  copies/mL) and elevated ALT level (at least twice the upper limit of the normal range)<sup>[27]</sup> or advanced fibrosis present upon liver biopsy. In clinical trials, among patients with chronic Hepatitis B and advanced stage fibrosis, longer term lamivudine therapy reduces the risk of HCC<sup>[28,29]</sup>. Although individuals with low viral load ( $< 4.0 \log_{10}$  copies/mL) are at decreased risk for HCC, continued monitoring is essential because of the fluctuating nature of chronic HBV infection. Treatment choices for patients with serum HBV DNA levels  $< 5.0 \log_{10}$  copies/mL are still controversial. In our study, HBV carriers with HBV DNA levels  $> 4.0 \log_{10}$  copies/mL have 2.834 times excess risk of HCC compared with HBV carriers with lower HBV DNA levels. Therefore, among patients with HBV DNA levels  $> 4.0 \log_{10}$  copies/mL, liver tests should be carefully monitored at 3-4-mo intervals, irrespective of age and ALT levels. Antiviral treatment should be advised when hepatitis flares and/or advanced fibrosis is present upon liver biopsy.

In conclusion, serum HBV DNA levels were found to be associated with increased risk of HCC. For chronic HBV carriers without antiviral therapy, HBV DNA levels changed little with the progression of HCC. Based on these findings, it is conceivable that patients with a high viral load have a high potential for hepatocarcinogenesis, and should be subjected to closer clinical monitoring<sup>[30]</sup> and even antiviral treatment.

We thank He-Jun Yuan, MD of the University of Texas Southwestern Medical School for his helpful comments and suggestions.

## COMMENTS

### Background

Chronic Hepatitis B virus (HBV) infection is still a worldwide health problem. The precise mechanisms by which chronic Hepatitis B leads to hepatocellular carcinoma (HCC) are not clearly understood. Viral, host (sex, age and genetic susceptibility) and environmental factors may play interactive roles in

hepatocarcinogenesis. Recent studies have indicated that serum level of HBV DNA may be a risk factor for HCC. However, the data are largely lacking in mainland China, where chronic HBV infection is highly endemic and accounts for half of the chronic Hepatitis B in the world. It is important to study different endemic regions to verify the relationship between active HBV replication and development of HCC, because there is geographic distribution of HBV genotypes.

### Research frontiers

Study on the prognostic factors in patients with chronic Hepatitis B, the relationship between Hepatitis B virus genotype and HBV DNA level, and HCC and treatment of chronic Hepatitis B patients who are resistant to antiviral therapy.

### Innovations and breakthroughs

The township of Qidong, at the mouth of the Yangtze River, is one of the highest endemic regions for chronic HBV infection and HCC in China. However, this is believed to be the first study of the relationship between HBV replication and development of HCC in that region.

### Applications

Base on our current findings, it is conceivable that patients with a high viral load have a high potential for hepatocarcinogenesis, and should be subjected to closer clinical monitoring and even antiviral treatment. The results provide a data-supported approach to patients with Hepatitis B.

### Peer review

This case-control study examined the relationship of HBV DNA quantitative levels and the risk of HCC in Qidong, China. They confirm other studies from Taiwan and elsewhere that demonstrate the risk of HCC occurs across a gradient of HBV DNA levels. This study is important.

### Abstract

**AIM:** To investigate the predictive clinical value of *in vitro* 3-(4,5-dimethylthiazolyl-2)-2, 5-diphenyltetrazolium bromide (MTT) assay for directing chemosensitivity in patients with gastric cancer.

**METHODS:** Results of a total of 353 consecutive patients with gastric cancer treated with MTT-directed chemotherapy or physician's empirical chemotherapy from July 1997 to April 2003 were reviewed and analyzed retrospectively.

**RESULTS:** The overall 5-year survival rate of MTT-sensitive group (MSG) and control group (CG) was 47.5% and 45.1%, respectively. The results of subgroup analysis with Cox proportional-hazards model were favorable for the MSG-sensitive group. However, no statistically significant difference in survival rate was observed between the two groups.

**CONCLUSION:** Individualized chemotherapy based on *in vitro* MTT assay is beneficial, but needs to be confirmed by further randomized controlled trials.

Wu B, Zhu JS, Zhang Y, Shen WM, Zhang Q. Predictive value of MTT assay as an *in vitro* chemosensitivity testing for gastric cancer: One institution's experience. *World J Gastroenterol* 2008; 14(19): 3064-3068 Available from: URL: <http://www.wjgnet.com/1007-9327/14/3064.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.3064>

### INTRODUCTION

Gastric cancer ranks second of all cancers and is the leading cause of cancer-related deaths worldwide<sup>[1,2]</sup>. The incidence of gastric cancer worldwide is reported to be especially high in Asia, South America, and Eastern Europe<sup>[2-5]</sup>. Gastric cancer patients are treated in clinical practice with various therapies, such as chemotherapy and radiation, though further improvement and progress would be required. With the development of new anti-cancer drugs, such as taxanes, CPT-11, oxaliplatin, gefitinib and S-1, significant improvements in the efficacy of chemotherapies against gastric cancer have been achieved<sup>[4,6-8]</sup>. However, some patients still fail to respond to chemotherapy and finally die of the critical toxicity of intensive chemotherapy<sup>[9]</sup>. Thus, new therapies and technologies are desperately needed for the treatment of gastric cancer. Advances in this area would have a major impact on the outcome of a large number of patients with this disease. Hence, chemosensitivity assay has been developed to individualize chemotherapy for gastric cancer patients<sup>[10]</sup>. 3-(4,5-dimethylthiazolyl-2)-2, 5-diphenyltetrazolium bromide (MTT) assay is a rapid and quantitative colorimetric method for determination of cell viability by measuring the anticancer drug effectiveness on human tumor cells. Several studies on advanced gastric cancer using this approach revealed that *in vitro* sensitivities are associated with *in vivo* tumor responses<sup>[11-15]</sup>. However, most of these studies were small-scale trials (< 100 patients).

In this study, MTT assay was used to predict the efficacy of individualized assay-directed chemotherapy for Chinese gastric cancer patients, and to prove whether *in vitro* chemosensitivities are associated with *in vivo* tumor responses by survival analysis.

### MATERIALS AND METHODS

#### Patients

This was a retrospective study. The medical records of

patients registered for adjuvant chemotherapy from July 1997 to April 2003 were reviewed. The criteria for case inclusion were as follows: (1) a diagnosis of histologically or cytologically proven gastric cancer, (2) without prior chemotherapy or radiotherapy, (3) adequate blood counts (hemoglobin  $\geq 10$  g/L, WBC count of 3000/ $\mu$ L, and platelets of 100 000/ $\mu$ L), normal renal function (creatinine clearance  $\geq 60$  mL/min), and normal liver function (serum transaminase level less than double the normal upper limit). Patients with esophageal cancer, small cell carcinoma, lymphoma, and squamous cell carcinoma were excluded from the study. A total of 353 eligible records of patients were collected and analyzed. The patients were divided into MTT-sensitive group (MSG) and control group (CG). One hundred and fifty-seven patients in the MSG-sensitive group were treated by chemotherapy containing at least one sensitive drug based on the MTT assay results, and 196 patients received physician's empirical chemotherapy. The chemotherapeutic drugs used were cisplatin (CDDP), 5-fluorouracil (5-Fu), mitomycin (MMC), doxorubicin (DOX), paclitaxel (PAC) and docetaxel (DOC). The protocols of chemotherapy have been described elsewhere<sup>[6,16,17]</sup>.

### MTT assay

Fresh tumor tissue obtained from the surgically resected specimens was tested within 6 h. The tumor tissue was cut into pieces (smaller than 1 mm<sup>3</sup>) and passed through No. 100 and No. 200 stainless steel meshes respectively into a complete medium containing RPMI 1640 solution, 100  $\mu$ g/mL penicillin, and 100  $\mu$ g/mL streptomycin, and washed twice gently with the same solution. The viable cells were assessed using trypan blue exclusion method. Cell viability was measured by MTT assay to assess the chemosensitivity of tumor cells. Cell suspension was collected into sterile 96-well flat-bottomed microtiter plates ( $1 \times 10^5$  cells/per well) with or without chemotherapeutic agents. The drug and testing drug concentrations used were 25  $\mu$ g/mL cisplatin (CDDP), 100  $\mu$ g/mL 5-fluorouracil (5-Fu), 10  $\mu$ g/mL mitomycin (MMC), 4  $\mu$ g/mL doxorubicin (DOX), 100  $\mu$ g/mL paclitaxel (PAC) and 30  $\mu$ g/mL docetaxel (DOC). Each drug was tested in triplicate. The plates were then incubated at 37°C in a humidified atmosphere containing 50 mL/L CO<sub>2</sub> for 72 h. Microtiter wells containing tumor cells but no anticancer agents were used to control cell viability, in which the total number of tumor cells was equivalent to that in the test wells, and wells containing only a complete medium were used as blank controls for nonspecific dye reduction. After incubation, MTT solution was added to each well at a final concentration of 1 mg/mL per well and the plates were incubated at 37°C for another 4 h. Then the mixture containing the medium, the drug, and the unconverted MTT was removed. DMSO was added to each well to dissolve the formazan and absorbance was read at 550 nm using a spectrophotometric microplate reader (Labsystems, Finland). The inhibition rate of tumor cells for each drug with different concentrations was calculated following the formula: inhibition rate (%) =  $(1 - \text{OD}_{\text{drug exposure}} / \text{OD}_{\text{control}}) \times 100$ . The effective anticancer activity was regarded as

**Table 1** Baseline clinical and pathological characteristics of the patients *n* (%)

Characteristic	MSG ( <i>n</i> = 157)	CG ( <i>n</i> = 196)
Gender		
Male	104 (66.2)	137 (69.9)
Female	53 (33.8)	59 (30.1)

Undifferentiated	84 (53.5)	93 (47.4)

sensitive when the tumor inhibitory rate was greater than or equal to 70%.

### Toxicity

All patients who started treatment were considered assessable for toxicity. Toxicity was analyzed following the National Cancer Institute Common Toxicity Criteria (version 2.0).

### Statistical analysis

All statistical analyses were done using the SAS 6.12 statistical software (SAS Institute, Cary, NC). The clinical and pathological characteristics, including gender, age, cancer stage (TNM), and histological type (differentiated *versus* undifferentiated type), were evaluated by Mann-Whitney's *U*-test and the Kruskal-Wallis test. The overall probability was calculated using the Kaplan-Meier method for censored failure time data, and the statistical significance was analyzed by the log-rank test for comparison of survival rate between the two groups. The Cox proportional-hazards model was used to calculate the hazard ratios. *P* < 0.05 was considered statistically significant. All *P* values were two-tailed and unadjusted for potential multiple comparisons.

## RESULTS

### Patient characteristics

The clinical and pathological characteristics of the patients are outlined in Table 1. Between the MSG and CG arms, there was no significant difference in baseline clinical characteristics and pathological findings which were considered to be related to the prognosis of gastric cancer patients.

### Overall survival analysis

The overall 5-year survival rate of the patients was 47.5% and 45.1% in the MSG-sensitive group and CG group, respectively, with no statistical difference (Figure 1). The

hazard ratio for deaths in the MSG-sensitive group, as compared with the CG group, was 0.92 [95% confidence interval (CI) = 0.69 to 1.23,  $P = 0.57$ ].

### Subgroup analysis

The overall survival rate of the patients was analyzed according to sex, age, cancer stage (TNM classification), and histologic type. The hazard ratio of deaths was favorable for the MSG-sensitive group (Figure 2). There were no significant interactions between the two groups and any of the variables studied.

### Adverse events and treatment compliance

Data on the 157 patients in the MSG-sensitive group and 196 patients in the CG group were analyzed for adverse events. The main emergent adverse toxicities (grades 3 and 4) related to treatment are listed in Table 2. The severe adverse events (defined according to NCI-CTC version 2.0), including hematologic and nonhematologic toxic effects, did not occur more frequently in the MSG-sensitive group than in the CG group.

## DISCUSSION

Conventional chemo-/radio-therapy for gastric cancer is limited to improve the treatment outcomes and quality of survival/life of human patients<sup>[18,19]</sup>. Physicians' empirical choice of chemotherapeutic regimen for gastric cancer is based on the data obtained from clinical trials<sup>[20]</sup>. However, even the same gastric cancer behaves so differently that the response rate of cancers to the chemotherapeutic agents varies. These variations are partly contributed to the failure of treatment of gastric cancer patients. The effectiveness of current chemotherapies for cancer is limited mainly due to its heterogeneity<sup>[21]</sup>. To overcome this problem, selecting a sensitive chemotherapeutic regimen *in vitro* for individual gastric cancer patients appears to be an attractive way. Chemosensitivity testing is an *ex vivo* means of determining the cytotoxic and/or cytostatic, or apoptosis-inducing effect of anticancer drugs. The most common *in vitro* assays include MTT and ATP-TCA

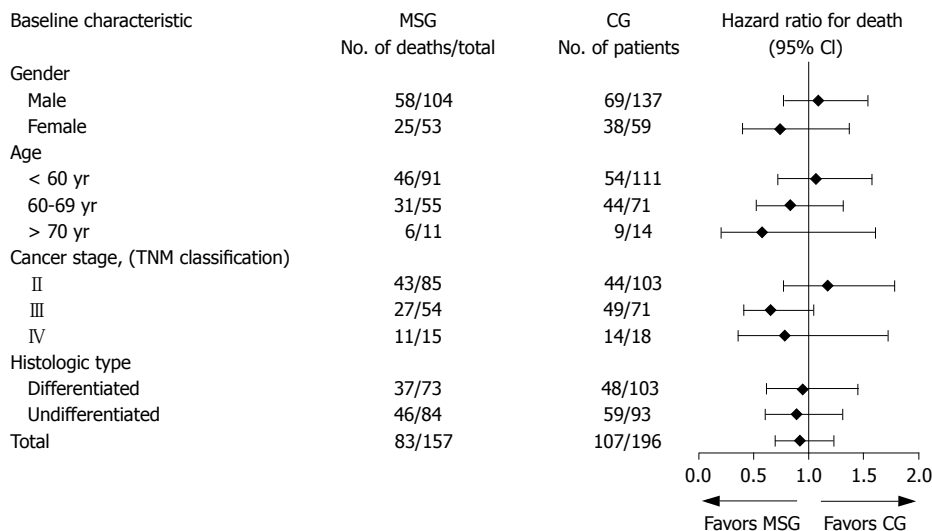

Figure 1 Kaplan-Meier curves of overall survival probabilities for gastric cancer patients, there was no significant difference between the two groups.

assays, *etc*<sup>[22]</sup>. These assays have been successfully used in the assay-guided chemotherapy for certain cancers, including breast, ovarian, melanoma and colorectal cancers<sup>[23-25]</sup>. MTT assay has been most widely used in different cancers, and is sensitive, accurate, and efficient in the *in vitro* evaluation of anticancer or immunological agents prior to preclinical and clinical testing. Some research groups have used MTT assay to guide individual adjuvant chemotherapy for gastric cancer<sup>[10]</sup>, showing that the therapy based on the chemosensitivity testing can improve the clinical outcomes of cancer patients. In the present study, based on the criteria for chemosensitivity *in vitro*, we predicted and evaluated the efficacy of chemotherapy for 353 gastric cancer patients according to the result of MTT assay. The overall survival rate of the patients, treated with chemotherapy regimen containing at least one sensitive agent, was higher in the MSG-sensitive group than in the CG group treated with the physicians' empirical therapy. The hazard ratio of most subgroups was favorable for the MSG-sensitive group as demonstrated in Cox proportional-hazards mode. However, no significant difference between the two groups was observed. These results indicate that MTT

**Figure 2** Hazard ratios of deaths for the baseline characteristics among gastric cancer patients. NS: No significant difference.

assay can lead to additional clinical outcomes as compared with physicians' empirical therapy. The real benefit of MTT assay for chemosensitivity testing is to predict which agent is useful or not useful. Although the results of this retrospective study are not all concordant with previous studies<sup>[11,12,22,26]</sup>, and do not definitively support the clinical values of MTT assay in detecting chemosensitivity to the adjuvant chemotherapy for patients with gastric cancer, they support chemosensitivity testing in patients with gastric cancer. Since the frequency of toxicity in patients is not reported in previous studies<sup>[11,12,26]</sup>, we compared the frequency of severe toxicity of grades 3 and 4 between the two groups, showing that chemotherapy regimen based on MTT assay could not reduce its the adverse effect and toxicity.

At present, although some studies have shown a potential clinical benefit of chemotherapy for patients with drug-sensitive cancer<sup>[22,27]</sup>, chemosensitivity testing has not been widely accepted by physicians. Meanwhile, prediction of chemosensitivity in clinical practice is a challenge because *in vitro* chemosensitivity testing systems have not considered the pharmacokinetic and pharmacodynamic variables affecting drug action *in vivo*. Because of varied pharmacogenetic make-ups of cancer patients, leading to interpatient variations in drug half-life, volume of distribution, types of metabolites formed, and route of elimination, dependence on *in vitro* and *in vivo* results is often not a straightforward process<sup>[28]</sup>. Ultimately, individualized chemotherapy based on cellular and genetic characteristics of cancer patients may be on the horizon<sup>[29-31]</sup>. The potential clinical benefits of individualized chemotherapy based on chemosensitivity testing need to be confirmed by further randomized controlled trials in comparison with standard chemotherapy.

information to help physicians choose sensitive chemotherapeutic agents for eliminating potentially ineffective agents used in chemotherapeutic regimens for each cancer patients.

### Research frontiers

At present, several new chemosensitivity assays, such as histoculture drug response assay (HDRA), collagen gel-droplet-embedded culture drug sensitivity test (CD-DST) and fluorometric microculture cytotoxicity assay (FMCA), are used in selection of an appropriate chemotherapeutic drug, showing the predictive value of chemotherapy for cancer patients.

### Innovations and breakthroughs

There is no evidence for the clinical benefits of MTT chemosensitivity assay. The present study evaluated the clinical usefulness of MTT chemosensitivity assay in gastric cancer patients, and showed no significant differences in clinical outcomes between the MTT-sensitive group (MSG) and the control group (CG), indicating that the potential value of MTT assay for patients with gastric cancer is limited.

### Applications

Although some studies have shown a potential clinical benefit for patients with drug-sensitive cancer, MTT assay of chemosensitivity is not widely accepted by physicians because there is no sufficient evidence obtained in the clinical setting. The potential clinical benefits of individualized chemotherapy based on chemosensitivity assay for gastric cancer patients need to be confirmed by further randomized controlled trials in comparison with standard chemotherapy.

### Terminology

MTT assay is a laboratory test and a standard colorimetric assay for measuring cellular proliferation. Yellow MTT is reduced to purple formazan in the mitochondria of living cells. A solution (usually dimethyl sulfoxide) is added to dissolve the insoluble purple formazan products into a colored solution. The absorbance of this colored solution can be quantified at a certain wavelength with a spectrophotometer.

### Peer review

This is an interesting report on the predictive value of MTT assay as an *in vitro* chemosensitivity testing for gastric cancer patients. Individualized chemotherapy based on *in vitro* MTT assay has clinical benefit, but needs to be confirmed by further randomized controlled trials.

## COMMENTS

### Background

Since cancer patients with histologically similar tumors respond differently to standard drug treatment, 3-(4,5-dimethylthiazolyl-2)-2,5-diphenyltetrazolium bromide (MTT) chemosensitivity assay is performed to provide predictive

### Abstract

**AIM:** To investigate the clinical significance of Bcl-xL gene in the pathogenesis of human colon carcinoma.

**METHODS:** Fifty-six pair tissue samples from patients with colon cancer were collected, and protein level of the Bcl-xL gene was measured by immunohistochemistry method. The correlation of Bcl-xL expression with clinical index was evaluated. After human colon cancer cell line HT29 was transfected with Bcl-xL small interfering RNA (siRNA), the anchorage-independent growth of cancer cells was detected by colony formation in soft agar and invasion ability of cancer cells was determined by a transwell model.

**RESULTS:** The Bcl-xL expression was higher in cancerous tissue samples than in normal tissue samples ( $38.78 \pm 11.36$  vs  $0.89 \pm 0.35$ ,  $P < 0.001$ ), and was associated with the pathological grade, lymphnode metastasis and Duke's stage of colorectal carcinoma. Transfection with Bcl-xL siRNA inhibited the colony formation and invasion ability of human colon cancer cell line HT29 *in vitro*.

**CONCLUSION:** Bcl-xL gene plays an important role in carcinogenesis of human colorectal carcinoma and is associated with malignant biological behaviors of human colorectal carcinoma.

### INTRODUCTION

Colorectal cancer is the third most common malignant neoplasm worldwide<sup>[1]</sup> and the second leading cause of cancer-related death<sup>[2]</sup>. Despite recent advances in diagnostic and therapeutic measures, the prognosis of colorectal cancer patients with distant metastasis still remains poor. Enhanced understanding of the signaling mechanisms that regulate metastasis of colon cancer may provide important insights into more effective therapeutic strategies.

Cells harboring multiple genetic alterations are normally eliminated by apoptosis. Diminished apoptosis plays a critical role in tumor initiation, invasion, metastasis, progression, and drug resistance. Results of numerous scientific and clinical studies link altered expression of apoptosis-regulatory proteins to the development of a lot of cancer cells. Among them, the Bcl-2 family of genes, which share sequence homology domains, plays a key role in the regulation of apoptotic cell death induced by a wide variety of therapeutic stimuli<sup>[3]</sup>. These genes can form homodimers and/or heterodimers that modulate one another's function, whereby their relative concentrations function as a rheostat for the apoptotic program<sup>[4]</sup>. Of them, Bcl-xL gene has been well characterized as a potential gene involved in the apoptotic signal pathway.

Bcl-xL, a mitochondrial membrane protein, promotes cell survival by regulating the electrical and osmotic homeostasis of mitochondria in response to a variety of stimuli<sup>[5,6]</sup>. Over-expression of Bcl-xL is reported to confer a multidrug resistance phenotype<sup>[7,8]</sup>. Moreover, inhibition of Bcl-xL expression by some ways results in an altered ratio of BAX to Bcl-xL and subsequent mitochondria-mediated cell death<sup>[9]</sup>. Thus, Bcl-xL might serve as an ideal molecular target of anticancer therapy

However, previous studies about Bcl-xL gene have mainly focused on the regulation of apoptosis and drug resistance. There is little information about the linkage of Bcl-xL with invasion in cancer cells. Increasing data show

that Bcl-xL over-expression might be related to invasion and metastasis of some solid tumors, such as breast cancer<sup>[10,11]</sup>, hepatocellular carcinoma<sup>[12]</sup>, ovarian cancer<sup>[13]</sup>, glioma<sup>[14]</sup>, and lung carcinoma<sup>[15]</sup>. We have found in previous works that human colon cancer cells transfected with signal transducer and activator of transcription 3 (STAT3) small interfering RNA (siRNA) can inhibit the invasion ability of cancer cells. Meanwhile, expression of Bcl-xL protein is also markedly down-regulated in transfected cancer cells<sup>[16]</sup>. However, the possible role of Bcl-xL in invasion of human colon cancer is not clear.

In the present study, we investigated the linkage of Bcl-xL with the invasion of human colon cancer *in vivo* and *in vitro*.

## MATERIALS AND METHODS

### Tissue samples

A total of 56 paired colon cancer tissue and distant normal colon tissue samples were obtained from 56 patients undergone surgical operation. Tumor histotype and grade of differentiation were defined according to the WHO criteria. The clinical and pathological stages were defined according to Duke's staging. These patients did not receive any chemotherapy or radiotherapy before operation. This study was approved by the Medical Ethical Committee of Affiliated Hospital of Jiangsu University, and all patients provided their written informed consent to participate in the study. All the specimens were fixed in 10% neutral-buffered formalin, dehydrated in ascending series of ethanol and routinely embedded in paraplast. Sections were cut at 4  $\mu$ m, stained with hematoxylin and eosin for histopathological and immunohistochemical evaluation. The clinicopathological parameters are summarized in Table 1.

### Immunohistochemical analysis and quantitative evaluation

All the tissue sections were deparaffinized, rehydrated and incubated in a citrate buffer (0.01 mol/L, pH 6.0) for 1 min at 121°C. The endogenous peroxidase activity was blocked by covering the sections with 3% H<sub>2</sub>O<sub>2</sub>/methanol for 15 min. The sections were then incubated in a 1:100 dilution of goat antihuman Bcl-xL IgG at 4°C overnight. After washed with PBS containing 0.05% Tween, the tissue sections were incubated in a 1:50 dilution of biotinylated donkey anti-goat IgG (Santa Cruz) for 30 min. The SABC reagents were used to amplify the immunoreactivity that was detected using 3'-diaminobenzidine according to the manufacturer's instructions. The sections were counterstained with hematoxylin. The positive unit (PU) represents the relative concentration of positive staining according to previous data<sup>[17]</sup>. Each section was observed randomly at five areas and the mean PU was assembled and calculated.

### Sequence of Bcl-xL siRNAs

The anti-sense sequence of siRNA (5'-CTCTGATATGCTGTCCCTG-3') corresponding to Bcl-xL mRNA with dTdT on 3'-overhangs was designed and chemically

Table 1 Relationship between Bcl-xL expression and clinical parameter in 56 cases of colorectal carcinoma (mean  $\pm$  SD)

Characteristic	n	Bcl-xL PU	P
Sex			> 0.05
Male	30	39.22 $\pm$ 11.35

synthesized according to the recommendation of the manufacturer (Dharmacon Research, USA). The scrambled siRNA served as a control, and its sequences are 5'-UUCUCCGAACGUGUCACGUTdTdT-3' and 5'-ACGUGACACGUUCGGAGAATdTdT-3'.

### Cell culture and Bcl-xL siRNA transfection

Human colon cancer cell line HT29 (Institute of Cell Biology, Shanghai, China) was cultured in RPMI 1640 (Invitrogen, Inc.) supplemented with 10% fetal bovine serum (FBS) in an atmosphere containing 50 mL/L CO<sub>2</sub> at 37°C. siRNA was transfected with a commercial reagent, oligofectamine (Invitrogen, USA) in 6-well plates following its manufacturer's instructions. Briefly, On the day before transfection, confluent layers of cells were trypsinized, counted and re-suspended. Cells ( $1 \times 10^5$ ) were plated into each well of the 6-well plates, so that they could become about 70% confluence next day at the time of transfection. Oligofectamine was diluted in serum-free RPMI 1640 and mixed with siRNA at a 1:2 ratio (4  $\mu$ L of 20  $\mu$ mol/L of siRNA formulated with 8  $\mu$ L of oligofectamine). The cells were then incubated for other 48 h. The number of cells was determined using a hemocytometer before subsequent assays.

### RNA isolation and complementary DNA synthesis

Total cellular RNA was isolated from cancer cell lines using Trizol. Final RNA pellets were dissolved in 20  $\mu$ L of diethyl pyrocarbonate-treated water. RNA yield was determined by spectroscopy. For complementary DNA (cDNA) synthesis, 2  $\mu$ g of total RNA was transcribed with cDNA transcription reagents using 0.2  $\mu$ g of the oligo(dT)18 primer for subsequent quantitative, real-time polymerase chain reaction (RT-PCR).

### Real time transcription polymerase chain reaction (RT-PCR)

Real-time RT-PCR analyses were performed on an ABI Prism 7700 sequence detection system (Perkin-Elmer Applied Biosystems, Foster City, CA). For Bcl-xL amplification, primers with the sequences 5'-TCCTTGTCTACGCTTTCCACG-3' and 5'-GGTCGCATTTGTGGCCTTT-3' were

used in combination with a sequence 5'-ACAGTGCCC CGCCGAAGGAGA-3'. Primers, Taqman and TaqMan probes were designed by the Primer Express™ 1.0 (Applied Biosystems) software and the probes were labeled at 5' end with the reporter dye molecule FAM (6-carboxy-fluorescein) and at 3' end with the quencher dye molecule TAMARA (6-carboxytetramethyl-rhodamine). Real-time PCR was conducted in a total volume of 50 µL with 1 × TaqMan Master Mix (Applied Biosystems) and primers. Thermal cycle parameters included one cycle at 95°C for 3 min, and 45 cycles involving denaturation at 95°C for 30 s, annealing at 52°C for 45 s, extension at 72°C for 45 s, followed by a final extension at 72°C for 10 min. The relative amount of each cDNA in each sample was calculated by dividing the CT value with the corresponding value of the housekeeping gene glyceraldehyde-3-phosphate dehydrogenase (GAPDH). All reactions were performed in triplicate.

#### **Western blotting analysis for Bcl-xL protein**

HT29 cells were harvested and lysed in a buffer containing 10 mmol/L Tris-HCl (pH 8.0), 150 mmol/L NaCl, 1% NP40, 0.5% sodium deoxycholate, 0.1% SDS, 1 mmol/L EDTA (pH 8.0), 2 mmol/L phenylmethylsulfonyl fluoride, 2 mg/L aprotinin, 2 mg/L leupeptin, and 1 mmol/L Na<sub>3</sub>VO<sub>4</sub>. For Western blotting analysis, 30 µg of total extracted proteins was applied per lane before SDS-PAGE. Following transfer to nitrocellulose membranes, protein expression levels were detected using anti-Bcl-xL (Alpha Diagnostics International, TX). The expression of β-actin (Sigma-Aldrich, MO) was used as a normalization control for protein loading.

#### **Anchorage-independent growth assay**

For the anchorage-independent growth experiments, HT29 cells ( $8 \times 10^3$  cells/well) were seeded in 0.3% Difco Bactoagar (Difco, MI) supplemented with a complete culture medium. This suspension was layered over 0.5 mL of 0.8% agar-medium base layer in 24 multiwell cluster dishes (Becton Dickinson, Italy). After 15 d, the colonies were stained with nitroblue tetrazolium, and colonies larger than 50 µm were acquired with a micro-Scopeman camera system (Moritex Europe Ltd, Italy) and analyzed with Image-Pro Plus (Media Cybernetics, MD) computer program.

#### **Cell invasion assay**

Transwell invasion assays were performed using HT29 cells cultured in 12-well plates containing either 8 µm pore matrigel-coated inserts according to the manufacturer's instructions (Becton Dickinson, Bedford, MA). The membranes were rehydrated with warm serum-free (SF) Dulbecco's modified Eagle's medium (DMEM) (1.0 mL/chamber) for 2 h. The upper chamber was filled with  $1 \times 10^5$  cells in L-15 medium containing 5% FBS. The lower chamber was filled with L-15 medium containing 25% FBS as a chemo-attractant. After the chambers were incubated for 24 h at 37°C in an atmosphere containing 50 mL/L CO<sub>2</sub>, non-invading cells were removed from the upper surface of the membrane by scrubbing, and

invading cells on the lower surface of the membrane were fixed and stained with HE. The number of cells penetrating the filter was counted by a technician blinded to the experimental settings in four microscopic fields of each filter, under  $\times 20$  magnification. The percentage of invasion was expressed as the ratio of the mean cell number from the invasion chamber to the mean cell number from the control chamber according to the manufacturer's recommendation.

#### **Statistical analysis**

All analyses were performed with *t* test and ANOVA using SPSS 11.5 software (Statistical Package for Social Science). *P* < 0.05 was considered statistically significant.

## **RESULTS**

#### **Expression of Bcl-xL PU in human colon cancerous and normal tissue samples**

Bcl-xL expression was rarely expressed in normal large intestinal mucosa. However, Bcl-xL was mainly expressed in cytoplasm of the para-cancerous or cancer cells. The nuclei were stained brownish yellow, located sporadically or in the form of sheets. Quantitative immunohistochemistry analysis is summarized in Table 1. Bcl-xL PU was significantly higher in cancerous tissue samples than in normal tissue samples ( $38.78 \pm 11.36$  vs  $0.89 \pm 0.35$ , *P* < 0.001).

#### **Relationship between Bcl-xL PU and clinicopathological parameters**

Correlation of Bcl-xL expression with clinicopathological parameters was evaluated. Bcl-xL PU, positive lymph nodes and Duke's C/D stage were higher in cancerous tissue samples with low differentiation than in cancerous tissue samples with high differentiation (*P* < 0.05, Table 1). However, Bcl-xL expression was not correlated with sex, age of the patients.

#### **Suppression of Bcl-xL by siRNA**

To further clarify the role of Bcl-xL gene, siRNA was used to knockdown the Bcl-xL expression in human colon cancer cells. Bcl-xL siRNA was transfected into the colon cancer cell line HT29. The ability of siRNA to down-regulate Bcl-xL expression was quantified by real time RT-PCR analysis and Western blot assay, respectively. siRNA significantly reduced the Bcl-xL mRNA and protein level in a dose- and time- dependent manner (Figure 1). However, the control scrambled siRNA treatment had no effect on Bcl-xL expression, thus supporting the specificity of Bcl-xL siRNA.

#### **Bcl-xL siRNA inhibited anchorage-independent growth of human colon cancer cells**

Next we evaluated the biological effects of Bcl-xL suppression on human colon cancer HT29 cells using several different types of assays. Colony formation in soft agar is a property closely associated with malignancy. Treatment with Bcl-xL siRNA significantly inhibited the anchorage-independent growth of human colon cancer cells in a dose-dependent manner (Figure 2A).

**Figure 1** Effects of siRNA on Bcl-xL expression in human colon cancer HT29 cells. **A:** Bcl-xL mRNA level; **B:** Bcl-xL protein level.

### Down-regulation of Bcl-xL decreased the ability of human colon cancer cells to grow in vitro

Given the known role of Bcl-xL siRNA in down-regulation of anchorage-independent HT29 cell growth, we attempted further to evaluate whether the Bcl-xL gene contributes to cell invasion of colon cancer cells. Cell invasion studies were performed using the matrigel matrix assays. The results showed that Bcl-xL siRNA treatment resulted in a dramatic low level of invasion potential of HT29 cells (Figure 2B), but not scrambled siRNA treatment.

## DISCUSSION

The Bcl-2 family is characterized by the presence of Bcl-2 homology domains and falls into two main groups: anti-apoptotic proteins, such as Bcl-2, Bcl-xL, Bcl-w, Mcl-1, A1, and proapoptotic proteins, such as Bax, Bak, Bad, Bid, and Bcl-xS<sup>[6]</sup>. The Bcl-x gene encodes two proteins, a long form (Bcl-xL) and a short form (Bcl-xS), through an alternative splicing mechanism. Bcl-xL, displaying remarkable amino acids and an overall structural homology to Bcl-2, can effectively block apoptosis, whereas Bcl-xS, lacking 63 amino acids in Bcl-xL, is a dominant inhibitor of Bcl-2 activity and thereby acts as a proapoptotic factor<sup>[9]</sup>.

Although there is evidence of cell apoptosis and Bcl-xL gene, the relationship between Bcl-xL and invasion of malignant tumors remains unclear. It was reported that Bcl-xL is related to the invasion and metastasis of some solid tumors. Zhang *et al.*<sup>[18]</sup> and Takada *et al.*<sup>[19]</sup> have reported the inhibition of invasion of cancer cells after treated with the Bcl-xL gene. Our previous study showed that STAT3 siRNA transfection inhibits the invasion ability of human colon cancer cell line HT29 and that the Bcl-xL protein is significantly inhibited in transfected cancer

**Figure 2** Effects of Bcl-xL siRNA on anchorage-independent growth (**A**) and invasion ability (**B**) of human colon cancer HT29 cell.

cells<sup>[16]</sup>, suggesting that Bcl-xL contributes to the invasion of human colon cancer cells. To verify it, we studied the relationship between Bcl-xL and invasion of human colon cancer *in vivo* and *in vitro*.

The expression of Bcl-xL protein in human colon cancer was determined by immunohistochemistry assay, showing that Bcl-xL protein was over-expressed in colon cancer tissue samples compared to normal tissue samples ( $P < 0.001$ ). Meanwhile, Bcl-xL expression had no significant correlation with sex and age of the patients, but was greatly correlated with differentiation stage, lymph node metastasis, and Duke's stage of colorectal carcinoma ( $P < 0.05$ ), indicating that Bcl-xL over-expression is related to the development and invasion of human colon cancer.

In order to further investigate the relationship between Bcl-xL and invasion of human colon cancer cells, we studied the effects of Bcl-xL down-regulated by siRNA on the invasion ability of human colon cancer cells. siRNA is a short oligonucleotide consisting of 21-23 nucleotides that can be used *in vitro* to induce sequence specific gene silencing of mammalian cells<sup>[20]</sup>. To elucidate the role of Bcl-xL gene in human colon cancer, siRNA was used to knockdown the Bcl-xL expression in human colon cancer cell line HT29. Real time RT-PCR and Western blot analysis showed that the expression of Bcl-xL in HT29 cancer cells transfected with siRNA was significantly reduced in a dose- and time-dependent manner. In addition, transfection of human colon cancer HT29 cells with Bcl-xL siRNA decreased the invasion ability and anchorage-independent growth of human colon cancer cells. The data *in vitro* suggest that the Bcl-xL gene plays an important role in regulating the invasion of human colon cancer cell.

In conclusion, the Bcl-xL gene is relevant to the invasion and progression of human colon cancer, and can be used in evaluating the carcinogenesis of human colon cancer. However, the precise mechanism of Bcl-xL underlying the

carcinogenesis of human colon cancer is still unclear, and further study is needed.

## COMMENTS

### Background

Despite recent advances in diagnostic and therapeutic measures, the prognosis of colorectal cancer patients with distant metastasis still remains poor. Enhanced understanding of the signaling mechanism underlying metastasis of colon cancer may provide important insights into more effective therapeutic strategies.

### Research frontiers

The results of this study indicate that the Bcl-xL gene plays an important role in the carcinogenesis of human colorectal carcinoma and is associated with the malignant biological behaviors of colorectal carcinoma.

### Innovations and breakthroughs

The results of the present study suggest that the Bcl-xL gene is relevant to the invasion and progression of human colon cancer and can be used in evaluating the carcinogenesis of human colon cancer.

### Applications

The paper helps to clarify the mechanism underlying the invasion and metastasis of colon cancer and contributes to the choice of therapeutic strategies.

### Peer review

This interesting article indicates that the Bcl-xL gene is relevant to the invasion and progression of human colon cancer, and might be used in evaluating the carcinogenesis of human colon cancer.

### Abstract

**AIM:** To evaluate the diagnostic role of serum *RASSF1A* promoter hypermethylation in gastric and colorectal adenocarcinoma.

**METHODS:** Methylation-specific polymerase chain reaction (MSPCR) was used to examine the promoter methylation status of the serum *RASSF1A* gene in 47 gastric adenocarcinoma patients, 45 colorectal adenocarcinoma patients, 60 patients with benign gastrointestinal disease (30 with benign gastric disease and 30 with benign colorectal disease), and 30 healthy donor controls. A

paired study of *RASSF1A* promoter methylation status in primary tumor, adjacent normal tissue, and postoperative serum were conducted in 25 gastric and colorectal adenocarcinoma patients who later were underwent surgical therapy.

**RESULTS:** The frequencies of detection of serum *RASSF1A* promoter hypermethylation in gastric (34.0%) and colorectal (28.9%) adenocarcinoma patients were significantly higher than those in patients with benign gastric (3.3%) or colorectal (6.7%) disease or in healthy donors (0%) ( $P < 0.01$ ). The methylation status of *RASSF1A* promoter in serum samples was consistent with that in paired primary tumors, and the MSPCR results for *RASSF1A* promoter methylation status in paired preoperative samples were consistent with those in postoperative serum samples. The serum *RASSF1A* promoter hypermethylation did not correlate with patient sex, age, tumor differentiation grade, surgical therapy, or serum carcinoembryonic antigen level. Although the serum *RASSF1A* promoter hypermethylation frequency tended to be higher in patients with distant metastases, there was no correlation between methylation status and metastasis.

**CONCLUSION:** Aberrant CpG island methylation within the promoter region of *RASSF1A* is a promising biomarker for gastric and colorectal cancer.

## INTRODUCTION

Gastric and colorectal cancers are two of the most common causes of cancer-related death worldwide. Development of efficient diagnostic methods to enable their early detection plays an essential role in increasing the survival rate of patients with these diseases. Although endoscopy is considered the most sensitive screening tool for gastric and colorectal cancers, its use is limited due to its considerable cost and risk, and patients' lack of acceptance of the invasive procedure. Therefore, reliable noninvasive test, preferably blood test, for screening and diagnostic purposes are obviously needed.

Conventional tumor markers in serum, such as carcinoembryonic antigen (CEA), are generally insensitive for screening purposes<sup>[1]</sup>. Consequently, novel serum biomarkers are clearly needed for the early detection of gastric and colorectal cancers.

Aberrant DNA methylation, a feature of many human cancers, frequently occurs as an early event in tumorigenesis and is characterized by general hypomethylation and regional hypermethylation<sup>[2]</sup>. The hypermethylation of CpG islands within the promoter and/or upstream exon regions is an important epigenetic mechanism underlying the inactivation of tumor-suppressor genes (TSGs)<sup>[3]</sup>. It was reported that quite a few TSGs, including the *Ras association domain family 1A* (*RASSF1A*) gene, are epigenetically silenced by aberrant promoter hypermethylation in gastric and colorectal cancer<sup>[4-10]</sup>. *RASSF1A* is a newly identified candidate TSG located in the 3p21.3 region<sup>[11]</sup>, and promoter hypermethylation of *RASSF1A*, which is its most common inactivation mechanism, has been observed in many human solid tumors, including gastric and colorectal cancers<sup>[11-17]</sup>.

It has been long known that the serum level of free DNA is increased in cancer patients, which is believed to be released from cancer cells<sup>[18,19]</sup>. It was reported that genetic and epigenetic alterations in serum DNA (such as point mutation, gene amplification, loss of heterozygosity, microsatellite instability, and aberrant methylation) are identical to those found in primary human cancers<sup>[20-24]</sup>. Because the promoter methylation status of TSGs in primary tumors and matched serum samples was consistent with each other<sup>[4,25,26]</sup>, promoter hypermethylation of TSGs in serum DNA may become a promising biomarker for gastric and colorectal cancers.

In the present study, we attempted to identify the *RASSF1A* promoter methylation status both in serum DNA and in available paired tumor genomic DNA from patients with gastric and colorectal adenocarcinomas by using methylation-specific polymerase chain reaction (MSPCR). We also analyzed the correlation between serum *RASSF1A* gene promoter hypermethylation and patients' clinicopathologic parameters to further evaluate the clinical significance of this molecular change.

## MATERIALS AND METHODS

### Study population

This study included 47 gastric adenocarcinoma patients and 45 colorectal adenocarcinoma patients diagnosed at

Table 1 Clinicopathologic characteristics of patients with gastric and colorectal adenocarcinoma

Characteristics		Patients (n)	
		Gastric cancer	Colorectal cancer
Sex	Male	29	24
	Female	18	21
Age (yr)	≤ 60	21	31
	> 60	26	14
Differentiation grade	G1/Broders' I	2	4
	G2/Broders' II	23	34
	G3/Broders' III & IV	22	7
Stage	TNM I /Duke's A	4	5
	TNM II /Duke's B	15	16
	TNM III /Duke's C	16	14
	TNM IV /Duke's D	12	10

Departments of General Surgery, Gastroenterology, and Medical Oncology of Jinling Hospital (Nanjing, China) between August 1, 2006 and November 30, 2007. All diagnoses were based on pathologic evidence, and only patients with adenocarcinoma, the most common histologic type of gastric and colorectal cancer, were included. The clinicopathologic characteristics of these patients are summarized in Table 1.

The control population consisted of 60 patients with benign gastrointestinal diseases (30 with benign gastric disease and 30 with benign colorectal disease, such as chronic gastritis, gastric ulcer, benign polyp, nonmalignant adenoma, and ulcerative colitis; data not shown) and 30 healthy donors.

Gastric adenocarcinoma was staged according to the sixth edition of the TNM staging system<sup>[27]</sup>, and colorectal adenocarcinoma was staged according to the Duke's staging system. Gastric and colorectal adenocarcinoma differentiation was graded according to the World Health Organization grading system and the Broders' grading system, respectively.

Our study was approved by the ethical committee of the hospital and informed consent was obtained from all patients.

### Sample collection

Five mL of peripheral venous blood was collected from each patient 1 day after the patients were admitted to our hospital. At this time, the patients did not start their treatment. Any previous treatment (surgery and/or chemotherapy), if given, was discontinued at least 4 wk earlier. Fresh tumor tissue and paired adjacent normal tissue were obtained from 16 gastric and 9 colorectal adenocarcinoma patients who later were underwent to surgical therapy in Jinling Hospital. An additional 5 mL peripheral venous blood was collected from these 25 patients 4 wk after surgery for a comparative study. All blood samples were kept in tubes containing clot activator at 4°C for 2 h, and samples were centrifuged at 3000 r/min for 10 min to isolate sera. Thirty serum samples from healthy donors were obtained from the Blood Center of Jinling Hospital as normal controls. All serum and tissue samples were stored at -80°C until use.

**Figure 1** Representative results showing *RASSF1A* promoter methylation status identified by MSPCR in gastric and adenocarcinoma patients. Identification of *RASSF1A* promoter methylation status in serum samples from gastric and colorectal adenocarcinoma patients (A) and in paired tumor and adjacent normal tissue from gastric and colorectal adenocarcinoma patients (B). A 100-bp DNA ladder marker (TaKaRa, Shiga, Japan) was used. Lanes M and U indicate the amplified products with primers recognizing specific methylated and unmethylated sequences, respectively. GC: Gastric adenocarcinoma; CC: Colorectal adenocarcinoma; T: Tumor tissue; N: Paired adjacent normal tissue.

### DNA extraction and bisulfite treatment

Serum DNA, extracted with the QIAamp blood mini kit (Qiagen, Hilden, Germany) according to the manufacturer's instructions, was stored at -80°C until use. Genomic DNA isolated from tissue samples was prepared using standard phenol/chloroform extraction protocols.

The extracted DNA was modified according to Herman *et al*<sup>[28]</sup> with minor modifications, to convert all unmethylated cytosines to uracils. Briefly, 1 µg of genomic DNA, or serum DNA extracted from 5 mL blood plus 1 µg of salmon sperm carrier DNA (Sigma, St. Louis, MO, USA), in a total volume of 50 µL, were denatured by NaOH (0.3 mol/L final concentration) at 40°C for 15 min. After 30 µL of freshly prepared 10 mmol/L hydroquinone (Sigma) and 520 µL of freshly prepared 3 mol/L sodium bisulfite (Sigma) at pH 5.0 were added, the samples were incubated under mineral oil at 55°C in darkness for 14 h. The modified DNA was purified using the Wizard DNA clean-up system (Promega, Madison, WI, USA), following its manufacturer's protocol. Modification was completed

by NaOH (0.3 mol/L final concentration) treatment for 10 min at room temperature, followed by ethanol precipitation. The modified DNA was resuspended in sterile deionized water (100 µL for genomic DNA and 25 µL for serum DNA) and used immediately or stored at -80°C.

### MSPCR

Two sets of primers, described elsewhere<sup>[29]</sup>, were used to discriminate between methylated and unmethylated alleles (Table 2). The PCR system has been described previously<sup>[30]</sup>. Briefly, the PCR mixture containing 2.5 µL of 10 × reaction buffer (100 mmol/L Tris-HCl (pH 8.3), 500 mmol/L KCl, 15 mmol/L MgCl<sub>2</sub>), 10 µL of modified DNA, 15 pmol of each primer (Shenry Biocolor, Shanghai, China), 2 µL of deoxynucleotide triphosphates (200 µmol/L each, final concentration), and 1 U TaKaRa Taq™ polymerase (Hot Start Version, TaKaRa, Shiga, Japan) was adjusted by H<sub>2</sub>O to a final volume of 25 µL. The cycling conditions consisted of an incubation period at 95°C for 15 min, 40 cycles of denaturation at 94°C for 30 s, annealing at 64°C or at 59°C for 50 s (Table 2), extension at 72°C for 30 s, and a final extension at 72°C for 10 min. PCR products were separated in 2% agarose gel and visualized under UV illumination.

Lymphocyte DNA, original or methylated *in vitro* by excessive CpG (Sss I) methylase (New England Biolabs, Beverly, MA, USA), was used as an unmethylated and methylated DNA positive control, respectively (Figure 1A). Water blank was used as a negative control.

### Statistical analysis

We analyzed the correlation between methylation status of serum *RASSF1A* promoter and clinicopathologic parameters. Chi-square test or Fisher's exact test was conducted to examine the association of two categorical variables using SAS software (SAS Institute, Cary, NC, USA). All statistical tests were two-sided, and *P* < 0.05 was considered statistically significant.

## RESULTS

### Serum *RASSF1A* promoter hypermethylation profile in gastric and colorectal adenocarcinoma patients

First we analyzed the methylation status of CpG islands within the *RASSF1A* promoter in serum DNA from 47 gastric adenocarcinoma patients, 45 colorectal adenocarcinoma patients, 60 benign gastrointestinal disease patients (30 with benign gastric disease and 30 with benign colorectal disease), and 30 healthy donors. Hypermethylation of the *RASSF1A* promoter was detected in 16 gastric adeno-

**Figure 2** Comparison of *RASSF1A* promoter methylation status in tissue and serum samples. For each patient, the *RASSF1A* promoter methylation status was analyzed in tumor tissue (T), adjacent normal tissue (N), preoperative serum (S-1), and postoperative serum collected 4 wk after surgery (S-2). Solid boxes indicate methylation, blank ones indicate unmethylation of *RASSF1A* promoter. GC: Gastric adenocarcinoma; CC: Colorectal adenocarcinoma.

carcinoma patients, 13 colorectal adenocarcinoma patients, 1 benign gastric disease patient (chronic fundal gastritis), and 2 benign colorectal disease patients (both colon adenomas). The representative agarose gel electrophoresis results are shown in Figure 1A. The frequencies of detection of serum *RASSF1A* promoter hypermethylation in gastric (34.0%) and colorectal (28.9%) adenocarcinoma patients were significantly higher than those in benign gastric disease patients (3.3%), benign colorectal disease patients (6.7%) and healthy donors (0%), respectively ( $P < 0.01$ ).

#### ***RASSF1A* promoter hypermethylation profile in paired tissue and serum samples from gastric and colorectal adenocarcinoma patients**

Next we compared the *RASSF1A* promoter methylation status in paired tissue and serum samples from 16 gastric and 9 colorectal adenocarcinoma patients who later were underwent to surgical resection in Jinling Hospital. For each patient, the *RASSF1A* promoter methylation status

was analyzed in tumor tissue, adjacent normal tissue, preoperative serum, and postoperative serum collected 4 wk after surgery. The representative agarose gel electrophoresis results and the paired MSPCR results are shown in Figure 1B and Figure 2, respectively. In seven patients, the *RASSF1A* promoter hypermethylation was detected both in cancer tissue samples and in serum samples. In two patients, the hypermethylated *RASSF1A* promoter was present in tumor tissue samples but not in paired serum samples. The *RASSF1A* promoter hypermethylation was never detected in serum samples if it was not present in tumor tissue. In addition, the preoperative and postoperative serum *RASSF1A* promoter methylation status remained unchanged in all patients.

#### ***Correlation between serum RASSF1A promoter hypermethylation and clinicopathologic parameters in patients with gastric and colorectal adenocarcinoma***

We further analyzed the relationship between serum *RASSF1A* promoter methylation status and clinicopathologic features in gastric and colorectal adenocarcinoma patients. The results are listed in Table 3. As indicated in the table, there was no correlation between *RASSF1A* promoter methylation status and patients' sex, age, tumor differentiation grade, or serum CEA levels. No difference in serum *RASSF1A* promoter hypermethylation frequencies was detected between postoperative patients and those whose tumor was not resected. Although the serum *RASSF1A* promoter hypermethylation frequency tended to be higher in patients with distant metastases, no correlation between methylation status and metastasis was found.

## **DISCUSSION**

*RASSF1A* protein is actively involved in microtubule regulation, genomic stability maintenance, cell-cycle regulation, apoptosis modulation, cell motility and invasion control<sup>[31-39]</sup>. The frequent inactivation of TSG *RASSF1A* due to aberrant promoter methylation has been reported in various tumor types<sup>[13]</sup>, suggesting that it plays a pivotal

role in human cancer development. It was reported that *RASSF1A* is inactivated by promoter hypermethylation in gastric and colorectal cancer, but the frequencies of aberrant *RASSF1A* methylation vary widely<sup>[8,9,14-16,40,41]</sup>. In addition, serum promoter methylation of *RASSF1A* in gastric and colorectal cancer has not been extensively studied, and few comparative studies using both primary tumor and serum samples are available. To our knowledge, there is only one related study with a limited sample size<sup>[10]</sup>. In the present study, we identified the *RASSF1A* promoter methylation status both in serum DNA and in available paired tumor genomic DNA from patients with gastric and colorectal adenocarcinoma, showing that serum *RASSF1A* promoter hypermethylation is a potential biomarker for gastric and colorectal cancer diagnosis.

In the present study, serum *RASSF1A* promoter hypermethylation was detected in 34.0% of patients with gastric adenocarcinoma and in 28.9% of those with colorectal adenocarcinoma. The frequencies were slightly higher than those reported by Tan *et al*<sup>[10]</sup> (25% in gastric cancer and 24% in colorectal cancer, respectively). The serum *RASSF1A* promoter hypermethylation frequencies in gastric and colorectal adenocarcinoma patients were significantly higher than those in patients with benign gastric or colorectal disease or in healthy donors ( $P < 0.01$ ). The sensitivity of serum *RASSF1A* promoter hypermethylation in detecting gastric and colorectal cancer is relatively low. Perhaps a simultaneous analysis of the methylation status of a panel of TSGs would be more sensitive in detecting gastric and colorectal cancer. On the other hand, the specificity of serum *RASSF1A* promoter hypermethylation was very high (approximate 98.3%). Since clinical tests with a high specificity are usually useful in confirming the diagnosis, serum *RASSF1A* promoter methylation status is a potential marker for the diagnosis of gastric and colorectal cancer.

We also compared the *RASSF1A* promoter methylation status in paired tissue and serum samples from 25 gastric and colorectal adenocarcinoma patients. For the seven patients with hypermethylated *RASSF1A* promoter detected in their serum samples, *RASSF1A* promoter hypermethylation was also present in the primary tumor, which supports the presumption that circulating DNA in peripheral blood of cancer patients reflects the epigenetic change in the primary tumor. In two patients, however, hypermethylated *RASSF1A* promoter could be detected in the primary tumor samples but not in the paired serum samples, suggesting that not all cancer patients have detectable tumor-originating DNA in their peripheral blood.

*RASSF1A* promoter hypermethylation was detected in adjacent normal tissue from 2 patients, which can be explained by the invisible invasion of the primary tumor to the adjacent tissue. Another possible reason is the presence of aberrant promoter methylation of TSGs in precancerous lesions adjacent to the primary tumor. Lee *et al*<sup>[9]</sup> reported that *RASSF1A* promoter hypermethylation occurs in 2.1% of colorectal adenomas, and Derks *et al*<sup>[42]</sup> found that aberrant *RASSF1A* promoter methylation is present in 19.1% of non-progressed adenomas and in 24.4% of progressive adenomas. In our study, we also detected methylated *RASSF1A* promoter in the serum from one patient with chronic fundal gastritis and two patients with colon adenoma, believed to be precancerous lesions in gastric and colon cancer, respectively.

These findings suggest that aberrant promoter hypermethylation of *RASSF1A* might be an early event in the development of gastric and colorectal cancer. Therefore, identification of serum *RASSF1A* promoter methylation status may contribute to the early diagnosis of gastric and colorectal cancer.

In the present study, no association was observed between *RASSF1A* promoter methylation status and patients' sex, age, tumor differentiation grade, distal metastasis, or surgical therapy. We also compared the methylation status of *RASSF1A* promoter in preoperative and postoperative serum samples from patients who were underwent to surgical therapy in our hospital, and the status remained unchanged in all patients. Theoretically, when the primary tumor is resected, tumor-specific methylated DNA would decrease considerably in peripheral blood. However, this does not seem to be the case. Fiegl *et al*<sup>[43]</sup> monitored the serum *RASSF1A* promoter methylation status in 148 breast cancer patients for up to 1 year after surgery, and only 21 patients showed positive to negative transition in MSPCR analysis of serum *RASSF1A* promoter. A possible source of persistently present methylated copy after surgery is the micrometastases that may present before surgery.

We investigated whether serum *RASSF1A* promoter hypermethylation is correlated with elevated serum CEA levels and found that there is no correlation between them. Koike *et al*<sup>[44]</sup> reported that the detection rate of TSG (*p16*, *E-cadherin*, and *RARβ*) hypermethylation is higher than that of conventional tumor marker (CEA and CA19-9) abnormalities in the serum from gastric cancer patients, and that there is no correlation between them. Since serum CEA and TSG hypermethylation are not correlated, a combinational analysis of serum *RASSF1A* promoter methylation status and serum CEA level may be useful in the diagnosis of gastric and colorectal cancer.

In conclusion, serum *RASSF1A* promoter hypermethylation is common in gastric and colorectal adenocarcinoma and aberrant CpG island methylation within the promoter region of *RASSF1A* is a promising biomarker for such cancers.

## COMMENTS

### Background

*RASSF1A* inactivation by promoter hypermethylation in gastric and colorectal cancer has been reported. However, serum promoter methylation of *RASSF1A* in gastric and colorectal cancer has not been extensively studied. Particularly, comparative studies using both primary tumor and serum samples are indicated can evaluate the diagnostic role of serum *RASSF1A* promoter hypermethylation in gastric and colorectal cancer.

### Research frontiers

Circulating nucleotide acid is a hotspot in the early diagnosis of cancer. Characterization of molecular changes in serum DNA reflecting the genetic and

epigenetic alterations in primary tumor would provide an alternative approach to the early detection of cancer.

### Innovations and breakthroughs

This is the first comprehensive study on *RASSF1A* promoter hypermethylation status both in tumor and normal tissue samples and in pre- and post serum samples from gastric and colorectal cancer patients. Our results indicate that aberrant hypermethylation of *RASSF1A* promoter is a promising serum biomarker for gastric and colorectal cancer diagnosis.

### Applications

A combined study on promoter hypermethylation of a panel of relevant tumor suppressor genes in serum samples may have a bright future in the early diagnosis of gastric and colorectal cancer.

### Terminology

In DNA, methylation is the addition of a methyl group to a cytosine residue to convert it to 5-methylcytosine. DNA methylation is the main epigenetic modification in humans, and changes in methylation patterns play an important role in tumorigenesis. In particular, hypermethylation of normally unmethylated CpG islands in the promoter region of tumor suppressor genes correlates with their loss of expression and may confer growth advantages to those cells that favor cancer development.

### Peer review

This paper is very interesting. The study is well designed. The authors evaluated the role of serum *RASSF1A* promoter hypermethylation in diagnosing gastric and colorectal adenocarcinoma, showing that aberrant CpG island methylation within the promoter region of *RASSF1A* is a promising biomarker for gastric and colorectal cancer.

### Abstract

**AIM:** To evaluate the safety and feasibility of biliary tract reoperation by laparoscopy for the patients with retained or recurrent stones who failed in endoscopic sphincterotomy.

**METHODS:** A retrospective analysis of data obtained from attempted laparoscopic reoperation for 39 patients in a single institution was performed, examining open conversion rates, operative times, complications, and hospital stay.

**RESULTS:** Out of the 39 cases, 38 (97%) completed laparoscopy, 1 required conversion to open operation because of difficulty in exposing the common bile duct. The mean operative time was 135 min. The mean post-operative hospital stay was 4 d. Procedures included laparoscopic residual gallbladder resection in 3 cases, laparoscopic common bile duct exploration and primary duct closure at choledochotomy in 13 cases, and laparoscopic common bile duct exploration and choledochotomy with T tube drainage in 22 cases. Duodenal perforation occurred in 1 case during dissection and was repaired laparoscopically. Retained stones were found in 2 cases. Postoperative asymptomatic hyperamylasemia occurred in 3 cases. There were no complications due to port placement, postoperative bleeding, bile or bowel leakage and mortality. No recurrence or formation of duct stricture was observed during a mean follow-up period of 18 mo.

**CONCLUSION:** Laparoscopic biliary tract reoperation is safe and feasible if it is performed by experienced

### INTRODUCTION

In the past, laparoscopic surgery was contraindicated for patients undergone any prior abdominal surgery. With the advances in laparoscopic instrumentation and skills, increasingly complex procedures can be performed for patients with or without prior operations<sup>[1-5]</sup>. Prior open biliary surgery in particular is associated with difficulty in placing the initial trocar and obtaining adequate exposure of the biliary tract. Two major concerns that have prevented surgeons from using a laparoscopic approach when performing a repeated biliary tract surgery include the risk of injury to organs adherent to the abdominal wall when Veress needle or trocar is inserted, and the complications associated with adhesiolysis. With the increased experience in our institution, we have attempted laparoscopic surgery for patients with retained or recurrent stones who failed in endoscopic sphincterotomy. We reviewed the data collected from our cases to study the effect of prior biliary surgery on biliary tract reoperation using laparoscopy.

### MATERIALS AND METHODS

#### Patients

Laparoscopic cholecystectomy was introduced in our institution in 1993. Based on the experiences with 16 605 laparoscopic cholecystectomies, 658 laparoscopic common bile duct explorations, and 851 laparoscopic

Table 1 Diagnosis and prior surgery of 39 patients

Diagnosis	Prior surgery			
	LC	OC	OC+ CBDE	OC+CBDE+left lateral lobectomy
Stones in residual gallbladder	1	2		
Stones in CBD		22	11	3

LC: Laparoscopic cholecystectomy; OC: Open cholecystectomy; CBDE: Common bile duct exploration; CBD: Common bile duct.

cholecystectomies for patients with prior upper or lower abdominal surgery, we attempted laparoscopic biliary tract reoperation for patients with retained or recurrent stones who failed in endoscopic sphincterotomy.

A total of 39 patients including 26 females and 13 males, with a mean age of 46.4 years (ranging 13-76 years) were underwent to laparoscopic biliary tract reoperations by two surgical teams between January 2001 and June 2007. Retained or recurrent stones were found at a prior biliary surgery for biliary stones. None of them had any other previous abdominal surgery. A prior surgery was performed at other hospitals for 36 of them. The time between prior surgery and reoperation ranged from 7 d to 28 years, with a mean time of 2 years. Right subcostal scars were present in 18 cases, while midline or right paramidline scars were present in 21 cases. The diagnosis and prior surgery history of the 39 cases are listed in Table 1.

Diagnosis of retained stones or recurrent stones was made by pre-operative ultrasonography, CT, and MRCP. Endoscopic sphincterotomy failed or was contraindicated in the 39 cases. As the study was begun at a time when our experience with endoscopic sphincterotomy was limited, endoscopic sphincterotomy was either contraindicated or failed due to stones greater than 1.5 cm in diameter in 16 cases, the presence of more than four stones in 12 cases, tortuous ducts in 4 cases, and periampullary duodenal diverticula in 7 cases, respectively. There were no contraindications for general anesthesia. The diameter of the common bile duct ranged from 1 cm to 2.2 cm in 36 cases of choledocholithiasis. Biliary stricture or neoplasms were ruled out by radiological examination and serological tumor markers.

### Operative procedure

General endotracheal anesthesia was used. The abdominal cavity was accessed near the umbilicus. If the previous scar was more than 3 cm from the umbilicus, the blind technique was used to insert the Veress needle. If the scar was less than 3 cm from the umbilicus, the open (Hasson) technique was used. Adhesions under the umbilical incision were dissected using blunt finger dissection.

After pneumoperitoneum was established, intraperitoneal adhesions were evaluated by a 30-degree angled laparoscopy. A 5 mm port was placed under direct vision into the right or left lower abdomen, 5 cm from the adhesions, allowing dissection of the prior surgical adhesions located below the scar using scissors, a harmonic scalpel. One 10 mm operative port and two 5 mm accessory ports were placed as a standard four-trocar

Table 2 Results of laparoscopic biliary tract reoperation for 39 cases

	Laparoscopic biliary tract reoperation (n = 39)
Mean operating time (min)	135 (45-185)
Conversion rate	1 (2.5%)
Postoperative hospital stay (d)	4 (1-6)
Intra-operative complication rate	2.5% (1/39)
Post-operative complication rate	5.1% (2/39)

technique of laparoscopic cholecystectomy.

To approach the hepatic-duodenal ligament, we freed the lateral parietes and then began dissection on the right side along the lateral inferior border of the liver, dissecting the adhesions on the right side of hepatic round ligament down to the hepatic-duodenal ligament. The common bile duct was identified by touching the stones, needle aspiration of bile from the duct, or by laparoscopic ultrasound.

After identification of the common bile duct, choledochotomy was performed. Stones in the common bile duct were retrieved by spontaneous evacuation at the incision of the duct, instrumental exploration with forceps, flushing of the common bile duct with saline, or Fogarty balloon catheter. Next, a fifth port (10 mm) was placed at the right subcostal margin, just above the gallbladder, through which a 5.0 mm fiberoptic choledochoscope (Olympus) was inserted to check the biliary duct and remove the stones.

As long as choledochoscopy certified a patent common bile duct and absence of stones, the incision was closed using absorbable 4/0 sutures with a running suture and intracorporeal knotting, otherwise a T-tube was placed for drainage, and intraoperative cholangiography was performed through the T tube. A No. 10 Jackson-Pratt drain tube was placed in the subhepatic space for all patients.

## RESULTS

Of the 39 cases, 38 were underwent to laparoscopic operation and 1 was converted to an open operation because of difficulty in exposing the common bile duct. The mean operative time was 135 min (range, 45-185 min) and the mean postoperative hospital stay was 4 d (ranging 1-6 d, Table 2). Procedures included laparoscopic residual gallbladder resection in 3 cases, laparoscopic common bile duct exploration and primary duct closure at choledochotomy in 13 cases and laparoscopic common bile duct exploration and choledochotomy with T tube drainage in 22 cases. The mean number of removed stones was 3 (ranging 1-15) and the mean diameter of removed stones was 1 cm (ranging 1-2.6 cm). The mean time of T tube drainage was 38 d (ranging 28-47 d).

There were no complications due to port placement. In one patient with a history of open cholecystectomy and common bile duct exploration, the duodenum perforation occurred during dissection was repaired laparoscopically. There were no mortality, postoperative bleeding, bile

or bowel leakage in any of the 38 cases. Asymptomatic hyperamylasemia present in 3 cases postoperatively was treated with conservative therapy. Retained stones found in 2 cases were removed by choledochoscopy through the sinus tract of the T tube. No recurrent stones or duct stricture formation was found during a mean follow-up period of 18 mo.

## DISCUSSION

Most patients with common bile duct stones are cured by minimally invasive endoscopic sphincterotomy<sup>[6-10]</sup>. In the absence of a remaining T-tube from a prior operation, endoscopic sphincterotomy is considered the procedure of choice for patients with retained or recurrent stones, and should be attempted before pursuing biliary tract reoperation. However, endoscopic sphincterotomy cannot be performed, and is itself associated with a significant morbidity<sup>[11-15]</sup>. Contraindications for endoscopic sphincterotomy, as mentioned above, include size of stones, number of stones, presence of tortuous ducts or presence of periampullary duodenal diverticula, *etc* and vary depending on institutional and individual techniques and experiences. With the advances in laparoscopic skills and instrumentation, laparoscopic common bile duct exploration<sup>[16-20]</sup> and other laparoscopic procedures have become an increasingly popular option for patients undergone any prior abdominal surgery<sup>[21-25]</sup>, making laparoscopic reoperation of the biliary tract a reasonable choice for patients with a history of prior biliary surgery who have failed in endoscopic sphincterotomy. The results of our study indicate that laparoscopic surgery was not only minimally invasive, but also safe and feasible in cases of biliary tract reoperation, suggesting that it is the best method for patients who have failed in endoscopic sphincterotomy.

A primary concern when considering laparoscopic reoperation is the formation of adhesions after abdominal surgery, particularly after open biliary surgery. Adhesions from prior surgery are associated with difficulty in establishing pneumoperitoneum, placing the initial trocar, and obtaining adequate exposure of the biliary tract. To avoid the potential risk of injury to organs adherent to either the abdominal wall or the previous operative field, certain techniques and principles should be followed during Veress needle and trocar insertion as well as adhesiolysis.

Safe establishment of pneumoperitoneum and placement of an initial trocar are the prerequisite to any laparoscopic biliary tract reoperation and related with half of the complications of laparoscopic surgery<sup>[26-29]</sup>. In our study, blind Veress needle and initial trocar insertion more than 3 cm from the previous scar were safe for patients with previous biliary surgery. The open Hasson procedure performed in a previously unoperated field can avoid potential underlying adhesions or injury. In our study, no complications were related to the entrance into the peritoneum, indicating that previous biliary surgery is not a contraindication for minimally invasive procedures.

After access has been achieved, sufficient adhesiolysis

should be performed to allow the insertion of a second port to aid in visualization, retraction and dissection, and to allow for additional ports as needed. The laparoscope can be moved to different port sites without the need to perform total adhesiolysis of all visible adhesions. Only the adhesions interfering with adequate access to the operative field or the performance of the procedure need to be lysed. Adhesions close to the abdominal wall should be dissected to avoid injury to the intestine. By using a harmonic scalpel to dissect adhesions, the operative time can be reduced, thus decreasing blood loss<sup>[30]</sup>.

Once the gallbladder has been removed or the common bile duct has been explored, dense adhesions are usually found during reoperation in the healed fossa and near the common duct. In many instances, the upper edge of the duodenum is tented sharply cephalad into the gallbladder fossa. At times, because it is difficult to recognize the anatomy or identify the common bile duct, one should approach to the hepatic hilum by freeing the lateral parietes, and then begin dissection on the right side along the lateral inferior border of the liver. This gives a better mobility of structures so the hepatic flexure of the colon and the lateral edge of the second part of the duodenum can be identified before beginning dissection in the area of dense adhesions. The adhesions on the right side of the hepatic round ligament should be dissected from Glisson's capsule down to the hepatic-duodenal ligament. When adhesions are dissected from Glisson's capsule, attempts at blunt dissection with heavy retraction can easily avulse the capsule and expose the bleeding liver parenchyma. Consequently, careful sharp dissection is a more expedient technique. To prevent thermal injury of the gastrointestinal tract, electrical cautery should be avoided. After exposure of the hepatic-duodenal ligament, the common bile duct can be identified by touching the stones and needle aspiration of bile or by laparoscopic ultrasound.

In summary, laparoscopic biliary tract reoperation has a reasonable operating time, low conversion rate, low intra-operative and postoperative complication rate, and short postoperative hospital stay. Given these results, a laparoscopic approach to biliary tract reoperation appears to be a minimally invasive, safe, feasible, and effective procedure when done by expert laparoscopic surgeons, and is a first choice of treatment for patients who have failed in endoscopic sphincterotomy.

## COMMENTS

### Background

In the past, a history of prior biliary tract surgery was considered a contraindication for performing a repeat biliary operation. In the absence of a remaining T-tube from a prior operation, endoscopic sphincterotomy is considered the procedure of choice for patients with retained or recurrent stones, and should be attempted before pursuing biliary tract reoperation. However, endoscopic sphincterotomy cannot be performed on everyone, and is itself associated with a significant morbidity. With the advances in laparoscopic skills and instrumentation, increasingly complex procedures have been performed in patients with or without prior operations.

### Research frontiers

It has previously been reported that laparoscopic common bile duct (CBD)

exploration is a common method for the management of choledocholithiasis, and laparoscopic procedures are safe for patients undergone prior abdominal surgery. Few studies are available on the safety and feasibility of reoperation of biliary tract by laparoscopy for the patients with retained or recurrent stones who have failed in whom endoscopic sphincterotomy.

### Innovations and breakthroughs

This study showed laparoscopic biliary tract reoperation appears to be a minimally invasive, safe, feasible, and effective method when done by expert laparoscopic surgeons.

### Applications

Laparoscopic biliary tract reoperation is an alternative method for patients with choledocholithiasis who have failed in endoscopic sphincterectomy.

### Peer review

The authors describe, in this paper, their experience in laparoscopic biliary tract reoperation, which is of a certain clinical value.

## Abstract

Inflammatory bowel disease (IBD) often affects women around the age of conception and pregnancy. Most drugs used to treat IBD are safe in pregnancy, but physicians must consider the clinical implications of certain treatment regimens in young, fertile females. We report an informative case of a pregnant patient with IBD who underwent treatment with infliximab during her pregnancy and while nursing her infant. Serum and breast milk infliximab levels were monitored throughout this time period. This case report suggests that targeted monoclonal antibodies and other biologic agents can be used with caution in pregnant and breastfeeding patients.

## INTRODUCTION

In recent years, targeted monoclonal antibodies and other biologic agents have been at the forefront of the numerous therapeutic options available to treat many immune-mediated disorders. A large number of young and fertile patients are afflicted with disorders like inflammatory

bowel disease (IBD), rheumatologic diseases, asthma, and multiple sclerosis. These circumstances force patients and physicians to consider the safety of biologic agents during the peripartum time period.

## CASE REPORT

A 22-year-old female (G<sub>1</sub>P<sub>1</sub>) was referred to the Gastroenterology Clinic for treatment of fistulizing ileocolonic Crohn's disease (CD). The patient was initially treated with high dose corticosteroids, 6-mercaptopurine, metronidazole, and mesalamine with only mild improvement in her symptoms. The patient was eventually treated with infliximab and had a positive clinical response allowing her to be weaned off corticosteroids. Unfortunately, her 6-mercaptopurine was discontinued because of high thiopurine methyltransferase (TMPT) activity resulting in excessive production of the hepatotoxic 6-methylmercaptopurine metabolite. The patient's CD continued to respond modestly to 3.6 mg/d mesalamine (1200 mg tid) and 5 mg/kg infliximab (500 mg) IV infusions every 8 wk. The patient responded well to the medications but continued to have progressive symptoms requiring a stepwise increase in the maintenance dose of infliximab to 10 mg/kg (1000 mg) IV infusions every 4 wk.

Three years after her diagnosis with CD, the patient was discovered to be pregnant with her second child. The patient was successfully treated with mesalamine and infliximab when she was discovered to be 12 wk pregnant. The patient was informed that her disease could potentially worsen, nutritional deficiencies could develop, and that her medications could be potentially harmful to the fetus. The patient understood the risks and decided to proceed with the pregnancy after multiple discussions regarding the side effects and potential teratogenicity of her medications. She continued to take daily mesalamine and received a total of six doses of infliximab during her pregnancy with the last infusion occurring approximately 2 wk before delivery.

A healthy male infant weighing 7 pounds 6 ounces was born at thirty-nine weeks' gestation by an uncomplicated caesarian birth. The patient desired to breastfeed the infant while continuing to receive her mesalamine and infliximab. Again, the potential dangers of her medications were discussed with particular emphasis on their impact on breastfeeding. After taking the discussion under advisement, the patient decided to attempt to begin breastfeeding and to continue treatment with infliximab.

In an effort to determine if the infliximab was actually excreted into the breast milk, the patient's breast milk was collected and sent to the laboratory for analysis

Table 1 IBD medications during pregnancy

Low risk	Limited data	Not recommended	Contraindicated
Oral mesalamine	Olsalazine	Tetracycline	Methotrexate
Topical mesalamine	Azathioprine	Sulfonamides	
Sulfasalazine	6-Mercaptopurine		
Ampicillin	Metronidazole		
Cephalosporins	Ciprofloxacin		
Corticosteroids	Infliximab		
Cyclosporine	Adalimumab		
Loperamide			

(Prometheus Laboratories, San Diego, CA) with an enzyme-linked immunosorbent assay. A spike and recovery study was performed to investigate whether any non-specific binding by breast milk components was interfering with the assay. A sample of breast milk was spiked with 40 ng/mL solution of infliximab, a concentration comparable to the mother's serum concentration. A dilutional analysis (1:2, 1:4, and 1:8) was also performed and the infliximab was detected by the laboratory in all the spiked breast milk samples, but was not identified in her regular breast milk. The patient then received her regularly scheduled infliximab infusion (10 mg/kg) and her breast milk was collected daily for 30 d. No infliximab was identified in any of the breast milk samples, even with dilutional analysis. At 27 mo, no developmental abnormalities were noted in the child.

## DISCUSSION

New medications and aggressive treatment approaches to medical management have put more women with IBD in the position of being healthy enough to consider pregnancy. In women with IBD, the key to a healthy pregnancy is adequate control of disease activity throughout pregnancy<sup>[1]</sup>. Biologic agents are increasingly becoming a mainstay in the treatment regimens of both CD and ulcerative colitis (UC). Unfortunately, little information is available about the short-term and the long-term consequences of treatment with target monoclonal antibodies on the maturing fetus<sup>[2,3]</sup>. The safety of IBD medications during pregnancy and nursing are summarized in Tables 1 and 2.

Infliximab (Remicade; Centocor Inc, Malvern, PA) is a chimeric monoclonal antibody to tumor necrosis factor- $\alpha$  (TNF- $\alpha$ )<sup>[4]</sup>. It is indicated for inducing and maintaining clinical remission in moderately to severely active CD and UC patients that have had an inadequate response to conventional therapy and maintenance of remission<sup>[5]</sup>. Infliximab is increasingly used to treat pregnant women and data on its safety during pregnancy are scarce. Infliximab is listed as a pregnancy category B medication and the product label states that "It is not known whether infliximab can cause fetal harm when administered to a pregnant woman<sup>[4]</sup>". Most clinicians believe that the chimeric structure of the infliximab molecule containing a human IgG1 constant region, limits placental transfer during the first trimester<sup>[6]</sup>. However, the safety of infliximab beyond the first trimester

Table 2 IBD medications during nursing

Low risk	Limited data	Not recommended	Contraindicated
Oral mesalamine	Olsalazine	Tetracycline	Methotrexate
Topical mesalamine	Infliximab	Sulfonamides	Cyclosporine
Sulfasalazine	Adalimumab	Azathioprine	
Corticosteroids		6-Mercaptopurine	
		Loperamide	
		Metronidazole	
		Ciprofloxacin	

is unknown because IgG subclasses are readily passed into the fetus during the second and third trimesters<sup>[7]</sup>. Until recently, the medical literature contained no evidence that engineered therapeutic antibodies could cross the placenta when administered to expectant mothers. A recent case report documents clinically significant fetal exposure to infliximab *via* placental transfer and a prolonged half-life of the medication in newborns<sup>[2]</sup>. The presumed mechanism of fetal exposure to infliximab is transplacental maternal IgG antibody transfer beginning in the second trimester and peaking at term. No fetal abnormalities were apparent in this case, but the long-term implications of infliximab exposure during early childhood development are unknown. These findings suggest that pregnant patients should avoid therapeutic antibody treatments after thirty weeks' gestation and if necessary, the expectant mother can be bridged with steroids to control the disease activity until delivery<sup>[2,8]</sup>.

Limited clinical data are available on the safety of infliximab in pregnancy, because no controlled study is available in pregnant women. The manufacturer's safety database contains information on the outcomes of 131 pregnant women who received infliximab for rheumatoid arthritis or IBD<sup>[9]</sup>. An analysis performed on this safety database suggests no significant difference in pregnancy outcomes in women with infliximab exposure<sup>[7]</sup>. A published retrospective review of 10 pregnancies in CD patients in which infliximab was continued throughout the course of the pregnancy reported favorable fetal and maternal outcomes<sup>[7]</sup>. The limited clinical results available suggest that the benefits of infliximab in attaining response and maintaining remission in pregnant IBD patients might outweigh the risks of drug exposure to the fetus<sup>[10]</sup>.

The primary concern of the case we report is the safety of infliximab while breastfeeding, because many drugs and immunoglobulins are excreted in human milk. The infliximab product label states that "It is not known whether infliximab is excreted in human milk or absorbed systemically after ingestion<sup>[4]</sup>". A commercially available infliximab assay was used to measure drug levels in breast milk taken daily from our patient over a 30 d time period. No infliximab was detected in our patient's breast milk. Other published reports only tested breast-feeding mothers for one or two days but the results were consistent with our data<sup>[2]</sup>. We believe the daily testing performed on our patient's breast milk before and immediately after receiving an infliximab infusion clearly demonstrates that infliximab is not excreted in breast milk in any clinically significant amount.

Several case reports have recently emerged describing

the off-label usage of other biologics during pregnancy. A pregnant woman with treatment-refractory CD who failed treatment with infliximab was successfully treated with adalimumab (Humira; Abbott Laboratories, Chicago, IL), a recombinant human IgG1 monoclonal anti-TNF antibody<sup>[11,12]</sup>. The pregnancy was uncomplicated and at 6 mo, the infant showed normal growth and development<sup>[13]</sup>. Another case reported the use of etanercept (Enbrel; Amgen, Thousand Oaks, CA), a soluble TNF receptor fusion protein that binds to and inactivates TNF, in an uneventful pregnancy of a patient with refractory rheumatoid arthritis<sup>[14]</sup>. Etanercept has been shown to be excreted in breast milk, but it is not known whether the drug can be absorbed orally because it is such a large protein<sup>[15]</sup>.

In conclusion, therapeutic monoclonal antibodies and other biologic agents are used to a greater extent to treat immune-mediated disorders in pregnant patients. The limited clinical data currently available show no significant difference in pregnancy outcomes of patients exposed to infliximab during pregnancy compared to a healthy population. Physicians should be aware that the fetus may be exposed to therapeutic monoclonal antibodies when administered to pregnant patients and the long term implications on the child's developing immune system are unknown at this time. While physicians must remain cautious about maternofetal exposure to medications like therapeutic monoclonal antibodies, additions to the literature from reports like this one will hopefully assuage some of the fears faced by gastroenterologists, obstetricians, and patients, alike.

## Abstract

Abscess of the spleen is a rare discovery, with about 600 cases in the international literature so far. Although it may have various causes, it is most usually associated with trauma and infections of the spleen. The latter are more common in the presence of a different primary site of infection, especially endocarditis or in cases of ischemic infarcts that are secondarily infected. Moreover, immunosuppression is a major risk factor. Clinical examination usually reveals a combination of fever, left-upper-quadrant abdominal pain and vomiting. Laboratory findings are not constant. Imaging is a necessary tool for establishing the diagnosis, with a choice between ultrasound and computed tomography. Treatment includes conservative measures, and surgical intervention. In children and in cases of solitary abscesses with a thick wall, percutaneous catheter drainage may be attempted. Otherwise, splenectomy is the preferred approach in most centers. Here, we present three cases of splenic abscess. In all three, splenectomy was performed, followed by rapid clinical improvement. These cases emphasize that current understanding of spleen abscess etiology is still limited, and a study for additional risk factors may be necessary.

Fotiadis C, Lavranos G, Patapis P, Karatzas G. Abscesses of the spleen: Report of three cases. *World J Gastroenterol* 2008; 14(19): 3088-3091 Available from: URL: <http://www.wjgnet.com/1007-9327/14/3088.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.3088>

## INTRODUCTION

Abscess of the spleen is a rather rare clinical entity. About 600 cases have been described so far in the international literature<sup>[1]</sup>. Most of these refer to patients with recognized risk factors. These include the synchronous presence of conditions that compromise the immune system, such as endocarditis, diabetes mellitus, congenital or acquired immunodeficiency and the administration of immunosuppressive medication (e.g. post-transplantation or as part of the treatment of connective tissue disorders)<sup>[2-5]</sup>. Trauma is an additional predisposing factor for splenic abscesses<sup>[6]</sup>. Instances of splenic abscesses are relatively increased among intravenous drug addicts. On the other hand, splenic abscesses are most uncommon in the general population. From an epidemiological point of view, they are more frequently detected in middle-aged and older individuals, with no obvious preference for either sex<sup>[1-3]</sup>.

The clinical manifestations of splenic abscesses usually include abdominal pain, exclusively located or, at least, more intensely described in the upper-left-quadrant area. Fever, nausea, vomiting and anorexia may be also present in various combinations<sup>[7-9]</sup>. Laboratory findings are consistent with the acute phase of infection, but their exact nature is determined by the pathogen isolated from the abscess<sup>[10,11]</sup>. The most common pathogens detected include *Staphylococcus* and *Streptococcus*<sup>[2,12]</sup>. Imaging by common abdominal X-ray or ultrasound may be suggestive, but the lesion is usually revealed *via* computed tomography (CT). Due to the seriousness of the potential implications, including a threat to life itself, the most usual treatment currently applied is splenectomy, which is followed by rapid clinical improvement<sup>[13-15]</sup>.

## CASE REPORTS

### Case 1

A 45-year-old man presented to our hospital's outpatient clinic with persistent pain in the upper-left-quadrant area of the abdomen. He was working as a clerk, having previously spent 10 years as a member of embassy personnel in Africa. The referred pain had initiated about 1 mo previously, with periods of temporary improvement and relapse. The pain was not altered after food intake or sleep. The patient recognized no other major symptoms, such as vomiting, nausea or fever. Moreover, the patient was not treated for any other disease at the time (including recent infection or operation), nor had he ever been admitted to the hospital in the past. Clinical examination reproduced localized sensitivity in the area of the spleen, with no other significant findings. Laboratory testing (standard hematological and

**Figure 1** Abdominal CT scan of a 45-year-old man. The spleen contained a large single abscess of 8 cm  $\times$  4 cm.

**Figure 2** Macroscopic image of the dissected spleen. Notice the extent of the pathological tissue.

biochemical controls) revealed a mild increase in the number of leukocytes, which was otherwise within the normal range. Blood and urine cultures failed to reveal any pathogens. Imaging included chest and abdominal X-ray, followed by a CT scan of the upper abdomen. The latter detected a large abscess of the spleen, of an average size of 8 cm  $\times$  4 cm (Figure 1). Aspiration of the abscess was performed under CT guidance and the material obtained was cultured, which led to the development of several colonies identified as *Streptococcus* spp. No other pathogen of any kind was detected in the cultures. Owing to the abscess being symptomatic and of considerable size, the decision to perform splenectomy was made. The operation was completed successfully (Figure 2). Follow-up 1 year later has revealed a completely asymptomatic postoperative period.

## Case 2

A 50-year-old woman visited the outpatient clinic of our hospital with referred acute abdominal pain, which was not related to dietary habits and/or sleep. She also reported mild fever for about 1 wk (up to 38.5°C). Prior to surgery, she had been evaluated by a physician at the internal medicine clinic, who reported no clinical findings other than localized pain in the left-upper-quadrant area of the abdomen. Our clinical examination verified this finding. The patient had no history of recent infection or surgery, nor had she received medication of any kind. Moreover, she did not suffer from diabetes, human immunodeficiency virus (HIV) infection, or any other condition that would justify a degree

**Figure 3** A: CT scan of a 50-year-old woman. The spleen contained a single abscess of 3 cm  $\times$  3 cm; B: CT scan of a 40-year-old male sailor, which featured multiple splenic abscesses.

of immunosuppression/immunocompromise. Laboratory testing was performed, which showed signs of on-going bacterial infection (leukocytosis, increased C-reactive protein and fibrinogen, and a mild decrease in blood albumin). Blood and urine cultures failed to reveal microbial infection. Imaging was also performed, including thoracic and abdominal X-ray, followed by CT of the upper and lower abdomen. The latter detected a single, small abscess of the spleen of 3 cm  $\times$  3 cm (Figure 3A). Subsequently, percutaneous aspiration of the lesion was performed and the material was sent for culture. The microbiological report referred to the presence of *Staphylococci*, a rather common finding in splenic abscesses. Due to the symptomatic nature of the lesion, the patient was advised to undergo surgical treatment, which she accepted. She was operated a week later and total splenectomy was performed under general anesthesia. A follow-up session took place 1 year after the operation, which revealed complete resolution of all symptoms. The patient has remained asymptomatic ever since.

## Case 3

A 40-year-old male sailor visited our hospital as part of a yearly check-up, as instructed by his employers. During a brief review of his medical history, he mentioned a persistent chronic pain in the upper-left quadrant of the abdomen. The pain was not directly related to food intake or sleep, although it was occasionally combined with mild episodes of nausea and anorexia. Moreover, the patient referred to moderate fever (up to 38.8°C) that had occurred 3-4 times in the past 3 mo, each time lasting for about 3 d, and retreated after the use of non-steroidal anti-inflammatory drugs, administered every 6 h. The patient also had a long history of infections of the respiratory

**Figure 4** Macroscopic postoperative image of the dissected spleen. Abscess areas are easily recognized.

and gastrointestinal tracts, although he reported that all of these had been treated successfully, leaving no remnant disease. Clinical examination revealed nothing significant, other than sensitivity in the abdomen, which was more intense in the upper-left quadrant. Laboratory findings were consistent with acute-phase reaction (leukocytosis, and increased acute-phase proteins). Imaging included thoracic and abdominal X-ray, abdominal ultrasound, and finally, CT. The latter revealed multiple abscesses in the spleen (Figure 3B). No abscesses were detected via imaging in any other organ examined, including the liver. Cultures from blood and urine samples were negative, but the sample obtained from the abscesses themselves developed numerous colonies of bacteria identified as *Streptococcus* spp. Evaluation of the clinical condition, laboratory and imaging data, as well as professional danger (minimal access to immediate medical referral in case of an emergency), led to the decision to perform splenectomy (Figure 4). The surgery was completed without any complications and the patient has been found healthy and free from all referred symptoms to this date.

## DISCUSSION

Abscesses of the spleen are rather rare, especially in developed countries in which the frequency of parasitic infections is low<sup>[2,13-17]</sup>. From this point of view, the random discovery of three such cases in a single Greek hospital in the course of two years may at first appear to signify an increased incidence. However, this may be misleading, since our hospital is a tertiary medical referral center for a densely populated area of about 4 million citizens. Moreover, it is closely located to the central port of the country, Pireaus, which makes access for foreign visitors, immigrants and Greeks returning from high-prevalence countries particularly easy<sup>[18]</sup>. Indeed, in case 3, the subject was a sailor and in case 1, there was a history of residence in Africa.

The age of the individuals in our small series is 40-50 years, which is consistent with the peak age group for initial diagnosis of splenic abscesses described in the literature<sup>[3,4,9,19,20]</sup>. However, it should be noted that in all three cases, medical care was only infrequently demanded prior to consultation by our department and therefore,

it might be suggested that the disease evolved over a considerable time prior to our diagnosis. The personal history of long-term presence abroad strengthens this assumption.

The clinical manifestations, and laboratory and imaging findings in all three individuals were similar, although some variety was definitely observed (e.g. presence, height and duration of fever, abdominal pain characteristics and blood leukocyte count). In fact, all the symptoms described by the patients are included in the most frequent clinical findings lists provided by other reported studies, which proves that the current general understanding of the disease's pathophysiology is reasonably accurate<sup>[1,10,21]</sup>.

Perhaps the most interesting parameter in our three cases of splenic abscess, however, is the lack of any obvious risk factors in any of the individuals<sup>[22,23]</sup>. Indeed, a detailed medical history and clinical examination were performed initially and post-diagnosis, in an attempt to reveal any of the factors known to be associated with the development of abscesses in the spleen and other organs. However, no such findings occurred, with the only exception of potential occupational risk in cases 1 and 3. This discovery, along with the detection of common pathogens in the abscess itself (*Streptococcus* and *Staphylococcus* spp., respectively), may imply that further factors, apart from those already described, must contribute to the etiology of the disease<sup>[6,10,24]</sup>. Their exact nature and involvement in immunity modification and regulation of the reaction to infectious agents remains to be determined in future<sup>[20]</sup>.

As far as treatment is concerned, our department proceeded to classic total splenectomy in all three cases discussed. This led to rapid and complete relief from all disease-associated symptoms, without any major complications. This policy is still considered the standard of care for splenic abscesses<sup>[1,6]</sup>. However, more recent studies have also referred to alternative options, including laparoscopic splenectomy and spleen-preserving protocols, such as percutaneous imaging-guided drainage<sup>[1,15,25,26]</sup>. These methods are minimally invasive and are expected to result in smaller operative risk and overall treatment period, although of course this may differ according to the exact cause of the abscess<sup>[27-31]</sup>. Although initial results from the application of these novel methods are most promising and the potential advantages most welcome, current experience is still rather limited to justify their place in splenic abscess treatment. Therefore, the current policy is to limit their use in centers with adequately trained surgeons and only for a selected subgroup of patients.

## Abstract

We describe here a case of 51-year-old woman with a symptomatic hepatic cyst that was misdiagnosed as a gastric submucosal tumor (SMT) with endoscopic ultrasound (EUS) and CT scan. The patient presented with an epigastric pain for two months. On endoscopy, a submucosal tumor was found on the cardia of the stomach. Based on EUS and abdominal CT scan, the lesion was diagnosed as a gastric duplication cyst or a gastrointestinal stromal tumor (GIST). The operative plan was laparoscopic wedge resection for the GIST of the gastric cardia. A cystic mass arising from the left lateral segment of the liver was found at the laparoscopic examination. There was no abnormal finding at the gastric cardia. She was treated by laparoscopic hepatic wedge resection including the hepatic cyst using an endoscopic linear stapler.

## INTRODUCTION

Although submucosal tumor (SMT) is benign and

asymptomatic, it should be evaluated by follow-up examinations. Certain gastric SMTs that are considered to be gastrointestinal stromal tumor (GIST) or symptomatic SMT require operative intervention because it is very difficult to confirm its malignant potential with endoscopic biopsy<sup>[1]</sup>.

SMT is usually asymptomatic and most often discovered accidentally at surgery and autopsy or at performing diagnostic procedures. Unspecific symptoms, such as abdominal pain, obstruction, hemorrhage and intussusception, may occur. Two advanced tools have been generally accepted for the diagnosis and treatment of gastric SMTs. Endoscopic ultrasound (EUS) is one useful accurate diagnostic method, and the other is a laparoscopic procedure that allows minimally invasive treatment for SMTs.

Extragastric compression may mimic the symptoms and endoscopic findings of gastric SMTs. EUS and CT scan can accurately differentiate extragastric compression from true SMTs. However, cases may arise that cannot be differentiated even after various methods are used. We report here a case of hepatic cyst which was misdiagnosed as a gastric submucosal tumor in a patient undergone various diagnostic modalities, including endoscopy, EUS and abdominal CT scan.

## CASE REPORT

A 51-year-old woman presented with epigastric pain for two months. Initial examination showed that she had tenderness in the epigastrium. The patient was taking no medications. Her past medical history and familial history were unremarkable. Routine laboratory data on admission did not show any abnormal findings.

Gastrointestinal endoscopy revealed a submucosal tumor in the cardia of the stomach (Figure 1). On EUS, the lesion was a hypoechoic mass (3.6 cm in diameter) suggestive of a gastric duplication cyst or a GIST (Figure 2). Abdominal CT scan showed a cystic lesion at the submucosal layer of the gastric cardia, and the impression of the radiologist was a gastric duplication cyst or a GIST with necrosis (Figure 3). The operative plan was laparoscopic wedge resection for the GIST of the gastric cardia. Laparoscopic exploration was performed for the patient under general anesthesia. On the laparoscopic examination, a cystic mass arising from the left lateral segment of the liver was found (Figure 4A). There was no abnormal finding at the gastric cardia. After the

**Figure 1** Endoscopic photograph demonstrating a protruding mass on the cardia of stomach.

**Figure 2** EUS showing a hypoechoic mass (3.6 cm in diameter) which was suspicious of a gastric duplication cyst or a GIST.

**Figure 3** Abdominal CT scan showing a low density lesion in the submucosal layer of the gastric cardia (arrow).

**Figure 4** Operative procedures for the hepatic cyst in the left lateral segment of liver (A), after dissection of the triangular ligament (B), liver wedge resection using an endoscopic linear stapler (C, D). Lv: Liver, Cs: Hepatic cyst, St: Stomach.

triangular ligament was divided with electrocautery (Figure 4B), wedge resection of the left lateral segment of the liver, including the hepatic cyst, was performed using an endoscopic linear stapler (Figure 4C and D). There was no specific complication during the procedure. An oral diet was permitted on the 1st postoperative day. She was discharged from the hospital on the 3rd postoperative day. The mass was diagnosed as a simple hepatic cyst.

## DISCUSSION

Hepatic cysts are usually asymptomatic and not associated with defective hepatic function. They are incidentally found at laparotomy or laparoscopy, and even at routine ultrasound or CT scan. However, they may become symptomatic if they grow. The symptoms depend on the size and location of the cyst. The patients may have a vague upper abdominal pain, a right upper quadrant abdominal mass, postprandial fullness, dyspnea and vomiting<sup>[2]</sup>. In our case, the hepatic cyst was located at the edge of the left lateral segment of the liver and caused epigastric pain by compressing the gastric cardia.

A left hepatic cyst may rarely mimic a SMT arising from the gastric cardia or fundus<sup>[3]</sup>. Various conditions can mimic gastric SMT due to extragastric compression. The most common source of extraluminal compression in the stomach is from the spleen and splenic vessels<sup>[4,5]</sup>. Other sources of extraluminal compression include normal abdominal organ structures such as liver and gallbladder,

and pathologic lesions such as tumors, abscesses, pancreatic pseudocysts and enlarged lymph nodes.

Whether the lesion is due to intramural or extrinsic compression can be distinguished by changing the patient's position to see if the location and appearance of the mass change. Also, a change in appearance of the mass with either air insufflation or deflation is helpful in determining if the lesion is due to extrinsic compression, yet it can be difficult to differentiate. It was reported that the sensitivity and specificity of endoscopy are 87% and 29%, respectively for distinguishing intramural lesion from extramural compression<sup>[6]</sup>. On the other hand, EUS is 100% accurate for differentiating extragastric compression from submucosal tumor and for identifying the compressing organ<sup>[7]</sup>.

In our case, however, the hepatic cyst was misdiagnosed as a GIST although various diagnostic methods such as EUS and CT scan were used.

In the best of our knowledge, this is the first report of a patient with asymptomatic left hepatic cyst that was misdiagnosed as a GIST and treated by laparoscopic resection of the hepatic cyst.

Surgical treatment for hepatic cyst is indicated when the cyst causes complaints and the diameter is at least 5 cm

or rapid growth is observed. Possible surgical treatments of the cyst include unroofing, extirpation or resection of the cyst. Conservative treatment (aspiration, sclerotherapy and percutaneous drainage) is not often recommended because of frequent relapse of the disease<sup>[2,8]</sup>.

With the advances in minimally invasive surgery, laparoscopic unroofing is generally recommended for the treatment of hepatic cyst<sup>[8]</sup>. In our case, since the cyst was located at the left edge of the liver and relatively small, laparoscopic wedge resection of the hepatic cyst was easily performed by using an endoscopic linear stapler.

In conclusion, a left hepatic cyst may mimic a SMT arising from the gastric cardia and cause nonspecific abdominal symptoms. For such a case, laparoscopic procedure is a useful option for making the accurate diagnosis, and laparoscopic resection of the hepatic cyst is a minimally invasive treatment.

## Abstract

Duodenal perforations caused by biliary prostheses are not uncommon, and they are potentially life threatening and require immediate treatment. We describe an unusual case of aortic aneurysm and rupture which occurred after retroperitoneal aortoduodenal fistula formation as a rare complication caused by biliary metallic stent-related duodenal perforation. To our knowledge, this is the first report describing a lethal complication of a bleeding, aortoduodenal fistula and caused by biliary metallic stent-induced perforation.

## INTRODUCTION

Endoscopic or percutaneous biliary stenting is the preferred method of palliative treatment for malignant biliary strictures<sup>[1-4]</sup>. As the stents are used frequently and for long periods of time, biliary stent-related duodenal perforation is not an uncommon complication, which is potentially life threatening<sup>[5-9]</sup>. Biliary metallic stent-induced retroperitoneal perforation resulting in aortoduodenal fistula has not been reported as yet. To our knowledge, this is the first report describing the lethal complication of a bleeding aortoduodenal fistula following biliary metallic stent-related duodenal perforation.

## CASE REPORT

A 69-year-old woman presented herself with symptoms of abdominal pain and melena that started to worsen 2 d or 3 d before. An uncovered biliary wall stent (Boston Scientific, Marlboro, MA), 5 cm in length, was inserted two years before when the patient was diagnosed with a locally advanced pancreatic cancer. One year later, endoscopic removal of the uncovered wall stent was attempted because of stent clogging and tumor ingrowth. However, the attempt was unsuccessful, and resulted in a partial deformity of the distal end of the stent. A covered biliary wall stent, 6 cm in length, was reinserted into the stent. The patient received gemcitabine chemotherapy for 2 mo and recently took analgesics. She also frequently received folk remedies, such as massage of the epigastrium with downward palm-pressure.

Upon presentation, clinical examination revealed mild epigastric tenderness and abdominal distension without rebound tenderness. Laboratory tests showed  $21.88 \times 10^9/L$  ( $4.0-10.8 \times 10^9/L$ ) white blood cells, 8.5 g/dL (13-18 g/dL) hemoglobin, 36 IU/L (60-160 IU/L) amylase, 10 IU/L (0-60 IU/L) lipase, and 152 IU/L (39-117 IU/L) alkaline phosphatase. Comparisons of two simple abdominal X-rays, one taken recently and the other 2 mo before, found that the stents were slightly migrated distally and the outer stent's distal tip was compressed, shooting out radially in all directions (Figure 1). Abdominal computer tomography (CT) scan demonstrated a biliary stent with lesions arising from the head of the pancreas, compressing the second part of the duodenum. Air bubble densities were traced from the pancreatic head to the lower para-aortic lesions (Figure 2).

An endoscopy demonstrated that the bare metal

**Figure 1** Simple abdomen examination demonstrating compression of deformed distal tip of the outer biliary metallic stent shooting out radially in all directions.

**Figure 2** Abdominal CT scan showing biliary metallic stents with a lesion arising from the pancreatic head and the trajectory of air bubble densities traced from the pancreatic head to the lower paraaortic lesions.

**Figure 3** EGD. **A:** On previous admission (one year ago), placement of a stent into a stent due to clogging; **B:** On the present admission, a circular hole with bleeding (arrow) caused by stent-induced perforation following removal of stents; **C:** Retrieved biliary metallic stents showing deformed barbs of the uncovered wall stent tip on the distal portion of the covered wall stent.

**Figure 4** Abdominal CT scan showing decreased air densities in the pancreatic head to the paraaortic area (**A**) and a circular contrast collecting aneurysm of aorta (**B**).

barbs deformed in the stent were seen to have impacted and penetrated the neighboring wall of the duodenum. Following removal of the stents with a rat-tooth forceps without any additional injury, a circular hole with bleeding corresponding to the perforation was evident (Figure 3). We then planned to place a covered self-expandable metal stent into the duodenum, instead of placing a nasobiliary drainage for a short time due to desaturation and instability of the patient. After removal of the stent and treatment with parenteral nutrition and intravenous antibiotics, the patient felt well with no abdominal pain. However, 3 d later, she complained again of abdominal

pain and melena. So a follow-up abdominal CT was performed, which showed decreased air densities in the same area. However, a newly developed circular contrast collecting aortic aneurysm was found in the adjacent para-aortic lesion (Figure 4). On the following day, unexpected and massive hematemesis and hematochezia occurred, and the patient died due to bleeding.

## DISCUSSION

Early occurrence of iatrogenic duodenal perforations is generally apparent during papillotomy and stent placement.

Late presentations of duodenal perforations caused by biliary prosthesis are much rarer, but they are potentially life threatening and require immediate management<sup>[10-12]</sup>.

Although the uncovered wall stent is easily embedded in the bile duct epithelium<sup>[13,14]</sup>, the prolonged *in situ* uncovered wall stent may lose its framework, causing the stent to become weak because of its woven structures. In the present case, the stent's distal end was partially destroyed by repeated tries to remove it and it might have migrated distally during the follow-up. Under these circumstances, with repeated external abdominal pressure, the inner covered stent might have acted on the distal tip of the outer uncovered wall stent as a vehicle with a straining and compressing force. These factors are believed to have increased the intensity of trauma to the adjacent duodenal wall. Consequently, the deformed wire barbs of the outer wall stent's distal tip caused stent-induced retroperitoneal perforation and fistula.

The mainstays of treatment for early perforations without systemic upset are nasogastric suction, antibiotics, bowel rest and parenteral nutrition<sup>[15]</sup>. Our patient received conservative treatment and improved after stent removal. However, the patient suddenly bled to death due to the onset of an aortic aneurysm, the aortic wall might have been eroded as a result of retroperitoneal para-aortic irritation or inflammation through the fistula.

In summary, we can learn some lessons from this case. One is that stent-induced late perforation and related lethal complications may develop as a result of a distally migrated uncovered stent with sharp distal barbs and deformity caused by repeated stent removal trials and external abdominal pressure. The other is that early diagnosis and management are essential to prevent significant complications.

## Abstract

Obstructive jaundice secondary to tuberculosis (TB) is extremely rare. It can be caused by TB enlargement of the head of the pancreas, TB lymphadenitis, TB stricture of the biliary tree, or a TB mass of the retroperitoneum. A 29-year-old man with no previous history of TB presented with abdominal pain, obstructive jaundice, malaise and weight loss. Ultrasonography (US), computer tomography (CT) scan and endoscopic retrograde cholangiopancreatography (ERCP) were suggestive of a stenosis of the distal common bile duct (CBD) caused by a mass in the posterior head of the pancreas. Tumor markers, CEA and CA19-9 were within normal limits. At operation, an enlarged, centrally caseous lymph node of the posterior head of the pancreas was found, causing inflammatory stenosis and a fistula with the distal CBD. The lymph node was removed and the bile duct resected and anastomosed with the Roux-en Y jejunal limb. Histology and PCR based-assay confirmed tuberculous lymphadenitis. After an uneventful postoperative recovery, the patient was treated with anti-tuberculous medication and remained well 2.5 years later. Though obstructive jaundice secondary to tuberculous lymphadenitis is rare, abdominal TB should be considered as a differential diagnosis in immunocompromised patients and in TB endemic areas. Any stenosis or fistulation into the CBD should also be taken into consideration, and biliary bypass surgery be performed to both relieve jaundice and prevent further stricture.

## INTRODUCTION

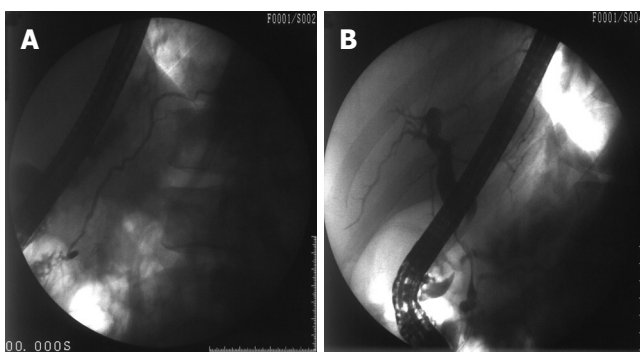

Abdominal tuberculosis (ATB) is rare and obstructive jaundice caused by tuberculosis (TB) is extremely rare. ATB can mimic more common noninfectious abdominal syndromes and is often overlooked because of its low incidence. The mechanisms by which ATB causes bile duct obstruction are varied. We describe a patient with biliary obstruction caused by enlarged tuberculous lymph nodes.

## CASE REPORT

A 29-year-old man presented to our unit with epigastric pain and tenderness on examination, and jaundice, steatorrhea, malaise and weight loss of 7 kg over the preceding 6 mo. Total bilirubin was 163  $\mu\text{mol/L}$  and direct bilirubin 88  $\mu\text{mol/L}$ ; SGOT, SGPT, gamma GT and alkaline phosphatase were moderately elevated. Other laboratory tests including the tumor markers CEA and CA19-9 were all within normal limits. HBsAg and HCV were negative. Abdominal ultrasonography (US) revealed a semi-solid hypoechogenic lesion 39 mm  $\times$  40 mm in size around the head of the pancreas, with two enlarged lymph nodes lying above this, and a common bile duct measuring 10 mm in diameter. Computer tomography (CT) scan showed a low density mass on the posterior aspect of the head of the pancreas with a contrast enhancing solid-rim (Figure 1). Pancreatography was normal, however severe narrowing of the distal common bile duct (CBD) was seen on endoscopic retrograde cholangiopancreatography (ERCP) (Figure 2A and B).

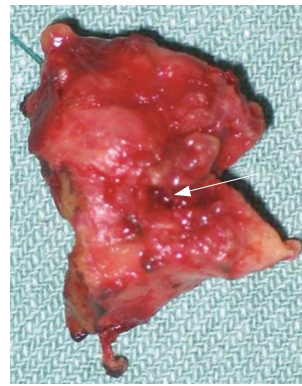

**Figure 1** Abdominal CT-scan showing a low density mass on the posterior aspect of the head of the pancreas with contrast enhancing solid rim (arrow).

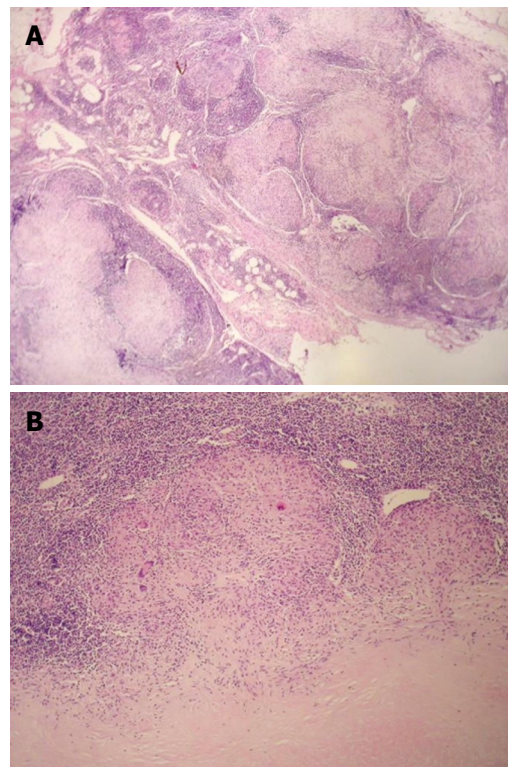

**Figure 2** A: ERCP with a normal pancreatogram; B: A smooth long severe narrowing of the distal common bile duct.

The patient underwent open surgery, and at operation the liver was found to be slightly firm, gallbladder moderately dilated, Lund's lymph node enlarged (about 1.5 cm), common bile duct moderately dilated and two lymph nodes close to the common hepatic artery also enlarged (2 cm and 3 cm). After mobilizing the duodenum and the head of the pancreas, an enlarged (4 cm) soft lymph node adherent to the distal CBD, was removed. The lymph node had a solid surface with a soft and caseous centre, and had a fistulous connection with the posterior aspect of the CBD. Frozen section histology of the lymph node revealed chronic granulomatous inflammation. The gallbladder, Lund's lymph node, the two other enlarged lymph nodes lying close to the common hepatic artery, and a specimen of liver was removed and sent for histology. The narrowed distal CBD was resected, the distal end over sewn, and the proximal end anastomosed with a Roux-en-Y jejunal limb. The resected specimen included the fistulous opening on the posterior wall of the CBD (Figure 3).

The patient had an uneventful postoperative recovery, and bilirubin levels normalised within two weeks. Histology of the liver and gallbladder was normal. The resected CBD showed epithelial ulceration and inflammation with a number of necrotizing granulomata. The lymph nodes had a chronic granulomatous appearance with large merged necrotic areas, and smaller epithelioid-type granulomata with occasional multinuclear giant cells (Figure 4A and B) suggestive of tuberculous lymphadenitis. The diagnosis was confirmed with a polymerase chain

**Figure 3** The resected part of the common bile duct with fistula on the posterior wall (arrow).

**Figure 4** A: Extensive chronic granulomatous lymphadenitis (HE, × 13); B: Focal tuberculoid granuloma formation (HE, × 64).

reaction (PCR) using automated analyzer Cobas/Roche/, with the Amplicor Mycobacterium tuberculosis assay. No previous specific risk for TB was found in the patient. He was treated with anti-tuberculous quadruple therapy and achieved gradual clinical improvement, with resolution of pain and malaise, and a weight gain of 10 kg over the next 6 mo. He remained well at 2.5 years postoperatively.

## DISCUSSION

Obstructive jaundice secondary to abdominal TB is extremely rare. Four mechanisms have been described: TB of the pancreas itself may cause pseudoneoplastic obstructive jaundice<sup>[1-10]</sup>; it may be secondary to TB lymphadenitis causing compression and inflammation of the lymph nodes and the CBD<sup>[6,11-19]</sup>, as in our case, with caseation of the lymph node causing fistulation into the CBD; biliary TB itself may lead to single or multiple

strictures, mimicking cholangiocarcinoma<sup>[20-25]</sup>; and TB can create a retroperitoneal mass leading to biliary tree obstruction<sup>[26]</sup>.

The diagnosis of abdominal TB should be considered in the context of a mass in the head of the pancreas in the immunocompromised patients and in countries with endemic TB<sup>[7]</sup>, after the exclusion of malignancy and other biliary inflammation. TB lymphadenitis can be suspected when a contrast-enhanced CT scan demonstrates low density masses surrounded by an enhancing solid rim<sup>[14]</sup>, or when ERCP demonstrates a normal pancreatogram with a smooth narrowing of the CBD<sup>[18]</sup>, as were seen in our patient. FDG-PET scanning has not been shown to be useful in distinguishing TB from pancreatic malignancy, as both conditions have an increased uptake of the FDG metabolite<sup>[18]</sup>. US or CT-guided percutaneous fine needle aspiration (FNA) of the enlarged lymph nodes may be useful<sup>[7]</sup>, but is often not definitive<sup>[21]</sup>. Cytology of CBD aspirate, however, obtained by ERCP, may be confirmatory in the presence of the acid-fast bacillus (*Mycobacterium tuberculosis*); alternatively PCR of the aspirate may be diagnostic<sup>[19]</sup>. However, in the case of a periportal lymphadenopathy causing obstructive jaundice, as in our patient, these FNA tests are only positive if a fistula exists between the TB lymph node and the CBD, allowing bacilli to pass into the CBD<sup>[19]</sup>. Other potential diagnostic methods include obtaining tissue specimens by laparoscopy<sup>[17]</sup> or endoscopic ultrasound with FNA<sup>[27]</sup>. Though in practice, the diagnosis is often established at operation<sup>[6,7,18,26]</sup> or even after surgery by histology<sup>[4]</sup> or PCR-based assay<sup>[2,4,6,8,10]</sup>, as was the case in our patient.

The great benefit of a preoperative diagnosis of TB causing the obstruction is that a more conservative path could be followed, involving removal of the obstructing lymph node alone, followed by anti-TB medications<sup>[18]</sup>. In our case more elaborate CBD resective surgery was undertaken for presumed malignancy.

However, even though TB lymphadenitis was suspected in our patient after intraoperative frozen section, resection of the involved part of the CBD was necessary as the bile duct was already strictured, and eventual closure of the fistula would probably result in additional stenosis or even complete obstruction of the CBD. Thus inexplicable stenosis of the CBD should be taken into consideration in the context of pancreatic or TB lymphadenitis associated with obstructive jaundice and be treated by biliary bypass surgery<sup>[7]</sup> in addition to anti-TB medication.

## Abstract

Primary stomach lymphoblastic B-cell lymphoma (B-LBL) is a rare tumor. We describe a primary stomach B-LBL in a 38 years old female who presented with nonspecific complaints of fatigue and vomiting for 2 mo. Gastrofiberscopy revealed a large gastric ulcer, which was successfully resected. Pathology showed a lymphoblastic cell lymphoma arising from the stomach, and there was no evidence of disease at any extrastomach site. Immunohistochemical staining and gene rearrangement studies supported that the stomach tumor was a clonal B-cell lymphoma. Therefore, the diagnosis of B-LBL was made based on the stomach specimen.

<http://dx.doi.org/10.3748/wjg.14.3101>

## INTRODUCTION

Precursor B-cell lymphoblastic lymphoma (B-LBL) is a

neoplasm of lymphoblasts committed to the B-cell lineage, which is an uncommon type of lymphoma and accounts for less than 10% of the total cases of lymphoblastic lymphoma. It usually affects people at a younger age. Most cases reported in a literature review are less than 18 years of age, some patients are under 35 years of age and the median age is 20 years<sup>[1]</sup>. Unlike precursor T-cell lymphoblastic lymphoma, precursor B-cell lymphoblastic lymphoma commonly involves lymph nodes or extranodal sites, mediastinal masses are infrequent. The most frequent sites of B-LBL lesions are the skin, bone, soft tissue, and lymph nodes<sup>[1-3]</sup>.

Primary stomach lymphoma is defined as an extranodal non-Hodgkin's lymphoma of any cell type, with no evidence of extrastomach dissemination. The majority of stomach cases reported in the English literature are extranodal marginal zone B cell lymphoma of mucosa-associated lymphoid tissue (MALToma), diffuse large B cell lymphoma (DLBCL), nasal type NK/T cell lymphoma, *etc*<sup>[3-5]</sup>. Primary stomach B-LBL is rare. Here we present a case of primary B-LBL involving the stomach.

## CASE REPORT

The patient was a 38 years old female who had an unremarkable past medical history. She presented with nonspecific complaints of fatigue and vomiting for 2 mo. Gastrofiberscopy revealed a large gastric ulcer. During surgery, a large neoplastic ulcer was found in the stomach and gastric wall was diffusely thickened. The tumor was successfully resected with adjacent portions of the stomach. Good macroscopic margins were obtained. No other masses or enlarged lymph nodes were present. Examination of the bone marrow showed 13% immature lymphoid cells, the leukocyte count of peripheral blood was  $12 \times 10^9/L$ , and the percentage of peripheral blood lymphocytes was 35%.

Grossly, the greater and lesser curvatures of the resected stomach measured 22 cm and 11 cm, respectively. There was a well circumscribed neoplastic ulcer measuring 10 cm × 8 cm × 2.5 cm in antro-pyloric region of the stomach (Figure 1). A small necrosis was found on surface of the neoplastic ulcer. The cut surface of the tumor was grey and firm. Tumor tissue was found in the gastric serosa. Portions of tumor tissue were fixed in formalin and embedded in paraffin and cut into sections which were stained with HE for routine histomorphology. Additional sections of paraffin-embedded tissue were used

**Figure 1** A large neoplastic ulcer in the stomach involving the whole gastric wall.

for immunohistochemical staining and gene rearrangement analysis.

Microscopically, the tumor cells were uniform, medium-sized immature lymphoid cells, their nuclei contained evenly dispersed nuclear chromatin with a high nuclear/cytoplasmic ratio. The nuclei were round or oval or convoluted in shape. A large number of mitotic figures were appreciated. The tumor cells were diffusely distributed in the gastric glands, and found in all layers of the gastric wall. There were tumor emboli within the gastric wall lymphatic vessels. Lymphoepithelial lesions were not found (Figure 2).

Immunohistochemistry analysis revealed immature lymphoid cells positive for cytoplasmic CD10 and CD79a, nuclear TdT and CD99 antigens, and negative for CD20 antigen. About 50%-70% of the tumor cells were reactive for Ki-67 (Figure 3). Gene rearrangement analysis showed monoclonal immunoglobulin high chain gene rearrangement (Figure 4).

The morphology, immunophenotype, and gene rearrangement of the neoplastic cells supported the diagnosis of stomach precursor B-LBL. There was no evidence that supported the diagnosis of precursor B lymphoblastic leukemia in the bone marrow and peripheral blood.

## DISCUSSION

Primary stomach lymphomas are in the minority, most of which are mucosa-associated lymphoid tissue B cell lymphoma, diffuse large B cell lymphoma, extranodal nasal type NK/T cell lymphoma, *etc.* Primary stomach B-LBL is rare<sup>[1-5]</sup>.

Ninety percent of lymphoblastic lymphomas are of precursor T cell lineage and only 10% are of precursor B cell lineage<sup>[1,2]</sup>. Precursor B lymphoblastic lymphoma (B-LBL)/leukemia (B-ALL) are originated from B cell lineage. ALL and LBL represent different clinical presentations of the same neoplasm and are grouped in the category of precursor B-cell lymphoblastic leukemia/lymphoma by the revised World Health Organization classification of lymphoid neoplasms<sup>[1]</sup>. Because of the biologic unity of B-ALL and B-LBL, the criteria for distinguishing B-LBL from B-ALL are also arbitrary and applied inconsistently. In some studies<sup>[2,6,7]</sup>, patients

**Figure 2** Diffuse proliferation of lymphoblastic cells between gastric glands of stomach B-LBL. A: HE, × 100; B: HE, × 200; C: HE, × 200; D: Tumor emboli within lymphatic vessels of the gastric wall (HE, × 100).

with B-LBL and acute leukemia are included, but in other studies<sup>[3,4,6]</sup>, patients with leukemic involvement are excluded. According to the new WHO classification of lymphoid neoplasms, when the process is confined to a mass lesion without any or minimal evidence of blood and marrow involvement, the diagnosis is lymphoma; when extensive marrow and blood are involved, lymphoblastic

**Figure 3** Stomach B-LBL (EnVision,  $\times 200$ ). **A:** Lymphoblasts diffusely stained with anti-CD79a; **B:** A large number of lymphoblasts positive for nuclear antigen TdT; **C:** Lymphoblasts diffusely stained with anti-CD10; **D:** A large number of lymphoblasts positive for Ki-67.

leukemia is the appropriate term; if a patient presents with a mass lesion and the number of lymphoblasts is less than 25% in the marrow, the diagnosis of lymphoma is preferred<sup>[1,3-5]</sup>. Precursor B lymphoblastic B-LBL most commonly involves the skin, bone, soft tissue, and lymph nodes, whereas stomach B-LBL is uncommon<sup>[6,8]</sup>.

**Figure 4** Polymerase chain reaction showing rearrangement of immunoglobulin heavy-chain genes. Lane 6, JVI, sample collected from stomach B cell lymphoblastic lymphoma showing a negative pattern; lane 7: JVI, sample collected from stomach B cell lymphoblastic lymphoma showing a negative pattern; lane 8: JVI, T cell lymphoma cell line Jurkat used as a positive control; lane 9: JVI, T cell lymphoma cell line Jurkat used as a positive control.

Leukemic presentation with involvement of peripheral blood and bone marrow is most common. Extramedullary involvement is frequent with particular pre-direction for the central nervous system, lymph nodes, spleen, liver, and gonads. The leukocyte count may be decreased, normal or markedly elevated. The etiology of B-LBL is unknown. However, there is evidence that suggests a genetic factor in some cases<sup>[9,10]</sup>. The neoplastic cells of B-LBL are morphologically indistinguishable from those of B-ALL and typically small to medium size blast cells, with scant cytoplasm, moderately condensed to dispersed fine chromatin, inconspicuous nucleoli, and a high mitotic rate. Immunophenotypically, the neoplastic cells express terminal deoxynucleotidyl transferase (TdT) and B-cell antigens, such as CD79a, CD10, CD19, and CD22<sup>[1,2,9]</sup>.

Our review of the literature revealed few case reports of stomach B-LBL lymphoma. In this report, we describe an exceptional primary stomach precursor B-LBL with no evidence of disease at any extrastomach site. The number of lymphoblasts was less than 25% in the marrow and there was no evidence in the peripheral blood. Since immunohistochemical study showed the neoplastic lymphoid cells of precursor B-cell type, the diagnosis of B-LBL was made in this stomach case<sup>[1,9]</sup>. Precursor B-LBL, a potentially curable disease, an aggressive therapy is very important<sup>[7,11-12]</sup>. In this report, after surgical resection and final pathologic diagnosis of B-LBL, the patient was treated with chemotherapy. Now, she is followed-up at the outpatient clinic and in complete remission half a year after the initial diagnosis.

The differential diagnosis of precursor B-LBL includes myeloid lymphoma/leukemia, Burkitt's lymphoma, and precursor T-LBL, *etc.* The tumor morphology and immunophenotype help differential diagnosis. Meanwhile, the precursor B-ALL should be excluded<sup>[1,13]</sup>.

### TO THE EDITOR

I read with great interest the work by Fang, Zhou, Jin and Hu, dealing with perivascular epithelioid cell tumour (angiomyolipoma) of the liver<sup>[1]</sup>. It is right that, in mesenchymal tissues, the tumour is common in the uterus. The most frequent localization generally is, however, in the kidney<sup>[2,3]</sup>. In the liver, 110 cases had been described by 1999<sup>[3]</sup>.

It is true that the malignant cases are much fewer.

Our interest in this entity was arisen, when we scrutinized a hepatic tumour, described from our department as an oncocytic adenoma<sup>[4]</sup>. However, the tumour later turned out to be positive for the melanocytic marker HMB-45 and is in fact a perivascular epithelioid cell tumour. The journal refused to publish the revised diagnosis!

## Abstract

Association of silica with diseases like cancers has been determined previously. This study was designed to determine the quantity of silis in flour produced in Golestan Province, and its relation to esophageal cancer (EC). We took flour samples from all flour millings in Golestan Province. Base-melting method in nickel crucible was used at 550°C. The extract was reduced with acids. Different silis concentrations in various regions were compared.  $P < 0.05$  was considered statistically significant. The median silis concentration was 0.0030 g, the mean silis concentration was  $0.008760 \pm 0.004265$  g in each 100 g flour. The difference of mean silis concentrations in various regions was not significant. No high level of silica was found in the flour of Golestan Province. We could not find any significant difference in various areas between silica contaminations. Studies on the consumed bread and rice in various regions of Golestan Province can be helpful.

## LETTER TO THE EDITOR

Silica ( $\text{SiO}_2$ ) is an oxide of silicon. Its existence in food

products is a presentation of contamination. Some studies revealed that silica exposure may play a role in diseases like cancer<sup>[1]</sup>, although its definite effect has not been confirmed in some cancers like esophageal cancer. The International Agency for Research on Cancer (IARC) has classified crystalline silica as a known human carcinogen in lung cancer<sup>[2]</sup>. The excess risk of esophageal cancer (EC) mortality among caisson workers with silicosis explains best by the very heavy exposure to free silica dust in their working environment<sup>[3-8]</sup> and their silicosis as an underlining disease.

A case-control study of the relationships among silica exposure, gastric cancer, and EC in Japan, suggested that gastric cancer and EC are related to silica exposure and silicosis in that area, although they did not reach a statistically significant level<sup>[9]</sup>.

O'Neill *et al*<sup>[9]</sup> reported that the contamination with fibrous silica contaminant is high in the diet of north-east of Iran. Low quality of wheat and its contamination with weed and sand are considered important<sup>[10]</sup>. The northeastern part of Iran in Golestan Province (Turkmen Sahra) is known to have the highest incidence of EC in the country and to be one of the highest areas in the world<sup>[11]</sup>. Golestan Province is located on the hot spots that are along a presumptive belt starting from northern China, extending along the southern parts of the former Soviet Union and ending in the Caspian littoral in northern Iran.

In 1982, O'Neill *et al*<sup>[9]</sup> reported an association of silica fibers in the millet bran and esophageal tumors in another study. In 1986, Newman<sup>[1]</sup> found that certain plants contain structures consisting of biogenic silica, which has been supposed as a causative agent in the high cancer areas of Southern Africa, Northeast Iran and North of China. It is hypothesized that these plant mineral fibers are involved in the etiology of EC in Iran and in other high incidence areas. *Phalaris minor* is a known common weed in the Mediterranean area, but it is not considered a region with a high incidence and prevalence of EC.

Some findings suggest that silica particles might be involved in the etiology of EC. In fact, different results are available about the significant relationship between silis exposure and EC, some are in agreement and suppose that silis plays a role in the etiology of EC, and others are in disagreement.

In our study, silis but not its compound or its biologic derivatives was considered a carcinogen. Flour samples from all flour millings in Golestan Province were taken. Base-melting method in nickel crucible was used at 550°C and the extract was reduced with acids. The complex was evaluated with a spectrophotometer (820 nanometer wavelength). Five control samples of wheat seeds and pedicles were examined, too. The different silis median concentrations in

wheat seeds, pedicles and flour were statistically significant. However, the total silis in the flour was in the normal range because a great deal of silis was omitted from the flour during the preparing process. The modern and new purification technologies may be effective in producing these results, so the previous contaminants can be supposed less important.

The mean silis concentration was 0.012, 0.01 and 0.003 in the central, western and eastern parts of Gorgan City, respectively. The differences were not statistically significant. The Golestan province was divided into 3 areas according to the incidence of EC and we matched the data with the location of flour millings on the map.

Our findings suggest that there are no significant differences in flours of various areas, revealing a less important role of silis in EC. However, from a medical point of view it is important. There is a great variation in the incidence of EC between countries and regions. The distribution of EC in Golestan Province is not concordant with the amount of silis reported in this study. Silis concentration is higher in the west part but EC is higher in the east.

Despite the high incidence of EC in Northeast Iran, no significant differences were seen between silis in wheat flour of this area and standard measures. It seems that silis could not play a major role in the etiology of EC or is considered a predisposing factor when we eat it. Perhaps, oral or inhalation absorption of silis has an effect on its carcinogenicity. This hypothesis becomes acceptable when we pay more attention to the main component of earth crust. Silis, an abundant mineral in rock, sand, and soil, is in contact with our skin, but it is not supposed as a carcinogen or a predisposing factor.

Previous studies have reported a considerable concentration of silica in the flour produced in this area and suggested a relationship between EC and silis. In this study, no high level of silica was found in the flour of Golestan Province. Thus, on the one hand, we could not confirm the hypothesis of high contamination of the flour in this area, which is considered a high risk of EC in Golestan Province. On the other hand, we could not rule out the probable role of this element in the etiology of EC. Studies on the consumed bread and rice in various regions of the province can be helpful.

## ACKNOWLEDGMENTS

The authors thank all colleagues in "Food and Drug Committee" of Golestan Province for their help in data collection, especially Dr. Hamidreza Yazdi (head of the deputy), Dr. Abbas-ali Keshtkar (MD, PhD) for their kind help in analyzing the data and Mr. Naderi for his cooperation in chemical analysis.

## Abstract

**AIM:** To discuss the variations and distributions of authors who published their papers in *World Journal of Gastroenterology* (*WJG*) during 2001-2007 and evaluate the development of *WJG* and gastroenterology core journals in recent years by comparing the contributions of the authors.

**METHODS:** *WJG* articles published in 2001-2007 were searched from *MEDLINE* database (by ISI Web of Knowledge). The variations (cooperation degree, cooperation rate) and distributions of the first authors were analyzed with bibliometric methods. SCIE was used to collect articles published in *Am J Gastroenterol*, *Gastroenterology*, *Scand J Gastroenterol* and *WJG* in 2007, and comparison of the data was made. Comparison indicators included the article number of annual journals, cooperation degree of authors, cooperation rate, mean number of articles published in each *WJG* issue, number of countries of the first *WJG* authors, geographical distribution and article contribution ratio of all *WJG* authors and domestic authors.

**RESULTS:** Of the 5851 articles covered in *MEDLINE*, 173, 236, 633, 826, 1496, 1382 and 1105 articles were cited from 2001 to 2007. The cooperation degree was 5.11, 5.56, 5.75, 5.76, 6.31, 5.90 and 5.64 respectively. The cooperation rates was 94.80%, 99.15%, 98.89%, 98.55%, 99.13%, 96.67% and 95.66%, respectively. The mean number of articles published in each *WJG* issue from 2001 to 2007 was 28, 39, 52, 34, 31, 28 and 23, respectively. The number of countries of the first *WJG* authors was 8, 8, 27, 32, 49, 61 and 56, respectively. The first authors of *WJG* came from 3 continents in 2001 and covered 6 continents in 2006-2007. The number of articles written by Asian authors was 136 (79.07%), 227 (96.19%), 575 (90.98%), 713 (87.81%), 1111 (75.32%),

712 (53.98%) and 555 (53.21%), respectively in 2001-2007. The number of articles written by European & American authors increased from 36 (20.93%) and 8 (3.39%) in 2001-2002 to 563 (42.68%) and 452 (43.34%) in 2006-2007. The number of countries except for China contributing papers was increased. The number of articles written by first authors of Japan rose from 0 (0%) in 2001-2002 to 287 (12.15%) in 2006-2007. The number of articles written by American authors increased from 6 (1.47%) in 2001-2002 to 158 (6.69%) in 2006-2007. The number of articles written by Chinese authors was 136 (79.07%), 227 (96.19%), 548 (86.71%), 669 (82.39%), 884 (59.93%), 380 (28.81%) and 320 (30.68%), respectively, in 2001 to 2007. The number of articles published in *Am J Gastroenterol*, *Gastroenterology*, *Scand J Gastroenterol* and *WJG* was 565, 586, 238 and 1118, respectively in 2007. The cooperation degree was 4.77, 6.14, 5.95 and 5.64, respectively, in 2007. The cooperation rate was 95.40%, 84.18%, 96.63% and 95.66%, respectively, in 2007. The number of countries of authors contributing papers was 44, 35, 42 and 62, respectively, in 2007.

**CONCLUSION:** The geographical distribution of *WJG* authors is wide for the past 2 years. *WJG* has made a step onto international publishing, and drawn even more attentions from gastroenterology researchers. Its authors are distributed over 74 countries in 6 global continents, and the journal has become the main intermediary for international gastroenterology researchers to demonstrate their research accomplishments.

Yang H, Zhao YY. Variations of author origins in *World Journal of Gastroenterology* during 2001-2007. *World J Gastroenterol* 2008; 14(19): 3108-3111 Available from: URL: <http://www.wjgnet.com/1007-9327/14/3108.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.3108>

## INTRODUCTION

*World Journal of Gastroenterology* (*WJG*) was first published

in 1995. This English journal is edited and published by The WJG Press and can be retrieved with the following citation tools: Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, Index Medicus, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, Nature Clinical Practice Gastroenterology and Hepatology, CAB Abstracts and Global Health, *etc.* In recent years, Ma *et al*<sup>[1]</sup> has analyzed the articles covered in SCIE during 1998-2004, claiming that the self-citation rate is decreased. However, the citation rate by others is increased and the journal citation status is improved. The variations of *WJG* authors' data in 2001 to 2007 were comparatively analyzed. The cooperation degree, cooperation rate, number of countries and author publishing ratios of domestic journal issues in *American Journal of Gastroenterology*, *Gastroenterology*, *Scandinavian Journal of Gastroenterology*, were also comparatively analyzed using the SCIE database.

A bibliometric analysis of the variations in distributions of authors was made to show the improvements and shortcomings of *WJG* and speed up its development.

## MATERIALS AND METHODS

*WJG* articles were searched from MEDLINE (by ISI Web of Knowledge)<sup>[2]</sup> in 2001-2007. Variations (cooperation degree, cooperation rate) and distributions of the first authors were analyzed with bibliometric methods. Articles published in *Am J Gastroenterol*, *Gastroenterology*, *Scand J Gastroenterol* and *WJG* covered in SCIE<sup>[3]</sup> in 2007 were analyzed using Web of Science (meeting summaries were not covered). The authors, titles, addresses and other relevant data of the four journals in 2007 were processed through the SCIE's 'Refine Results' function, and countries of authors, *WJG* authors, research institutions and their distribution were closely consistent with the current status and authors of articles published in *WJG* experienced difficulties.

## RESULTS

### *WJG* articles retrieval status with MEDLINE citation in 2001-2007

*WJG* was published bimonthly in 2001-2002, monthly in 2003, semimonthly in 2004, and weekly from 2006. In 2001-2007, 173, 236, 633, 826, 1496, 1382 and 1105 articles published in *WJG* were covered in MEDLINE. The number of articles published in each issue of *WJG* was 28, 39, 52, 34, 31, 28 and 23, respectively, in 2001-2007.

### Co-author articles published in *WJG*

A total of 5851 articles published in *WJG* during 2001-2007 were cited. The number of authors of these papers was 34415 and the cooperation degree was 5.11, 5.56, 5.75, 5.76, 6.31, 5.90 and 5.64, respectively, with a mean cooperation degree of 5.88. The number of articles written by a single author was 137, accounting for 2.34% of all articles. The number of co-author articles published in 2001-2007 was 5714 and the cooperation rate was

Figure 1 Distribution of first authors and countries in 2001-2007.

94.80%, 99.15%, 98.89%, 98.55%, 99.13%, 96.67% and 95.66% respectively, with a mean cooperation rate of 97.66%. The cooperation degree was slightly increased from 2001 to 2005 (Table 1).

### Distribution of first authors in *WJG*

Only addresses of the first authors were marked in MEDLINE, and 5851 articles published in *WJG* were retrieved in 2001-2007, in which only 5689 articles had available addresses. The number of countries with their articles covered in MEDLINE was 8, 8, 27, 32, 49, 61 and 56, respectively (Figure 1). The geographical distribution of *WJG* authors was increasingly broadened, especially in 2006 and 2007 during which the number of countries increased multiple folds.

The geographical distribution of the authors with addresses in 5689 articles was categorized into 6 continents (Table 2). During 2001-2005, the majority authors were from Asia, accounting for 136 (79.07%), 227 (96.19%), 575 (90.98%), 713 (87.81%) and 1111 (75.32%), respectively. During 2006-2007, the number of authors from Asia was 712 (53.98%), 555 (53.21%) respectively, showing that the number of Asian authors is declining. During 2006-2007, the geographical distribution of *WJG* authors covered all the 6 continents and the number of European and North America authors increased from 36 (20.93%) and 8 (3.39%) in 2001-2002 to 563 (42.68%) and 452 (43.34%) in 2006-2007 respectively.

### Geographical distribution of the first authors

In order to reflect the geographical distributions of authors, a comparison of the distribution of *WJG* authors was performed. The number of articles contributed to *WJG* by the top 15 countries (Table 3) was 5167 (90.82%), the number of articles contributed to *WJG* by Chinese authors was 136 (79.07%), 227 (96.19%), 548 (86.71%), 669 (82.39%), 884 (59.93%), 380 (28.81%) and 320 (30.68%), respectively, in 2001-2007. The number of articles contributed by Japanese authors increased from 0 (0%) in 2001-2002 to 287 (12.15%) in 2006-2007, the number of articles contributed by the American authors was also increased from 6 (1.47%) in 2001-2002 to 158 (6.69%) in 2006-2007. All countries, except for China showed an increased number of contributed articles.

Table 1 Co-author articles published in *WJG* during 2001-2007

Yr	Distribution of co-author articles											Total (articles)	Authors	Cooperation degree	Cooperation rate (%)
	1	2	3	4	5	6	7	8	9	10	> 11				
2001	9	18	20	33	26	20	20	14	5	2	6	173	884	5.11	94.80
2002	2	20	23	44	35	39	30	20	10	2	11	236	1313	5.56	99.15
2003	7	30	65	88	131	110	79	55	25	22	21	633	3637	5.75	98.89
2004	12	47	82	112	146	154	105	71	43	25	29	826	4755	5.76	98.55
2005	13	59	113	188	243	273	202	154	86	56	109	1496	9434	6.31	99.13
2006	46	111	149	169	210	191	150	119	74	57	106	1382	8160	5.90	96.67
2007	48	107	129	148	158	139	120	83	48	59	66	1105	6232	5.64	95.66
Total	137	392	581	782	949	926	706	516	291	223	348	5851	34415	5.88	97.66

Table 2 Geographical distribution of the authors in *WJG*

Yr	Distribution of the authors in 6 continents					
	Africa	Asia	Europe	North America	Oceania	South America
2001	0	136	32	4	0	0
2002	0	227	6	2	1	0
2003	1	575	45	6	2	3
2004	3	713	85	6	0	5
2005	7	1111	314	28	4	11
2006	11	712	453	110	10	23
2007	9	555	359	93	13	14

Among the top 15 countries, 7 are in Asia, 7 in Europe, and 1 in North America.

#### Data comparisons of gastroenterology-related journals

The articles of *Am J Gastroenterol*, *Gastroenterology* and *Scand J Gastroenterol* were selected to compare with those of *WJG*. *Am J Gastroenterol* is an official publication of the American College of Gastroenterology, and its IF was 5.608 in 2006, ranking 5<sup>th</sup> in Journal Citation Report (JCR). *Gastroenterology* is the official journal of the American Gastroenterology Association (AGA) and its IF was 12.457 in 2006, ranking 1<sup>st</sup> in JCR. *Scand J Gastroenterol* published by Taylor & Francis Group is the membership journal of the Gastroenterologic Societies of Denmark, Finland, Iceland, Norway and Sweden, and its IF was 1.869 in 2006. These four journals are most typical of all journals related to the field of gastroenterology. The number of articles published in *Am J Gastroenterol*, *Gastroenterology*, *Scand J Gastroenterol* and *WJG* covered in SCIE was 565, 586, 238 and 1118, respectively, in 2007. The cooperation degree of authors was 4.77, 6.14, 5.95 and 5.64, respectively; the cooperation rate was 95.40%, 84.18%, 96.63% and 95.66% respectively, in 2007. The geographical distribution of authors' was 44, 35, 42 and 62, respectively (Table 4). In 2007, The number of American authors contributing to *Am J Gastroenterol* and *Gastroenterology* accounted for 47.43% and 50.85% respectively, the number of Swedish authors contributing to *Scand J Gastroenterol* accounted for 18.07%, the number of Northern Europe authors contributing to *Scand J Gastroenterol* accounted for 45.38%, the number of Chinese authors contributing to *WJG* accounted for 30.4%.

## DISCUSSION

In 2001-2007, the number of articles covered in

Table 3 Distribution of the top 15 countries in *WJG* during 2001-2007

Country name	2001	2002	2003	2004	2005	2006	2007	Total
China	136	227	548	669	884	380	320	3164
Japan			6	19	133	170	117	445
Germany	10	2	4	10	68	92	66	252
Italy			9	15	56	79	56	215
United States	4	2	5	6	19	77	81	194
Turkey			17	24	31	43	62	177
South Korea			5	9	37	53	38	142
Greece			2	6	34	45	31	118
United Kingdom	18		3	1	16	28	22	88
India			5	2	7	35	30	79
Spain			1	2	13	34	21	71
Poland		1	2	6	31	17	4	61
Hungary			2	12	20	20	5	59
Iran			2	2	7	25	18	54
Thailand			1	4	14	16	13	48

*MEDLINE* was 173, 236, 633, 826, 1496, 1382 and 1105 respectively, the mean number of articles published in each issue was 28, 39, 52, 34, 31, 28 and 23 respectively. The number of articles published increased by 932 (638.73%) in 2007 compared to 2001.

In 2001-2007, the cooperation degree was 5.11, 5.56, 5.75, 5.76, 6.31, 5.90 and 5.64 respectively (mean 5.88), the cooperation rate was 94.80%, 99.15%, 98.89%, 98.55%, 99.13%, 96.67% and 95.66% respectively (mean 97.66%). The mean number of co-authors and single authors showed a tendency to increase from 2001 to 2005, while slightly decreased in 2006 to 2007.

The geographical distributions of authors in *WJG* were expanded from 4 continents in 2001 to the 6 continents in 2006-2007, the number of countries increased in multiple folds. The number of authors from Europe and North America increased while that from Asia decreased. The number of countries increased from 8, 8, 27, 32 and 49 in 2001-2005 to 61 and 56 in 2006-2007.

The number of Chinese authors accounted for 79.07%, 96.19%, 86.71%, 82.39%, 59.93%, 28.81% and 30.68% respectively, in 2001-2007, showing a maximum decrease of 67.38%. The number of Japanese, American, German and Italian authors increased greatly, showing an increasing trend of international authors contributing to *WJG*.

When compared with *Am J Gastroenterol*, *Gastroenterology*, *Scand J Gastroenterol*, the geographical distribution of

Table 4 Data comparisons of the 4 representative gastroenterology journals in 2007

Journal name	Articles published in 2007	Cooperation degree in 2007	Cooperation rate in 2007	Geographical distribution of authors	Ratio of articles contributed by domestic authors (%)
<i>Am J Gastroenterol</i>	565	4.77	95.40	44	United States 47.43
<i>Gastroenterology</i>	586	6.14	84.18	35	United States 50.85
<i>Scand J Gastroenterol</i>	238	5.95	96.63	42	Sweden 18.07
<i>WJG</i>	1118	5.64	95.66	62	China 30.4

authors in *WJG* was greatly expanded in the order of China, Asia and 6 continents. The mean number of published articles in each issue showed a prominent decrease, which may improve the quality of articles published in *WJG*. The cooperation degree and rate were reasonable, and the number of Chinese authors was slightly increased in 2007.

In conclusion, the geographical distribution of *WJG* authors is worldwide. *WJG* has made a step onto international level, thus drawing more attentions from gastroenterology researchers. The journal has become the main intermediary for international researchers in

gastroenterology to demonstrate their research accomplishments.

### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (WJG, ISSN 1007-9327 CN 14-1219/R) is a weekly open access peer-reviewed journal supported by an editorial board consisting of 1208 experts in gastroenterology and hepatology from 60 countries. The aim of the journal is to deliver the most clinically relevant original and commentary articles to readers, and to make the full text publicly available to all clinicians, scientists, patients and biomedical students on an unrestricted platform, so that they can access and learn about the most recent key advances in the field.

In addition to the open access nature, another key characteristic of WJG is its reading guidance for each article which includes background, research frontier, related reports, breakthroughs, applications, terminology, and comments of peer reviewers for the general readers.

WJG publishes articles on esophageal, gastrointestinal, hepatobiliary and pancreatic tumors, and other esophageal, gastrointestinal, hepatic-biliary and pancreatic diseases in relation to epidermiology, immunology, microbiology, motility & nerve-gut interaction, endocrinology, nutrition & obesity, endoscopy, imaging and advanced hi-technology.

The main goal of WJG is to publish high quality commentary articles contributed by leading experts in gastroenterology and hepatology and original articles that combine the clinical practice and advanced basic research, to provide an interactive platform for clinicians and researchers in internal medicine, surgery, infectious diseases, traditional Chinese medicine, oncology, integrated Chinese and Western medicine, imaging, endoscopy, interventional therapy, pathology and other basic medical specialties, and thus eventually improving the clinical practice and healthcare for patients.

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297 mm × 210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or

damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjgnet.com>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjgnet.com](mailto:submission@wjgnet.com), or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. font with ample margins. The preferred font is Book Antiqua. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was carried out; author contributions; disclosure of any financial support for the research; and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (remove all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s), and full family name.

**Author contributions:** The format of this section should be like this: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed research; Wang CL, Zou CC, Hong F and Wu XM performed research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed data; and Wang CL, Liang L and Fu JF wrote the paper.

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in WJG, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

#### Abstract

An informative, structured abstract of no more than 350 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipment, and the experimental procedures should be included. RESULTS: The observed and experimental results, including data, effects, outcome, *etc.* should be included. Authors should present *P* value where necessary, and also include any significant data. CONCLUSION: Accurate view and the value of the results should be included.

The format for structured abstracts can be found at: <http://www.wjgnet.com/wjg/help/11.doc>.

**Key words**

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

**Text**

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, should be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

**Illustrations**

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

**Tables**

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

**Notes in tables and illustrations**

Data that are not statistically significant should not be noted. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P* < 0.05 and <sup>d</sup>*P* < 0.01 are used. A third series of *P* values can be expressed as <sup>e</sup>*P* < 0.05 and <sup>f</sup>*P* < 0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

**Acknowledgments**

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

**REFERENCES****Coding system**

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

**PMID requirement**

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information for journal citations is very important. Using the reference testing system, the authors and editor should check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in an ASP file so that the readers can immediately access the abstract of the citations online.

**DOI requirement**

A CrossRef DOI® (Digital Object Identifier) name is a unique string created to identify a piece of scholarly content in the online environment. The author should supply the DOIs for journal citation (doi:10.3748/wjg.13.6458). This link (<http://www.crossref.org/SimpleTextQuery/>) allows you to retrieve Digital Object Identifiers (DOIs) for journal articles, books, and chapters by simply cutting and pasting the reference list into the box. You may use the form with any reference style, although the tool works most reliably if references are formatted in a standard style such as shown in this example: Assimakopoulos SF, Scopa CD, Vagianos CE. Pathophysiology of increased intestinal permeability in obstructive jaundice. *World J Gastroenterol* 2007; 13(48): 6458-6464

The accuracy of the information of journal citations is very important. We will interlink all references with DOI in ASP file so that readers can access the abstracts of cited articles online immediately.

**Style for journal references**

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

**Style for book references**

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

#### Patent (list all authors)

- 16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

### Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those linked with a hyphen when the difference between the two numbers is greater than five. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered inappropriate references. Authors should not cite their own unrelated published articles.

### Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

### Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as *v* (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

### Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5  $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: <http://www.wjgnet.com/wjg/help/15.doc>.

### Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless

they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

### Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindII*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *H pylori*, *E coli*, etc.

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

### Editorial Office

#### World Journal of Gastroenterology

Editorial Department: Room 903

Ocean International Center, Building D

No. 62 Dongsihuan Zhonglu

Chaoyang District, Beijing 100025, China

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

Telephone: +86-10-59080039

Fax: +86-10-85381893

### Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

### Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/9.doc>.

### Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/10.doc>.

### Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

### Links to documents related to the manuscript

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

### Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

### Publication fee

Authors of accepted articles must pay a publication fee.

EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

## Contents

### EDITORIAL

- 3117 Liver transplantation: Yesterday, today and tomorrow  
*Abbasoglu O*

### REVIEW

- 3123 Strategy for treatment of nonerosive reflux disease in Asia  
*Hiyama T, Yoshihara M, Tanaka S, Haruma K, Chayama K*

### TOPIC HIGHLIGHT

- 3129 Intraductal biliary and pancreatic endoscopy: An expanding scope of possibility  
*Judah JR, Draganov PV*
- 3137 Pain management in chronic pancreatitis  
*Gachago C, Draganov PV*
- 3149 Pancreatic function testing: Here to stay for the 21st century  
*Lieb II JG, Draganov PV*

### CLINICAL RESEARCH

- 3159 Analysis of surgical and perioperative complications in seventy-five right hepatectomies for living donor liver transplantation  
*Gruttadauria S, Marsh JW, Vizzini GB, di Francesco F, Luca A, Volpes R, Marcos A, Gridelli B*

### RAPID COMMUNICATION

- 3165 Treatment and survival in a population-based sample of patients diagnosed with gastroesophageal adenocarcinoma  
*Cronin-Fenton DP, Mooney MM, Clegg LX, Harlan LC*
- 3174 *In vitro* activity of moxifloxacin and piperacillin/sulbactam against pathogens of acute cholangitis  
*Weber A, Huber W, Kamereck K, Winkle P, Voland P, Weidenbach H, Schmid RM, Prinz C*
- 3179 Are acute exacerbations of chronic inflammatory appendicitis triggered by coprostanosis and/or coproliths?  
*Sgourakis G, Sotiropoulos GC, Molmenti EP, Eibl C, Bonticous S, Moege J, Berchtold C*
- 3183 Retrospective analysis of old-age colitis in the Dutch inflammatory bowel disease population  
*Hadithi M, Cazemier M, Meijer GA, Bloemena E, Felt-Bersma RJ, Mulder CJ, Meuwissen SGM, Peña AS, van Bodegraven AA*
- 3188 Effect of probiotic *Lactobacillus rhamnosus* GG intervention on global serum lipidomics profiles in healthy adults  
*Kekkonen RA, Sysi-Aho M, Seppänen-Laakso T, Julkunen I, Vapaatalo H, Orešič M, Korpela R*
- 3195 Factors that influence outcome in non-invasive and invasive treatment in polycystic liver disease patients  
*Barahona-Garrido J, Camacho-Escobedo J, Cerda-Contreras E, Hernández-Calleros J, Yamamoto-Furusho JK, Torre A, Uribe M*

- 3201** Hepatitis B virus prevalence and transmission risk factors in inflammatory bowel disease patients at Clementino Fraga Filho university hospital  
*Tolentino YFM, Fogaça HS, Zaltman C, Ximenes LLL, Coelho HSM*
- 3207** Contrast-enhanced intraoperative ultrasonography equipped with late Kupffer-phase image obtained by sonazoid in patients with colorectal liver metastases  
*Nakano H, Ishida Y, Hatakeyama T, Sakuraba K, Hayashi M, Sakurai O, Hataya K*
- 3212** Incidence of reflux esophagitis and *Helicobacter pylori* infection in diabetic patients  
*Ariizumi K, Koike T, Ohara S, Inomata Y, Abe Y, Iijima K, Imatani A, Oka Y, Shimosegawa T*
- 3218** Reactive oxygen species and chemokines: Are they elevated in the esophageal mucosa of children with gastroesophageal reflux disease?  
*Tutar E, Ertem D, Unluguzel G, Tanrikulu S, Haklar G, Celikel C, Ademoglu E, Pehlivanoglu E*
- 3224** Prognostic factors in patients with advanced cholangiocarcinoma: Role of surgery, chemotherapy and body mass index  
*Farhat MH, Shamseddine AI, Tawil AN, Berjawi G, Sidani C, Shamseddeen W, Barada KA*
- 3231** Prevention and treatment of gastrointestinal dysfunction following severe burns: A summary of recent 30-year clinical experience  
*Xiao SC, Zhu SH, Xia ZF, Lu W, Wang GQ, Ben DF, Wang GY, Cheng DS*
- 3236** Venous diethylene glycol poisoning in patients with preexisting severe liver disease in China  
*Lin BL, Zhao ZX, Chong YT, Li JG, Zuo X, Tao Y, Lou TQ, Gao ZL*
- 3242** Effects of quercetin on hyper-proliferation of gastric mucosal cells in rats treated with chronic oral ethanol through the reactive oxygen species-nitric oxide pathway  
*Liu JL, Du J, Fan LL, Liu XY, Gu L, Ge YB*
- 3249** Proteasome inhibitor ameliorates severe acute pancreatitis and associated lung injury of rats  
*Chen X, Li SL, Wu T, Liu JD*
- 3254** Change of intestinal mucosa barrier function in the progress of non-alcoholic steatohepatitis in rats  
*Li S, Wu WC, He CY, Han Z, Jin DY, Wang L*

**CASE REPORT**

- 3259** Multiple giant diverticula of the foregut causing upper gastrointestinal obstruction  
*Balducci G, Dente M, Cosenza G, Mercantini P, Salvi PF*
- 3262** Acute ischemic colitis during scuba diving: Report of a unique case  
*Goumas K, Poulou A, Tyrmpas I, Dandakis D, Bartzokis S, Tsamouri M, Barbati K, Soutos D*
- 3266** A symptomatic cyst of the ligamentum teres of the liver: A case report  
*Lagoudianakis EE, Michalopoulos N, Markogiannakis H, Papadima A, Filis K, Kekis P, Katergiannakis V, Manouras A*

## Abstract

With the advances in technical skills, management of postoperative complications and improvements in immunosuppressive drugs, liver transplantation is the standard treatment for many patients with chronic liver disease. Today, shortage of donor organs seems to be the major limiting factor for the application of liver transplantation. This review focuses on five issues that are challenging to clinical practice of liver transplantation and relevant to gastroenterologists. These include living donor liver transplantation, recurrent viral hepatitis, non-heart-beating donors, hepatocellular carcinoma, and ABO incompatible liver transplantation. Living donor and non-heart beating donor transplantations were initiated as a solution to increase the donor organ pool and it is expected that there will be an increase in the number of these donors. Recurrent hepatitis C and hepatocellular carcinoma following liver transplantation are among major problems and ongoing research in these diseases may lead to better outcomes in these recipients.

## INTRODUCTION

Liver transplantation is one of the most important advances in medicine. First cadaveric liver transplantation was performed by Thomas Starzl in 1963 in Denver. After this failed trial, liver transplantation was successfully performed in humans in July 1967 again by Dr. Starzl. Although rejection was a major concern, many recipients from this early era have survived for more than 20 years using immunosuppression with azathioprine, prednisone, and antilymphocyte globulin (ALG)<sup>[1]</sup>.

For clinical transplantation, the historical beginning was Medawar's recognition that rejection is an immune reaction<sup>[2]</sup> (Table 1). With the advances in immunosuppression, postoperative care and surgical technique, liver transplantation has become the golden standard in the treatment of many chronic liver diseases. Since then, the number of patients on the waiting list has increased and organ shortage appeared to be one of the major problems in clinical transplantation.

Raia of Brazil performed the first living donor liver transplantation (LDLT) in 1987 as a promising method to resolve the organ shortage, but the recipient died of a transfusion reaction despite a successful operation<sup>[3]</sup>. After this trial, LDLT has been performed by many other pioneer surgeons in other countries. In the last decade LDLT has become a widely accepted treatment modality. The most extensive experience in LDLT was initially gained in Asia. In countries such as Japan, where the availability of organs from deceased donor is limited, LDLT seems to be the only solution in the treatment of end stage liver diseases. According to the data of Japanese Liver Transplantation Society, the adult to adult LDLT is increasing per year. Despite this increase in adults, cases in children have reached a peak around 100 cases per year. The 1 and 5-year survival rates of all recipients were reported to be 81.8%, and 77%, respectively, while those of recipients of less than 18 years old was 85.6%, and 82.6% respectively. The prognosis of adult recipients was poor when compared to children<sup>[4]</sup>. It was suggested that the original disease recurrence such as hepatitis C and hepatocellular carcinoma (HCC) has influenced a significant decline in the survival of adult cases.

## MAJOR ISSUES RELATED WITH LIVER TRANSPLANTATION

### LDLT

The shortage of cadaveric liver organs has significantly

**Table 1** History of liver transplantation<sup>[1,3]</sup>

Yr	Author	Application
1943	Gibson	Defined the immunologic nature of skin allograft rejection in humans
1955	Welch	First mention of liver transplantation in the literature in a dog study
1960	Medawar	Definition of acquired transplantation tolerance
1960	Starzl	Transplantation in dogs of multiple abdominal viscera
1963	Starzl	World's first three attempts of liver transplantation in humans with maximum survival of 21 d
1968	Starzl	First long-term survival of four patients after liver transplantation
1978	Calne	Introduction of cyclosporine
1984	Bismuth	Reduced-sized adult liver transplanted into a small child
1987	Raia	First living donor liver transplantation
1988	Pichlmayr	Split one donor liver and two graft were used for two recipients
1988	Kalayoglu	Introduction of University of Wisconsin solution for preservation
1992	Starzl	Baboon to human xenotransplantation

inhibited further expansion of liver transplantation. Split liver transplantation has reduced waiting-list mortality in children, but not in adults. LDLT is currently the most effective alternative to overcome the organ shortage in adults. With the efforts of transplant surgeons in the establishment and popularization of LDLT, the number of LDLT has increased dramatically not only in Japan but also in Europe and the United States as well. Major advantages of LDLT include the good viability of the liver harvested from a healthy individual, the careful selection of the timing of the transplantation, and the potential good tissue matching. The reduced waiting period for a living donor organ may decrease the risks of decompensation or death before transplantation, thereby improving the overall chances for success. Disadvantages are the risk to healthy donors and also that, this modality has a potential psychological burden on the donor<sup>[5,6]</sup>. The surgical procedures for LDLT are technically more challenging and LDLT requires a full understanding of the hepatobiliary anatomy.

A wide range of complication rates are reported in the literature in donors after LDLT. Donor safety has a major importance in LDLT. Published reports on donor outcomes indicated a wide range of complication rates that varied between 9% and 67%<sup>[7,8]</sup>. In the Kyoto University experience 50 complications in 222 right lobe grafts have been encountered, including surgical complications is 18.5% and non-surgical complications is 3.2%<sup>[9]</sup>. On the other hand, the American Society of Transplant Surgeons reported a donor complication rate of only 10%. Thus it seems that donor morbidities have not been adequately reported and true extend of complications may be underestimated. A standardized system for reporting complications to a registry should be developed to allow meaningful data analysis. Donor mortality is also a major concern of LDLT. In the United States at least 3 deaths were confirmed. Another 3 deaths in Europe and 1 in Japan had been reported<sup>[10]</sup>.

As living donation permits transplantation to take place independent of either waiting time or the severity of liver disease, the criteria required for LDLT may be modified when compared to deceased donor liver transplantation (DDLT). Estimation of liver volume needed in individual situations is an important factor in donor selection. Aged liver, steatotic liver, and special anatomic variants have the risk of a relatively poor graft quality. Recipient factors such as metabolic load, preoperative latent infections and other organ failures have negative impact on graft survival. The minimally required quantity of graft volume has not been fully clarified, which is one of the major issues of the adult to adult LDLT. The following two methods were developed to express the graft volume: First the ratio of graft volume (GV) in the standard liver volume (SLV) of the recipient, which is calculated by the recipient's height and body weight. Second, the ratio of graft weight in the recipient's weight (GRWR: graft to recipient weight ratio). The reported safe limit of small-for-size graft is from 30% to 40% in GV/SLV, while from 0.6 to 0.8 in GRWR<sup>[11-14]</sup>.

Recipients with a small-for-size graft, suffer from graft dysfunction including hyperbilirubinemia, massive ascites, poor synthetic function that leads to serious conditions such as gastrointestinal bleeding and renal failure. When a graft size is conversely too large for a recipient such as a newborn infant, the graft necrosis occurs due to insufficient blood inflow into the graft.

As pointed out by Ghobrial and Bussuttil, future application of LDLT will be based on the accurate definition of risks imposed on donors compared with potential benefits realized by recipients<sup>[15]</sup>. As an example to this statement, the number of adult LDLT declined from approximately 400 in 2001 to 280 in 2002. Such a precipitous reduction may have occurred in response to the donor death in US in 2002 which raised increasing concerns for donor safety. While the number of LDLT in the US has declined, the number in Asia as a whole has continued to increase. LDLT accounted for less than 5% of liver transplants in the US but more than 95% of the transplants in Asia excluding mainland China. The overall number of LDLT procedures performed in Asian countries and areas with well-established programs (Japan, Korea, China Hong Kong and China Taiwan) has steadily increased over years<sup>[16]</sup>.

In summary, the overall results with good patient and graft survival, together with acceptable donor morbidity and mortality has led to the acceptance of LDLT in the transplant community. To maintain this procedure as a treatment modality in the future, satisfactory risk-benefit analysis and long-term morbidities imposed on living donors should be further investigated.

### Recurrent viral hepatitis

The most common single cause of late graft loss after liver transplantation is the recurrence of the disease for which the liver transplantation has been performed<sup>[17]</sup>. Until last decade, successful long-term outcome after liver transplantation in patients with chronic active hepatitis-B has been limited because of high rate of recurrent

of recurrent hepatitis. Long-term passive immunization with high-dose intravenous hepatitis B immunoglobulin (HBIG) led to a significant improvement in the prognosis of these patients. High-dose intravenous HBIG may prevent recurrent hepatitis B virus infection, but the cost has limited its widespread use in countries with endemic hepatitis B virus infection. Low-dose intramuscular HBIG plus nucleoside analogs such as lamivudine was shown to be equally effective and safe and in the long-term prophylaxis against recurrent hepatitis B at less than 10% the cost of the high-dose regimen<sup>[18,19]</sup>. Although lamivudine is effective in most of the patients, lamivudine resistance is becoming a major concern. With adefovir, a potent antiviral drug that became available in recent years, these patients with lamivudine-resistant tyrosine-methionine-aspartate-aspartate mutant can also be treated<sup>[20,21]</sup>. Currently, liver transplantation can be safely performed in chronic active hepatitis B patients with similar survival as for patients transplanted for other indications.

The recurrence of hepatitis C is also a great concern after transplantation. Although short-term graft and patient survival rates of chronic active hepatitis C patients are comparable to those observed in other patients undergoing liver transplantation, HCV recurrence is universal and is associated with poor graft and patient survival<sup>[22]</sup>. In contrast, survival after retransplantation for recurrent hepatitis C is poor and retransplantation for these patients is controversial<sup>[23,24]</sup>. In a previous study Abbasoglu *et al* showed that recurrent hepatitis was the most common cause of late graft loss in patients who had undergone liver transplantation for chronic active hepatitis C<sup>[17]</sup>.

Treatment of recurrent hepatitis C, whether pre-emptive or not, is an important issue. Despite recent achievements in the treatment of hepatitis C infection with pegylated interferons and ribavirin, patients with recurrent hepatitis C after liver transplantation are difficult to treat. Virological response rates in prophylactic and therapeutic approaches of hepatitis C reinfection after liver transplantation are low compared to the pre-cirrhotic hepatitis C infection. Moreover, optimal treatment duration and dosage of recurrent infection with pegylated interferon in combination with ribavirin remains to be defined<sup>[25]</sup>. Despite side effects, long-term antiviral maintenance therapy might be an effective approach for preventing progression to severe allograft fibrosis and thereby improving long-term survival in liver transplant recipients with recurrent hepatitis C<sup>[26]</sup>.

Two large studies have shown that the incidence and severity of hepatitis C recurrence do not differ between DDLT and LDLT recipients; however another study has found that the incidence of cholestatic hepatitis is significantly greater in LDLT recipients<sup>[24,27,28]</sup>. Several studies have identified a number of potential risk factors for recurrent hepatitis C infection including hepatitis C virus related factors (virus load, genotype) as well as coinfection with other viruses such as cytomegalovirus, hepatitis B virus and hepatitis D virus<sup>[29]</sup>. There are still no well-defined parameters that would predict which patients are

at risk to develop recurrent hepatitis C and those who will not. Strategies including pre- and post-transplant antiviral therapy may further improve the results.

### **Non-heart-beating donors**

The first liver transplantation from a non-heart beating donor (NHBD) was performed by Nakayama in Japan in 1964. NHBD livers are considered as a potential for expanding donor pool. The critical problem with NHBD livers is prolonged warm ischemia time. Despite calls for the use of hepatic grafts from NHBD, there are few studies examining long-term outcome. Although metabolism is slowed 1.5- to 2-fold for every 10°C drop in temperature, considerable metabolic activity still occurs during cold preservation. In NHBD organs, the effects of cold ischemia are superimposed on the injury occurred during warm ischemia. The pattern of injury sustained during warm and cold ischemia is slightly different. Cold ischemia leads to initial injury to sinusoidal endothelial cells whereas warm ischemia mainly injures the hepatocytes<sup>[30]</sup>. It seems that the additional injury resulting from warm ischemia in NHBD donation requires alternative preservation strategies to minimize the ischemic injury. Donor warm ischemic time may predispose hepatic allografts to an increased incidence of ischemic type biliary strictures. Although graft and patient survival has been reported to be similar to that of heart beating donor transplants, caution is urged with the use of these organs<sup>[31]</sup>.

Despite the increased risk of graft and patient survival, NHBD livers are being increasingly used with acceptable results. Abt *et al* analyzed data from the United Network for Organ Sharing database. In 144 NHBDs and 16856 heart beating donors (NHBDs) the 1-year (70.2% *vs* 80.4%) and 3-year (63.3% *vs* 72.1%) graft survival were inferior in the NHBD group. The primary non-function risk after transplantation was also significantly higher (11.8 % *vs* 6.4%) in the NHBD group<sup>[32]</sup>.

New strategies in organ preservation, normothermic recirculation, normothermic preservation, cytoprotection, and development of reliable markers to predict postoperative graft function may improve results in clinical transplantation with NHBD liver grafts. Based on the clinical studies and continued shortage of liver allografts, the use of NHBD organs are recommended, however, with several caveats. Careful donor (< 60 years of age) and recipient (stable, not intubated) selection, minimizing warm (< 30 min) and cold (< 8 h) ischemia, utilization of histology, and discarding organs with significant steatosis may provide acceptable results<sup>[32,33]</sup>.

### **HCC**

HCC is the most common primary liver cancer and most patients with HCC also suffer from coexisting cirrhosis. For the treatment of patients without cirrhosis, resection should be considered whenever possible. Hepatic reserve is the one of the major determinants of liver resection. When compared with resection, transplantation restores liver function and has the advantage of removing tissue with an oncogenic potential<sup>[34]</sup>. To obtain the optimal

benefit from the limited number of organs available, strict selection criteria has been developed to offer liver grafts to patients with the highest likelihood of survival after transplantation. In 1996 Mazzaferro *et al* showed that when strict criteria were applied, transplantation of patients with early HCC has resulted in excellent results with 4-year survival rate of 75%. This led to the development of Milan criteria from a retrospective analysis of 48 patients. This survival rate was achieved in patients with solitary tumor of less than 5 cm and those who have up to 3 tumor nodules each of which is smaller than 3 cm without vascular invasion or extra hepatic metastasis<sup>[35]</sup>. With the achievement of good results in HCC patients with more advanced tumors, the Milan criterion was expanded. Yao *et al* proposed UCSF criteria (solitary tumor smaller than 6.5 cm or 3 of fewer nodules with the largest lesion smaller than 4.5 cm or total tumor diameter less than 8.5 cm without vascular invasion<sup>[36]</sup>. In this study the expansion of Milan criteria did not impact on survival adversely. On the other hand, this approach reduced the availability of cadaveric grafts for patients with other liver diseases. The Barcelona Clinic Liver Cancer Group has proposed expanding the Milan criteria to single tumor of 7 cm or less, or 5 tumors of 3 cm or less, in patients who showed a partial response to any treatment lasting for more than 6 mo<sup>[37]</sup>. However organ shortage, higher drop-out rate, and less favorable results render these attempts to a controversial issue. With the expansion of listing criteria, liver transplantation could be performed in more advanced cancer patients but this lead in turn to poor survival rates. All patient selection criteria rely on radiological imaging to assess intrahepatic disease and exclude extra hepatic spread. It may be possible to improve patient selection by increasing the sensitivity of imaging studies and detection of micrometastasis<sup>[38]</sup>.

About 50% of HCC patients who are initially candidates for liver transplantation will become ineligible, if the median waiting period exceeds 1 year<sup>[39,40]</sup>. As a result of tumor progression during the waiting period, LDLT gained popularity to transplant HCC patients in a better clinical condition without a long waiting time. Although controversial, it may be claimed that LDLT can be performed in patients with HCC that exceeds the Milan criteria as 3-year survival rate of greater than 50 has been showed in other studies<sup>[41]</sup>. In two studies it was shown that LDLT is superior to DDLT for patients with HCC meeting Milan criteria, when waiting times for organs from deceased donors exceed six months<sup>[42,43]</sup>. Despite the availability of LDLT tumor progression is still a major concern and strategies like chemoembolization and radiofrequency ablation to reduce tumor growth during waiting period have shown promising results<sup>[44]</sup>. Although many studies have shown that microvascular invasion and histological grade are significant risk factors for poor prognosis, these are difficult to know clearly before transplantation. Noninvasive markers to predict the prognosis of HCC may help better patient selection in the future<sup>[45]</sup>.

### **ABO incompatible liver transplantation**

Two antigen systems (ABO and HLA) play role in trans-

plantation. In liver transplantation the ABO system is important while HLA system has a minor role. Crossing the ABO barrier in liver transplantation is usually not performed except for emergency conditions and results of ABO incompatible liver transplantation have been markedly inferior with an increased incidence of vascular and biliary complications and rejection, when compared to ABO compatible grafts. In children below the age of three years, ABO incompatible liver transplantations have been more successful<sup>[46]</sup>. In recent years, promising results with ABO incompatible liver transplantation using A<sub>2</sub> donors (subgroup of A which is less reactive and occur in approximately 20% of group A individuals) have been reported. In a Swedish study of 10 adult blood group O recipients who received A<sub>2</sub> cadaveric grafts, patient and graft survival was 10/10 and 8/10 respectively at 8.5 mo median follow up with tacrolimus based protocol and initial immunosuppression with antithymocyte globulin, interleukin-2-receptor antagonists or anti-CD20 antibody<sup>[47]</sup>. In 16 pediatric ABO-incompatible pediatric liver transplantation, Heffron *et al* reported one-year actuarial graft survival of 92% utilizing standard immunosuppression with selective post-operative plasmapheresis and without splenectomy<sup>[48]</sup>. Plasmapheresis may be useful by reducing the recipients' antibody titers before and after transplantation. ABO incompatible liver transplantation may be the only available option in LDLT, if the patients have no ABO identical or compatible donors. According to the Japanese Registry of LDLT Across ABO Blood Type Barrier, 97 ABO incompatible LDLTs were performed in Japan before 2005 and 5-year survival rate of the patients was 38% before 2001 and improved to 63% among patients who underwent transplantation after 2002<sup>[49]</sup>.

Although recent studies support the concept of ABO-incompatible liver transplantation both in adults and children, further studies are needed to draw a conclusion. More well-designed, controlled clinical trials are necessary to establish optimal pretransplantation management protocols including immunosuppressive regimens in this group of patients.

### **CONCLUSION**

Liver transplantation is the only definitive treatment modality of end stage liver diseases. Although LDLT has been widely performed with results similar to whole organ cadaveric transplantation, the benefits of the recipients *versus* the risks and long-term morbidities imposed on the donors require further studies. The overall reported donor mortality is 12 in about 6000 transplantations (0.2%)<sup>[50]</sup>. Recurrent viral hepatitis and HCC are among the major causes of late graft loss after liver transplantation. Current antiviral treatment for recurrent HCV offer limited chance of long-term success. To overcome organ shortage there is now a resurgence of interest in NHBD liver transplantation. Although ABO incompatible liver transplantation especially using A<sub>2</sub> donors is promising particularly in children, more studies are needed to draw a conclusion.

### INTRODUCTION

Gastroesophageal reflux disease (GERD) is a condition that develops when reflux of stomach contents causes troublesome symptoms and/or complications<sup>[1]</sup>. GERD is more common in Western countries than in Asian countries, such as China, Korea, and Japan. Epidemiologic studies show a prevalence of GERD symptoms in Western countries ranging from 20% to 40%<sup>[2,3]</sup> and in Asian countries ranging from 5% to 17%<sup>[4]</sup>. The prevalence in Asian countries has increased gradually<sup>[4]</sup>. Esophagogastroduodenoscopy (EGD) is the gold standard for the diagnosis of erosive GERD [reflux esophagitis (RE)], and the Los Angeles (LA) classification of esophagitis is generally accepted as the best means for endoscopic assessment of GERD<sup>[5]</sup>. In Japan, the prevalence of RE (LA classification grades A, B, C, and D) is approximately 15%, and most of these cases are grade A or B<sup>[6]</sup>. The majority of GERD cases are cases of nonerosive reflux disease (NERD).

NERD was previously considered a mild/early type of RE that would progress to severe RE. However, it was reported that, regardless of therapy, only 2.7% of NERD patients develop RE after 3 years and only 3% of patients develop RE after 6 years<sup>[7]</sup>. A recent retrospective study of 2306 GERD patients found that these patients at least two separate upper endoscopic examinations during the 7-year (mean) follow-up period. Examinations revealed that 69% of the patients were unchanged, 21% were improved, and 11% became worse<sup>[8]</sup>. Another study<sup>[9]</sup> reported similar results. These studies suggest that NERD rarely progresses to RE over time. In addition, NERD is significantly more refractory to treatment than RE<sup>[3]</sup>. Therefore, it was recently suggested that the underlying mechanism of development of NERD is different from that of RE. Here we review the clinical and pathophysiologic differences between NERD and RE and propose a treatment strategy for NERD, especially for patients in Asia.

### Abstract

The paper is to review the clinical and pathophysiologic differences between of nonerosive reflux disease (NERD) and reflux esophagitis (RE), and to propose a treatment strategy for NERD, especially for patients in Asia. A Medline search was performed regarding the clinical and pathophysiologic differences between NERD and RE, and treatment of NERD and RE. The characteristics of NERD patients in Asia are as follows: (1) high proportion of female patients, (2) low frequency of hiatal hernia, (3) high frequency of *H pylori* infection, (4) severe glandular atrophy of the gastric mucosa, and (5) frequent resistance to proton pump inhibitor (PPI) therapy. In Asian NERD patients, exposure of the esophagus to acid is not increased, and esophageal motility is normal. These characteristics are similar to those of patients in Western countries. Our recommended first-choice treatment is administration of PPI in combination with a prokinetic agent. However, at present, because there is limited evidence regarding effective treatments for NERD, it is best to try several different treatment strategies to find the best treatment for each patient.

**Table 1 Clinical characteristics of NERD and RE patients in Asia**

	NERD	RE
Male/Female	0.59-1.65	1.18-7.13
Average age (yr)	45.2-57.5	49.0-59.7
Mean body mass index (kg/m <sup>2</sup> )	22.1-23.1	21.7-24.2
Complication of hiatal hernia (%)	17.7-34.8	35.1-77.0
<i>H pylori</i> infection (%)	36.3-48.3	18.0-32.3
Glandular atrophy of the gastric mucosa (open-type) (%)	25.0-43.0	6.7-25.0
Efficacy of proton pump inhibitor (%)	29.5-64.0	55.4-90.3

## METHODS

Studies on GERD were identified by computerized and manual searches of the available literature. The Medline search (1975-2007) was performed using the following medical subject headings: reflux disease and Asia. Papers published in English were considered.

## CLINICAL AND ESOPHAGEAL MOTILITY CHARACTERISTICS OF NERD IN ASIA

Several researchers examined characteristics of NERD and RE patients in Asia<sup>[10-18]</sup>. The male/female ratios ranged from 0.59 to 1.65 in NERD patients. On the other hand, those of RE patients ranged from 1.18 to 7.13. A higher proportion of female patients was observed in NERD patients compared with RE patients. There were differences between NERD patients and RE patients in frequency of hiatal hernia, frequency of *H pylori* infection, grade of glandular atrophy of the gastric mucosa, and effect of proton pump inhibitor (PPI) therapy as well. Namely, compared with the RE patients, the characteristics of NERD patients in Asia are as follows: (1) higher proportion of female patients, (2) lower frequency of hiatal hernia, (3) higher frequency of *H pylori* infection, (4) severe glandular atrophy of the gastric mucosa, and (5) frequent resistance to PPI therapy (Table 1). In addition, Asian NERD patients are more frequently affected by functional dyspepsia, irritable bowel syndrome, and psychiatric diseases than RE patients<sup>[13]</sup>. These characteristics are similar to those of Western NERD patients. However, there are several other characteristics in Western NERD patients, such as younger age and less obese<sup>[3]</sup>. As the prevalence of *H pylori* infection in Asian populations has decreased to levels similar to those in Western populations, these additional characteristics may be observed in Asian patients in the near future.

With respect to esophageal motility, NERD patients have several characteristics that differ from those of RE patients. In NERD patients, the resting lower esophageal sphincter (LES) pressure is not decreased. In addition, exposure of the esophagus to acid is not increased, and esophageal motility is normal (Table 2)<sup>[19]</sup>. These characteristics are similar to those of patients in Western countries, although the grades of motility index abnormalities in Asian RE patients are lower than those in Western RE patients<sup>[20]</sup>.

**Table 2 Esophageal motility characteristics in NERD and RE patients in Asia**

	NERD	RE
Resting LES pressure	Mildly increased	Moderately decreased
Reflux episodes/hour	Moderately increased	Moderately increased
Primary peristalsis	Normal	Moderately decreased
Secondary peristalsis	Mildly decreased	Moderately decreased
Acid clearance	Mildly delayed	Moderately delayed

LES: Lower esophageal sphincter.

It seems that there are differences in pathophysiology between Asian RE patients and Western RE patients, because the grades of motility index abnormalities are different between them. However, there seems no significant difference in pathophysiology between Asian NERD and Western NERD patients, because clinical and esophageal motility characteristics are considerably similar between them.

## PATHOPHYSIOLOGY OF NERD

The main pathophysiology of RE is excessive exposure of the esophagus to gastric acid. Approximately 90% of patients with RE can be cured with a PPI, which is the strongest type of gastric acid suppressor<sup>[3]</sup>. In contrast, only one-third of NERD patients can be cured with a PPI. Although the cause of NERD that is responsive to PPI may be excessive exposure of the esophagus to acid, PPI-resistant NERD may be associated with the factors described below.

### Incomplete acid suppression

In some patients, even the highest approved dose of PPI cannot sufficiently suppress gastric acid secretion. In patients with insufficient gastric acid suppression, gastric juice may reflux, exposing the esophagus to acid. The time required for metabolism of PPI differs between patients possibly due to polymorphisms in the genes encoding metabolic enzymes, such as CYP2C19<sup>[21,22]</sup>. In patients with the rapid metabolic phenotype, administration of twice the approved dose of PPI and concomitant administration of PPI and H<sub>2</sub>-receptor antagonist (H<sub>2</sub>RA) may be more effective<sup>[23,24]</sup>. It has also been reported that administration of an aluminum- and magnesium-containing antacid may be effective for some NERD patients<sup>[25]</sup>.

### Esophageal hypersensitivity to acid

Some patients with severe RE do not have symptoms of acid regurgitation, even if severe esophageal acid exposure is confirmed<sup>[26]</sup>. However, many NERD patients have a normal level of esophageal acid exposure. Therefore, there appears to be significant esophageal hypersensitivity to acid exposure in PPI-resistant NERD patients, and symptoms may occur when gastric acid is refluxed<sup>[27]</sup>. Hyperosmotic foods, such as cake and chocolate, and alcoholic beverages may be the cause of this esophageal hypersensitivity<sup>[28]</sup>. Ingestion of such

foods and drinks may cause heartburn. It has been suggested that ingestion of hyperosmotic foods/drinks loosens the tight junctions between esophageal epithelial cells, and when gastric acid is refluxed, it easily intrudes between epithelial cells and stimulates the terminals of sensory nerves<sup>[26]</sup>.

### **Esophageal hypersensitivity to esophageal wall distension**

In NERD patients, heartburn symptoms are induced by distension of the esophageal wall by balloon dilatation or by pumping saline into the esophageal lumen<sup>[29]</sup>. These findings suggest the possibility that foods, air, and fluids that contain no acid may cause heartburn symptoms simply by distending of the esophageal wall.

### **Reflux of duodenal juice (bile and pancreatic juice)**

PPI suppresses gastric acid excretion but has no effect on reflux itself. Therefore, in patients with duodenogastric reflux, duodenal juice (bile and pancreatic juice) may be refluxed into the esophagus. It is possible that the refluxed duodenal juice may affect the esophageal mucosa<sup>[30]</sup>. NERD patients frequently have functional dyspepsia<sup>[4]</sup>, and significant duodenogastric reflux and delayed gastric emptying time in patients with functional dyspepsia have been reported<sup>[31,32]</sup>. These findings support the idea that reflux of duodenal juice into the esophagus causes NERD.

### **Esophageal motility abnormalities**

It has been reported that NERD patients show normal resting LES pressure and primary contraction waves but significantly reduced frequency of secondary contraction waves<sup>[19,33]</sup>. This may be due to a reduced response to distension of the esophageal wall. Secondary contraction waves are stimulated by distension of the esophageal wall and act to discharge refluxed gastric acid and air into the stomach. Heartburn symptoms may be associated with reduced motility function in the esophageal wall.

### **Sustained esophageal contraction**

Sustained contraction of the longitudinal muscles of the esophagus causes heartburn, and prolonged contraction may lead to chest pain. This phenomenon is called sustained esophageal contraction (SEC) and is identified by intraluminal ultrasonography<sup>[34,35]</sup>. SEC occurs just before the onset of heartburn symptoms. There are two types of SEC: SEC with or without subsequent acid reflux. Because patients with the latter type also have heartburn symptoms, the association of SEC with NERD is of great interest.

### **Psychological factors**

NERD patients frequently have mental disorders<sup>[13]</sup>. Psychological factors are associated with response to treatment as well as symptoms<sup>[36]</sup>. A high level of anxiety is predictive for the nonresponse to acid suppression therapy.

### **Eosinophilic esophagitis**

Eosinophilic esophagitis affects both children and adults

and is characterized by symptoms of GERD and dense esophageal eosinophilia, both of which are unresponsive to PPI<sup>[37,38]</sup>. This disease is caused by food allergies or by aeroallergens. Effective treatment include systemic/topical corticosteroids, or specific food elimination. Esophageal stricture is a potential complication, and the natural history of the disease is still unknown. Eosinophilic esophagitis may be diagnosed as PPI-resistant NERD, but should be excluded from the diagnosis of NERD.

## **TREATMENT STRATEGY FOR NERD IN ASIA**

At present, PPI-based step-down treatment is recommended for GERD patients<sup>[39,40]</sup>. In a meta-analysis, the relative risks of PPI and H<sub>2</sub>RA treatment for NERD compared with placebo were 0.69 (95% confidence interval, 0.62-0.78) and 0.84 (0.74-0.95), respectively, indicating that PPI is a more effective treatment than H<sub>2</sub>RA<sup>[41]</sup>. PPI treatment can eliminate NERD symptoms faster than H<sub>2</sub>RA treatment. In addition, PPI treatment has been reported to be more cost-effective than other treatment<sup>[42]</sup>.

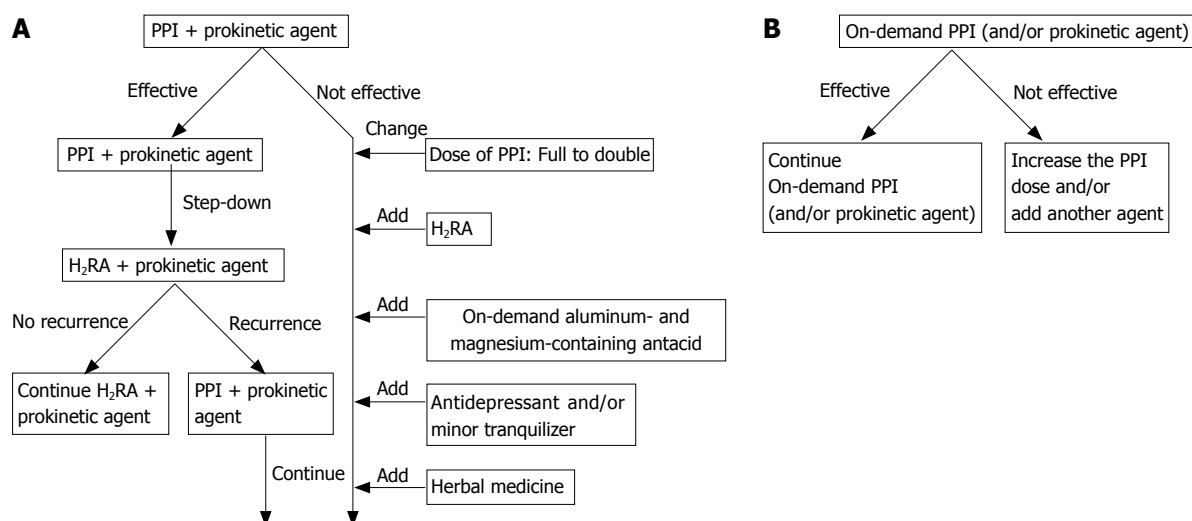

Prokinetics such as mosapride, itopride, metoclopramide, and domperidone are also effective for treatment of NERD<sup>[43-45]</sup>. Prokinetics are thought to work by reducing reflux of duodenal juice into the esophagus<sup>[31]</sup> and speeding absorption of PPI. In addition, mosapride improves esophageal motility, whereas metoclopramide and domperidone do not have this ability<sup>[46]</sup>. Mosapride shortens bolus transit time in the esophagus, reduces the duration of the longest reflux episode and reflux fraction time, and enhances the contraction strength in the lower esophagus.

Reflux of stomach contents is related to transient LES relaxation (TLESR) in NERD patients<sup>[47]</sup>. Therefore, control of TLESR is another important point for NERD treatment. 5-HT<sub>3</sub>, cholecystokinin (CCK)-A, and gamma-aminobutyric acid (GABA) receptors influence TLESR<sup>[48-50]</sup>. 5-HT<sub>3</sub> receptor antagonist, CCK-A receptor antagonist, and GABA receptor agonist reduce the frequency of TLESR. Mosapride is a selective 5-HT<sub>4</sub> receptor agonist, and the metabolite acts as a 5-HT<sub>3</sub> receptor antagonist<sup>[51,52]</sup>. Therefore, mosapride reduces the frequency of TLESR, leading to reduced gastric acid reflux in NERD patients.

Some NERD cases are refractory to PPI and/or prokinetics. In these patients, psychological factors may be associated with symptoms. In these patients, administration of an antidepressant and/or minor tranquilizer should be considered. However, evidence for the benefits of these agents in treatment of NERD is weak<sup>[53]</sup>, and further studies are needed to clarify the effects of such medications on NERD.

For NERD patients with infrequent symptoms of heartburn, on-demand therapy with PPI (and/or prokinetics) is proposed as the best treatment option<sup>[54,55]</sup>. Additional studies of the effectiveness of this treatment regimen are needed.

Here we propose a new strategy for treatment of NERD in Asia based on the basic idea of step-down

**Figure 1** Proposed treatment strategy for NERD patients in Asia. **A:** Patients with moderate or severe symptoms; **B:** Patients with infrequent symptoms.

therapy (Figure 1). The recommended first-choice treatment is administration of PPI in combination with a prokinetic agent such as mosapride. PPI can cure only one-third of NERD patients, a prokinetic agent in conjunction with the PPI can increase the efficacy. NERD is frequently associated with functional dyspepsia that can be treated with prokinetic agents. In addition, because the quality of life of NERD patients is quite low, NERD patients need quicker and more effective treatment options<sup>[56]</sup>. If this treatment is not effective, twice the recommended dose of PPI or combined treatment with PPI and an H<sub>2</sub>RA is recommended. PPI together with on-demand aluminum- and magnesium-containing antacid might be effective. If these treatments are not effective, administration of an antidepressant or minor tranquilizer should be considered. Herbal medicines such as rikkunshito may provide relief for some patients<sup>[57]</sup>, and are often administered especially in Asian countries.

For patients with infrequent symptoms, on-demand treatment with PPI and/or a prokinetic agent is recommended. However, there is not sufficient evidence for a best treatment for NERD. Further studies are needed to clarify the efficacy of treatment. Large-scale, double-blind, randomized controlled trials of PPI *vs* PPI with a prokinetic agent are also needed to clarify the benefit of the prokinetic agent.

Further trials are needed to establish the strategy for treatment of NERD. At present, because there is limited evidence regarding effective treatments for the disease, it is best to try several different treatment strategies to find the best treatment for each patient.

### Abstract

Intraductal endoscopy describes the use of an endoscope to directly visualize the biliary and pancreatic ducts. For many years, technological challenges have made performing these procedures difficult. The "mother-baby" system and other various miniscopes have been developed, but routine use has been hampered due to complex setup, scope fragility and the time consuming, technically demanding nature of the procedure. Recently, the SpyGlass peroral cholangiopancreatography system has shown early success at providing diagnostic information and therapeutic options. The clinical utility of intraductal endoscopy is broad. It allows better differentiation between benign and malignant processes by allowing direct visualization and targeted sampling of tissue. Therapeutic interventions, such as electrohydraulic lithotripsy (EHL), laser lithotripsy, photodynamic therapy, and argon plasma coagulation (APC), may also be performed as part of intraductal endoscopy. Intraductal endoscopy significantly increases the diagnostic and therapeutic yield of standard endoscopic retrograde cholangiography (ERCP), and as technology progresses, it is likely that its utilization will only increase. In this review of intraductal endoscopy, we describe in detail the various endoscopic platforms and their diagnostic and clinical applications.

### INTRODUCTION

Intraductal endoscopy describes the use of an endoscope to evaluate the biliary and pancreatic ducts. There are significant technological challenges encountered in creating a scope that allows direct visualization of these ducts. However, attempts have been made, and technology is developing that promises greater opportunity to provide improved diagnosis and therapy regarding lesions in the biliary and pancreatic ducts.

### HISTORY AND TYPES OF SCOPES

Cholangioscopy was considered as early as the 1950's<sup>[1]</sup>. However, technology at that time caused severe limitations. In the 1960's, intraoperative cholangioscopy was first successfully utilized<sup>[2-4]</sup>. Peroral cholangioscopy (POCS) was initially described in the mid-1970's. One of the first reports demonstrated that a fiberscope of 8.8 mm diameter could be directly inserted through the mouth, into the biliary system after an endoscopic papillotomy, without the need of using a second scope as a guide<sup>[5]</sup>. This scope did provide a biopsy channel to obtain tissue samples. Other investigators also successfully demonstrated the use of POCS to directly visualize the biliary system during this time<sup>[6-10]</sup>.

The idea of guiding a small caliber "baby" cholangioscope through the channel of a "mother" duodenoscope into the common bile duct (CBD) gained acceptance. This "mother-baby" system is also known as duodenoscope-assisted cholangiopancreatography (DACP). However, use of the early cholangioscopes was difficult since

their optical fibers were prone to break easily from pressure applied with the elevator of the duodenoscope. Regardless, Urakami demonstrated successful access to the ductal system in 25 of 30 cases in 1980 by using this technique<sup>[11]</sup>. The University of Chicago published their experience with a conventional “mother-baby” system utilizing a set of Olympus scopes (TJF-M20 and CHF-B20) (Olympus Inc, Tokyo, Japan), where the “baby” scope had a diameter of 4.5 mm, two-way deflection and included an instrument channel<sup>[12]</sup>. This system was used in patients 18 times over a 3-year study period. Initially, they demonstrated a steep learning curve, when they intubated the papilla in only 2 of 5 cases. They subsequently found it was necessary to perform a papillotomy before the “baby” scope could be passed. After this adjustment, they were successful at intubating the papilla in 13 of 13 cases. While the 1.7 mm working channel on the cholangioscope did allow for diagnostic and therapeutic intervention, the system was found to be cumbersome to use. Average time of the procedure was around 2 h. Two endoscopists were required (i.e. one for each scope). The cholangioscopes continued to be fragile and prone to breaking. Further, these cholangioscopes only had two-way deflection at the tip as opposed to the typical four-way deflection offered by other endoscopes. These limitations led this group to conclude that while this “mother and baby” system certainly offered new endoscopic potential, it would best be utilized in only select patients at highly specialized tertiary referral centers. Another study at Case Western Reserve University further validated the use of this Olympus system by successfully visualizing the biliary tree in five patients<sup>[13]</sup>. The steerable properties of the cholangioscope combined with the presence of the accessory channel allowed it to have significant advantages over past attempts at POCS.

The search for a less cumbersome technique to directly visualize the biliary tree led to a small pilot study with an attempt to perform direct visualization of the biliary tree with an ultra-slim upper endoscope<sup>[14]</sup>. This technique used endoscopic retrograde cholangiography (ERCP) to place a super-stiff 0.035-inch diameter Jagwire (Boston Scientific Corp, Natick, Mass) in the CBD. Using the wire to maintain access, the duodenoscope was removed and an ultra-slim upper endoscope (GIF-XP 160, Olympus America Inc, Center Valley, PA) with an outer diameter of 5.9 mm was back loaded over the guidewire under fluoroscopic and endoscopic control into the duodenum and then across the ampulla of Vater into the CBD. Endoscopic sphincterotomy was required in order to permit passage of the endoscope into the CBD. This procedure was successful in providing direct cholangioscopy in 3 of 3 patients. Further studies will show whether this technique may have broader application. However, this technique can be performed by only one endoscopist, and the larger working channel (2.0 mm) of the endoscope allows for larger biopsies and the potential for more therapeutic applications.

Several miniscopes have been developed which allow the ability to examine the biliary and pancreatic ducts. The extreme small size of some of these scopes,

ranging as small as 1 to 15 French in diameter, allowed for their delivery into even the smallest of ducts, and could allow access without the presence of papillotomy when the outer diameter of the scope is less than 2.5 mm<sup>[15-19]</sup>. While these very small scopes raise interesting possibilities, their use is limited by their fragility, lack of tip deflection and lack of an inner working channel. A fine-caliber flexible miniscope created by Soda<sup>[20]</sup>, allowed access to the bile duct without necessitating sphincterotomy due to its external diameter of only 2.09 mm. However, unlike many other fine-caliber miniscopes, this scope did have a central working channel of 0.72 mm.

Slightly larger miniscopes with bi-directional angulation systems and instrument channels were developed by Olympus (CHF BP 30 with 3.4 mm diameter) and Pentax (FCP-9P with 3.1 mm diameter and FCP-8P with 2.8 mm diameter)<sup>[21]</sup>. Sander and Poehl developed a new miniscope (2.3 mm in diameter) for POCS (PolyDiagnost, Reichertshausen, Germany), with a less fragile, steerable tip, which had two different degrees of stiffness. This scope has a working channel measuring 1.2 mm (3.6 Fr), through which a probe for electrohydraulic lithotripsy (EHL) and a stone extraction basket can be passed<sup>[22]</sup>. These two authors demonstrated successful pancreatoscopies with their scope in 8 of 10 cases and successful choledochoscopies in 11 of 11 cases. The presence of the instrument channel in all three of these scopes allows for therapeutic applications. Also, common to these miniscopes is their ability to be introduced through a standard therapeutic duodenoscope, hence these scopes could become part of a DACP (DACP) system. However, none of these scopes had separate air/water channels, and it is frequently necessary to continuously irrigate the bile ducts due to stone debris or sludge obscuring the view. Thus, at times, nasobiliary drainage tubes have been inserted in the bile duct along with the cholangioscope in order to allow irrigation to be effectively performed during the cholangioscopy examination.

While some of the fine-caliber miniscopes have been used to perform pancreatoscopy, one group of Japanese researchers has focused on developing a miniscope specifically designed to perform pancreatic duct visualization. Kodama and others developed a prototype peroral electronic pancreatoscope (external diameter 2.1 mm) and found its images did provide fine detail of the pancreatic duct<sup>[23]</sup>. They utilized an ultraminiature charge-coupled device with sequential color wheel method to generate images. This initial prototype scope was limited by its lack of a working channel. The group continued their development and in 2004 published their experience with another peroral electronic pancreatoscope prototype with a 2.6 mm external diameter and an inner working channel of 0.5 mm<sup>[24]</sup>. This scope was successfully inserted into the pancreatic duct without sphincterotomy in 7 of 9 cases. A duodenoscope was required to insert the scope into the pancreatic duct, and two endoscopists were required to perform the case. However, images were obtained that

provided excellent visualization of the pancreatic duct and sampling of pancreatic fluid could be performed *via* the working channel.

Recently, the SpyGlass peroral cholangio-pancreatography system (Boston Scientific Corp, Natick, Mass) has been introduced<sup>[25]</sup>. This system makes use of a reusable optical probe, a disposable access and delivery catheter (SpyScope), and disposable biopsy forceps. The outer diameter of the SpyScope is 10 French. This system offers several advantages over previous cholangioscopes. It allows for single-operator control of both the duodenoscope and the SpyScope because the SpyScope catheter is mounted on the duodenoscope by a silastic belt. The endoscopist can sequentially manipulate the controls of both the duodenoscope and the SpyScope with one hand; thus, the need for two endoscopists is eliminated. This system also uses 4-way tip deflection, which allows for improved access of tertiary ducts. Further, the irrigation channel (0.6 mm) is separate from the working channel (1.2 mm), which allows for sustained continuous irrigation regardless of whether the working channel is in use. These advances have allowed this system to be used clinically in a number of tertiary referral centers.

Clinical data regarding the SpyGlass system continues to be collected; however, an initial feasibility study is available<sup>[26]</sup>. In this study, 35 patients underwent cholangioscopy with the SpyGlass system. Procedural success defined as attaining the diagnostic or therapeutic goal of the procedure. Procedural success was documented in 91% (32 of 35 patients). Sphincterotomy was frequently required in patients, in that 8 of 10 patients with intact sphincters required sphincterotomy at the time of the SpyGlass procedure. SpyGlass directed biopsy yielded promising results in that 19 of 20 (95%) of optically guided biopsies yielded specimens with adequate tissue for histologic evaluation. EHL was successful in 5 of 5 (100%) of patients when performed *via* the SpyGlass working channel. Two patients (6%) experienced procedure-related complications, namely ascending cholangitis in one patient and cholangitis with intrahepatic abscess in the other patient. Both patients recovered without sequelae. While this initial data is promising, the prospective data currently being collected from clinical use of the SpyGlass system will provide a better analysis of its potential impact on cholangiopancreatography.

## DIAGNOSTIC APPLICATIONS

Intraductal endoscopy may be used for multiple diagnostic indications (Table 1). Direct visualization of the ducts may increase the ability to differentiate and diagnose lesions accurately in comparison with standard imaging and ERCP techniques. In 1999, Siddique reported an experience of 61 choledochoscopies performed *via* the transpapillary route for diagnostic purposes<sup>[27]</sup>. Importantly, this study showed that direct visualization provided additional unsuspected diagnostic information in 18 of the 61 (29.5%) patients,

**Table 1** Diagnostic uses of intraductal endoscopy

Optically guided biopsies of stricture
Indeterminate stricture
Dominant stricture in primary sclerosing cholangitis
Evaluate fixed filling defect noted on cholangiogram or other imaging
Differentiate benign <i>versus</i> malignant intraductal mass
Optical examination yields visual clues
Improved yield from tissue sampling under visual guidance
Precisely map intraductal tumor prior to resection
Collect significant fluid sample for cytology
Visually evaluate intraductal mucinous neoplasms
Visually evaluate choledochal cyst
Visually evaluate for post-liver transplant ductal ischemia
Visually evaluate for intraductal spread of ampullary adenoma
Evaluate with visual exam and tissue sampling for infection
Cytomegalovirus
Fungal infection

beyond that which had been achieved by previous workup. A Korean study reviewed cholangioscopic findings from 111 patients with benign or malignant bile duct tumors<sup>[28]</sup>. By evaluating mucosal changes, presence of neovascularization, and patterns of luminal narrowing, it was determined that bile duct tumors did indeed demonstrate unique optical characteristics, that could allow optical differentiation among adenocarcinoma, adenoma, hepatocellular carcinoma, mucin-hypersecreting cholangiocarcinoma, biliary cystadenocarcinoma, and squamous cell carcinoma. Thus, it was felt that cholangioscopy can provide additional information that would be useful in differentiating benign from malignant lesions and would help characterize the type of malignant lesion. Another Korean study of 63 patients<sup>[29]</sup> with indeterminate strictures reported that cholangioscopy could potentially improve the diagnosis of cholangiocarcinoma by allowing for the optical recognition of an irregularly dilated and tortuous vessel, the so-called “tumor vessel.” They found that this “tumor vessel” was noted in 25 of 41 patients with malignancy (61%), while no patients with benign stricture had this characteristic appearance. The value of direct cholangioscopy could be seen best in this study by combining the optical observation of tumor vessel with percutaneous transhepatic cholangiography-guided biopsy resulting in a diagnosis of malignancy in 39 of 41 patients (96%). This is a significantly increased rate of preoperative diagnosis when compared with percutaneous transhepatic cholangiography-guided biopsy alone (80.4% sensitivity for diagnosis in this study). In 2005, data from 97 patients showed the additive value of combining direct POCS with standard ERCP<sup>[30]</sup>. The combination of POCS and ERCP improved the sensitivity of diagnosing malignant lesions from 58% to 93%. Additionally, POCS was especially useful in evaluating 21 filling defects of uncertain etiology which had been noted on ERCP cholangiogram. POCS was able to correctly diagnose all 8 malignant lesions and all 13 benign lesions (i.e. accuracy of diagnosis was 100%). In particular, 4 fixed and immobile bile duct stones had the appearance of

tumor on ERCP, but were diagnosed correctly as benign stones at a glance with POCS.

Biliary strictures, with the exception of those clearly following surgery or trauma, are frequently concerning for malignancy. Obtaining adequate tissue from these biliary strictures, which can provide definitive diagnosis, is often challenging. Traditionally, ERCP may be of assistance in characterizing the stricture by providing tissue sampling; however, the low yield rates of ERCP-based methods for securing the pathologic diagnosis of malignancy has been demonstrated in multiple studies. The diagnostic yield is variable in the range of 35% to 70%<sup>[31-43]</sup>. Percutaneous transhepatic cholangioscopy (PTCS) and POCS have both been used to obtain visually guided biopsies. However, a risk of percutaneous cholangioscopy is the potential for tumor seeding along the tract. In 1997, Sato published results obtained from 25 bile duct carcinomas showing carcinomas and invasive carcinomas were diagnosed histologically from biopsy specimens obtained with PTCS guidance in 96% and 91% of the cases, respectively<sup>[44]</sup>. However, the sensitivity of a single biopsy for diagnosis for invasive carcinoma was only 62%, which demonstrated the need for multiple biopsies in order to obtain a higher diagnostic yield. In 2003, Somogyi reported the feasibility of using POCS with visually-guided biopsy to successfully directly biopsy an intraductal papillary mucinous tumor within the common hepatic duct<sup>[45]</sup>. Cholangioscopy additionally allowed precise mapping of the tumor in preparation for surgical resection. A 2006 report further details the usefulness of cholangioscopy in patients with indeterminate pancreaticobiliary pathology by evaluating 62 patients<sup>[46]</sup>. If a lesion was initially observed with direct POCS, biopsies were obtained under direct visualization (cholangioscopy-directed) or through the duodenoscope (cholangioscopy-assisted). Overall in this study, sensitivity to detect malignancy by utilizing POCS was 89%, and specificity was 96%, which continues to mark a significant improvement over utilization of only ERCP techniques to obtain tissue. As mentioned previously, the SpyGlass system has also been used for optically guided biopsy<sup>[26]</sup>. The sensitivity and specificity for diagnosis utilizing SpyGlass-directed biopsy was 71% and 100%, respectively, in evaluation of 20 patients' intraductal lesions. Current multi-center trials will shed more light on the use of this new system.

Attempts have been made to utilize POCS in patients with primary sclerosing cholangitis (PSC). A study from the University of Colorado examined 41 PSC patients with POCS<sup>[47]</sup>. In order to evaluate dominant strictures, POCS-directed biopsies were obtained. In cases where the cholangioscopic biopsy forceps could not pass through the operating channel due to angulation, POCS-assisted biopsies were obtained. Impressively, tissue samples were adequate for histologic evaluation in 32 of 33 patients. The median follow-up period of 17 mo, has shown that this method of evaluation was able to successfully exclude cancer in 31 of 31 patients (100%) where biopsies were negative. The predominant difficulty in this study came due to limitations of technology with

the cholangioscopes which were used (Olympus CHF BP30, Olympus CHF B160, Pentax FCP 9P), in that the stricture of interest could not be traversed in 14 cases. Another study detailing the use of POCS in PSC was published by a German group in 2006<sup>[48]</sup>. In this study, 53 PSC patients with dominant bile duct stenoses underwent transpapillary cholangioscopy and POCS-assisted tissue sampling in addition to ERCP. This study found that utilization of cholangioscopy was statistically significantly superior to ERCP for detecting malignancy in terms of its specificity (93% *vs* 51%) and accuracy (93% *vs* 55%). Thus, this group concluded that transpapillary cholangioscopy significantly increases the ability to distinguish between malignant and benign dominant bile duct stenoses in patients with PSC.

Direct pancreatoscopy can also play a diagnostic role in differentiating pancreatic duct lesions<sup>[49]</sup>. Pancreatoscopy can visualize chronic scarring and stenosis of the duct, pancreatic duct stones, and intraductal papillary-mucinous neoplasms (IPMN's) of the pancreas. In 1997, peroral pancreatoscopy was utilized to evaluate carcinoma *in situ* of the pancreas<sup>[50]</sup>. The carcinoma *in situ* in the main duct had the optical appearance of papillary mucosa, irregular mucosa, or nodular mucosa. Pancreatic juice collected during pancreatoscopy provided a better yield than traditional catheter collection, in that fluid collected during pancreatoscopy from all 11 patients with carcinoma *in situ* yielded positive cytology, while only 7 of 11 patients' cytology was positive when collected without direct pancreatoscopy. Thus, this study concluded that peroral pancreatoscopy and pancreatoscopic cytology are indeed useful for locating and diagnosing carcinoma *in situ* of the pancreas. In 1998, further evidence of the additive value of pancreatoscopy to supplement traditional diagnostic techniques was published<sup>[51]</sup>. In this report, pancreatoscopy was performed in 24 patients with intraductal mucinous neoplasms of the pancreas. Pancreatoscopy was able to detect 10 cases of intraductal mucinous neoplasms (IPMN's) that were not diagnosed with endoscopic ultrasound (EUS) or ERCP. Multiple other studies have evaluated the benefits of pancreatoscopy, especially in regard to evaluating intraductal mucinous neoplasms<sup>[52-58]</sup>. However, more recently, peroral pancreatoscopy has been combined with narrow-band imaging to emphasize certain image features often seen with IPMN's, such as mucosal structures and capillary vessels<sup>[59]</sup>. It is thought that the addition of narrow band imaging may aid in the diagnosis of the primary tumor and help in the determination of the extent of the tumor.

Other diagnostic uses of intraductal endoscopy include the evaluation of choledochal cysts<sup>[60-62]</sup>. Hemobilia of unknown etiology has been evaluated by cholangioscopy<sup>[63]</sup>. Infectious etiologies of bile duct pathology, such as cytomegalovirus (CMV) and fungal infections, have also been exposed by the use of direct cholangioscopy<sup>[27,64]</sup>. There also may be a role for evaluation of the biliary tree after liver transplant. A case report exists detailing the use of methylene blue-

**Table 2** Current therapeutic applications of intraductal endoscopy

Photodynamic therapy
Nd-YAG laser ablation
Cystic duct stent placement

aided chromoendoscopy *via* POCS to optically diagnose extensive bile duct necroses and inflammation consistent with ischemic-type biliary lesions after transplant<sup>[65]</sup>. Other diagnostic uses of POCS will become evident as better technology allows for greater use of this modality.

## THERAPEUTIC APPLICATIONS

Intraductal endoscopy is useful not only for diagnostic purposes, but it also has therapeutic applications (Table 2). Intraductal endoscopy has been frequently used to remove stones from within the ducts that cannot be removed by standard ERCP techniques in 5% to 10% of cases, due to size, location, or adherence to biliary epithelium<sup>[66]</sup>. EHL has been used in combination with POCS in multiple reports. EHL employs the use of a bipolar electrode in an aqueous medium. The probe is placed at the surface of the stone and directly observed using the cholangioscope. The probe emits spark discharges, which create a shock wave that fragments the stone<sup>[67]</sup>. Binmoeller reported, in 1993, that this technique was successful in removing stones where standard mechanical lithotripsy had failed in 64 of 65 patients<sup>[68]</sup>. Arya reported, in 2004, on experience with 94 patients who received POCS combined with EHL<sup>[69]</sup>. Of this group, 93 patients had failed previous standard stone extraction with ERCP. In this retrospective review, POCS combined with EHL was successful in performing stone fragmentation in 96% of cases, and stones were completely removed in 90% of cases. In both of these studies, there were no significant complications associated with the procedures. In elderly patients where biliary stone removal with traditional methods is unsuccessful, permanent biliary stenting has been attempted. However, Hui demonstrated in a prospective study of 36 high-risk patients with difficult CBD stones that POCS guided lithotripsy, when compared to stenting alone, allows for significantly less mortality and cholangitis<sup>[70]</sup>. Another study using EHL with POCS reported a 100% success rate for large bile duct stone removal after failure to remove the stone with a mechanical lithotripter during ERCP<sup>[71]</sup>. In 2002, data from 36 patients who had strictly intrahepatic stones underwent POCS guided lithotripsy<sup>[72]</sup>. Indeed, this form of therapy was successful in these difficult cases to achieve complete stone removal in 64% of cases. Most recently, the SpyGlass-directed EHL system allowed for success in 5 of 5 patients, although after the initial procedure two patients did require repeat SpyGlass-directed EHL and one patient required repeat ERCP in

order to achieve complete stone clearance<sup>[26]</sup>.

Standard surgical management has been difficult for patients with gallstones which erode into the common hepatic duct and form a cholecystobiliary fistula (i.e. Mirizzi types 2-4). In 25 patients (23 patients with Mirizzi type 1 syndrome and two with Mirizzi type 2 syndrome), POCS combined with EHL allowed for successful treatment of the stone in all patients with type 2 Mirizzi syndrome, while it failed in both patients with type 1 Mirizzi syndrome<sup>[73]</sup>. Thus, it was felt that POCS guided therapy may offer a safe and effective alternative to surgery in patients with type 2 Mirizzi syndrome.

There are other therapeutic interventions which have been coupled with POCS. Multiple reports describe the use of cholangioscopy along with laser lithotripsy<sup>[12,74,75]</sup>. Laser lithotripsy may be used under fluoroscopic or direct cholangioscopy guidance. Current evidence indicates that POCS-guided laser lithotripsy is especially preferred in cases of intrahepatic stones or in patients with stones situated proximal to a bile duct stenosis<sup>[76]</sup>. Photodynamic therapy, under peroral cholangioscopic guidance, has also been utilized for patients with biliary tumors. In 1998, Ortner reported on the use of photodynamic therapy under cholangioscopic guidance to treat nonresectable Bismuth type III and IV cholangiocarcinoma<sup>[77]</sup>. In this study, therapy was successful at restoring biliary drainage, improving mortality and enhancing quality of life. In 2003, Ortner reported results of a randomized trial of cholangioscopically guided photodynamic therapy with stenting *versus* stenting only for nonresectable cholangiocarcinoma<sup>[78]</sup>. The improvement of survival in the group receiving photodynamic therapy was so impressive that it was considered unethical to continue with randomization after the first 39 patients. Specifically, the photodynamic therapy group had median survival to 493 d, while the stenting only group had median survival to 98 d ( $P < 0.0001$ ). Treatment with photodynamic therapy and stenting also led to improvement of cholestasis and quality of life compared with endoscopic stenting alone. Argon plasma coagulation (APC) has also been utilized under direct optical guidance to treat an intraductal papillary mucinous neoplasm involving the extrahepatic bile ducts<sup>[79]</sup>. However, in this case, after cholangioscopic evaluation, a thin gastroscope (Olympus GIF-H180, Olympus America Inc, Center Valley, PA) was introduced across the papilla into the bile duct, since the APC probe would not fit down the working channel of the cholangioscope. Other therapeutic applications reported in concert with cholangioscopy include Nd-YAG laser ablation of tumor stent ingrowth and biliary angiodysplastic lesions<sup>[27]</sup>.

## COMPLICATIONS AND SAFETY

There are no large trials specifically addressing the safety of intraductal endoscopy. Most information regarding safety and complications comes from individual case series, often with small numbers of patients enrolled. However, intraductal endoscopy is generally believed to

be a safe procedure with relatively few complications. Complications typically include minor bleeding at the time of sphincterotomy or lithotripsy<sup>[73]</sup>. There was one report of bile duct perforation following POCS guided EHL in 1993<sup>[68]</sup>. Obviously, the incidence of cholangitis is increased in patients with incomplete biliary drainage, from causes such as a biliary stricture or residual biliary stones; however, cholangitis has not been reported as a direct cause POCS<sup>[73]</sup>. Reports in the literature generally demonstrate a low threshold to give antibiotics in POCS guided procedures, but the use of antibiotics is based on the needs of an individual clinical situation. Pancreatitis has been reported in 2 of 52 (3.8%) of pancreatoscopy cases<sup>[49]</sup>. Complication rates will be better calculated as more intraductal endoscopic procedures are performed and further prospective data is collected.

## COMPARATIVE PROCEDURES

There are two other significant methods which allow optical examination of the ductal systems and deserve brief mention due to their association with POCS. PTCS, also known as percutaneous choledochoscopy, and laparoscopic choledochoscopy have both been used extensively to for diagnostic and therapeutic purposes. While PTCS is more invasive than POCS, there are times when it allows excellent visualization, even in difficult anatomic situations where a POCS technique has failed<sup>[80]</sup>. Many of the same diagnostic and therapeutic techniques utilized with POCS are also used with PTCS, including targeted biopsy and management of stones with lithotripsy. One unique use of PTCS was documented, where a push-type sphincterotome was used *via* PTCS to create a papillary sphincterotomy and allow drainage of obstructing biliary stones in 3 patients who each had an endoscopically inaccessible papilla<sup>[81]</sup>. There are no reports of percutaneous pancreatoscopy. There have been no significant randomized studies directly comparing PTCS *versus* POCS. Generally, POCS is preferred as the initial therapy, due to its less invasive nature. However, if POCS is not available, or if POCS techniques fail, then PTCS may be used.

Laparoscopic choledochoscopy has been utilized to explore the CBD. Frequently, this technique has been utilized at the time of laparoscopic cholecystectomy, when intraoperative cholangiogram shows concern for retained CBD stones<sup>[82]</sup>. There are multiple surgical techniques which have been used to explore the CBD, but choledochoscopy *via* the cystic duct appears to be the safest and most effective approach, with success rates of 90%<sup>[83]</sup>. A benefit of this procedure is that the papilla may be left intact without sphincterotomy<sup>[84]</sup>. There is minimal experience with using laparoscopic techniques to perform pancreatoscopy; however, reports do exist<sup>[85]</sup>.

## CONCLUSION

Experience with intraductal endoscopy has shown its advantages over conventional ERCP in regards to

the diagnosis and treatment of biliary and pancreatic disease. Direct optical examination may provide significant additional information about ductal lesions. Furthermore, the ability to guide instrumentation in the ducts under direct optical guidance provides significant advantages. As technology advances, the utilization of this endoscopic modality will only increase and new uses for this technology will likely develop.

### INTRODUCTION

Chronic pancreatitis remains an enigma in the field of gastroenterology. Challenges can be encountered in defining the etiology and pathogenesis, in securing the diagnosis, and finally in providing adequate therapy. Chronic pancreatitis is a common problem, but the exact prevalence is unclear. Many patients suffering from chronic abdominal pain may indeed have unrecognized chronic pancreatitis. The prevalence in the developed world is reported from 0.4% to 5%<sup>[1]</sup>.

In the western world alcohol abuse is the overwhelming etiologic factor. Of patients with chronic pancreatitis, 60% to 70% have 6 to 12 years history of heavy consumption of alcohol (150-175 g/d)<sup>[2]</sup>. Less common, but important etiologic factors to consider, are ductal obstruction (from tumors and strictures), autoimmune, hypercalcemia, hyperlipidemia, toxins, and genetic. In a small number of cases, there is no identifiable causative factor and the pancreatitis is deemed idiopathic. It should not be surprising in view of this array of etiologic factors that there exist uncertainties in both diagnosis and ultimately treatment of chronic pancreatitis. Adding to the perplexity of this clinical situation are the multiple treatment options that can be provided by primary care physicians, gastroenterologists, interventional endoscopists, and surgeons. Despite the evolution of new medications and tools in the last two decades no clear consensus has emerged on the management of chronic pancreatitis. Most reports are either anecdotal or collected experiences of a single approach.

It is the purpose of this review to discuss the different modalities that are currently being used for the treatment of pain in chronic pancreatitis and to attempt to integrate them in a patient centered comprehensive approach.

### Abstract

Abdominal pain is a major clinical problem in patients with chronic pancreatitis. The cause of pain is usually multifactorial with a complex interplay of factors contributing to a varying degree to the pain in an individual patient and, therefore, a rigid standardized approach for pain control tends to lead to suboptimal results. Pain management usually proceeds in a stepwise approach beginning with general lifestyle recommendations. Low fat diet, alcohol and smoking cessation are encouraged. Analgesics alone are needed in almost all patients. Maneuvers aimed at suppression of pancreatic secretion are routinely tried. Patients with ongoing symptoms may be candidates for more invasive options such as endoscopic therapy, and resective or drainage surgery. The role of pain modifying agents (antidepressants, gabapentin, pregabalin), celiac plexus block, antioxidants, octreotide and total pancreatectomy with islet cell auto transplantation remains to be determined.

### PATHOPHYSIOLOGY OF PAIN IN CHRONIC PANCREATITIS

At least 85% of patients with chronic pancreatitis

develop pain at some point during the course of their disease. Painless chronic pancreatitis is rare, and more commonly late in the natural history of idiopathic chronic pancreatitis<sup>[3]</sup>. The frequency, severity and other characteristics of pain in chronic pancreatitis have a major impact on its management, the number of treatments, and the choice between medical and surgical interventions.

Several hypotheses exist as to the basis for pain in chronic pancreatitis; however, the exact mechanism is still not completely known. Possible mechanisms for pain include acute inflammation of the pancreas, increased pressure within the ductal system and parenchyma, neuritis, recurrent ischemia of the parenchyma; intra-pancreatic causes such as acute pseudocysts; and extra-pancreatic causes such as common bile duct or duodenal stenosis<sup>[4,5]</sup>. The relative contribution of each factor is unknown.

## THERAPY OF PAIN IN CHRONIC PANCREATITIS

### Medical therapy

**Nonspecific supportive therapy:** The first line in pain management is the use of medical therapy. The initial step of medical therapy usually is nonspecific supportive treatment. Supportive therapy is aimed at treating the concurrent symptoms and not the underlying factors in pain causation. Analgesic drugs are still the most commonly adopted method for pain relief. The obvious problem with this method of treatment is that patients often become dependant on heavy narcotic use. Most patients with chronic pancreatitis have their pain treated with analgesics on an episodic or continuing basis. Although the use of narcotics for the treatment of chronic pancreatitis is widespread, there are no controlled trials testing their efficacy as compared to the other modalities. Time intervals and doses of drug application must be adapted to the individual pain pattern. Although reluctance to use of narcotics is understandable, it should not be withheld if the treatment would otherwise not lead to adequate pain control<sup>[6]</sup>.

There may be significant psychiatric, psychological, or psychosomatic contributions to the pain syndrome in these patients. Many physicians and surgeons use antidepressant medications as concomitant therapy, acknowledging the difficulty in assessing the psychological contributors to patients' pain syndrome. The benefits are anecdotal and variable in any individual experience and have never been rigorously assessed. It has been suggested that the natural path of chronic pancreatitis is toward progressive glandular insufficiency and calcification, and with the eventual 'burnout' would come spontaneous remission of pain<sup>[7]</sup>. There is a school of thought against conservative therapy. Pain is endured until burnout. This theory sheds light on the uncertainty regarding the duration of clinical pain, and if burnout is indeed a certainty and not solely a proposed hypothesis<sup>[8,9]</sup>. In conclusion, a strategy of waiting

for spontaneous pain relief is not reliable and may be unreasonable advice for the patient with persistent or frequent severe pain.

**Pancreatic enzymes:** The presumed mechanism for pain relief after the administration of oral pancreatic enzymes is thought to involve the negative feedback inhibition to the pancreas. A cholecystokinin (CCK)-releasing peptide in the duodenum is normally denatured by pancreatic trypsin. In chronic pancreatitis, damage to acinar cells results in decreased secretion of pancreatic trypsin and consequently insufficient denaturing of the CCK-releasing peptide. This then leads to the potentiation and increased release of CCK, which causes pancreatic pain related to an increase in pancreatic enzyme output. When pancreatic enzymes are administered orally, there is more complete denaturing of the CCK-releasing peptide, thereby diminishing the release of CCK<sup>[10,11]</sup>. The results of studies examining the use of pancreatic enzymes that are administered orally to treat the pain of chronic pancreatitis have been variable, in part because of a high placebo response rate of over 35%, the potential for exogenously administered digestive enzymes to be inactivated by gastric acid and pancreatic proteases, and the lack of efficacy of enteric coated preparations<sup>[12-16]</sup>.

In one of the earliest double-blind randomized trials of pancreatic enzymes, Isakson *et al* showed the pain relieving effect of oral enzyme preparations in a proportion of patients with chronic pancreatitis<sup>[16]</sup>. They took 19 patients with chronic pancreatitis, and treated them for 1 wk with a granulated pancreatic enzyme preparation (Pankreon<sup>®</sup>; five times daily 7.5 mL) or placebo and vice versa. Pain was evaluated using an analog scale and by questioning. A 30% pain reduction was seen after treatment with pancreatic extract compared to placebo. Fifteen of the nineteen patients had less pain during the week of treatment with pancreatic extracts. These results could not be confirmed by Halgreen, who conducted a 4-wk double-blind cross-over study with pancreatic enzymes (Pancrease<sup>®</sup>) in 20 chronic pancreatitis patients. There was no significant pain reduction<sup>[17]</sup>. In a placebo-controlled, double-blind, crossover study, pancrelipase (Viokase), in a dose of six tablets taken four times per day for one month, significantly reduced pain in 75% of patients with mild-to-moderate disease<sup>[15]</sup>. The best response was in young women with idiopathic chronic pancreatitis, whereas patients with advanced disease, including those with steatorrhea, had no response.

Of the 6 randomized trials published to date two studies using a non-enteric coated enzyme preparation reported benefit and four studies using an enteric-coated capsule showed no effect on pain in chronic pancreatitis. The conflicting study results led to investigators questioning the mechanism of negative feedback inhibition in the proximal small bowel<sup>[18]</sup>. As noted, the presumed mechanism for pain relief with administration of oral pancreatic enzymes is thought to involve feedback inhibition of the exocrine pancreas by the

degradation of CCK-releasing peptide in the duodenum. The administered enzymes would need to release activated serine proteases into the duodenum. This is much more likely with the non-enteric coated than the enteric-coated preparations, and hence the suspicion that the former are more effective. A meta-analysis of the six randomized, double-blind, placebo-controlled trials for the treatment of chronic pancreatitis with pancreatic enzymes showed no benefit in improving pain. The pooled estimate of the percentage of patients per study who preferred enzymes relative to placebo was 52% (95% confidence interval 45%-60%). This was not statistically different from 50%. Thus, this analysis demonstrates no significant benefit of pancreatic enzyme therapy to relieve chronic pancreatitis-associated pain<sup>[19]</sup>. It should be noted that this meta-analysis combines studies using enteric-coated and studies using non enteric-coated preparations. In that way, the potential benefit of non enteric-coated enzymes may have been negated by the lack of positive effect with non-enteric-coated preparation. The role of oral pancreatic enzymes in reducing pain in chronic pancreatitis, therefore, remains unclear. Additional studies are required to establish the effectiveness of this modality of treatment and to define whether certain subsets of pain: chronic *versus* intermittent pain; patients with or without exocrine insufficiency; alcoholic *versus* idiopathic pancreatitis; minimal *versus* extensive pancreatic duct changes; are more likely to benefit from enzyme therapy than others. Non-enteric coated enzymes are certainly safe and reasonable to try before considering more invasive or risky therapies.

**Octreotide:** Cholecystokinin-receptor antagonists or somatostatin analogues, such as octreotide, have been postulated to work on the negative feedback inhibition as well as hypertension of the pancreatic duct due to outflow obstruction. Inhibition of pancreatic secretion using somatostatin might, therefore, be effective in reducing pain in chronic pancreatitis. Octreotide is a synthetic somatostatin-analogue with an increased half-life, higher potency and the possibility of subcutaneous application. Experimental data suggest that octreotide increases the contractibility of the sphincter of Oddi, while somatostatin decreases it. This has, however, not consistently been demonstrated<sup>[20]</sup>. Normally, the release of cholecystokinin from specific intestinal cells is regulated by a cholecystokinin-releasing peptide in the proximal small intestine that is luminally active and trypsin-sensitive<sup>[13]</sup>. In chronic pancreatitis, exocrine insufficiency may lead to increased cholecystokinin-mediated stimulation of the pancreas. Theoretically, this process could be interrupted by the administration of cholecystokinin-receptor antagonists, or somatostatin. In a multicenter pilot study, octreotide, in a dose of 200 µg administered subcutaneously three times per day for 4 wk, reduced pain scores by 25% or more in 65% of patients with severe chronic pancreatitis<sup>[21]</sup>. On the other hand in a randomized, prospective, double-blind, placebo-controlled study conducted in Europe

[100 mg subcutaneously (*sc*) every 8 h] administered to 10 patients for only 3 d was no more effective than placebo in relieving pain in chronic pancreatitis<sup>[22]</sup>. In a second study<sup>[23]</sup>, octreotide (100 mg *sc* every 8 h for 3 wk) administered to six patients in a nonblinded fashion provided relief of pain in some but not all patients. In a third study<sup>[24]</sup>, octreotide was administered to 84 patients for 4 wk in a randomized, prospective, double blind trial and showed a trend toward benefit at the highest dosage used (200 mg *sc* every 8 h). However, this effect did not reach statistical significance in this dose-ranging study. The longevity of the possible benefit was not established. Clearly further studies are needed before the use of octreotide can be widely adopted.

**Antioxidant therapy:** Bhardwaj *et al*<sup>[25]</sup> reported a decreased micronutrient intake (Vitamin E, riboflavin, choline, magnesium, copper, manganese and sulphur) in patients with chronic pancreatitis. This was due to diet modifications due to pain, as well as to a lower caloric intake. This points to the possibility that micronutrients deficiency may contribute to increased oxidative stress. In a comparison between patients with chronic pancreatitis and acute pancreatitis, the antioxidant profiles appeared to be different. Patients with chronic pancreatitis had significantly lower plasma concentrations of selenium, Vitamins A and E, beta-carotene, xanthine, beta-cryptoxanthine and lycopene in comparison with patients with recurrent acute pancreatitis<sup>[26]</sup>. Cullen *et al*<sup>[27]</sup> reported a decrease in antioxidant enzyme expression in pancreatic cells from normal pancreas to chronic pancreatitis to pancreatic cancer. Another observation concerning antioxidants is the altering of antioxidant status in chronic pancreatitis patients, which is worsened in patients with diabetes mellitus<sup>[28]</sup>. A 1-year clinical trial with 10 patients studied the effect of food supplementation using a complex containing l-methionine, beta-carotene, Vitamins C and E and organic selenium<sup>[29]</sup>. This resulted in a significant decrease in the intensity of pain as well as in days of hospital admission. Based on a placebo-controlled trial, followed by a retrospective cross-sectional study in 94 patients, some authors recommend antioxidant therapy consisting of supplements of methionine, Vitamin C and selenium<sup>[30]</sup>.

Based on the observations that activation of oxygen free radicals can cause metabolic changes leading to pancreatic ischemia, antioxidant treatment with allopurinol seems a valid option. A trial with 13 patients with chronic pancreatitis investigated the effect of allopurinol on pain in a cross-over double-blind, randomized treatment trial<sup>[31]</sup>. Allopurinol, which is believed to reduce oxidative stress by inhibiting xanthine oxidase and thereby preventing the formation of oxygen derived free radicals, was given to 13 patients with pain occurring at least three times each week. Allopurinol was not effective in reducing pain or improving activities of daily living compared to placebo. In contrast, others showed that addition of allopurinol or dimethyl sulfoxide to intramuscular pethidine hydrochloride significantly

enhanced the efficacy of the analgesic regime<sup>[32]</sup>. This report suggests that removing oxygen free radicals in chronic pancreatitis may result in a beneficial therapeutic effect. The results of the most recent randomized trial presented only in abstract form showed that the combination of selenium, Vitamin C,  $\beta$ -carotene, Vitamin E, and methionine was significantly better in controlling pain compared to placebo<sup>[33]</sup>. In summary, there are conflicting data about the effectiveness of antioxidant therapy. A few trials show potential benefit, but further research is needed before it can become standard of therapy.

### Endoscopic therapy

Endoscopists have shown that they can overcome pancreatic duct obstruction caused by ampullary stenosis, strictures, or stones. However, there have been no published validated guidelines for defining significant obstruction, and methodology for assessing patients before treatment and then judging the efficacy of that treatment. It should be noted though that the alternative to endoscopy, surgical sphincterotomy and sphincteroplasty, have already proven to be less efficient<sup>[34,35]</sup>. These interventions are hardly ever used now. This may also be due to the more acceptable rate of complication with endoscopic procedures, in conjunction with stent placement and stone extraction. For the present, the decision to perform endoscopy is based partially on subjective judgments that include assessment of the need for long-term narcotic therapy, marked diminution of the quality of life because of intractable pain, or major nutritional consequences of pain. When major pain episodes cannot be controlled by major, but acceptable maintenance analgesics, intervals of narcotics, or reasonable and brief periodic hospitalizations, a trial of interventional therapy can be justified. Among three recent studies involving stent therapy in 98 patients, at times associated with other interventional therapies such as lithotripsy and/or sphincterotomy<sup>[36-38]</sup>, two studies<sup>[36,38]</sup> reported amelioration of pain and one did not<sup>[37]</sup>.

The ideal treatment for patients with pancreatic-duct stones, dilated pancreatic ducts, and pain is not known. The stones can be easily removed coincidentally with the performance of a surgical-drainage procedure, such as pancreaticojejunostomy. Alternatively, however, they can be fragmented by extracorporeal shock-wave lithotripsy (ESWL) and removed endoscopically after sphincterotomy of the pancreatic duct. Stones can be cleared by this approach in roughly 80 percent of patients, and approximately 50% of these have long-term relief of their symptoms<sup>[39,40]</sup>. Dumonceau *et al* conducted a randomized trial comparing pain relief after extracorporeal shock wave lithotripsy alone *versus* in combination with endoscopic drainage of the main pancreatic duct in patients with painful calcified chronic pancreatitis. Two years after trial intervention, 10 (38%) and 13 (45%) patients of the ESWL alone and ESWL combined with endoscopy group, respectively, had presented pain relapse. In both groups, a similar and significant decrease was seen after treatment in

the number of pain episodes/year (mean decrease 3.7 episodes). There was no difference between the treatment groups and the treatment costs per patient were three times higher in the ESWL combined with endoscopy group compared with the ESWL alone group<sup>[41]</sup>. The claims for the efficacy of stone removal for pain relief should be considered in context with the observations that the presence or absence of stones does not necessarily correlate with the existence of pain. In the absence of randomized prospective trials comparing stone ablation either with placebo or with surgical decompression, it is difficult to assess the results of pancreatic stone removal.

An alternative involves the use of endoprotheses or stents placed in the pancreatic duct endoscopically. Reports indicate that 30%-76% of patients receiving such stents had symptomatic improvement over a period of 14 to 36 mo of observation<sup>[42-46]</sup>. Cremer *et al*<sup>[42]</sup>, for example, noted initial improvement of symptoms in 94% of patients who were so treated for pancreatic-duct strictures and upstream ductal dilatation. In that group of patients, 53% remained free of symptoms over a mean follow-up period of 36 mo. Similarly, Grimm *et al*<sup>[43]</sup> showed that 57% of their patients were symptomatically improved by this treatment over a mean follow-up period of 19 mo. Although these results seem encouraging, a criticism is that most of the data reported to date were from relatively short term, nonrandomized studies. The issue is further complicated by the fact that pancreatic-duct stents may not be entirely harmless; for example, they may cause further pancreatic duct changes and potentiation of chronic pancreatitis<sup>[47-49]</sup>. Endoprosthesis occlusion and migration also seem to be relatively common.

Analyzing all the endoscopic modalities taken together it is usual to find a report of 80%-90% complete stone clearance and good immediate pain relief<sup>[47]</sup>. The long term results were not as favorable in the larger series. Delhaye *et al*<sup>[39]</sup> found that of 123 patients, only 60% experienced complete or partial pain relief during 14 mo follow-up. So far there are two randomized control trials comparing endoscopic therapy with surgery<sup>[50,51]</sup>. The study from Dite *et al* randomized 72 patients with large duct chronic pancreatitis to endoscopic therapy *versus* surgical lateral pancreaticojejunostomy. In addition, 68 patients were treated with endoscopy or surgery based on patient preference. The results between the randomized and nonrandomized study groups are similar. After 5 years of follow-up only 14% of the patients treated by endoscopy were pain free compare with 36% in the surgery group. The latest randomized controlled study comparing endoscopy with surgery (lateral pancreaticojejunostomy) enrolled 36 patients. The results are strikingly similar to the previous study. Pain was absent in 16% of patients treated with endoscopy and 40% in patients treated with surgery. Based on these trials it appears that surgery provides better pain relief compared to endoscopy, but even surgery fails to provide substantial pain relief in more than half of the patients<sup>[51]</sup>.

Endoscopic treatment may have a place in the prevention of acute relapsing pancreatitis, more so than treatment of the pain of chronic pancreatitis. To avoid this potential problem, some have suggested that endoscopically placed pancreatic-duct stents should be used only for relatively short periods. This serves as a screening procedure, to identify those patients most likely to benefit from surgical drainage<sup>[42,45,52]</sup>. At present, endoscopically placed stents should be considered an unproved, but potentially useful approach to the treatment of chronic pancreatitis.

Kozarek and Traverso<sup>[53]</sup> have analyzed collected experiences and indicate that the likelihood of symptomatic improvement with combination endotherapy is reported to be 50%-85% at 15 to 25 mo. Successful pain relief has been correlated anecdotally with stone removal and subsequent decrease in diameter of the pancreatic duct. As a rule, the focus is on stones in the main duct and the morbidity of side-branch stones has not been defined. Better selection of patients for endotherapy may be helpful in order to maximize results. Due to its low degree of invasiveness, however, endotherapy can be offered as a first-line treatment, with surgery being performed in case of failure and/or recurrence.

### **Nerve blockade**

Although this modality is thought to be medical management, it may be administered *via* endoscopic or interventional radiological means. Although widely used, there have been relatively few formally reported experiences with nerve blocks for long-term therapy of chronic pancreatitis. Leung *et al*<sup>[54]</sup> studied the use of celiac block in 23 patients with chronic pancreatitis. Twelve of the 23 had complete analgesia, whereas six had partial relief. There was no effect in five patients. The mean pain-free period in the chronic pancreatitis patients was only 2 mo, and the longest 4 mo. Benefit was least in patients with previous pancreatic surgery and repeat blocks were unhelpful.

Because of possible concerns about potential irreversible nerve injury, including very rare anecdotes of paraplegia from neurolytic agents, injection of steroids for the treatment of chronic pancreatitis has been recommended, instead of the use of alcohol injected into the celiac plexus (principally used in the treatment of cancer pain)<sup>[55,56]</sup>. In one study, steroid injection provided relief of pain (lasting two mo) in only 4 of 16 patients<sup>[57]</sup>. Eleven of the 12 patients who did not obtain relief were narcotic dependent, whereas none of the four who obtained relief were narcotic dependent. This finding emphasizes the complexity of treating pain in a population of patients with chemical dependencies and other abnormal psychological and psychosomatic behavior. In another report<sup>[58]</sup>, which investigated the mode of delivering the nerve block, only 2 of 8 patients with a CT-guided celiac plexus block experienced relief of pain compared with 6 of 14 who were treated by endoscopic ultrasonography-guided celiac plexus block with 10 mL of bupivacaine. The benefit from endoscopic ultrasonography-guided celiac plexus block

seemed to persist longer than CT-guided block. More importantly, paraplegia has not been described after endoscopic ultrasonography-guided celiac plexus block, probably because of the anterior transgastric approach taken during endoscopic ultrasonography-decreasing or even eliminating the risk of nerve or spinal cord injury. The same group of investigators more recently published their prospective experience with endoscopic ultrasonography-guided celiac plexus block with steroids in 90 patients with pain resulting from chronic pancreatitis<sup>[59]</sup>. A significant improvement in pain score occurred in 55% of the patients. The benefit persisted beyond 12 wk in 26% of patients and beyond 24 wk in only 10%. Younger patients (< 45 years) and patients with previous pancreatic surgery for chronic pancreatitis did not appear to benefit from the block.

The current evidence indicates that endoscopic ultrasonography-guided celiac plexus block is safe and well tolerated, with excellent temporary results in some patients. Unfortunately, reliable predictors of success are lacking. In the absence of long-term studies with follow-up in patients with chronic pancreatitis whose pain is chronic, the role of endoscopic ultrasonography-guided celiac plexus block should be limited to treating flares of chronic pain in patients with otherwise limited therapeutic options.

### **Surgical treatment**

Duval pioneered efforts to treat the pain of chronic pancreatitis by surgical means in the 1950s with transduodenal sphincteroplasty and with caudal pancreatojejunostomy (the Duval procedure). The results of this procedure were fraught with variable and usually poor results, perhaps only helping some of those patients with true recurrent acute pancreatitis<sup>[60]</sup>. A more extensive drainage procedure, lateral pancreatojejunostomy, described by Puestow and Gillesby<sup>[61]</sup> and subsequently modified by Partington and Rochelle<sup>[62]</sup>, was applied to the subset of patients with dilated main pancreatic duct and became the first surgical treatment widely considered to be effective for pain in this disease. At that time, however, its application was hampered because there was no way to determine preoperatively if a patient with chronic pancreatitis had the dilated ducts required for this procedure because neither ERCP nor CT was available until the 1970s. Thus, at exploration an intraoperative pancreatogram was used to select who would be candidates for lateral pancreatojejunostomy. In those without dilated ducts, the remaining options were to perform a sphincteroplasty (which was largely abandoned because of its failure) or to do nothing further. In the 1960s, surgeons began performing pancreatic resections for chronic pancreatitis, initially distal pancreatectomies (with poor results) and later distal subtotal (95%) resections, which were relatively more effective for pain, but rendered most patients diabetic<sup>[63]</sup>. Proximal resections of the head of the pancreas (i.e. Whipple procedures) were not widely applied until the 1980s, when the associated operative morbidity and mortality fell substantially<sup>[64-66]</sup>.

Patients whose pain persists in spite of aggressive noninvasive treatment should undergo endoscopic retrograde pancreatography to define the caliber and morphologic characteristics of their pancreatic ducts. Depending on the population being studied, up to half of these patients may have dilated ducts, frequently with areas of stricture-the "chain of lakes" or "string of pearls" appearance; the remainder have either ducts of normal caliber (2 to 4 mm in diameter) or small ducts that may lack side branches-the "tree in winter" appearance<sup>[67,68]</sup>. Ducts larger than 8 mm in diameter can be successfully decompressed by an internal surgical-drainage procedure, such as a longitudinal pancreaticojejunostomy (the modified Puestow procedure)<sup>[60,62]</sup>, but smaller ducts are not amenable to internal surgical drainage or resection.

Like most surgical procedures currently in use, those for chronic pancreatitis gradually became part of the armamentarium without undergoing rigorous testing and were never compared against medical treatment or no treatment. The vast majority of patients are still operated on when they continue to have intractable pain despite medical treatment. There are very few controlled trials in the surgical literature on this disease. The two randomized controlled studies comparing surgery with endoscopic therapy are discussed in the endoscopic therapy section. Surgical options include decompression/drainage operations, pancreatic resections, and denervation procedures. As with endoscopic interventional therapy, objective transferable criteria for the need for surgical intervention have not been developed or agreed upon.

**Decompression/drainage operations:** At present, the ultimate role of these various invasive approaches to the treatment of patients with large-duct, symptomatic chronic pancreatitis has not been established. Given the information available at the present time, most physicians recommend longitudinal pancreaticojejunostomy for patients with pain and dilated ducts. This operation may also retard the progression of exocrine and endocrine insufficiency<sup>[69,70]</sup>. Surgical decompression of the obstructed main pancreatic duct was for a long time the gold standard<sup>[71]</sup>. Drainage procedures today are most commonly side to side pancreaticojejunostomy. This particular procedure preserves parenchymal function. Longitudinal pancreaticojejunostomy is also used based on the concept the ductal obstruction leads to distention and that this in turn gives rise to pain and should thus be favored if the duct is widened. Ebbehøj *et al*<sup>[72]</sup> were able to show a relationship between the degree of pain and intrapancreatic pressure. Pancreatic pressure was measured by a percutaneously placed needle preoperatively, postoperatively, and one year after pancreatic duct drainage. Patients whose pressure decreased after surgery and remained low were pain free, whereas those with recurrent pain had increased pressure.

Theoretically, any procedure that improves drainage, either by improving flow into the jejunum or stomach, might be expected to relieve pain. Pancreatic decom-

pression results in immediate and lasting pain relief in a high proportion (80%-90%) of patients with non-alcoholic chronic pancreatitis<sup>[73]</sup>. These procedures have been less successful with alcoholic chronic pancreatitis with pain relief averaged at 60%<sup>[74]</sup>. Although early good results have also been reported after a lateral pancreaticojejunostomy in patients with alcoholic pancreatitis, when these patients are followed for 5 years only 38%-60% of them continue to be pain free<sup>[75]</sup>. These operations are predicated upon the presence of a widely dilated main pancreatic duct (generally taken as > 6 to 7 mm) and the presumption that the dilated ducts imply an abnormally high pressure in the duct system<sup>[75]</sup> and in the pancreatic parenchyma<sup>[72,76]</sup>. The operation most commonly performed is a variant of the Puestow procedure, which is actually the Partington-Rochelle modification (lateral pancreaticojejunostomy)<sup>[62]</sup>.

Many of the studies of lateral pancreatico-duodenectomy find that short-term pain relief is achieved in about 80% of patients and that the operation can be performed with a very low morbidity and mortality (0%-5%). Although the short-term studies shine a positive light on the procedure, long-term follow-up studies show that pain not uncommonly recurs. As time goes by, pain recurs, perhaps related to progression of the pancreatic injury and fibrosis. Pain relief for greater than two years is achieved in only 60% of patients<sup>[77,78]</sup>. Strategies for salvage in patients with persistent or recurrent pain after drainage procedures include redoing or extending the pancreatojejunostomy and resection procedures<sup>[79]</sup>. Of patients undergoing pancreatic duct drainage procedures, 25%-66% require concomitant biliary or gastric drainage, because of functionally significant obstruction of the bile duct or duodenum<sup>[80,81]</sup>. Biliary or duodenal strictures have been reported to be more likely in patients with large-duct disease than in their counterparts without dilated ducts<sup>[81]</sup>.

The only reported attempt made to compare pancreatic duct drainage with no intervention in the management of pain is that of Nealon and Thompson<sup>[70]</sup>. In a series of 143 patients with chronic pancreatitis, 85% of the 87 patients who were treated by pancreatic duct decompression achieved pain relief, whereas pain abated spontaneously in only 1.3% of the 56 nonoperative patients. The study was not randomized, however, the principal criterion to determine candidacy for the operation was the presence of a dilated pancreatic duct. Thus, what the study actually reports is the outcome of pancreatojejunostomy in patients with dilated ducts *versus* the natural history of patients with chronic pancreatitis and no duct dilation. The study also found that deterioration of pancreatic function was slower in their patients with dilated ducts than in those with small ducts. Although this effect was ascribed by the investigators to the protection or relief afforded by the surgical drainage procedure, the cause and effect relationship is uncertain because of the differences in the patient population.

The consensus, albeit based on evidence from collected experiences, states that pancreatic duct decompression *via* lateral pancreatojejunostomy (a Puestow-type operation) can be accomplished with low associated morbidity and mortality and that pain relief will be achieved in the

majority of patients. For most experienced pancreatic surgeons, it is the preferred surgical treatment option in patients whose main pancreatic duct measures 6 mm or more because of its simplicity, safety, and benefits, including the advantage that remaining pancreatic tissue and function are at least not compromised further by loss from resection.

Drainage of pancreatic pseudocysts provides another form of pancreatic decompression in conjunction and even in continuity with a lateral pancreaticojejunostomy when the main duct is also dilated. Up to 39% of patients undergoing lateral pancreaticojejunostomy have evidence of pseudocysts disease at the time of surgery<sup>[82]</sup>. Pseudocysts are found in about 25% of patients with chronic pancreatitis and have a much lower rate of spontaneous resolution than those that are a consequence of an attack of acute pancreatitis<sup>[82-84]</sup>. They can be the source of pain indistinguishable from that of the underlying chronic pancreatitis. In one study, surgical drainage resulted in complete short-term pain relief in 96% of 55 patients, and 53% remained pain free after a median follow-up of 11 years<sup>[84]</sup>. Endoscopic drainage of pseudocysts into the stomach or duodenum may be an alternative, especially in patients who do not have associated duct dilation. Studies directly comparing surgical with endoscopic drainage of pseudocyst are lacking.

It should also be mentioned that there are numerous variations of the previously mentioned operations. Frey *et al*<sup>[85,86]</sup> combined a coring out of the pancreatic head with a lateral pancreaticojejunostomy. In his series, the pain relief after 5 years was complete or improved in 87% of cases. There is also one randomized series of patients comparing the Beger and Frey procedure<sup>[86-90]</sup>, with no difference in decrease of pain, but less morbidity with the Frey procedure.

**Resection procedures:** The therapeutic principle of resection is based on the assumption that pain in chronic pancreatitis is predominantly caused by inflammation. This inflammation then becomes the nidus for qualitative and quantitative changes of nerve fibers. This is especially seen in the clinical scenario of normal sized ducts and masses of the head of the pancreas. Thirty percent of patients with chronic pancreatitis develop inflammatory enlargement of the pancreatic head with subsequent obstruction of the pancreatic duct, and sometimes also of the common bile duct and duodenum. In these cases a pancreaticoduodenectomy, "Whipple procedure", has been the procedure of choice for a long time, as it provides reasonably effective pain relief. These resections, however, have both immediate postoperative morbidity and long-term morbidity. Insulin dependent diabetes mellitus has an increase in the incidence from 20% preoperatively to 60% in the years that follow<sup>[81]</sup>. Also, postgastrectomy complications detract significantly from the overall quality of life. The long-term mortality rate and quality of life after this procedure in patients with chronic pancreatitis has not always been encouraging, and in some studies disappointing<sup>[71]</sup>.

Distal pancreatectomy alone had poor results unless the disease is largely confined to the body and tail of the gland, e.g. with an occlusion of the mid-pancreatic duct or with a pseudocyst in the tail. By contrast, resection of the pancreatic head by either a conventional or pylorus-preserving pancreaticoduodenectomy will provide pain relief in up to 85% of patients, even if the disease extends into the distal pancreas. In order to deal with these undesirable consequences of the Whipple procedure, surgeons turned to the pylorus preserving pancreaticoduodenectomy (PPPD) and the "Beger procedure"<sup>[88-91]</sup>. Russel<sup>[92]</sup>, in studying the results of preservation of the duodenum in total pancreatectomy compared with those of standard pancreaticoduodenectomy, found no difference in pain relief between the results of the two operations. He noted that 13 (14%) of the 32 still had severe pain after duodenum preserving total pancreatectomy, and that six required major analgesics. The purported benefits of better postoperative nutritional status and glucose control in the duodenum-preserving procedure were addressed in two randomized trials<sup>[93,94]</sup>.

Frey and Amikura have recently reported a surgical modification that combines removing part of the anterior segment of the pancreatic head with longitudinal duct anastomosis to the jejunum<sup>[86]</sup>. A randomized trial<sup>[87]</sup> found little difference between the Frey procedure and the duodenum-preserving resection of the pancreatic head as described by Beger and Buchler<sup>[95]</sup>.

Noteworthy in recent years has been the very low operative morbidity and mortality of pancreatic resection, which may be one reason for the larger numbers of patients with benign disease being referred for surgical treatment. In a recent series of 231 pancreatic resections, the most frequent indication being chronic pancreatitis, the operative mortality was 0.4%<sup>[66]</sup>. McLeod *et al*<sup>[96]</sup> studied the morbidity of the Whipple operation. Although the study focused on resections for neoplasms, the observations pertain as well to those for chronic pancreatitis and show satisfactory digestion, weight maintenance, and activity level in the great majority of patients. A study of quality of life after pancreatic resections found that diabetes and its complications had the greatest negative influence on everyday well-being<sup>[97]</sup>.

Distal pancreatectomy<sup>[98]</sup> has a very limited role in management of pain, and only in patients with non-dilated pancreatic duct and pseudocysts involving the tail of the pancreas does this procedure seem to be associated with a good outcome<sup>[99]</sup>. Keith *et al*<sup>[100]</sup>, analyzed the results of 80% distal pancreatectomy, pancreaticoduodenectomy and total pancreatectomy. After an average follow-up of 5 years, 9 years, and 6 years, respectively, he found that four of five patients after pancreaticoduodenectomy required narcotics. Thirteen of 32 patients had complete pain relief after 80% distal pancreatectomy. Finally total pancreatectomy is usually reserved as a last resort following a failed partial pancreatic resection.

Resection of pancreatic tissue results in the loss of

some exocrine and endocrine function and increases the possibility or hastens the onset of fat malabsorption and diabetes. Whereas only 20% of normal pancreatic tissue is required for clinically adequate function, the pancreas already damaged by chronic pancreatitis may have substantially reduced reserves even before resection. Because of the complete lack of insulin and glucagon after total pancreatectomy, very brittle diabetes may ensue and can be the source of considerable morbidity and even mortality. In an attempt to lessen these adversities, autotransplantation of either part of the organ<sup>[101]</sup> or of islet tissue<sup>[102]</sup> has been described. In the latter study, Farney *et al* obtained insulin independence in 20% of 24 patients at a mean follow-up of 5.5 years. A more extensive experience with islet cell autotransplantation was reported by the Minnesota group in 1995 comprising 48 patients<sup>[103]</sup>. Forty-seven of the 48 patients had small duct chronic pancreatitis. Only one postoperative death resulted, but 25% of patient's encountered complications. There were 8 deaths in the follow-up period, none apparently attributable to the operation. In follow-up, from 1 mo to 17 years, 39% of patients reported that pain was resolved, and 61% still had some degree of pain. Twenty of 39 evaluable patients (51%) had initial (less than 1 mo) insulin independence, but this dropped to 15 patients (38%) beyond 1 mo. A more recent European experience of 13 patients indicated sustained insulin independence in 5 of 9 surviving patients (4 late deaths) from 9 to 48 mo after surgery<sup>[104]</sup>. The latest studies suggest improvement in both the areas of brittle diabetes and in pain control. Rodriguez *et al*<sup>[105]</sup> recruited 22 patients who underwent pancreatectomy and autologous islet cell transplantation. All patients demonstrated C-peptide and insulin production indicating graft function. Forty-one percent were insulin dependent, and 27% required minimal amount of insulin or a sliding scale. Eighty-two percent no longer required analgesics postoperatively and 14% experienced a decrease in need for narcotics. Their success was attributed due to the provision of pancreatectomy and islet cell transplantation earlier in the course of the disease. Clayton *et al*<sup>[106]</sup> followed 40 patients who had pancreatectomy followed by islet cell transplantation. At 2 years post-transplant, 18 patients had a median HbA1c of 6.6% (5.2%-19.3%), fasting C-peptide of 0.66 ng/mL (0.26-2.65 ng/mL), and required a median of 12 (0-45) units of insulin per day. At 6 years, these figures were 8% (6.1%-11.1%), 1.68 ng/mL (0.9-2.78 ng/mL) and 43 U/d (6-86 U/d), respectively. The majority of patients (68%) no longer require opiate analgesia. Finally, Gruessner *et al*<sup>[107]</sup> performed 112 islet autotransplants at the time of total pancreatectomy. They found that islet autotransplants, at the time of total pancreatectomy in patients who had not had previous operations on the body and tail of the pancreas, were associated with > 70% of the recipients achieving complete insulin independence. In contrast, a previous distal pancreatectomy or a Puestow drainage procedure was associated with complete insulin independence in < 20%. Islet autotransplantation offers a valuable addition to surgical resection of the

pancreas, as a treatment for chronic pancreatitis; and even in cases in which insulin independence is not achieved, the potential beneficial effects of C-peptide make the procedure worthwhile, particularly in early disease.

Many studies on pancreatic resection and even those on drainage procedures show that up to 15% of patients undergoing these surgical treatments for treatment of pain due to chronic pancreatitis will be found to have pancreatic cancer<sup>[7,79,99,108]</sup> and it has been shown that a chronic pancreatitis is in fact, a small, but real risk factor in the development of pancreatic cancer<sup>[109]</sup>. This is an important consideration to keep in mind during the diagnostic work-up and choice of operation. The morphology of the pancreas by CT imaging and by cholangiopancreatography may fail to discriminate between cancer and chronic pancreatitis. Cytological confirmation by fine-needle aspiration is helpful when positive, but the true diagnosis may become known only with resection (10% of cases). This consideration in some cases may determine the treatment strategy.

**Surgical denervation:** Most of the sensory nerves returning from the pancreas pass through the celiac ganglion and splanchnic nerves. It is hypothesized that interruption of these fibers may lessen pain. Mallet-Guy<sup>[110]</sup> reported an experience with 215 patients over 30 years whose principal treatment for pain was by sensory denervation. These patients first underwent abdominal exploration to document the absence of pancreatic ductal dilation or pseudocysts and to correct any associated biliary pathology; this was immediately followed by resection of the greater splanchnic nerve and celiac ganglion through a left translumbar approach. Although excellent long-term results are reported (90% of patients were pain-free, with 60% followed for more than five years), the heterogeneity of the patient population and the simultaneous use of biliary diversion procedures in many cases precludes meaningful conclusions. This treatment has not been widely accepted.

The celiac block can be done during laparotomy or percutaneously, usually from the back. The placement of the injection can be done simply by using anatomical landmarks or by checking the position with an imaging modality: fluoroscopy, scout X-ray films, ultrasonography, computed tomography, or at angiography. A nerve block with 25 mL of 50% alcohol on each side should be preceded by a positive diagnostic block with long acting local anesthesia, carried out at least 1 d earlier. The method aims at blockage of the splanchnic nerves before they reach the celiac plexus<sup>[111]</sup>.

Stone and Chauvin reported on 15 patients with chronic pancreatitis who had previous unsuccessful operative procedures for pain<sup>[112]</sup>. Denervation was accomplished with a transthoracic left splanchnicectomy with concomitant vagotomy, and all 15 patients had immediate pain control. Five later suffered recurrent pain, but were successfully treated with a right splanchnicectomy. The long-term outcomes are not

known. The advent of thoracoscopic surgery has made this procedure more attractive, and a few small series have reported its feasibility and early results<sup>[113,114]</sup>. Maher *et al* recently reported on 15 patients with chronic pancreatitis, mostly idiopathic, with chronic pain measured by visual analogue pain scale<sup>[115]</sup>. Unilateral thoracoscopic splanchnic nerve resection in eight patients and bilateral in seven patients resulted in significant decreases in pain frequency and intensity, as well as in narcotic consumption. Overall, 80% of patients had good results or were improved, with a mean follow-up of 16 mo. A controlled trial comparing this procedure to other surgical options or to medical treatment is needed. Of note, pancreaticoduodenectomy and duodenum-preserving resection of the pancreatic head may well confer pain relief at least in part through denervation.

## CONCLUSION

Pain is the most difficult to treat symptom of chronic pancreatitis. The current approach is largely based on data from studies of suboptimal quality and expert opinions. At present, a step wise strategy is recommended starting with life style modifications such as alcohol abstinence and low fat diet, then moving to high dose non-coated pancreatic enzymes and oral analgesic therapy. In patients with dilated main pancreatic duct unresponsive to medical therapy, endoscopy or decompressive surgery should be considered. Patients with debilitating pain, non-dilated pancreatic duct and inflammatory masses may be candidates for resective surgery. The role of pain modifying agents (antidepressants, gabapentin, pregabalin), celiac plexus block, antioxidants, octreotide and total pancreatectomy with islet cell auto transplantation remains to be determined.

### Abstract

The diagnosis of Chronic Pancreatitis (CP) is based on the detection of abnormal structure or function of the diseased pancreas. The pancreatic function tests more accurately determine the presence of CP than tests of structure, especially for early stage disease. The function tests can be divided into two categories: non-invasive and invasive. The invasive "tube" tests can reliably detect mild, early CP, but are only available at a few referral centers and tend to be poorly tolerated by patients. The non-invasive tests are easy to obtain, but tend to perform poorly in patients with early, mild disease. Therefore, no one test is useful in all clinical situations, and a detailed understanding of the rational, pathophysiologic basis, strengths, and limitations of various tests is needed. This review highlights the role of various pancreatic function tests in the diagnosis of CP including fecal fat analysis, fecal elastase, fecal chymotrypsin, serum trypsin, the secretin stimulation test, the cholecystokinin (CCK) stimulation test, the combined secretin-CCK stimulation test, the intraductal and endoscopic secretin stimulation tests, and the functional magnetic resonance imaging of the pancreas after secretin stimulation.

### INTRODUCTION

Gastroenterologists frequently encounter patients with Chronic Pancreatitis (CP), which is responsible for 86 000 annual admissions in the United States alone<sup>[1]</sup>. Even more frequently encountered is the patient with chronic abdominal pain and suspected CP based on equivocal imaging or laboratory findings. Although defined by irreversible histologic damage to the pancreas, histologic specimens are difficult and morbid to obtain. Therefore, in practice, the diagnosis of CP is based on the detection of abnormal structure or function (endocrine and exocrine) of the diseased pancreas. However, gross radiographic and endoscopic structural changes are insensitive and can be nonspecific - especially for early stage disease. Therefore, gastroenterologists are often forced to rely on tests of pancreatic function, the so-called, pancreatic function tests (PFT's), to diagnose CP. Arguably, these more accurately determine the presence of CP than tests of structure. Unfortunately, many of these PFT's themselves have significant drawbacks.

Several new PFT's have been introduced in the last 5-10 years, such as fecal elastase, Secretin-stimulated Magnetic Resonance Cholangio-pancreatography (S-MRCP), and endoscopic Pancreatic Function Testing (ePFT).

A few key points in using and interpreting PFT's are: first, they can be falsely positive for at least a few months after an attack of acute pancreatitis; second, negative PFT's do not exclude acute relapsing pancreatitis in patients who do not yet have structural or functional pancreas damage; third, although the best PFT's, especially the secretin-based stimulation tests, are more sensitive in the detection of CP than nonfunctional tests, rarely they still can miss early stage CP.

### NORMAL PANCREATIC PHYSIOLOGY

In order to appreciate the utility of pancreatic function

testing, one has to understand the normal functioning of the pancreas. In the basal or fasting state, the pancreas excretes small amounts of protein - rich and mildly alkaline fluid. During a meal, gastric distension and acid production stimulate the duodenal S cells to release secretin into the blood, which signals the ductal cells of the small ducts of the pancreas to secrete a large volume of bicarbonate-rich, clear, watery fluid (so called *hydraulic secretion*). Similarly, the postprandial increase in amino acids and fatty acids in the duodenal fluid stimulates the I cells of the duodenum to secrete cholecystokinin (CCK, aka pancreozymin). CCK, in turn, signals the acinar cells of the pancreas to release enzyme-rich fluid into the pancreatic duct. This is so called *ecbolic secretion*<sup>[2]</sup>. For completeness, vago-vagal pathways also stimulate pancreatic secretion and modulate hormone release. These are primarily responsible for an increase in pancreatic secretion during the cephalic phase of digestion. The effects of these two hormonal systems (Secretin and CCK) are measurable and are abnormal in CP. For example, CCK levels are elevated in patients with early CP compared to controls, and these levels are often low in advanced disease<sup>[3]</sup>. In general terms, the chronically damaged pancreas produces decreased volume, bicarbonate, and enzymes in pancreatic juice in response to a stimulus than the normal pancreas. These decrements can be exploited during pancreatic function testing.

## NATURAL HISTORY OF CP

Pancreatic function testing is clinically important for a number of reasons. First, CP is a heterogenous disease. Patients lie on a spectrum ranging from early, painful disease (so called minimal change, or small duct CP) with relatively preserved physiology to end stage disease with very little endocrine or exocrine function. Patients with early stage CP are very difficult to diagnose and distinguish from other causes of chronic abdominal pain. For example, conventional testing, such as pancreas-protocol computed tomography (CT) scans, Magnetic Resonance Imaging (MRI), and Magnetic Resonance Cholangio-Pancreatography (MRCP), generally detects patients with late stage CP, typically when 50% or more of the gland is fibrotic and has been essentially destroyed. Some experts suggest that the traditional pancreatic function tests may detect patients with as little as 30% damage to the pancreas<sup>[4]</sup>.

Another reason that PFT's are useful is that clinical assessment of steatorrhea (exocrine dysfunction) is unreliable. Many patients can have steatorrhea with only a single formed bowel movement a day. Further complicating the prediction of steatorrhea is the often long course of acute pain relapses or early CP that occurs for many years before the development of steatorrhea. In natural history studies, the time to the development of steatorrhea is quite long, about 20 years. Part of this lag time is explained by the pancreas' extensive reserve of lipase secreting capacity. The pancreas has to lose ninety percent of its lipase

production before steatorrhea is measurable by fecal fat testing. Yet, lipase depletion occurs earlier and is more profound than protease and amylase deficiency<sup>[5]</sup>. This fact can be exploited during pancreatic function testing. Part of lipase's vulnerability is its dependence on bicarbonate secretion by the pancreas to ensure a high duodenal pH - up to 7.5-9.0 for optimum activity. Endocrine dysfunction may occur at, or slightly after, the development of steatorrhea<sup>[6]</sup>. Certainly, the time course of exocrine and endocrine dysfunction varies depending on the etiology of the CP. As an extreme example, cystic fibrosis patients can present in infancy with failure to thrive due to exocrine failure<sup>[7]</sup>.

## PROBLEMS WITH STRUCTURAL (NONFUNCTIONAL) TESTS FOR CP

Besides the subtle progression of the natural history of CP as a reason for the utility of pancreatic function testing, many of the conventional tests in the detection of CP have a number of drawbacks.

### CT

CT is fairly sensitive for the detection of advanced CP with calcification, atrophy, fat replacement, and ductal dilation. In some studies as high as 75%<sup>[8]</sup> to 80%<sup>[9]</sup>. However, others have found that when compared to better tests such as ERCP and Secretin-CCK function testing, CT is only 47% sensitive in the diagnosis of CP. The specificity of CT is considerably higher than the sensitivity, around 90%<sup>[10]</sup>. CT carries the additional benefit of evaluating the pancreas for other pathology (e.g. pancreatic cancer), and the whole abdomen for alternative explanation of the patient symptoms.

### MRCP

MRCP is a fairly good test for the detection of advanced CP. However, even compared to the relatively insensitive endoscopic retrograde cholangiopancreatography (ERCP), MRCP is only about 75% sensitive for advanced disease and 25% for small duct CP<sup>[11]</sup>. Generally, MRCP detects many of the same changes that are seen on CT. An added benefit of MRCP is improved detection and characterization of biliary and pancreatic strictures compared to other noninvasive imaging tests. However, the visualization of the pancreatic duct (PD) can be difficult by MRCP, which depends on volume and flow in the pancreatic duct that is already quite low in CP. Non-occluding strictures can make visualization of the PD difficult. Generally, conventional MRCP, like CT, does not detect subtle side branch abnormalities of minimal change CP<sup>[12]</sup>.

### ERCP

This test involves cannulation of the pancreatic and biliary ducts. ERCP is generally considered the gold standard in the diagnosis of structural pancreatic duct diseases. In several studies, ERCP can even detect a very small number of patients with negative PFT's<sup>[13]</sup>.

However, these changes can be seen in the normally aging pancreas, and, overall, the sensitivity of ERCP for small duct CP is significantly less than that of the best pancreatic function tests, even at the quaternary centers most proficient at ERCP<sup>[14,15]</sup>. Overall, ERCP has sensitivity of 66% for detecting minimal change CP and is 93% sensitive for late stage CP, compared to secretin stimulation testing<sup>[5]</sup>. In addition, ERCP is highly operator dependent. Furthermore, it is fairly invasive and carries a risk of up to 20% of acute post-ERCP pancreatitis which is greatest in the patients suspected of having minimal change CP (with non-dilated ducts). Recent preliminary data suggest that even a relatively mild episode of acute post ERCP pancreatitis may lead to CP when evaluated several years after the episode of post-ERCP pancreatitis<sup>[16]</sup>.

### **Endoscopic ultrasound (EUS)**

EUS is an excellent initial test of choice in the diagnosis of minimal change CP. It has relatively few risks, even if fine needle aspiration is used, and is as sensitive as MRCP in the detection of occult choledocholithiasis<sup>[17]</sup>, and is superior to MRCP and transabdominal ultrasound in detecting cholecystolithiasis. However, it does have several drawbacks. It still requires sedation so a full day of work is missed - not only by the patient, but by a driver/chaperone - making it relatively expensive. EUS is highly operator dependent. In addition, even more than ERCP, EUS can be falsely positive due to the echotexture changes of the normal aging pancreas or in diabetics. Therefore, EUS is better at "ruling out" CP than it is at "ruling in" CP. Sensitivities and specificities of EUS vary from 90% and 85% *versus* histology for advanced disease<sup>[18]</sup> to 97% and 60%, respectively for EUS-FNA compared to ERCP<sup>[19]</sup>, to 57% and 64%, respectively for plain EUS compared to secretin stimulation testing<sup>[20]</sup>, to 83% and 80%, respectively in a mixed population of early and advanced disease compared to histology<sup>[21]</sup>. Much controversy surrounds the endosonographic definition of CP, with some groups still using 3 EUS criteria for CP, while most agreeing that 5 or more criteria must be present diffusely<sup>[22]</sup>. Unfortunately, to date no consensus exists on the exact EUS diagnostic criteria for CP.

## **PANCREATIC FUNCTION TESTS FOR CP**

### **Noninvasive "tubeless" pancreatic function tests**

In an effort to discover a sensitive and specific function test for CP that avoids risk and invasive procedures and that can be performed on outpatient basis, several tests have been developed, all of which suffer several severe shortcomings, but may be useful in diagnosing CP in a patient with a long alcohol history or with equivocal imaging findings. Generally, these tests only detect advanced CP with steatorrhea, but are fairly cheap and reliable.

**Seventy-two hour fecal fat:** The 72 h fecal fat collection was once a routine part of the workup for malabsorption,

and it remains the gold standard for quantification of steatorrhea. However, it suffers from many drawbacks, including its nonspecificity for pancreatic disease. For example, bacterial overgrowth, short bowel syndrome, and small bowel mucosal disease (e.g. celiac disease and Crohn's disease) can present with steatorrhea. However, the diarrhea of CP tends to be less voluminous yet fattier than other diarrheal illnesses. In addition, the 72 h fecal fat is inaccurate when performed in the outpatient setting for several reasons. First, it is unrealistic to expect the patient to refrigerate 72 h worth of stool. Second, adherence to a standardized 100 g/24 h fat diet per day for a total of 6 d (the 3 d preceding the test and then the test itself) is difficult. Achieving at least 100 g/d, typical for a large fast food lunch of double cheeseburger and French fries with milkshake, is relatively easy (of course, false negatives can occur in the patient unable to consume that much fat due to pain, though, these are typically early CP patients, who do not yet have steatorrhea). However, quantification of daily fat intake with food diaries as an outpatient is unreliable, making calculation of the coefficient of fat absorption similarly unreliable. Third, for this test, the patient must be off of oral pancreatic enzymes supplements for about a week prior to collection. As a result, some patients have bloating, abdominal discomfort, and gas from malabsorption or are otherwise unwilling to stop the enzymes.

In our institution, for the above reasons, we reserve the 72 h stool collection for research purposes, during which time the patient is admitted to a metabolic ward with a dietician familiar with the protocol to monitor consumption and adjust later meals to account for what has not been consumed. A 72 h stool collection during a high fat diet showing more than 7 g/d fat in the stool is abnormal<sup>[23]</sup>. The levels of steatorrhea seen in CP tend to be much higher (often > 20 g/d). For practicality, most pancreatologists have abandoned this test. However, a modified 24 h protocol can be used for clinical purposes to monitor response to enzyme therapy in patients experiencing an unexplained increase in steatorrhea, especially in growing children with cystic fibrosis, despite alleged compliance with enzymes.

**Spot fecal fat:** Sudan staining of a random stool sample for fecal fat is relatively insensitive for fat malabsorption. Generally, it detects steatorrhea only at 25 g/d or more. As a stool collection, it suffers many of the drawbacks of the 72 h fecal fat, including patient embarrassment, need to stop pancreatic enzyme supplements, need to be on a high fat diet for several days before the collection, *etc.* Greater than 6 droplets of fat per high power field are indicative of steatorrhea. As in the case of the 72 h fecal fat analysis, fat substitutes in foods such as Olestra<sup>®</sup>/Olean<sup>®</sup> or drugs such as orlistat or ezetimibe can give false positive results.

**Fecal chymotrypsin:** In advanced CP, lower concentrations of pancreatic proteases reach the stool than in controls. Trypsin is the principal protease secreted by the

pancreas, however, it undergoes degradation in the distal small bowel so is not a good fecal marker for pancreas enzyme output<sup>[24]</sup>. On the other hand, several other proteases made by the pancreas, such as chymotrypsin are useful stool markers. As with all fecal protease assays, the fecal chymotrypsin should be thought of as a surrogate for the 72 h fecal fat rather than for the conventional, “tube,” pancreatic function tests. Chymotrypsin evades degradation in stool by binding to insoluble debris in stool and is stable for several days at room temperature, enabling a sample to be shipped to a reference lab. A fecal chymotrypsin below 3 U/g of stool suggests advanced CP. This test is altered by exogenous pancreatic enzyme supplementation so is useful to monitor for compliance, but is not available in the United States<sup>[25]</sup>. The fecal chymotrypsin assay is of little clinical value to detect early stage CP, but it has a reasonable sensitivity for advanced disease of from 50% to 80%, increasing to 80%-90% in cystic fibrosis<sup>[26]</sup>, with a specificity of 50%-100%<sup>[27-29]</sup>. As in all fecal protease assays, watery diarrhea, such as from short bowel syndrome, can give false positive results (low fecal chymotrypsin) by diluting the sample.

**Fecal elastase (FE):** Pancreatic elastase-1 is a pancreas-specific protease that is minimally degraded during intestinal transit. In fact, it is concentrated 6-fold in stool compared to duodenal juice<sup>[30,31]</sup>. The concentration of fecal elastase in stool measured by Enzyme Linked Immunosorbant Assay (ELISA) correlates well with duodenal amylase, lipase, and trypsin in both CP patients and controls<sup>[32]</sup>. Typically, a fecal elastase less than 100 mcg/g of stool indicates severe pancreatic insufficiency. A value between 100-200 mcg is indeterminate, but in the face of other evidence, is suggestive of CP. Values over 200 mcg are normal.

FE suffers from many of the same limitations of the fecal chymotrypsin assay, notably that it only detects patients with steatorrhea and severe CP that likely could have been detected by other means. In various studies, compared to conventional pancreatic function testing and ERCP, the sensitivity of FE varies from between 0%-65% for mild disease to 33%-100% for severe CP, with generally good specificity (from 29% to 95%)<sup>[33-37]</sup>. FE may be superior to fecal chymotrypsin. For example, in one small study the FE had a sensitivity of 64% for detecting CP compared to 25% for fecal chymotrypsin<sup>[38]</sup>. Also, like fecal chymotrypsin only a spot stool sample is required rather than a 24 h or 72 h collection. FE also does not cross react to exogenous porcine enzymes so patients can remain on therapy for the test. However, FE is more expensive than fecal chymotrypsin.

**Serum trypsin:** The serum trypsinogen (a.k.a. trypsin) assay is unique among pancreatic function tests in being a serum sample, making it convenient and relatively cheap. Low levels, less than 20 ng/mL, are specific for CP, but are sensitive only for advanced disease. Levels from 20-29 are indeterminate, but sometimes represent early CP<sup>[39]</sup>. Sensitivities for mild to severe CP patients

combined range from 33%-65%, but specificity is quite high<sup>[40]</sup>. Sensitivity for exocrine dysfunction is quite high, at about 95%<sup>[39]</sup>. One added benefit is that trypsin levels over 150 ng/mL are indicative of pancreatic inflammation. For example, the trypsin can be positive for a relapse of CP even when amylase and lipase levels are normal. Conversely, it can help differentiate benign, chronically elevated amylase and lipase from pancreatic inflammation<sup>[41]</sup>. The test used in our institution is a Radio-Immune Assay (RIA), so it has the disadvantage of requiring several days to obtain a result. We typically obtain this test along with the fecal elastase and pancreatic protocol CT as an initial battery in all patients suspected of having CP referred to our clinic. However, like the fecal assays, it is basically a marker of advanced disease and steatorrhea.

### ***Invasive, traditional, “tube” pancreatic function tests***

Since first described in the 1930s and 1940s, several techniques have been developed to measure pancreatic function after physiologic or supraphysiologic stimuli<sup>[42,43]</sup>. The central theme of these tests is to collect and quantitate the quality of pancreatic secretions to determine pancreatic secretory capacity.

**Secretin stimulation test (SST):** In a technique more widely publicized by Dreiling<sup>[44]</sup>, a double lumen, 26 Fr, oro-duodenal tube with both gastric and duodenal ports is introduced fluoroscopically, stiffened with a guidewire, with only topical anesthesia (benzocaine spray and viscous lidocaine) applied to the posterior pharynx. The weighted tip should be advanced close to the ligament of Treitz and the tapered radiopaque portion of the tube should be positioned at the pylorus. Placement can be hampered by multiple factors including patient discomfort, nausea, gastroparesis, and pyloric stenosis.

We place both the gastric and duodenal ports to low constant suction by an electric flywheel pump whose gauge measures 2-5 inches Hg (51-127 mmHg). However, the suction produced by these pumps may be lower than the gauge suggests: our lab has found that standard wall units are too strong and inconsistent and may result in adherence of the tube to the duodenal wall with clogging of the ports. Constant vigilance is required to prevent clogging of ports which decreases yield of duodenal fluid. During experiments with Polyethylene Glycol (PEG) labeled with carbon 14 (<sup>14</sup>C), 85% or more of duodenal fluid can be collected with this double lumen “Dreiling” tube with relatively little reflux of duodenal contents into the stomach<sup>[45,46]</sup>. We then measure basal duodenal and basal gastric pH and volume over 15 min. Next, we give a bolus of intravenous (IV) secretin, because bolus administration has been shown to be equivalent<sup>[47]</sup> or superior<sup>[48]</sup> to continuous infusion. The typical dose of porcine secretin is a 1 U/kg IV bolus. This is a supraphysiologic dose, but is usually well tolerated other than some flushing. However, the cost of secretin is fairly high. One study showed that an even higher dose of secretin (4-5 U/kg) might be more sensitive<sup>[49]</sup>. We now use synthetic human secretin at

dose 0.2 mg/kg which has been shown to be equivalent to porcine secretin<sup>[50]</sup>. We then measure three parameters of the duodenal fluid collected over one hour in four 15 min aliquots: volume, pH, and bicarbonate concentration in mEq/L measured by back titration with hydrochloric acid. Others have found that automated analyzers are almost as good as the standard labor intense back titration<sup>[51]</sup>. The gastric pH and volume at the end of the study are also recorded. The highest concentration of bicarbonate obtained among the four 15 min aliquots is the peak bicarbonate concentration. For completeness, a microscopic exam is performed on the duodenal aspirate for Giardia, Gram stain, and Crystals. Then, the bicarbonate output (the product of bicarbonate concentration and volume) for that hour long post-stimulation period is calculated. The tube is then removed and the patient can resume normal activities and can drive home. Standardized ranges are 80-130 mEq/L for the peak bicarbonate, 1.5-5.7 mL/kg for the volume/kg of patient weight, and 10.1 to 37.0 mEq/h for the bicarbonate output. If the peak bicarbonate is less than 80 mEq/L, the patient is very likely to have CP. If the volume is low and proper position of the collecting tube is reconfirmed, we typically state that the patient should be evaluated further for a pancreatic duct obstruction.

The SST is arguably the most sensitive test for CP. Classically, bicarbonate is thought to be produced by small pancreatic ducts<sup>[2]</sup>. Consequently, one might anticipate that the SST would be the most sensitive test to diagnose small duct, minimal change CP. This hypothesis was upheld in several studies. The SST, when compared with histology, is 75% sensitive in detecting early stage CP, and up to 97% for late stage disease with a specificity of 90%<sup>[52,53]</sup>. Compared to SST, ERCP has about a 66% sensitivity for early disease, though it comes close to SST for late stage disease<sup>[4,54]</sup>.

In addition, several histologic studies suggest bicarbonate production may be the best way to diagnose early CP. A study in dogs indicates that the maximal bicarbonate output is closely related to functional pancreatic mass<sup>[55]</sup>. In addition, an early study by Dr. Dreiling found an excellent correlation between findings on histology and findings of the SST. The SST picked up 20/24 patients (83%) who had CP by pathology whereas ERCP was only 17/24 (71%) sensitive. All underwent SST first, followed by ERCP, and 24 went on to exploratory laparotomy<sup>[54]</sup>.

However, the SST does have some shortcomings, notably difficulty with tube placement and that false positives can be seen for several months after an attack of acute pancreatitis. This is the reason we delay EUS, S-MRCP, fecal elastase testing, fecal fat testing, and SST for several months after an attack of acute pancreatitis.

**CCK stimulation testing:** In use almost as long as the SST, the classical CCK stimulation test is a useful test, developed and used primarily at the Mayo Clinic in Rochester, Minnesota. Because this test measures ecboic (enzyme) output, it is, in theory, a measure of

the processes that lead to steatorrhea, and could be less sensitive than SST. However, it is still one of the most sensitive tests for the presence of CP. One study of normal controls in Japan found no differences between the SST and the CCK stimulation test<sup>[56]</sup>. The CCK stimulation test has a number of drawbacks including the need for placement of two specialized 2-lumen tubes with simultaneous gastric and duodenal aspiration and duodenal perfusion of a solution containing mannitol and PEG. CCK is also administered under constant infusion at 40 ng/kg per hour, but it can be given as a bolus<sup>[57,58]</sup>. Caerulein, which is found on the skin of tree frogs and can be produced synthetically, can substitute for CCK. Caerulein is, in fact, many times more potent a secretagogue than CCK<sup>[59]</sup>. Bombesin can also substitute for CCK<sup>[60]</sup>.

In the classical CCK stimulation test, as in most tube tests, the basal 20 min aspiration of duodenal and gastric contents is discarded. The gastric and duodenal ports are continually withdrawn under low intermittent suctioning and duodenal fluid is collected over 80 min into four 20 min aliquots. Also during the first 20-40 min, the contraction of the gallbladder by CCK (and resultant flow of bile into the duodenum) affects the measurement of pancreatic output. In addition, as CCK can delay gastric emptying<sup>[61]</sup>, and is thought to cross the blood brain barrier and mediate central pain mechanisms<sup>[62]</sup>, symptoms of nausea and vomiting are common during infusion and more common than symptoms from secretin infusion<sup>[63]</sup>. The classic CCK stimulation test also requires measurement, and constant intestinal perfusion, of a nonabsorbable marker, and recovery rates vary significantly<sup>[64]</sup>. If the illustration in the *Gastroenterology* article which first described it is still in use today, it has fewer aspiration ports in the duodenum than the conventional Dreiling tube, and uses pressure suctioning of 40 mmHg<sup>[65]</sup> which, as mentioned above, may be somewhat different than the suction used at University of Florida with the conventional Dreiling tube.

A modified version of this test using a conventional Dreiling tube, placed under light sedation, and measuring only lipase by a hospital based lab assay was found to be very sensitive in patients with both early (Cambridge 2) and late stage CP by ERCP (Cambridge 3 and 4)<sup>[66]</sup>. However, no one has compared this test directly to the SST. In addition, as we shall discuss later in the section on endoscopic secretin stimulation testing, use of sedation may affect recovery of secretions and cost.

**Combined secretin-CCK (secretin-pancreozymin) stimulation testing:** This test is used mostly in Europe and Japan and allows measurement of both bicarbonate and enzyme production by the pancreas. In theory, the simultaneous administration of Secretin with CCK has the potential to dilute the measurement of enzyme activity by watery, bicarbonate solution. However, CCK can also be given before<sup>[67]</sup> or after<sup>[57]</sup> Secretin. It also shares one of the drawbacks of the CCK stimulation test: increased bile secretion into the duodenum.

In one study of the Secretin-CCK test, the peak bicarbonate - rather than CCK-related parameters - was correlated nearly linearly to the severity of histologic changes in CP. Also in this study, the second and third best measures of histologic damage were the amylase activity and the total volume, respectively. In that study, the secretin-CCK test was 67% sensitive for various stages of CP, which is somewhat less than other studies of the SST. However, this study used stringent requirements for the diagnosis of CP. All 3 parameters (peak bicarbonate, volume of duodenal secretions, and amylase output) had to be decreased in order to qualify as CP. Applying our cutoffs for peak bicarbonate, only, to this data would give greater sensitivity with only some loss of specificity<sup>[4,68]</sup>.

Another study found that the trypsin activity in pancreatic fluid was not as sensitive a measure of CP as the peak bicarbonate during Secretin-CCK testing<sup>[69]</sup>. A recent, and probably the largest, study of Secretin-CCK stimulation testing supported this finding, mostly in cystic fibrosis patients. In this study, 336 CCK-Secretin tests were reviewed. Using enzyme (trypsin) activity alone (cutoff < 50 U/kg per hour) would have had 25% false positives if enzyme recovery were not corrected for losses (if a marker had not been used); i.e. 25% of patients with good enzyme activity would have been falsely classified as pancreas-insufficient<sup>[70]</sup>.

A third study of 19 alcoholic CP patients and 6 patients with idiopathic CP who underwent CCK-secretin testing and went on to surgery for refractory symptoms, 18/18 of whom had an abnormal ERCP, found that the peak bicarbonate concentration and output were the best measures of small duct dilation seen on histology. In addition, peak bicarbonate output was the best measure of acinar atrophy with a Spearman correlation coefficient of -0.71 ( $P$  between 0.001 and 0.01) and the chymotrypsin output was also significantly correlated (Spearman, -0.57), but with a higher  $P$  of between 0.01 and 0.02. Peak volume also correlated fairly well with acinar atrophy (Spearman -0.44,  $P$  between 0.02 and 0.05), but peak bicarbonate concentration was weaker (Spearman -0.17,  $P > 0.05$ ). In summary, this study found that the hydraulic parameters (volume, peak bicarbonate concentration, peak bicarbonate output) were overall better predictors of abnormal histology than the ebolic parameters (chymotrypsin)<sup>[2]</sup>.

These studies indicate that the CCK portion of the Secretin-CCK stimulation test adds little information in the diagnosis of CP that the secretin stimulation portion alone (or perhaps the classic SST) already provides. However, the Secretin-CCK test is certainly a more sensitive measure of pancreatic enzyme production than the bentiromide test, which tests primarily protease production by the pancreas<sup>[71]</sup>.

**Perfusion testing:** Researchers in the Gastroenterology Division at the University of Florida in Gainesville over the last 25 years have developed and implemented a method of measuring endogenous and exogenous pancreatic enzyme activity in the duodenum of patients

with CP analogous to the Mayo clinic CCK methodology. This “perfusion test” enables quantification of delivery of exogenous pancreatic enzymes to the duodenum. Some notable differences between this perfusion test and the CCK stimulation test include use of a standardized meal rather than CCK to stimulate the pancreas, use of a modified Dreiling tube attached to a 7 Fr Dobhoff tube, placed without sedation under fluoroscopy, and the perfusion of radiolabeled Carbon-14 Polyethylene Glycol (PEG) to enhance assessments of recovery. This perfusion test measures endogenous enzyme production in the fasted and fed states with a standardized Ensure<sup>®</sup> meal. Volume of both gastric and duodenal collections, pH, and enzyme activity are recorded over a 3 h period. The test is then repeated immediately after intake of an exogenous pancreatic enzyme<sup>[72]</sup>. The inconvenience and time required for this test render it useful only for the research setting.

**Intraductal SST:** In the intraductal secretin stimulation test, typically the main pancreatic duct is cannulated using ERCP techniques and then pancreatic fluid is collected, after the administration of secretin alone, or secretin followed by CCK. The patient is sedated without anticholinergic medications such as diphenhydramine (Benadryl<sup>®</sup>) or opiates, usually with benzodiazepines. Typically, the pancreatic fluid collected in this manner has a higher bicarbonate concentration than in the classical SST, around 130 mEq/L for controls, and less than 105 mEq/L for CP patients, owing to lack of contamination by bile and duodenal content. Some of the disadvantages of this test include the complication rate of ERCP, the need for sedation, and the relatively short time periods of collection (usually 15 min, as limited by sedation and fluoroscopy room time). An advantage of the intraductal test is that pure pancreatic juice is collected without contamination with bile or duodeno-gastric contents and that it can be used in patients with Billroth I and II gastric resections.

One group showed that the intraductal test could not reliably differentiate between 19 CP patients, 14 “early CP” patients, and 14 controls<sup>[73]</sup>, despite a long intraductal collection period of 60 min. The investigators used extra CCK with secretin after the initial secretin boluses in 15 patients. They used only 70 U maximum of secretin and did not adjust for weight of the patients. In addition, their aspiration catheter was prefilled with a dye to assist in identifying the start of the collection, which may have been problematic due to mixing. Also their “early CP” patients had only acute relapsing pancreatitis with no evidence of chronicity by imaging or conventional pancreatic function testing.

For the analyses, it appears they combined the patients with “early CP” and those with CP. They found that this combined group of CP patients produced significantly less volume of pancreatic secretions than controls after stimulation with 1 CU of secretin and 70 CU of secretin but not after 4 CU of secretin. CP patients also had significantly less bicarbonate concentrations only after 4 CU of secretin compared to

controls. Bicarbonate output was decreased significantly at all time points for CP patients compared to controls. Interestingly, at only the first minute time point, in patients with CP, the protein content of fluid was higher but not significantly so, than controls, perhaps due to concretions of inspissated enzymes in this group from PD stasis. However, after 70 CU of secretin, the protein output of CP patients was significantly less than controls.

A second, larger study of 12 patients with CP and 33 controls (22 normals and 11 with other nonpancreatic GI disorders), which used only a 20 min collection time, found that the sensitivity of the intraductal test peak bicarbonate compared to SST was 100% with a specificity of only 66%. Volume had an 88% sensitivity and a 91% specificity for CP by SST<sup>[74]</sup>.

The most recent study of the intraductal secretin stimulation test was less favorable. In this comparison of the intraductal secretin stimulation test and SST, in which 19 patients served as their own control, the sensitivity of the intraductal secretin stimulation test compared to the conventional SST was only 80%, with a very poor specificity of 20%. Against pancreatogram, the intraductal test was 100% sensitive but only 55% specific<sup>[75]</sup>. This group used three 5-min collections (as is customary for most intraductal secretin stimulation tests) and the first was discarded. Based on these results, we do not recommend the use of the intraductal secretin stimulation test for routine diagnostic or research purposes.

#### **Endoscopic secretin stimulation testing (eSST):**

An alternative to traditional pancreatic function testing is to sedate the patient, and collect duodenal juice under endoscopic guidance from a polyethylene tube passed through the biopsy channel of a standard upper endoscope after stimulation with secretin<sup>[51,76]</sup> or the combination of secretin-CCK<sup>[77]</sup>. This offers the advantage of patient comfort and sedation. The eSST has been extensively studied by a group of investigators from the Cleveland Clinic. The overall impression is that the eSST has the potential to yield results similar to the conventional SST. This comes to no surprise since the two tests are very similar with the main differences being the use of sedation in the eSST and the use of the endoscope to collect duodenal secretions rather than a Dreiling tube for the conventional SST. However, it should be noted that the eSST and the SST have only been directly compared in one small cross over study of healthy controls only, without any CP patients, in which the SST group also received sedation, which we do not do and could have confounded the results in favor of the eSST<sup>[78]</sup>.

Unfortunately, the eSST has several disadvantages. Although the eSST is technically easy to perform, it is impractical, and to date it has not gained acceptance. The main problem appears to be that occupying an endoscopy room and keeping the patient sedated for more than one hour are cost-prohibitive. Although the Cleveland Clinic group has shown that a 45 min

endoscopic collection is reasonable with good sensitivity with some loss of specificity<sup>[79]</sup>, we have shown that a full 60 min is necessary for full sensitivity and specificity of the classical secretin stimulation test<sup>[80]</sup>. Furthermore, patients and their escorts will also have to miss a whole day of work. In addition, medications used for sedation may have effects on pancreatic secretions<sup>[81]</sup>. Opiates may constrict the sphincter of Oddi, and propofol contains 5% triglyceride which may have effects on pancreatic secretion. Although one small study of normal subjects did not find an effect of light sedation on secretion during endoscopic secretin stimulation testing, it used fairly low doses - 2.5 mg of midazolam and 62.5 mg of meperidine<sup>[82]</sup>. However, we have found that greater amounts of sedatives are required in most patients with chronic abdominal pain who are referred for evaluation of possible CP.

#### **“Enhanced imaging” pancreatic function tests (S-MRCP):**

Because of some of the shortcomings of conventional MRCP in the diagnosis of pancreatic disorders, some have investigated the use of MRI with secretin stimulation to increase the flow and volume in the pancreatic duct. The filling of the duodenum can be semi-quantitated to assess for CP. One possible problem with this technique is that it measures volume of pancreatic flow rather than bicarbonate concentration. In theory, obstructive lesions, or sphincter of Oddi spasm could give positive results in the absence of true CP<sup>[83]</sup>. In addition, MR images are acquired over at most 30 min, which is often an insufficient length of time during secretin stimulation and which may lead to reduced sensitivity.

One German study of 18 CP patients, defined by ERCP, many of whom had previously undergone pancreatic duct stenting and removal, and 5 diseased controls exemplified some of these issues with S-MRCP. This study, even on these patients with obviously advanced CP, showed a 69% sensitivity of S-MRCP with 1 CU/kg of secretin and 90% specificity as compared to relatively insensitive pancreatic function tests, such as the fecal elastase and <sup>13</sup>C Mixed Chain Triglyceride Breath Test (MCT-BT)<sup>[83]</sup>.

Another method that S-MRCP uses to assess for CP is parenchymal enhancement during gadolinium infusion (also used during conventional MRI, but which is not used during conventional MRCP). To assess for parenchymal enhancement, T1-weighted sequences with fat suppression are crucial. Also important is the pattern of gadolinium enhancement of the parenchyma: CP patients show decreased enhancement in the arterial phase and increased enhancement in the early venous phase, which are thought to be due to decreased pancreatic blood flow. On T2 imaging, enhancement is seen in CP patients compared to controls, indicating fatty or fibrous replacement of the parenchyma. After 0.5 IU/kg of secretin, the reduced T2 signal changes showed a good correlation with the Lundh test, a pancreatic function test using meal based stimulation. This study also showed a good correlation between

duodenal diameter after S-MRCP and the Lundh test. Patients with severe CP had an average increase in duodenal diameter of 1.7 mm. In mild CP the increase was 4.7 mm, and in controls, 14 mm. However, in this study, the patient population was not well defined. They did have a cohort with mild pancreatitis but again we do not know the criteria used to establish this<sup>[84]</sup>.

Another group, this time from Japan, has distinguished S-MRCP, which they reserve to look for duct changes, from "Secretin-Stimulated, Diffusion Weighted MRI" which focuses on secretin-induced changes within the parenchyma of the gland. This new type of MRI calculates the Apparent Diffusion Coefficient (ADC) which measures diffusion of water molecules in the microcirculation. They claim that this type of MRI is even more sensitive than S-MRCP and that it evaluates local and regional pancreatic exocrine function. They also measured changes in alcoholic patients, known not to have structural pancreatic disease by conventional CT. Notably these patients did not undergo pancreatic function testing or ERCP<sup>[11]</sup>.

## CONCLUSION

Most pancreatic function tests have high sensitivity and specificity to accurately diagnose patients with advanced CP. The noninvasive tests tend to perform poorly in patients with early, mild disease. Some specialized invasive "tube" tests can reliably detect mild, early CP but are only available at a few quaternary referral centers. S-MRCP and Diffusion Weighted, Secretin Stimulated MR are promising technologies but, for the near future, are not likely to provide the same discriminating power as the best "tube" tests. The quest for a simple, noninvasive, cheap, and accurate pancreatic function test continues.

**CONCLUSION:** The need to define, categorize and record complications when healthy individuals, such as living donors, undergo a major surgical procedure, such as a right hepatectomy, reflects the need for prompt and detailed reports of complications arising in this particular category of patient. Perioperative complications and post resection liver regeneration are not influenced by anatomic variations or patient demographic.

## Abstract

**AIM:** To present an analysis of the surgical and perioperative complications in a series of seventy-five right hepatectomies for living-donation (RHLD) performed in our center.

**METHODS:** From January 2002 to September 2007, we performed 75 RHLD, defined as removal of a portion of the liver corresponding to Couinaud segments 5-8, in order to obtain a graft for adult to adult living-related liver transplantation (ALRLT). Surgical complications were stratified according to the most recent version of the Clavien classification of postoperative surgical complications. The perioperative period was defined as within 90 d of surgery.

**RESULTS:** No living donor mortality was present in this series, no donor operation was aborted and no donors received any blood transfusion. Twenty-three (30.6%) living donors presented one or more episodes of complication in the perioperative period. Seven patients (9.33%) out of 75 developed biliary complications, which were the most common complications in our series.

## INTRODUCTION

Lortat-Jacob reported the first anatomic right hepatectomy in 1952<sup>[1]</sup>. Since then, and particularly in the past two decades, hepatic surgery has achieved important technical breakthroughs, such as intermittent portal triad clamping, total vascular exclusion, preoperative portal vein embolization with two-stage hepatectomy, and sophisticated methods of parenchymal transection.

An increased interest in the outcomes of right hepatectomy for adult to adult living-related liver transplantation (ALRLT) has likely contributed to these breakthroughs<sup>[2]</sup>.

Although surgical techniques of excellence and major improvements in perioperative management are now a

reality in referral centers for liver surgery, there are still several issues that make this major surgical procedure extremely worrisome when performed in healthy individuals, such as living donors.

In particular, there is still no definite consensus regarding the amount of liver that can be safely resected<sup>[3]</sup>, a crucial point for the recipient and perhaps more important for the healthy donor.

Recent studies have emphasized that in living-related liver transplantation, results and survival appear to correlate with stratification in the volume of the liver allograft transplanted, expressed either as a graft-to-body weight ratio or as a percentage of the standard liver volume of the recipient<sup>[4]</sup>.

Clearly, living-related liver transplantation (LRLT) represents the natural evolution of other surgical procedures, namely reduced-size liver transplantation and split-liver transplantation<sup>[5]</sup>, and is based on the segmental anatomy of the liver and on its peculiar capacity to regenerate.

This procedure represents a major challenge for the centers involved, though it has been widely reported that it is a valuable option for decreasing mortality rates and drop out from waiting lists<sup>[6,7]</sup>.

However, potential risk for the donor makes this procedure unique, and when complications in the healthy donor arise, the implications for the medical community are potentially devastating<sup>[8]</sup>. A recent systematic review<sup>[9]</sup> that focused on adult donor outcomes concluded that there are small but real risks when using the right lobe for living donors, though it also claimed that nearly all donors returned to normal function within 6 mo. Moreover, due to the short history of ALRLT, the long-term risks for the living donor are still largely unknown.

Numerous single-institution series have reported their complications for liver living-related donors<sup>[10-15]</sup> and a recent large study from the U.S. reported an analysis of administrative data on a group of 433 right- and left-lobe living donors identified as those at risk for perioperative complications<sup>[16]</sup>.

The ethical debate over the potential risk to the donor<sup>[17]</sup> renders this field of surgery controversial and, as a result, we believe, worthy of reports on all single center experiences.

The aim of this study is, in fact, to present an analysis of the surgical and perioperative complications in a series of seventy-five consecutive right hepatectomies for living related liver transplantation (RHLD) performed in our center.

## MATERIALS AND METHODS

From January 2002 to September 2007, we performed 75 RHLD, defined as removal of a portion of liver corresponding to Couinaud segments 5-8, in order to obtain a graft for ALRLT. Two left-hepatectomies, corresponding to Couinaud segments 2-4, were performed for the same purpose during the initial phase of our experience, but are not reported in this study. The number of cases per year has been progressively increasing, with

a peak reached in 2006, when 24 RHLD were performed. The trend has continued through this year (2007), with 17 RHLD performed so far. ALRLT represented the 20% of our total liver transplant activity over the last 2 years.

### Donor selection and characteristics

All living donors went through a complete evaluation process, managed by a multidisciplinary team consisting of clinical psychologists, hepatologists, anesthesiologists, transplant surgeons, referring physicians and family doctors. The evaluation process was completed in 3 d, with blood work, ultrasound and consults on the first day; Volumetric Angio computed tomography (CT) Scan and Cholangio nuclear magnetic resonance imaging (MRI) on the second day; and liver biopsy on the third day.

Initially, the work-up included endoscopic retrograde cholangiography; this has since been replaced by Cholangio MRI.

Beginning in 2002, a total of 254 potential living donors were evaluated; 165 (65%) were excluded, and of those accepted for living donation, 12 (5%) are still undergoing work-up. At first we were more restrictive; as a result, all patients with aberrant vascular or biliary anatomy, or steatosis greater than 10%, were rejected. Then 20% macrovesicular steatosis was categorized as the upper limit.

Of the 75 living donors accepted, the ages ranged between 18 and 54, and all were biologically or emotionally related to the recipients. There were 46 ABO identical couples and 29 compatible couples (Table 1). These demographic data are quite similar to those reported online by the European Liver Transplant Registry concerning the activity of 135 institutions in 35 European countries in the period 1991-2005.

The CT-scan-calculated graft to recipient body-weight ratio was always above 0.8%, and all anatomic anomalies of the vascular and biliary system were detected by preoperative imaging (Table 1).

Two anti-hepatitis B core positive donors were immediately accepted<sup>[6]</sup> in accordance with the far-eastern experience, and were transplanted in two recipients with end stage liver disease secondary to hepatitis C virus, treated after transplant with lamivudine 100 mg/d.

Seven other donors were initially excluded because of their elevated body weight, which was a body mass index (BMI) of > 30. After nutritional assessment (nutritional and dietary past history, and life-style evaluation) the dietician arranged a personal diet, moderately hypocaloric (carbohydrates 55%-57%, proteins 17%-19%, and lipids 24%-27%) and encouraged the donor to perform physical activity. Acceptable monthly weight loss was considered approximately 2-4 kg, with a final BMI of < 30 kg/m<sup>2</sup>. After 3 mo of a low calorie diet all seven living donors had a protocol liver biopsy that showed hepatic steatosis of < 20%, and were therefore considered eligible for donation.

Surgical complications were stratified according to the Clavien classification of postoperative surgical complications<sup>[18]</sup> (Table 2).

The perioperative period was defined as within 90 d

of surgery. Detailed descriptions of this surgical technique have been previously reported elsewhere<sup>[6,19]</sup>.

### Postoperative management and follow-up

After surgery, all donors were extubated before leaving the theater, and transferred to the intensive care unit (ICU) for at least 24-h monitoring. Deep venous thrombosis prophylaxis was based on early administration of low molecular heparin, started as soon as the prothrombin activity reached 50%, together with compression devices and early mobilization. Liver function tests were checked daily for at least 7 d, and then weekly for the first 2 mo. The subcutaneous administration of low molecular heparin was discontinued 14 d after surgery.

In order to guarantee optimal analgesia and early mobilization, all but two donors underwent epidural catheter placement immediately before surgery. Catheter removal was performed after 72 h, and after having normalized the coagulation parameters. Antimicrobial

prophylaxis changed over time: the first 13 donors received piperacillin tazobactam for the first 72 h, after which prophylaxis consisted of ceftriaxone.

A CT scan of the abdomen was performed 2 mo after surgery, with volumetric analysis of the liver.

Three months after surgery all the donors were seen at the outpatient clinic for check up.

### Statistical analysis

Data are expressed in mean  $\pm$  SD for continuous variables and as percentage for categorical variables. Data were compared with chi-square test or Fisher's exact test 2 tailed for categorical variables and Student's *t*-test for continuous variables; *P* < 0.05 were considered significant.

All statistical analyses were performed using SPSS (SPSS Inc., Chicago, Ill, United States).

## RESULTS

None of patients manifested any complications from pre-operative liver biopsy.

No living donor mortality was present in this series. No donor operation was aborted and no donors received any blood transfusion.

After the first 9 cases, we started to reinfuse the blood aspirated during surgery with the Cell Saver System (median: 250 mL; min: 0; max 1680).

Length of surgery, length of stay in the ICU, and total hospitalization are reported in Table 1, while all complications, codified according to the Clavien system, and their management, are reported in Table 2.

Twenty-three (30.6%) living donors presented one or more episodes of complication in the perioperative period. All these complications were resolved within the perioperative period.

Two donors (I.D. 1 and 12) had a small re-laparotomy because the intra-abdominal drain could not be removed.

One donor (I.D. 6) experienced a transient partial portal vein thrombosis, asymptotically detected by ultrasound and completely resolved with low molecular heparin.

Two donors (I.D. 17 and 18) developed complications graded IV by the Clavien system. They were both admitted to the ICU: in one case for monitoring of an acute pancreatitis following an endoscopic retrograde cholangiopancreatography (ERCP) performed because of a biliary leak, and in the second case for monitoring of a pulmonary embolism with no cardiac derangements.

Five patients (I.D. 13, 14, 17, 20, 21) presented complications that required multiple treatments: i.e. percutaneous drainage and stent placement.

Two patients (I.D. 19 and 21) presented two discrete, unrelated complications each: pleural effusion plus intra abdominal collection in one case and pleural effusion plus biliary leak in the other case.

Seven patients (9.33%) (I.D. 5, 9, 13, 14, 17, 20, 21) out of 75 developed biliary complications, which were the most common complications in our series. However, all of them were successfully treated by interventional procedures with removal of all stents or catheters within 6 mo

Table 2 Classification of surgical complications in RHL

Patients ID	Complications/Treatment	Classification of surgical complications Clavien annals of surgery 2004	Frequency (%) of complication for every classification grade
1	JP retained in the abdomen/Relaparotomy	Grade IIIb	13.04
2	Edema, ascites/None	Grade I	21.74
3	Prolonged hyperbilirubinemia/None	Grade I	
4	Fluid collection/Percutaneous drainage	Grade IIIa	17.39
5	Biliary leak /ERCP with stent placement	Grade IIIb, d	21.74
6	Transient portal vein thrombosis/Enoxaparin	Grade II	13.04
7	Bilateral massive pleural effusion/Percutaneous drainage	Grade IIIa	
8	Colitis by CD/Metronidazole	Grade II	
9	Biliary leak/ERCP (stent placement)	Grade IIIb, d	
10	Mild pleural effusion/None	Grade I	
11	Intraabdominal fluid collection/Percutaneous drainage	Grade IIIa	
12	JP retained in the abdomen/Relaparotomy	Grade IIIb	
13	Intraabdominal fluid collection; biliary leak/Percutaneous drainage; ERCP (sphincterotomy)	Grade IIIb	
14	Intraabdominal fluid collection; biliary leak/Percutaneous drainage; ERCP (sphincterotomy and stent placement)	Grade IIIb, d	
15	Intraabdominal fluid collection/Percutaneous drainage	Grade IIIa	
16	Prolonged hyperbilirubinemia/None	Grade I	
17	Intraabdominal fluid collection; Biliary leak/Percutaneous drainage, ERCP (sphincterotomy, stent placement X 3, acute pancreatitis, PTBD placement)	Grade IIIb, d/ Grade IV	4.35
18	Pulmonary embolism and iliac vein thrombosis/Anticoagulation	Grade IV	4.35
19	Moderate pleural effusion; intraabdominal fluid collection/Percutaneous drainage; percutaneous drainage	Grade IIIa- Grade IIIa, d	4.35
20	Biliary leak/ERCP (Sphincterotomy, endoscopic stent placement failure); PTBD	Grade IIIb, d	
21	Intraabdominal fluid collection; biliary leak, moderate pleural effusion/Percutaneous drainage; ERCP (sphincterotomy, endoscopic stent placement); percutaneous drainage	Grade IIIb, d	
22	Prolonged hyperbilirubinemia/None	Grade I	
23	Fever/Antibiotic treatment	Grade II	

Table 3 CT scan calculated donors mean liver volume (mean  $\pm$  SD)

Total liver volume	CT scan calculated	
	Right lobe volume	Remnant liver volume
1538.94 $\pm$ 277	954.67 $\pm$ 219.6	584.28 $\pm$ 121.67
	CT scan calculated right lobe volume 2 mo after surgery into the recipient	CT scan calculated remnant liver volume 2 mo after surgery
	1511.60 $\pm$ 257.88	1065.08 $\pm$ 195.24
	98% regeneration	69% regeneration

from surgery.

CT-scan-calculated donor mean total liver volume, mean right lobe volume, mean remnant liver volume, plus mean liver volume 2 mo after surgery in the donor and in the recipients, are reported in Table 3.

Mean value of donor liver volume was restored to 98% of the preoperative mean volume within 2 mo of surgery in the recipient and to 69% of the preoperative mean volume in the donor.

There was an 18% difference ( $P = 0.0001$ ) between CT-scan-calculated right lobe donor mean volume (954.67) and right lobe weight mean value (784.56) on the back table.

There were no differences in distribution of anatomical variations in the groups of complicated and uncomplicated RHL (Table 4). In addition, there were no differences between the complicated and uncomplicated RHL regarding the baseline and post regeneration mean value of calculated liver volumes (Table 5).

Table 4 Distribution of anatomic variations in the complicated and uncomplicated groups of RHL,  $n$  (%)

## DISCUSSION

Donor safety has to be the first priority during the entire process of living-related transplantation, from the first day of evaluation through the entire follow-up period.

Therefore, an accurate and comprehensive step-by-step work-up protocol for donor evaluation has been designed in our center in order to ensure donor safety and, additionally, to confirm that the donor is capable of providing a suitable graft for the recipient.

In our experience, use of routine liver biopsy, though not generally accepted in all centers, allowed the exclu-

**Table 5** CT scan calculated donors mean liver volume in the complicated and uncomplicated groups of RHL D (mean  $\pm$  SD)

	23 complicated RHL D	54 RHL D without complications	P value
CT scan calculated total liver volume	1517.7 $\pm$ 292.4	1547.20 $\pm$ 292.43	0.68
CT scan calculated right lobe volume	957.67 $\pm$ 226.37	953.50 $\pm$ 219.16	0.94
CT scan calculated remnant liver volume	560.05 $\pm$ 89.19	593.70 $\pm$ 131.69	0.28
CT scan calculated remnant liver volume 2 mo after surgery	1078.6 $\pm$ 201.65	1059.57 $\pm$ 194.42	0.72

sion of potential donors who otherwise would have been considered fit to donate based on other tests<sup>[20]</sup>.

On the other hand, the biopsy allowed us to enroll donors who were anti-hepatitis B core positive.

Moreover, the routine use of liver biopsy as a screening tool in the living donor work-up allowed us to explore more safely the very common problem of steatosis.

The usefulness of steatotic livers depends on the percentage of fat, as livers with moderate to severe steatosis decrease graft and patient survival (with an additional unpredictable risk for liver donor regeneration). A BMI of  $> 30$  may reliably predict a higher degree of steatosis in most donors. In order to enlarge the pool of living donor livers, but also to improve post-transplant outcomes, we made an attempt to lower the percentage of steatosis, rather than to turn down such overweight donors, by applying a short-term treatment of diet and exercise in all living-donor candidates with hepatic steatosis. After RHL D, no such donors experienced life-threatening complications or died. No long-term clinical impairment of treated donors has been observed and, after donation, all of them have returned to previous activity.

A strategy of careful evaluation of the living donor performed by an interdisciplinary team cannot be over-emphasized.

A wide range of living donor complication rates are reported in the literature, with an estimated risk of mortality and morbidity after RHL D of 0.4% and 35%, respectively.

Overall, the complication rates range from 0% to 67%, with an overall crude complication rate of 31%<sup>[21]</sup>. The literature has reported 11 deaths, and 2 liver transplants in donors who have undergone RHL D. Additionally, one donor is in a persistent vegetative state after donation<sup>[22]</sup>.

Organ shortage is a dramatic problem which can be limited by the rational use of ALRLT. So, based on our previous experience with liver resection<sup>[2]</sup> and use of partial livers from deceased donors<sup>[23]</sup>, we began the living-related liver transplant program. Moreover, our partnership with one of the most active living-related liver transplant programs in the world<sup>[24]</sup> has allowed us to gain experience rapidly in this controversial field of surgery.

In our series, 30.6% of living donors developed a complication in the perioperative period, this not different from data recently reported in the literature<sup>[24]</sup>. In this group, RHL D with complications, there was no major incidence of anatomic variants, or difference in terms of liver regeneration after surgery, when compared with patients who did not develop any complications.

Additionally, our data regarding CT-scan-calculated liver volume confirmed that volumetric imaging may

overestimate the actual liver volume<sup>[24]</sup>.

Biliary complications (9.33%) were the most common complications after RHL D in our series, though no patients had to undergo repeated laparotomy for this reason. In two cases, after the failure of the endoscopic treatment, we were able to resolve the biliary leak due to a combined “rendezvous” procedure between endoscopist and interventional radiologist, who were able to pass an internal external transhepatic biliary drainage.

None of the 75 live donors in this series, regardless of their post-operative course, manifested any regrets about live donation.

In conclusion, this study reports the largest Italian experience with RHL D, focused on perioperative complications and on donor safety, which must be the first priority in right-lobe living-related donation.

Strict donor selection, detailed informed consent validated by the Italian law, together with a growing volume of cases performed every year, have allowed us to safely perform right hepatectomies for living donation in our center.

The need to define, categorize and record complications when healthy individuals, such as living donors, undergo a major surgical procedure like a right hepatectomy, reflects the need for prompt and detailed reports of complications arising in this particular category of patient.

Perioperative complications and post resection liver regeneration are not influenced by anatomic variations or patient demographic.

## COMMENTS

### Background

Adult to Adult living related liver donors play an essential role in filling the gap of transplants needed due to a heavy shortage of cadaveric donations. Considering that living related donors are healthy individuals at baseline, it is imperative to ensure good outcomes and return to quality of life.

### Research frontiers

The study improved measures to assure safety in the healthy donor, improved overall diagnostic capability by non-invasive tools in the donor work-up, and provided possibility of expanding Milan Criteria for recipient of living-related liver transplantation (LRLT). It indicated improvements in prevention of biliary complications and small-for-size syndrome.

### Innovations and breakthroughs

Authors designed an accurate, comprehensive step-by-step work-up protocol for donor evaluation to ensure donor safety and to confirm that the donor is capable of providing a suitable graft. Their research has proven the necessity of evaluat-

ing the overall health of both the donor and recipient at many different levels from biopsy to body mass index. It indicated liver biopsy in the exclusion of potential donors otherwise considered fit to donate. These biopsies assess the quality of the donation to ensure the likelihood of success of the transplant and the health of both the donor and the recipient. These biopsies also confirm the true donor status of Hepatitis B, thereby allowing us to enroll donors who had false positive serum tests. They also test body mass index in order to prescribe a diet and exercise program to heavier donors to allow their inclusion. Their experience shows that heavier donors, when subjected to an exercise and diet program, all return to previous activity. In fact, no life threatening complications, long term impairments, or deaths have occurred in these donors. It indicated improvements in prevention of biliary complications and small-for-size syndrome.

### Applications

It would be applied in improving in prevention of biliary complications and measures to assure safety in the healthy donor.

### Peer review

This is an important issue that needs reporting. The authors performed a single institution series-report study of 75 patients stratifying them into two groups, complicated (23) and uncomplicated resections (54) to try to identify factors that might have influenced outcome. For this purposed, they analyzed anatomical variations and the liver remnant volume. With high wait list mortality and rather static donor levels, ALRLT is an option that needs serious consideration and historically the high rate of donor complications has held units back from moving forward with this procedure.

## Abstract

**AIM:** To examine the extent of use of specific therapies in clinical practice, and their relationship to therapies validated in clinical trials.

**METHODS:** The US National Cancer Institutes' Patterns of Care study was used to examine therapies and survival of patients diagnosed in 2001 with histologically-confirmed gastroesophageal adenocarcinoma ( $n = 1356$ ). The study re-abstracted data and verified therapy with treating physicians for a population-based stratified random sample.

**RESULTS:** Approximately 62% of patients had stomach adenocarcinoma (SAC), while 22% had gastric-cardia adenocarcinoma (GCA), and 16% lower esophageal adenocarcinoma (EAC). Stage IV/unstaged esophageal cancer patients were most likely and stage I - III stomach cancer patients least likely to receive chemotherapy as all or part of their therapy; gastric-cardia patients received chemotherapy at a

rate between these two. In multivariable analysis by anatomic site, patients 70 years and older were significantly less likely than younger patients to receive chemotherapy alone or chemoradiation for all three anatomic sites. Among esophageal and stomach cancer patients, receipt of chemotherapy was associated with lower mortality; but no association was found among gastric-cardia patients.

**CONCLUSION:** This study highlights the relatively low use of clinical trials-validated anti-cancer therapies in community practice. Use of chemotherapy-based treatment was associated with lower mortality, dependent on anatomic site. Findings suggest that physicians treat lower esophageal and SAC as two distinct entities, while gastric-cardia patients receive a mix of the treatment strategies employed for the two other sites.

## INTRODUCTION

The incidence and mortality of esophageal and gastric-cardia adenocarcinoma (GCA) has increased dramatically since the 1970s in western countries, while that of stomach cancer has decreased<sup>[1-3]</sup>. Gastroesophageal

adenocarcinomas have a poor prognosis<sup>[4-8]</sup>. However, numerous randomized clinical trials (RCTs) have evaluated, and continue to evaluate, the survival benefit of various treatment regimens.

Surgery remains standard care for early stage esophageal cancer. The MAGIC trial, a large phase III European RCTs found that patients with resectable lower esophageal or gastric adenocarcinomas treated with peri-operative chemotherapy had better progression-free and overall survival rates compared to surgery only<sup>[9]</sup>. This benefit was supported by the Fédérale Nationale des Centres de Lutte Contre Le Cancer (FNLCC) for patients with gastroesophageal adenocarcinoma who received pre-operative chemotherapy compared to surgery alone<sup>[10]</sup>. However, RCTs evaluating pre-operative chemoradiation compared to surgery alone have had conflicting results; some indicate better survival for esophageal cancer patients<sup>[11,12]</sup>. For locally advanced esophageal cancer, a phase III RCT, RTOG 85-01, demonstrated improved survival in patients who received chemoradiotherapy compared to radiation alone<sup>[13]</sup>, although most of these patients had squamous esophageal cancer. Another small RCT in patients with locally advanced esophageal cancer found chemoradiation superior to radiation alone<sup>[14]</sup>. These trials support the use of definitive chemoradiotherapy for locally advanced disease and its potential use for some patients with resectable disease. Current National Comprehensive Cancer Network (NCCN) guidelines for patients who are medically unfit for surgery or have unresectable disease recommend radiation and concurrent chemotherapy as treatment or best supportive care if patients cannot tolerate chemotherapy<sup>[15]</sup>.

Surgery is also the standard of care for early stage gastric cancer. A US Intergroup phase III trial, INT-0116, demonstrated post-surgical chemoradiation improved overall and disease-free survival in patients with stomach adenocarcinoma (SAC) and GCA<sup>[16]</sup>. The MAGIC and FNLCC trials also included patients with SAC and GCA. RCTs have also evaluated various chemotherapy treatments for patients with advanced or metastatic stomach and gastric-cardia cancer and have demonstrated improved survival for particular regimens<sup>[17,18]</sup>. The current NCCN guidelines for patients with metastatic stomach cancer recommend chemotherapy as treatment or best supportive care for those unable to tolerate chemotherapy<sup>[19]</sup>.

Few studies have examined community-based patterns of care for these cancers. A study on esophageal adenocarcinoma (EAC) and squamous cell carcinoma patients diagnosed between 1996 and 1999 found that chemoradiation was most frequently given although patients with chemoradiation followed by surgery had better survival compared to definitive chemoradiation<sup>[20]</sup>. Research suggests, however, that community-based use of treatment and the observed survival of patients in the community can vary depending on clinical and non-clinical factors<sup>[21-26]</sup>.

We present a population-based study, analyzing the receipt of various treatment strategies among a stratified

random sample of patients with gastroesophageal adenocarcinoma. This study aims to determine whether treatment strategies used in routine community practice are based on anatomic location or cancer origin and to examine community-based use of specific chemotherapy regimens, especially those evaluated in RCTs. Finally, we assess factors that influence treatment receipt and patient survival.

## MATERIALS AND METHODS

We included individuals aged  $\geq 20$ , newly diagnosed during 2001 with histologically-confirmed lower esophageal (EAC), GCA and SAC. Patients were ineligible if diagnosis was by death certificate only, autopsy, if they had a previous cancer diagnosis, other than non-melanoma skin, or were simultaneously diagnosed with another cancer. Patients were sampled from the National Cancer Institute's Surveillance, Epidemiology and End-Results Program (SEER) including Atlanta, Detroit, Seattle, New Mexico, Iowa, Louisiana, New Jersey, Connecticut, Utah, and California (Los Angeles County, San Francisco/Oakland, San Jose/Monterey, and greater California). Individuals were stratified by registry and race/ethnicity, and randomly sampled within strata. Non-Hispanic blacks, Hispanics, Asians/Pacific Islanders and Native Americans were over-sampled to obtain more stable estimates.

Data from medical records were re-abstracted to verify patient demographics, tumor characteristics, and treatment. Abstractors from each registry were centrally trained to ensure consistency of abstracting and coding. Because therapy is frequently provided in an outpatient setting, each patient's physician was contacted to verify treatment received, and provide names of any other physician who may have administered therapy. That physician was then contacted. All co-morbid conditions recorded at the hospitalization for most definitive treatment were abstracted. These were coded centrally by a single Registered Health Information Technologist and analyzed using the Charlson score<sup>[27]</sup>; an index of nineteen conditions, weighted according to the adjusted risk of one-year mortality.

We included 1411 cases. Patients were grouped by anatomic sites based on ICD-O2 codes; EAC (ICD-O: C15.2, C15.5,  $n = 165$ ), GCA (the portion of the stomach surrounding the gastroesophageal junction) (C16.0,  $n = 246$ ), and SAC (C16.1-C16.9,  $n = 1000$ ) and stage, I - III and IV/unstaged. Because of small numbers (18) of IVb EAC, these were grouped with IV/unstaged.

Treatments were defined as the receipt of surgery, radiotherapy, chemotherapy, in any combination. Non-adenocarcinoma cases were excluded from the therapy analyses ( $n = 55$ ); 1356 adenocarcinoma patients were included in the treatment analyses.

Data analyses were performed using Stata 8.0 and SUDAAN (Research Triangle Institute, Research Triangle Park, NC). Analyses were weighted to reflect the SEER population from which the sample was drawn. Multivariable analyses were conducted using logistic

and multinomial logistic regression. Cancer survival was analyzed using Cox regression models with a maximum two-year follow-up (through December 2003). All *P*-values were two-sided.

## RESULTS

Approximately 62% of patients had SAC, 22% GCA, and 16% lower EAC (Table 1). Median age was highest (76 years) for stage I-III SAC patients and lowest (67 years) for stage IV/unstaged GCA (data not shown).

### Lower EAC

Over 12% of stage I-III patients with EAC received surgery alone (Table 2). About 27% of patients with stage I-III EAC received tri-modality therapy (surgery, radiation and chemotherapy), while 36.5% of these patients received chemotherapy plus radiation therapy with no surgery. One-quarter of stage I-III EAC patients received no chemotherapy. The most frequently administered agent was 5-FU, frequently with cisplatin. Few patients with late/unstaged EAC received surgery, in any combination. Chemoradiotherapy, however, was given to nearly 47% of these patients. In multinomial logistic regression, age  $\geq 70$  was associated a 70%-80% decreased use of chemotherapy and chemoradiation in patients with EAC (Table 3).

Non-Hispanic blacks and Asian/Pacific Islanders with EAC had significantly higher hazards of cancer deaths than non-Hispanic white patients (Table 4). Patients age  $< 70$  with a Charlson score of  $\geq 1$  had a significantly increased risk as did those with late/unstaged disease. EAC patients who received chemotherapy had better survival, although not statistically significant. In a separate model, EAC patients who received chemoradiation had decreased hazards (HR = 0.69, 95% CI = 0.43-1.06 model not presented). The prognostic factors in the Cox proportional hazards model containing chemoradiation were otherwise the same as those significantly associated with death in the model which adjusted for chemotherapy.

### GCA

Patients with GCA received therapies at a rate between that of EAC and SAC patients. Surgery alone was provided to 34% of stage I-III GCA patients (Table 2). One-quarter of stage I-III GCA patients received trimodal therapy. Nearly twice as many GCA patients as EAC patients but less GCA than SAC patients received no chemotherapy. Fewer patients received chemoradiotherapy compared to EAC patients. 5-FU was the most frequently used chemotherapeutic agent. Nearly twice as many late/unstaged GCA patients as EAC received no therapy. In multinomial logistic regression, age  $\geq 70$  was associated with a 70%-80% decrease in chemotherapy alone or chemoradiotherapy (Table 3). Women and patients with a Charlson Score of  $\geq 1$  were significantly less likely to receive chemotherapy, but not chemoradiation. In the Cox proportional hazards models patients, with late/unstaged disease or

poorly/undifferentiated tumors had an increased risk of cancer deaths while married individuals had a decreased risk (Table 4).

### SAC

Of the three anatomic sites, patients with SAC were most likely to receive surgery alone (Table 2). Nearly 50% of stage I-III SAC patients received surgery alone. Less than 20% of stage I-III SAC patients received trimodal therapy. Fewer SAC patients than EAC or GCA patients received chemotherapy. As with the other two anatomic sites, 5-FU was most frequently administered. Of the three anatomic sites, late/unstaged SAC patients received no definitive cancer treatment most often. In multinomial regression, age  $\geq 70$  was associated with 80% less chemotherapy alone or chemoradiation (Table 3). Late/unstaged disease was associated with decreased use of chemoradiation but a substantial increased use of chemotherapy alone. Proportional hazards models for cancer deaths showed that in non-surgical patients, late/unstaged disease or a poor/undifferentiated tumor was associated with increased risk of cancer death (Table 4). However, patients receiving chemotherapy had a significantly decreased risk. Among surgical patients, a Charlson Score of  $\geq 1$ , regardless of age and having late/unstaged disease was associated with increased hazards. Lower risks were seen among Asian/Pacific Islanders, and a non-significant decreased risk among patients who received chemotherapy (Table 4). Patients who received chemoradiation had a statistically significant decreased risk both with (HR = 0.56, 95% CI = 0.35-0.89) and without surgery (HR = 0.62, 95% CI = 0.43-0.92) (model not presented) but all other prognostic factors had similar associations with hazard ratios as the Cox models which adjusted for chemotherapy.

## DISCUSSION

RCTs have demonstrated that certain treatment strategies and regimens improve survival for patients with esophageal and gastric cardia adenocarcinoma. Variation in gastroesophageal cancer survival, however, has sometimes been attributed to case mix<sup>[28]</sup>. We therefore selected adenocarcinoma cases only and categorized patients by anatomic site to assess rates of treatment and survival among a population-based sample of patients treated in the community. We found significant differences in treatment and survival by anatomic site, stage, age, and race/ethnicity. This study highlights the considerably varied approach that community physicians take to treat adenocarcinomas at each anatomic site.

### Lower EAC

While there is no consensus definition of the optimal therapy for patients with resectable EAC, clinical trials have indicated survival improvements when surgery is supplemented with additional therapies. Of the three cancer sites investigated in the current study, stage I-III EAC patients had the lowest rates of surgery alone

as their primary treatment, but highest rates of pre-operative chemotherapy and chemoradiation as well as definitive chemoradiation. This may reflect the significant morbidity associated with esophageal surgery<sup>[29-32]</sup>. However, toxicities associated with pre-operative chemotherapy or chemoradiation can preclude a patient from further treatment<sup>[33]</sup>.

RCTs and a meta-analysis have suggested a survival benefit associated with pre-operative and adjuvant chemoradiation compared to surgery alone<sup>[11,33-37]</sup>. The US-Intergroup trial, CALGB-9781, closed early due to poor accrual, but an intent-to-treat analysis on the 56 enrolled patients, demonstrated better median survival in favor of trimodal therapy<sup>[12]</sup>. In our study, over a quarter of stage I -III EAC patients received trimodality therapy. The MAGIC and FNLCC phase III trials support the use of perioperative or preoperative chemotherapy; however, we found that few (2.5%) stage I -III EAC patients received surgery and chemotherapy as primary treatment. Chemoradiation was the treatment strategy received by the largest percentage of patients with stage I -III EAC (36.5%) and late/unstaged EAC patients (47%).

## GCA

Optimal therapy for GCA is not clear. Most RCTs have included patients with this cancer in trials conducted for either or both of the other two anatomic sites<sup>[18,38]</sup>.

Reflective of this, we found that GCA patients seemed to receive treatment at a rate that fell midway between the other two anatomic sites. In the current population-based study, stage I -III GCA patients were most frequently treated with surgery alone (34%) or trimodal therapy (22%). For late/unstaged disease less than 25% received chemotherapy alone and a significant percentage received no therapy (39%).

## SAC

In contrast to EAC and GCA patients, SAC patients received surgery alone most frequently (50% of stage I -III and 16% of stage IV/unstaged disease) and radiotherapy and chemotherapy less frequently than the other two anatomic sites. Although the MAGIC and FNLCC trials demonstrated a survival advantage for patients with gastroesophageal adenocarcinoma<sup>[9]</sup>, this was not evident in the current population-based study, where less than 20% of stage I -III SAC patients received chemoradiation with surgery.

With respect to advanced disease, several RCTs for SAC have demonstrated survival benefits for chemotherapy compared to best supportive care for stage IV (late-stage) disease<sup>[17]</sup>. However, we found that only 22% of patients with late/unstaged SAC received chemotherapy alone, with an additional 15% receiving chemotherapy with surgery, with surgery and radiation, or as chemoradiation. Furthermore, for late/

unstaged disease, SAC patients received no therapy most frequently (43%).

Overall, our results do suggest that RCT-validated therapies have been incorporated into community practice, albeit at low levels. However, a significant percentage of patients, especially those with stage IV/ unstaged disease, across all anatomic sites received no cancer-directed therapy. Our findings also highlight that the sequence and combination of chemotherapy, radiotherapy and surgery in the adjuvant setting was distinct for each anatomic site. For example, of stage I - III EAC patients who received surgery plus chemotherapy and radiation, 81% received this therapy pre-operatively [most frequently with 5-fluorouracil (5-FU) and cisplatin], while of stage I - III SAC patients who received surgery plus chemotherapy and radiation, 91% received this therapy post-operatively (most frequently with 5-FU and leucovorin). These sequences of therapy as well as the chemotherapeutic agents selected were also consistent with RCTs conducted in these disease sites<sup>[11]</sup>.

### Chemotherapeutic agents

Overall, the most frequently administered chemotherapeutic agents in our study were 5-FU, cisplatin, and leucovorin. Newer agents (paclitaxel, irinotecan) have been investigated in phase II trials<sup>[39,40]</sup> for use in EAC patients. We found that these drugs were used in community practice (Table 2). Use of these compounds was much lower among patients with SAC and GCA cancers. No

patients received oxaliplatin, possibly because these cases were diagnosed in 2001 and findings advocating oxaliplatin for esophageal cancer were only presented in 2006<sup>[38]</sup>. Specific chemotherapeutic agents used alone or in combination with surgery and radiation are listed in Table 5. Whether patients received chemotherapy alone, chemoradiation, or trimodal therapy, the majority of patients received 5-FU in combination with another chemotherapeutic agent.

### Age disparities

Less frequent treatment of elderly patients has been widely reported<sup>[21-25,41]</sup>. Sabel *et al*<sup>[31]</sup> reported that 50% of patients age < 70 and 32% of those age ≥ 70 were suitable for surgery at diagnosis. Similar to this, we found that in stage I - III EAC, 30% of patients aged ≥ 70 compared to 51% of those age < 70 underwent cancer-directed surgery and 56% of gastric-cardia patients aged ≥ 70 compared to 80% of those age < 70. The age-related treatment decline is likely attributable to a number of factors: (1) Potentially higher morbidity among elderly patients; (2) Compromised treatment options due to delayed presentation by elderly patients; (3) Increased anesthesiological risk<sup>[31,42]</sup>; and (4) A higher prevalence of co-morbidities.

Median age at diagnosis for stomach cancer is approximately 70 years<sup>[43]</sup>, an age when patients have a reasonable life-expectancy<sup>[43]</sup>. Selected medically-fit elderly patients do as well as younger patients after surgical or adjuvant therapy<sup>[44,45]</sup>. Our models indicate

that in EAC or GCA patients, being age < 70 with a Charlson score of 1+ was significantly and inversely associated with surgery (data not shown). Older patients ( $\geq 70$ ) were also less likely to have surgery even with a Charlson score of 0. In our multinomial models, being age  $\geq 70$  was associated with a decreased use of chemotherapy or chemoradiation even after adjusting for co-morbid conditions. Although we saw this disparity in the use of chemotherapy or chemoradiation by age group, there was no evidence of treatment-related differences by racial/ethnic groups. This suggests that in a community-based setting, age, in addition to co-morbidity, influences whether or not a patient receives surgery, chemotherapy, and chemoradiation.

### Survival

Survival from gastric adenocarcinoma is extremely poor<sup>[46]</sup>. Theuer *et al.*<sup>[46]</sup> reported that patients aged  $\geq 70$  had higher risk of death even after adjusting for clinical, non-clinical and treatment-related factors. In contrast, we observed that in GCA and non-surgical SAC patients,

age and co-morbidity were not significant predictors of survival, perhaps due to the poor prognosis for these patients. We noted higher mortality in non-Hispanic blacks and Asian/Pacific Islanders with EAC. Such racial disparities have been reported in other cancers<sup>[47,48]</sup>, however the underlying cause for this poorer survival is not clear.

A US-based survey of 59 radiotherapy facilities indicated improved survival associated with pre-operative chemoradiation for patients with esophageal cancer<sup>[20]</sup>. In the current study, chemotherapy and chemoradiation were associated with decreased mortality for SAC and EAC patients, although not GCA patients. This suggests that the receipt of chemotherapy and/or radiotherapy may improve outcome in these poor prognosis cancers. This analysis was not a randomized study of therapy and although we adjusted for Charlson comorbidity score and additional potential confounders, patients who had better baseline health and who were selected for chemotherapy, may have been more likely to respond to such treatment or may have had better survival regardless of the use of chemotherapy.

In conclusion, RCTs have demonstrated that specific treatment strategies prolong survival in certain patient groups. We note that the use of these therapies was very low in US community-based practice despite their demonstrated survival benefits. Our study shows lower mortality among patients with EAC and SAC who received chemotherapy and significant disparities in terms of age in treatment receipt. Our findings highlight the distinctly individualized approach taken by community physicians in treating adenocarcinoma at these three anatomic sites. Community physicians appear to differentiate gastroesophageal adenocarcinoma as two distinct entities (i.e. EAC and SAC) and use different treatment strategies and chemotherapeutic agents for each, while patients with GCA are treated with a mixture of those employed for the other two anatomic sites. Improvements in community-based treatment of gastroesophageal adenocarcinoma will require better differentiation of treatments for the different anatomic sites and more extensive incorporation of those treatments proven effective in clinical trials. Future RCTs should be designed and appropriately powered to account for differences related to the anatomic site or origin of the tumor as well as the underlying tumor biology.

## ACKNOWLEDGMENTS

## COMMENTS

### Background

Randomized clinical trials (RCTs) have demonstrated that specific treatment strategies prolong survival in certain patient groups with gastric, gastroesophageal and esophageal adenocarcinomas. However, the extent of use of these treatments in routine clinical practice is not clear. Research suggests that community-based use of treatment and the observed survival of patients in the

community can vary depending on clinical and non-clinical factors.

### Research frontiers

To determine whether treatment strategies used in routine community practice are based on anatomic location or cancer origin. To examine community-based use of specific chemotherapy regimens especially those evaluated in RCTs. To assess factors that influence treatment receipt and patient survival.

### Innovations and breakthroughs

We document relatively low community-based use of treatments tested in RCTs in patients with gastroesophageal adenocarcinoma. The use of these therapies was very low despite their demonstrated survival benefits. Our study shows lower mortality among patients with esophageal adenocarcinoma (EAC) and stomach adenocarcinoma (SAC) who received chemotherapy and significant disparities in terms of age in treatment receipt. Community physicians appear to take an individualized approach in treating adenocarcinoma at these three anatomic sites; differentiating between gastric and EAC and using different treatment strategies and chemotherapeutic agents for each, while patients with gastric cardia adenocarcinoma are treated with a mixture of those employed for the other two anatomic sites.

### Applications

Improvements in community-based treatment of gastroesophageal adenocarcinoma will require better differentiation of treatments for the different anatomic sites and more extensive incorporation of those treatments proven effective in clinical trials. Future RCTs should be designed and appropriately powered to account for differences related to the anatomic site or origin of the tumor as well as the underlying tumor biology.

### Peer review

This is a retrospective study of a large number of patients with gastroesophageal adenocarcinoma focusing on treatment modalities and survival. This is an excellent and relevant study, which was well conducted and presented.

**CONCLUSION:** *Enterococcus species*, *E.coli* and *Klebsiella species* were the most common bacteria isolated from bile and/or blood from patients with acute cholangitis. Overall, a mixed infection with several species was observed, and bacteria showed a comparable *in vitro* activity for piperacillin/sulbactam and moxifloxacin.

### **Abstract**

**AIM:** To analyze the *in vitro* activity of moxifloxacin and piperacillin/sulbactam against pathogens isolated from patients with acute cholangitis.

**METHODS:** In this prospective study a total of 65 patients with acute cholangitis due to biliary stone obstruction ( $n = 7$ ), benign biliary stricture ( $n = 16$ ), and malignant biliary stricture ( $n = 42$ ) were investigated with regard to spectrum of bacterial infection and antibiotic resistance. Pathogens were isolated from bile cultures in all study patients. In 22 febrile patients, blood cultures were also obtained. *In vitro* activity of moxifloxacin and piperacillin/sulbactam was determined by agar diffusion.

**RESULTS:** Thirty-one out of 65 patients had positive bile and/or blood cultures. In 31 patients, 63 isolates with 17 different species were identified. The predominant strains were *Enterococcus species* (26/63), *E.coli* (13/63) and *Klebsiella species* (8/63). A comparable *in vitro* activity of moxifloxacin and piperacillin/sulbactam was observed for *E.coli* and *Klebsiella species*. In contrast, *Enterococcus species* had higher resistances towards moxifloxacin. Overall bacteria showed antibiotic resistances *in vitro* of 34.9% for piperacillin/sulbactam and 36.5% for moxifloxacin.

### **INTRODUCTION**

Acute cholangitis, first described by Charcot in 1877 is a frequent and potentially serious complication in patients with bile duct obstruction. Ductal obstruction leads to a raised intrabiliary pressure with cholangiovenous reflux and bacteremia, which may progress to septicemia<sup>[1]</sup>. Ductal stones, benign or malignant biliary strictures are reasons for the obstruction. Biliary decompression by endoscopic or percutaneous transhepatic procedures and selection of appropriate antibiotics are crucial in the therapy of these patients<sup>[2-5]</sup>. The efficacy of antibiotics in the treatment of biliary infections depends on the microbiological activity against the most common pathogens and the excretion of the antibacterial agents in the obstructed biliary tract. In case of complete obstruction of the common bile duct, no significant biliary excretion of the antibiotics occurs, so that biliary

bactericidal concentrations cannot be achieved<sup>[6,7]</sup>. However, recently a sufficient biliary concentration of the fluoroquinolone moxifloxacin in patients with obstructive cholangitis was reported<sup>[8]</sup>. Because bacteremia may progress to septicemia, a high level of serum concentrations of the antibiotic agents is also important for the treatment of biliary tract infections. Although acute cholangitis is a common clinical problem associated with a high level of morbidity and mortality, there is no standardized approach for therapy of this disease. The selection of antibacterial agents is based on the severity of the disease, the expected biliary pathogens or the activity of antibacterial agents against the isolated bacteria from blood or bile cultures. Broad spectrum antibiotics, active against gram negative and gram positive organisms, are the preferred treatment<sup>[2,9-11]</sup>. Therefore, in case of severe cholangitis, the mostly preferred drug is piperacillin, a broad spectrum penicillin. In a prospective randomised trial including patients with acute cholangitis, equal clinical efficacy was observed with piperacillin alone compared to ampicillin plus tobramycin<sup>[12]</sup>. The combination of piperacillin with the  $\beta$ -lactamase inhibitor sulbactam might be an alternative procedure when the resistance pattern shows a relatively high incidence of ureidopenicillin-resistant *E.coli* or *Klebsiella species*<sup>[13]</sup>. Because of increasing resistance and allergic reactions against penicillin, other antibacterial agents for the treatment of acute cholangitis become necessary. Moxifloxacin is characterized by an enhanced activity against gram positive, gram negative and in anaerobic organisms and by a sufficient concentration in the obstructive bile duct. Therefore it may be an alternative antibacterial treatment in patients with acute cholangitis. To address this question, we performed a prospective trial to analyze the *in vitro* activity of moxifloxacin and piperacillin/sulbactam against pathogens isolated from patients with acute cholangitis.

## MATERIALS AND METHODS

### Study population

The study included 65 consecutive patients suffering from acute cholangitis who were treated between February 2004 and November 2005 in the Department of Gastroenterology at the Technical University of Munich. All of the following criteria had to be fulfilled: (1) clinical diagnosis of acute cholangitis, (2) elevated cholestasis parameter (bilirubin > 3 mg/dL), (3) elevated infection parameters (leucocytes > 12 G/L, c-reactive protein > 3 mg/dL) or fever (> 38.5°C), and (4) age 18-90 years. Exclusion criteria were as follows: (1) primary sclerosing cholangitis, (2) liver cirrhosis, (3) liver transplantation, (4) acquired immunodeficiency syndrome (AIDS), (5) primary immunodeficiency syndrome, (6) therapy with glucocorticoids and other immunosuppressant drugs, (7) leucopenia (leucocytes < 1 G/L), and (8) infection focus other than acute cholangitis.

### Isolation of bacteria

From all patients included in this study, bile samples for culture were taken. Bile was obtained by endoscopic retrograde cholangiography (ERC) or by percutaneous transhepatic biliary drainage (PTBD). ERC and biliary drainage were performed with a standard videoduodenoscope OlympusTFJ 160-R. Endoscopic sphincterotomy (EST) was conducted using an Olympus papillotome introduced over a Terumo guide wire. At ERC, intraductal bile was collected before contrast agent injection by passing a sterile standard ERC catheter into the obstructed bile duct and aspirating bile into a sterile 10 mL syringe. In case of PTBD, 2-4 mL bile was collected into a sterile 10 mL syringe after penetration of the bile duct with the puncture needle. Thereafter, a percutaneous transhepatic biliary catheter was inserted by the Seldinger technique. Because of the percutaneous placement of this catheter, bile could be obtained all the time in case of fever, chills and increasing infection parameters (leucocytes, c-reactive protein). In 22 febrile patients (temperature > 38.5°C), blood cultures were also obtained. Typically, 10 mL of blood was obtained and transferred into aerobic and anaerobic culture broth (BacTec system, Becton Dickinson, Heidelberg, Germany).

### Microbiological investigation

In case of positive blood- and/or bile cultures, the *in vitro* activity of moxifloxacin and piperacillin/sulbactam was performed by agar diffusion assay test.

The bile/specimen sampled was examined for aerobic and anaerobic bacteria. In each case, 50-100  $\mu$ L bile/specimen were both transferred into liquid nutrient media (glucose broth, thioglycollate broth) and spread on solid culture media (Columbia sheep blood agar, chocolate agar, McConkey agar, Schädler anaerobic agar, Schädler KV anaerobic agar, and Sabouroud agar). Subsequently, the culture media were incubated at 37°C. The aerobic cultures were incubated for 48 h, with the first readout taken after 24 h. The anaerobic cultures were monitored for the first time after 48 h and processed further as required. To identify bacteria in the blood, one aerobic and one anaerobic blood culture bottle (BacTec system, Becton Dickinson, Heidelberg, Germany) were each inoculated with 10 mL of venous blood. The blood cultures were incubated at 37°C for 5 d. For control purposes and to exclude failure of automatic detection of the BacTec system each flask was subcultivated under aerobic (chocolate agar in 10% CO<sub>2</sub>) and anaerobic conditions (Schädler anaerobic agar) at the end of the incubation period. Cultivable germs were identified using the ATB, API or VITEK system (BioMérieux, Nürtingen, Germany). In order to identify antimicrobial inhibitors approximately 10  $\mu$ L of fluid specimen were placed in the depression of an agar plate containing a suspension of spore forming bacteria. With an antibiotic being present and taking effect in the specimen a clear inhibition zone was to be seen around the point of application. Colony forming units were

not determined in this study. Antibiotic susceptibility testing was performed using both the disk diffusion test or the MIC test using the VITEK system (BioMérieux, Nürtingen, Germany) or the Etest system (AB Biodisk, Solna, Sweden) according to the recommendations of the CLSI (Clinical Laboratory Standards Institute; formerly NCCLS/National Committee for Clinical Laboratory Standards).

## RESULTS

During the study period from February 2004 to November 2005, a total of 65 consecutive patients with acute cholangitis were included in the current clinical trial. The patients had the following characteristics: mean age 68 ± 12.3 years, 32 male and 33 female, bilirubin 7.9 ± 7.4 mg/dL, alkaline phosphatase 675 ± 510 U/L, γ-glutamyltransferase 697 ± 682 U/L, aspartate aminotransferase 193 ± 300 U/L, alanine aminotransferase 136 ± 147 U/L, leucocytes 16.9 ± 10.7 G/L, c-reactive protein 17.3 ± 9.5 mg/dL (Table 1).

Obstruction of the bile duct was caused by gallstones in 7/65 (10.8%) patients, benign strictures in 16/65 (24.6%) patients and malignant strictures of the biliary tract in 42/65 (64.6%) patients.

Thirty-one out of 65 patients had positive bile- and/or blood cultures. Sixty-three bacterial isolates and 17 different bacterial species were identified from 31 patients. The predominant isolated bacteria were *Enterococcus species* (26/63), *E.coli* (13/63), and *Klebsiella species* (8/63). Thereby, three quarter (74.6%) of the isolated bacteria were obtained from these predominant species, while the remaining quarter (25.4%) consisted of 7 different types. Within the group infected with *Enterococcus species*, *Enterococcus faecium* and *Enterococcus faecalis* were most frequent with 8 and 7 isolates, respectively. Bacteriobilia was documented in 22/65 patients and was polymicrobial in 17 patients (77.3%). Positive blood culture were obtained in 13/65 patients and was polymicrobial in only 1 patient (7.7%).

The resistance pattern of the isolated pathogens was investigated by an *in vitro* activity assay. Table 2 gives an overview of all bacterial pathogens and their resistance patterns regarding moxifloxacin and piperacillin/

**Figure 1** Comparison of *in vitro* activity of moxifloxacin and piperacillin/sulbactam in all isolated bacterial pathogens.

sulbactam. In summary, 34.9% (22/63) of all isolated pathogens were resistant, 6.4% (4/63) were intermediately resistant, and 58.7% (37/63) were susceptible to piperacillin/sulbactam. In comparison to these results 36.5 % (23/63) of all isolated pathogens were resistant, 9.5% (6/63) intermediate resistance, and 54% (34/63) susceptible to moxifloxacin (Figure 1).

## DISCUSSION

Acute cholangitis is an infection of the obstructed biliary tract with a wide spectrum of pathogens. Common microbial populations associated with cholangitis include gram-negative bacteria like *E.coli* and *Klebsiella species*. Gram-positive organisms, mainly *Enterococcus species* and anaerobes, are also found<sup>[14-21]</sup>. While previous works found *E.coli* infection in 20.9% and *Enterococcus species* in 20.9%<sup>[17]</sup>, our current results reveal that the most common isolates are *Enterococcus species* [41.3% (26/63)], *E.coli* [20.6% (13/63)] and *Klebsiella species* [12.7% (8/63)]. In addition to this a lot of other bacterial pathogens were isolated by blood and/or bile cultures (Table 2). Thus, the shift towards the higher rate of *Enterococcus species* and the high prevalence of *Klebsiella* infections might be related to the use of wide-spectrum antibiotics used in the past years.

Establishment of biliary drainage is the mainstay of therapy for patients with acute cholangitis. Endoscopic sphincterotomy with subsequent biliary drainage is the therapy of choice, but in case of therapy failure percutaneous transhepatic bile drainage is an alternative method for biliary drainage<sup>[22-24]</sup>. Nevertheless, once endoscopic and/or percutaneous transhepatic procedures have been performed, the spectrum of bacterial infection might change, and increased frequency of mixed infections has been reported<sup>[17]</sup>. Our current data are in line with this observation and reveal polymicrobial infections of the biliary tract in 17 out of 22 patients.

Overall, our results indicate that bacterial pathogens could only be isolated in 48% of the patients. Antibiotic treatment has to start early during the infectious process. In clinical practice, it is not possible to isolate bacterial pathogens in all patients and the time to receive the resistance pattern creates a delay of several days. Therefore, knowledge of bacterial spectrum and resistance pattern of antimicrobial agents are essential for the treatment of patients suffering from acute cholangitis.

Table 2 Resistance pattern for moxifloxacin and piperacillin/sulbactam in all pathogens

Pathogens	Moxifloxacin			Piperacillin/Sulbactam		
	Susceptible	Intermediate	Resistant	Susceptible	Intermediate	Resistant
<i>Enterococcus species</i>	9	4	13	16	1	9
<i>Enterococcus NS</i>	2	4	2	7		1
<i>Enterococcus faecium</i>	1		7	2	1	5
<i>Enterococcus faecalis</i>	4		3	5		2
<i>Enterococcus casseliflavus</i>	2			2		
<i>Enterococcus gallinarum</i>			1			1
<i>Escherichia coli</i>	8	1	4	11		2
<i>Klebsiella species</i>	5	1	2	4	1	3

Coagulase neg. <i>Staphylococcus</i>			2			2
Gram negative rod NS	1			1		
<i>Streptococcus anginosus</i>	1			1		

NS: Not specified.

Finally, it has to be mentioned that in patients with an obstructed biliary tract, the biliary excretion of several antibiotic agents is limited<sup>[6,25]</sup>. Recently, it was reported that moxifloxacin, a fluoroquinolone, can reach clinically significant concentrations in obstructed biliary tract<sup>[8]</sup>. Therefore it may be a superior treatment in patients with acute cholangitis that suffer from biliary obstruction. Until now, no data about antimicrobial activity of moxifloxacin against pathogens of acute cholangitis exists. Therefore, we isolated pathogens from patients with acute cholangitis and analyzed the *in vitro* activity of moxifloxacin and piperacillin/sulbactam. Our data show a comparable *in vitro* activity of moxifloxacin and piperacillin/sulbactam in patients with acute cholangitis. Kiesslich *et al.*<sup>[26]</sup> reported a resistance rate of 71.8% (28/39) for piperacillin and 76.7% (33/43) for ampicillin (both without  $\beta$ -lactamase inhibitors) in bacteria isolated from obstructed biliary tract during endoscopic retrograde cholangiography. In this study, the resistance rate for other fluoroquinolones ciprofloxacin and levofloxacin was 19.0% (8/42) and 2.2% (1/45), respectively. In agreement with these results, 96% (122/127) sensitivity to ciprofloxacin and 29% (37/127) sensitivity to ampicillin was reported in other studies<sup>[27]</sup>.

The *in vivo* benefit of fluoroquinolones in patients with biliary tract infections was investigated in several clinical trials. Karachlios *et al.*<sup>[28]</sup> performed a prospective, randomized trial with ofloxacin in one, and ceftriaxone in the other group. The clinical cure or improvement of clinical symptoms was the same in both groups. In another prospective randomized trial, an adequate clinical benefit was shown for ciprofloxacin mono therapy in comparison to a triple therapy with ceftazidime, ampicillin and metronidazole<sup>[29]</sup>. Also levofloxacin, a newer enantiomer of ofloxacin showed an adequate clinical effect when compared to ceftriaxone<sup>[30]</sup>. In this

prospective randomized trial, patients of both study groups received metronidazole additionally.

Although, moxifloxacin and piperacillin/sulbactam appears to have a comparable *in vitro* activity against pathogens of acute cholangitis, moxifloxacin may have a clinical benefit due to its extensive biliary excretion in obstructed biliary tract. Randomized clinical trials should be performed to evaluate clinical outcome of moxifloxacin in patients with acute cholangitis.

## COMMENTS

### Background

Cholangitis is a frequent and potentially serious complication in patients with bile duct obstruction. Biliary decompression by endoscopic intervention and selection of appropriate antibiotics are crucial for therapy of these patients. The use of broad-spectrum penicillin is generally accepted. Because of increasing resistance and allergic reactions against penicillin, other antibacterial agents for the treatment of acute cholangitis are essential moxifloxacin is characterized by an enhanced activity against gram-positive and -negative anaerobic organisms as well by a sufficient concentration in the obstructive bile duct. Therefore it may be an alternative antibacterial treatment for acute cholangitis.

### Research frontiers

To our knowledge, no study exists investigating the *in vitro* activity of moxifloxacin against pathogens isolated from patients with acute cholangitis. The current study was designed to analyze the *in vitro* activity of moxifloxacin and piperacillin/sulbactam against pathogens of acute cholangitis.

### Innovations and breakthroughs

The predominant pathogens isolated from patients with acute cholangitis were *Enterococcus species*, *E.coli* and *Klebsiella species*. A comparable *in vitro* activity of moxifloxacin and piperacillin/sulbactam was observed for *E.coli* and *Klebsiella species*. In contrast, *Enterococcus species* had higher resistances towards moxifloxacin. Overall bacteria showed antibiotic resistances of 34.9% for piperacillin/sulbactam and 36.5% for moxifloxacin.

### Applications

These data suggest that moxifloxacin can be used as an alternative antibiotic therapy in patients with cholangitis that show allergic reactions to piperacillin/sulbactam. Additionally, due to the extensive excretion of moxifloxacin in the obstructed biliary tract it may have a clinical advantage compared to the

standard therapy. Randomized controlled trials should be performed to evaluate the clinical outcome of moxifloxacin in patients with acute cholangitis.

### Terminology

Acute cholangitis with the triad of jaundice, fever and abdominal pain: was first described by Charcot in 1877. It is a frequent and potentially serious complication in patients with bile duct obstruction due to ductal stones, benign and malignant bile duct strictures. Bile duct obstruction leads to a raised intrabiliary pressure with cholangiovenous reflux and bacteraemia, which may induce sepsis.

### Peer review

This manuscript evaluates the relative resistance of bacterial cultures isolated from patients suffering acute cholangitis to piperacillin/sulbactam (the current antibiotic therapy) versus moxifloxacin. It is well designed, performed and written. It is of clinical relevance.

### Abstract

**AIM:** To examine the role of coprostasis and coproliths in recurrent appendicitis.

**METHODS:** We evaluated four hundred and twenty seven consecutive pathology reports of all appendectomy specimens from January 2003 to December 2004. Findings were categorised as showing acute appendicitis, acute recurrent appendicitis, subacute recurrent appendicitis, chronic appendicitis, or appendices without inflammation. All patients had presented with acute right lower quadrant pain. In 94 instances, there was a history of recurrent similar episodes in the past.

**RESULTS:** Of the 427 histology reports, 294 were interpreted as showing acute appendicitis, 56 acute recurrent appendicitis, 34 subacute recurrent appendicitis, 28 chronic appendicitis, and 15 non-inflamed appendices. Coprostasis was observed in 58 patients (13.58%) and the presence of coprolith in 6 (1.4%). Coprostasis, and age, were among the predictors in the final model.

**CONCLUSION:** Coprostasis but not coproliths seems to be a contributing factor to acute exacerbations of chronic inflammatory appendicitis.

### INTRODUCTION

Despite the disrepute associated with the term “recurrent appendicitis,” there is evidence to suggest that such appendectomies are associated with improvement of the symptoms that lead to admission of the patients<sup>[1-4]</sup>. The pathophysiology of recurrent inflammation of the appendix is uncertain. Acute appendicitis is thought to be associated with obstruction of the appendiceal lumen, leading to bacterial overgrowth, inflammation, ischaemia, and ultimately perforation. Some authors have thus hypothesized that recurrent lower quadrant pain can be due to either incomplete obstruction of the lumen of the appendix, or a disproportionate production of mucus<sup>[5,6]</sup>. Recurrent symptom alleviation after appendectomy in a proportion of our patients compelled us to examine the potential role of coprostasis and coproliths in recurrent appendicitis.

### MATERIALS AND METHODS

#### Patients

We evaluated prospectively all consecutive pathology reports for appendectomy specimens at the Department

of General Surgery, Marien Hospital Bottrop, Germany from January 2003 to December 2004. Specimens were categorized as acute appendicitis, acute recurrent appendicitis, subacute recurrent appendicitis, chronic appendicitis, and appendices showing no signs of inflammation. The presence of a coprolith (thickened “stone-like” faeces) and coprostasis (appendiceal lumen filled with faeces, completely impacted and not just the presence of a little stool) was noted. Clinical details were supplemented by review of selected case notes.

Specimens were doubly evaluated and classified into five categories by two pathologists separately and the presence of coprostasis and coprolith was also recorded. In those cases with discrepancy in the diagnosis or in the presence of a coprolith or coprostasis specimens ( $n = 4$ ) were reviewed by an experienced independent pathologist.

Patients were divided in 5 groups: Group A for acute appendicitis, group B for subacute recurrent appendicitis, group C for acute recurrent appendicitis, and group D for chronic inflammation of the appendix. Histology reports with normal non-inflamed appendices were classified as group E. Definitions of the pathologic entities were as follows:

**Acute appendicitis (group A):** At early stages the serosa is intensely erythematous due to congestion of the subserosal blood vessels. In advanced stages few intact crypts exist lined with intact mucosal epithelium, lamina propria is hypercellular due to neutrophil infiltration, hemorrhage and ulcers are found at the surface caused by the sloughing off of the inflammatory necrotic tissue.

**Subacute recurrent appendicitis (group B):** This entity is characterized by lympho-follicular hyperplasia, discrete granulocytes, mucocutaneous infiltration and hyperaemic serosa.

**Acute recurrent appendicitis (group C):** In different sections of the appendix, there can be recognized relative diffuse, inflammatory mucocutaneous and appendiceal wall infiltrations. Primarily neutrophils exist that spread out also within the subserosal tissue. Erosive lesions are additionally observed.

**Chronic inflammatory (group D):** This is characterized by the presence of unequivocal mural granulation tissue, with or without frank fibrosis, partial or total obliteration of the lumen by fibrous tissue and hyperplasia or atrophy of the lymphoid tissue.

### Statistical analysis

Statistical methods included nonparametric Yates correction chi-square, Fisher's exact test (two tails) for categorical variables, and Mann-Whitney *U* test for quantitative variables. The Random Forest test (data mining procedure) was used to disclose the variables for use in regression analysis. The General Discriminant analysis model was used to evaluate the discriminating

**Table 1** Incidence of coprostasis and coproliths among groups (%)

Pathology classification	Coprostasis ( $n = 58$ )	Coprolith ( $n = 6$ )
Acute	33/294 (11.22)	3/294 (1.02)
Subacute recurrent	12/34 (35.20)	1/34 (2.94)
Acute recurrent	9/56 (16.07)	1/56 (1.78)
Chronic	3/28 (10.71)	0/28 (0.00)
No inflammation	1/15 (06.66)	1/15 (6.66)

effect of coprostasis and coproliths on the defined groups. A Receiver Operating Characteristic (ROC) curve was used to define the ideal cut-off separator for continuous predictor variables. A significance level of 0.05 was assigned. Statistica release 7 (Statsoft) was used for statistical analysis.

## RESULTS

There were 427 appendectomy pathology reports, corresponding to 265 females and 162 males. Mean patient age was  $24.40 \pm 17.16$  years (range, 4-89 years). All patients were referred for acute right lower quadrant pain. In 94 cases, there was a reported history of recurrent similar episodes in the past. Among these 94 patients 56 had acute recurrent, 34 subacute recurrent and 4 chronic appendicitis.

Of the 427 histology reports, 294 were diagnostic of acute appendicitis, 56 of acute recurrent appendicitis, 34 of subacute recurrent appendicitis, 28 of chronic appendicitis, and 15 of non-inflamed appendices.

Coprostasis was observed in 58 patients (13.58%) and the presence of a coprolith was noted in 6 (1.4%) cases. The incidence and the respective percentages of coprostasis and coprolith among separate histology groups are shown in Table 1.

Associated findings were noted in 6 patients: sigmoid cancer in one, corpus luteum cyst in one, and Meckel's diverticulum in four. Yersinia infection was observed in 1 patient of group B and in one patient of group C. Parasitic infections were diagnosed in 3 patients of group A. Among the 15 cases of group E (non-inflamed appendices), there were four diverticular ruptures, two Meckel's diverticulitis, one carcinoid tumor, one mesenteric arterial embolism, three adnexitis, two tubo-ovarian abscesses, one endometriosis, and one bilateral ovarian biopsy negative for malignancy.

Prominent pathologic findings were encountered more frequently among group A patients. Appendiceal lumen dilatation greater than 10 mm was noticed in 12 patients of group A, one of group B, and 2 of group C. Forty five appendices of group A were gangrenous, and 38 were perforated. This contrasts with the appendices of patients within groups B and C, which were neither gangrenous nor perforated. The incidence of peri-appendicitis was higher in group A (205/294, 69.38%) than in group B (3/34, 8.82%) and group C (28/56, 50%; Table 2). Appendiceal plastrons were documented in 10 patients of group A and one of group D. There were none among patients of groups B and C.

**Table 2** Pathological findings

	Acute (A: <i>n</i> = 294)	Sub-acute recurrent (B: <i>n</i> = 34)	Acute recurrent (C: <i>n</i> = 56)	Chronic (D: <i>n</i> = 28)	<i>P</i>
Gangrenous	45	0	0	0	A vs B, <i>P</i> = 0.0101, A vs C, <i>P</i> = 0.0007
Perforated	38	0	0	0	A vs B, <i>P</i> = 0.0199, A vs C, <i>P</i> = 0.0019

The presence of coproliths did not discriminate among groups. Summary of stepwise regression; variable appendicitis forward stepwise *P* to enter, < 0.05; *P* to remove, > 0.05.

In order to find the potential role of coprostasis and coprolith as predictors of the various appendicitis classes as described in methods section, we applied Random Forest classification test (this Data Mining technique - Random Forest algorithm developed by Breiman - can be used for classification problems in order to predict a categorical dependent variable). Importance (from high to low) was attributed to Age = 1, Gender = 0.32, Coprostasis = 0.25, Oxyuriasis and Yersinia cases = 0.12 and Appendicolith = 0.05.

Taking into account the potential predictors suggested from the Random Forest test we proceeded for further analysis. Coprostasis, age, gender and oxyuriasis and Yersinia cases were prognostic factors among the four groups (excluded was the “No inflammation” group of patients) by univariate analysis. The presence of a coprolith did not achieve statistical significance. Coprostasis (*P* = 0.0032), age (*P* = 0.0077), and oxyuriasis and Yersinia cases (*P* = 0.0354), but not the presence of coprolith, were also found to be predictive variables by forward stepwise regression analysis. The level of significance for “coprostasis” in each group is reported in Table 3. The null hypothesis was rejected in groups D (*P* = 0.0351) and E (*P* = 0.0496), but substantiated in groups A (*P* = 0.6885), B (*P* = 0.0796) and C (*P* = 0.1311),

implying coprostasis as an etiologic factor in acute, subacute recurrent and acute recurrent appendicitis.

A further Discriminant forward stepwise analysis was employed in order to find the predictive model only for subacute recurrent and acute recurrent cases (Table 3). Only age and coprostasis were among predictors in the final model.

A Receiver Operating Characteristic (ROC) curve was used to select the optimum decision threshold for patient age. Patients less or equal to 40 years had a higher prevalence of subacute (29/5, *P* = 0.0012) and acute recurrent (45/11, *P* = 0.0003) appendicitis. Subacute and acute recurrent appendicitis was also found to be more prevalent in females (27/7, *P* = 0.0083; 39/17, *P* = 0.0241).

## DISCUSSION

The perception that acute appendicitis might subside spontaneously and re-emerge with bouts of right lower quadrant pain (so-called recurrent appendicitis) has met debate and disbelief. Nonetheless, 10% of patients presenting with acute appendicitis report previous similar physical findings that settled without surgery<sup>[7,8]</sup>. Subsequent appendectomy is remedial<sup>[3]</sup>.

It has been assumed that the likely pathophysiologic

mechanism of recurrent appendicitis is either incomplete obstruction of the lumen of the appendix or disproportionate mucus production. Except for two cases of yersiniosis associated with coprostasis, we did not observe any disorder involving the gastrointestinal system (such as inflammatory bowel disease, sarcoidosis, tuberculosis, polyarteritis nodosa, endometriosis, parasitosis, changes in neuroendocrine cells) that could account for the chronic or recurrent inflammation of the appendix.

Our study specifically addressed the presence of coprostasis, as opposed to previous series in which only coproliths were considered as causative of either acute or recurrent disease. A radiographically visualized coprolith was considered by many authors as a specific and unquestionable indicator of appendicitis due to obstruction<sup>[9]</sup>. A growing body of evidence however, suggests that luminal obstruction is not an indispensable factor in the development of appendicitis. Arnbjornsson and Bengmark<sup>[10]</sup> measured intraluminal pressures in acute appendicitis, and concluded that obstruction was the result rather than the cause of the inflammatory process. The incidence of coproliths in our series was 1.21%. The frequency of coprolith in acute appendicitis according to others ranges from 0.02%<sup>[11,12]</sup> up to 65%<sup>[13]</sup>. Our present study also rejects the role of coproliths as causative factors in recurrent appendicitis and imposes the use of high fiber diet after an atypical episode.

The reasons we followed this methodology to trace the relationship of coprostasis to the recurrent appendicitis were: (1) The distinction between subacute and acute recurrent appendicitis helps to better delineate the role of coprostasis as a causative factor since these are two sequential phases of the same entity from its initiation to the well established clinical presentation. (2) The use of data mining procedure disclosed the variables for use in regression analysis. The Random Forest test consists of a collection (ensemble) of simple tree predictors, each capable of producing a response when presented with a set of predictor values. For classification problems, this response takes the form of a class membership, which associates (classifies) a set of independent (predictor) values with one of the categories present in the dependent variable. (3) We had to establish first the predictors of all the patients' cohort and subsequently to insert them in analysis for the recurrent appendicitis (subacute or acute) group of patients only in order to avoid a type II error.

According to previous reports, the cut-off age after which the incidence of acute appendicitis declines is about thirty years. Based on our observations, the cut-off age in recurrent appendicitis is around forty.

In summary, it seems from our data that coprostasis rather than coproliths could be a contributing factor to acute exacerbations of chronic inflammatory appendicitis, and that its clinical and histologic findings are milder than those of acute appendicitis.

## COMMENTS

### Background

According to our experience, pain associated with chronic or recurrent appendicitis decreases after elective appendectomy in selected patients. There is little information about the causal factor. Some authors have hypothesized that recurrent lower quadrant pain can be due to either incomplete obstruction of the lumen of the appendix or to a disproportionate production of mucus.

### Research frontiers

We have recently hypothesized that coprostasis and or coproliths may be the contributing factor to acute exacerbations of chronic inflammatory appendicitis.

### Innovations and breakthroughs

The present data provide circumstantial evidence that adds to the standing of 'chronic or recurrent appendicitis' as a separate clinical entity. Its clinical and histologic findings are milder than those of acute appendicitis and the cut-off age in recurrent appendicitis is around forty. Coprostasis and not coproliths are the contributing factor to acute exacerbations of chronic inflammatory appendicitis.

### Applications

High fiber diet after an atypical recurrent episode is of potential clinical relevance.

### Peer review

This study raises an interesting hypothesis about the role of coprostasis in acute exacerbations of "chronic inflammatory appendicitis" by examining the histologic findings of various manifestations of this entity. It also clarifies the definition and the clinical relevance of this disreputed term.

### Abstract

**AIM:** To describe the characteristics of Dutch patients with chronic inflammatory bowel disease (IBD) first diagnosed above 60 years of age—a disease also known as old-age colitis (OAC) and to highlight a condition that has a similar appearance to IBD, namely segmental colitis associated with diverticular disease (SCAD).

**METHODS:** A retrospective longitudinal survey of patient demographic and clinical characteristics, disease characteristics, diagnostic methods, management and course of disease was performed. The median follow-up period was 10 years.

**RESULTS:** Of a total of 1100 IBD patients attending the Department of Gastroenterology, 59 (5%) [median age 82 years (range 64-101); 25 male (42%)] were identified. These patients were diagnosed with ulcerative colitis ( $n = 37$ , 61%), Crohn's disease ( $n = 14$ , 24%), and indeterminate colitis ( $n = 8$ , 15%). Remission was induced in 40 (68%) patients within a median interval of 6 mo (range 1-21) and immunosuppressive therapy was well tolerated. Histological evaluation based on many biopsy samples and the course of the disease led to other diagnosis, namely SCAD instead of IBD in five (8%) patients.

**CONCLUSION:** OAC is not an infrequent problem for the gastroenterologist, and should be considered in the evaluation of older patients with clinical features

### INTRODUCTION

Inflammatory bowel disease (IBD), a lifelong uncontrolled inflammation of the intestinal mucosa, is broadly subdivided into ulcerative colitis, Crohn's disease, and in 10%-15% of patients, indeterminate or unclassified colitis, when a definitive diagnosis of ulcerative colitis or Crohn's disease cannot be made at colonoscopy, colon biopsy or colectomy<sup>[1,2]</sup>.

The pathogenesis of IBD remains obscure. While it is clear that there are genetic, environmental, and immunological factors involved in the pathogenesis of IBD, the exact contribution of each and the sequence of events that culminates in clinically apparent IBD remains the subject of intense investigation.

Although IBD may occur at any age, the peak age of onset is 15-30 years old and approximately 10% of cases occur in individuals < 18 years old<sup>[3]</sup>. Old-age colitis (OAC) refers to patients older than 60 years, who are affected by a broad group of colonic diseases, such as infection, carcinoma, drug-induced disease, vasculitis, microscopic colitis, ischemic colitis, and IBD. Diagnosis of IBD in older patients may be difficult because it can easily be confused

with other forms of colitis commonly occurring at this age.

Earlier reports have indicated that both ulcerative colitis and Crohn's disease have a bimodal age distribution, with a second, smaller peak incidence occurring in individuals aged 50-70 years<sup>[4-7]</sup>. Two recent studies have shown that 21%-23% of ulcerative colitis occurs after the age of 50 years and 5% after 70 years<sup>[8,9]</sup>. This age group comprises around 12% (range 8%-20%) and 16% (range 7%-26%) of all newly diagnosed patients with ulcerative colitis and Crohn's disease, respectively<sup>[10]</sup>.

An additional group of disorders called segmental colitis associated with diverticular disease (SCAD) has been found to masquerade as IBD on both a clinical and histological basis<sup>[11]</sup>, since colonic diverticula, most often involving the sigmoid colon, commonly affect middle-aged and elderly individuals<sup>[12,13]</sup>.

In this retrospective cohort, we attempted to differentiate the broad nomenclature OAC and to describe the characteristics of Dutch IBD patients older than 60 years. In addition, we wanted to highlight one of the conditions that is similar to IBD, namely SCAD, since an overlap of IBD and diverticular disease has long been recognized and is not infrequent in clinical practice<sup>[14]</sup>.

## MATERIALS AND METHODS

An IBD database review of more than 1100 patients, covering the years 1990 to the current time, provided 64 cases with OAC. The diagnosis of IBD was determined according to conventional endoscopic, radiological and histological criteria<sup>[15-17]</sup>. Medical records of each patient in this study were reviewed for the following information: sex, age, diagnosis, duration of disease, presenting symptoms, medications (including non-steroid anti-inflammatory drugs), anatomic location of disease, coexistence of diverticulosis, extraintestinal manifestations, laboratory results, radiological results, histopathological examinations, previous medical and surgical treatment strategies, remission rate and development of refractory disease, postoperative morbidity and mortality, overall outcome, and development of malignancy. Dedicated gastroenterological pathologists revised histological specimens from all subjects. Extraintestinal manifestations included erythema nodosum, pyoderma gangrenosum, peripheral arthritis, sacroiliitis/spondylitis, and episcleritis or uveitis. Refractory disease was defined as patients who were not adequately controlled with conventional therapy or immunosuppressive agents, or who required surgical intervention<sup>[18]</sup>. The diagnosis of colonic diverticular disease was established by colonoscopy, barium enema, or both. SCAD was considered when colitis was restricted to a diverticular segment of the left colon (excluding the rectum); the rectum and proximal colon were endoscopically and histologically normal; and when there was no recurrence of segmental colitis following surgical resection of the affected segment<sup>[11]</sup>.

### Statistical analysis

Descriptive analysis was performed and continuous data

Table 1 General characteristic of patients with OAC

Characteristic	Total (n = 59)
Age, median (range, yr)	82 (64-101)
Men, n (%)	25 (42)
Body mass index, median (range)	21 (17-29)
Patient subsets, n (%)	
Ulcerative colitis	37 (63)
Crohn's disease	14 (24)
Indeterminate colitis	8 (13)
Presenting symptoms, n (%)	
Rectal bleeding	35 (65)
Diarrhea	27 (50)
Abdominal pain	23 (42)
Weight loss	18 (33)
Constipation	7 (13)
Fever	5 (9)

Figure 1 Bowel segment involvement in OAC.

were expressed as the median (range) and categorical data as numbers (percentage). Differences in erythrocyte sedimentation rate, serum albumin and hemoglobin were compared by using one way analysis (ANOVA).  $P \leq 0.05$  was considered statistically significant. Sensitivity and predictive values of radiographic examinations were calculated by using  $2 \times 2$  tables when the diagnosis was based on endoscopic and histological results. Statistical analysis was performed using the Statistical Software Package version 11.0 (SPSS Inc., Chicago, IL, USA).

## RESULTS

### Patients and disease characteristics

A total of 64 patients with OAC were identified. Five patients were excluded because the required histopathological studies were not available, and the remaining 59 patients were included in the analysis. Table 1 summarizes the general and disease-related characteristics and Figure 1 illustrates the bowel involvement in patients with Crohn's disease and ulcerative colitis. Colonic involvement was the rule in all eight patients with indeterminate colitis. Seven patients, including one with indeterminate colitis presented with pancolitis, and one patient had fistulous Crohn's disease. Extra-intestinal

**Figure 2** Endoscopic images showing signs of mucosal inflammation of sigmoid segment affected by diverticulosis coli, the inflammatory signs are stressed along the crests of the colonic folds in (A), and diffusely spread in (B).

manifestations included peripheral arthritis ( $n = 5$ ), uveitis ( $n = 2$ ) axial spondylitis ( $n = 1$ ), and erythema nodosum ( $n = 1$ ).

High erythrocyte sedimentation rate was found in 41 (69%) patients at presentation, exceeding in frequency decreased serum albumin or anemia (30% and 29%, respectively,  $P < 0.001$ ). A total of 51 radiographic examinations were performed including barium enema ( $n = 36$ ), small bowel follow-through ( $n = 8$ ), and abdominal computerized tomography ( $n = 7$ ), and depicted features suggestive of IBD in 17 (29%) patients (sensitivity 0.36 and PPV 0.79). An average of five (range 3-17) biopsies were obtained from separate segments of the colon and usually from affected and normally appearing mucosa on each endoscopic examination. Histology of surgically removed bowel segments was further evaluated in eight patients.

Infiltration of inflammatory cells was confined to the mucosa in the majority of patients [35 (95%) patients with ulcerative colitis, 10 (71%) with Crohn's disease, and seven (87%) with indeterminate colitis], and extended from the mucosa with reactive involvement of muscularis propria in the remaining patients. The inflammatory infiltrate was transmural in one patient with Crohn's disease. Crypt abscesses were identified in 26 (70%) patients with ulcerative colitis, four (29%) with Crohn's disease, and four (50%) with indeterminate colitis. Granulomas on the other hand, were recognized in three (8%) patients with ulcerative colitis, five (36%) with Crohn's disease, and four (50%) with indeterminate colitis.

### Management and course of the disease

Mesalazine preparations, corticosteroids and azathioprine were administered to either induce or maintain remission in a total of 43 (73%), 23 (40%) and seven (12%) patients, respectively. No marked side effects were reported during a median follow-up period of 10 years (range 1-14). Remission was induced in 27 (73%), seven (50%) and six (75%) patients with ulcerative colitis, Crohn's disease and indeterminate colitis, respectively, within a median interval of 6 mo (range 1-21).

Eighteen (30%) patients were considered to

have refractory disease that necessitated surgical intervention, such as sigmoid resection, partial colectomy, pancolectomy, or ileal or ileocecal resection. However, postoperative recurrence was documented in two patients with Crohn's disease and postoperative morbidity and mortality was 66% and 6%, respectively. Two patients died due to terminal cholangiocarcinoma, one patient postoperatively (*Klebsiella pneumonia* sepsis), and three patients due to causes unrelated to IBD, with an overall mortality of 10%.

### SCAD

Diverticulosis coli was present in 61% of patients with OAC. Five (8%) patients showed features that were suggestive of a diagnosis of SCAD. All five had endoscopic as well as histopathological features of colitis that affected the sigmoid colon, with sparing of the rectum and proximal colon. Endoscopic examinations showed either a circumferential localization of erythema, granularity and friability, and sparing of the ostia, as shown in Figure 2A, or diffuse periosteal distribution of erythema, as shown in Figure 2B. Two patients underwent surgery and remained in remission without maintenance treatment. The other three patients were treated initially with a course of mesalazine preparations and were further maintained in remission by increasing daily fluid intake and using fiber-rich laxative preparations. These patients were retrospectively considered to have SCAD and not IBD as initially diagnosed.

### DISCUSSION

This retrospective cohort study showed that 5% of IBD patients who attended our referral center were aged  $> 60$  years old, and could be categorized as having OAC. On the other hand, 8% of patients with OAC have retrospectively non-IBD colitis that the so-called OAC implicates a broader diagnosis than IBD.

With respect to the predominance of ulcerative colitis, anatomic location in Crohn's disease, presenting symptoms, management, and postoperative morbidity and mortality, our findings were in agreement with earlier observations<sup>[10,19-21]</sup>. Unlike our findings, higher incidence rates of IBD in older patients and higher frequency rates of isolated proctitis within the ulcerative colitis subgroup have been reported<sup>[22-24]</sup>. The difference in these rates is very likely related to the retrospective nature of the studies. Noticeably, two patients developed cholangiocarcinoma and none developed colorectal carcinoma during the follow-up period. The available data disallowed further disclosure of underlying sclerosing cholangitis. The use of immunosuppressive agents in this older population appears to warrant broadened application, even if there is little objective data on which to base this practice<sup>[25]</sup>. The use of infliximab as an anti-inflammatory treatment in patients with IBD has been reported to be safe, including in those aged  $> 60$  years old<sup>[26]</sup>. However, there appears to be a significant risk of deleterious and fatal adverse events when infliximab is used in older patients<sup>[27]</sup>. More

safety data about the use of biological agents in older populations are needed, especially when more new agents with proven efficacy are evolving.

Some attribute one-third of the small incidence peak of IBD in this age group to ischemia<sup>[28]</sup>. However, the chronic course of the disease and the emergence of refractory colitis made the diagnosis of ischemic colitis unlikely in our study, along with the histological findings that were also not supportive of a diagnosis of ischemic colitis.

A recognized pitfall in clinical practice appeared in this series; misdiagnosing SCAD as IBD in 8% of patients<sup>[29-33]</sup>. SCAD has long been recognized as an example of the overlap of IBD and diverticular disease<sup>[14,16,29,30]</sup>. The pathogenesis of this apparently distinct form of colitis is unclear<sup>[14]</sup>.

Factors such as age and the high predilection of Crohn's disease for distal localization in older patients contribute to the simultaneous occurrence of both disorders in this population<sup>[34]</sup>. Differentiating between IBD and SCAD imposes a challenging task to the clinician as well as the pathologist. Clinical evaluation, laboratory tests, radiological results and endoscopic examinations (especially in diffuse type), in addition to histological studies, may be misleading. Sometimes even intestinal resection cannot provide the clinician with a definitive diagnosis. Luminal mucosal inflammation, although unusual, may occur in diverticular disease due to redundancy and mucosal prolapse<sup>[35]</sup>. When the luminal inflammation appears in what is called crescentic fold disease, a diagnosis of SCAD seems more probable<sup>[36]</sup>. A diagnosis of SCAD becomes more difficult when the inflammation affects a colon segment diffusely. The histology of SCAD may closely mimic ulcerative colitis and the hallmarks of Crohn's disease<sup>[16,37]</sup>. To complicate the issue, many cases of SCAD seem to respond post operatively favorably to treatment with mesalazine preparations similar to that given for IBD<sup>[30]</sup>. That is why a definitive diagnosis may remain obscure for a long time, and only the course of the disease may bring to light the underlying nature of the disorder. Newly emerging instruments in the diagnostic panel such as serological markers<sup>[38-40]</sup>, advanced radiological examinations such as contrast-enhanced magnetic resonance imaging<sup>[41]</sup>, wireless capsule video endoscopy<sup>[42]</sup>, and double-balloon small enteroscopy<sup>[43]</sup> may facilitate an early and correct definite diagnosis. These diagnostic modalities appear to be valuable for patients who have indeterminate colitis or who are failing medical therapy. The multiple harvest of biopsy specimens at each endoscopic session seems to be helpful in differentiating colitis in segmental fashion, especially SCAD that can be cured by limited resection of affected segments, although this conclusion is based on limited data from this retrospective study.

In summary, OAC is not an infrequent problem for the gastroenterologist and should be considered in the evaluation of older patients with clinical features suggestive of IBD. This entity is broader than IBD alone and therefore more challenging. Extra awareness is

required in order to avoid an erroneous diagnosis purely based on histological mimicry of changes seen in SCAD when diagnosing IBD in the presence of diverticulosis coli, and taking multiple biopsies from each part of the colon is recommended.

## COMMENTS

### Background

Inflammatory bowel disease (IBD) is a lifelong uncontrolled inflammation of the intestinal mucosa that mainly affects the young age group but also older individuals.

### Research frontiers

Diagnosis of IBD in older patients may be difficult because it can easily be confused with other forms of colitis commonly occurring in this age group, such as segmental colitis associated with diverticular disease (SCAD).

### Applications

Old-age colitis (OAC) is not an infrequent problem for the gastroenterologist and should be considered in the evaluation of older patients with clinical features suggestive of IBD. Extra awareness is required in order to avoid an erroneous diagnosis.

### Terminology

OAC refers to patients older than 60 years affected by a broad group of colonic diseases, such as infection, carcinoma, drug-induced disease, vasculitis, microscopic colitis, ischemic colitis, and IBD. SCAD has been found to masquerade as IBD on both a clinical and histological basis.

### Peer review

The authors described the characteristics of Dutch patients with chronic IBD with a first diagnosis above 60 years of age, also known as OAC, and highlighted one of the conditions that has the appearance of IBD, namely SCAD. This is an interesting study. The authors concluded that OAC is not an infrequent problem for the gastroenterologist and should be considered in the evaluation of older patients with clinical features suggestive of IBD.

### Abstract

**AIM:** To investigate the effect of three weeks' intervention with a probiotic *Lactobacillus rhamnosus* GG (LGG) bacteria on global serum lipidomic profiles and evaluate whether the changes in inflammatory variables (CRP, TNF- $\alpha$  and IL-6) are reflected in the global lipidomic profiles of healthy adults.

**METHODS:** We performed UPLC/MS-based global lipidomic platform analysis of serum samples ( $n = 26$ ) in a substudy of a randomised, double-blind, placebo-controlled 3-wk clinical intervention trial investigating the immunomodulatory effects of probiotics in healthy adults.

**RESULTS:** A total of 407 lipids were identified, corresponding to 13 different lipid classes. Serum samples showed decreases in the levels of lysophosphatidylcholines (LysoGPCho), sphingomyelins (SM) and several glycerophosphatidylcholines (GPCho), while triacylglycerols (TAG) were mainly increased in the probiotic LGG group during the intervention. Among the inflammatory variables, IL-6 was moderately

associated by changes in global lipidomic profiles, with the top-ranked lipid associated with IL-6 being the proinflammatory LysoGPCho (20:4). There was a weak association between the lipidomic profiles and the two other inflammatory markers, TNF- $\alpha$  and CRP.

**CONCLUSION:** This was the first study to investigate the effects of probiotic intervention on global lipidomic profiles in humans. There are indications that probiotic LGG intervention may lead to changes in serum global lipid profiles, as reflected in decreased GPCho, LysoGPCho and SM as well as mainly increased TAG.

### INTRODUCTION

The new global metabolic profiling techniques or 'metabolomics', have made it possible to measure large numbers of different metabolites, and are currently being applied to increase our understanding of the health and disease continuum<sup>[1]</sup>. High-dimensional lipid analysis technologies (lipidomics) provide an opportunity to measure lipids on a broad scale<sup>[2]</sup>. The majority of lipid pathways involved in lipid metabolism are known, but new lipid metabolites are being discovered all the time. It is not fully known how different pathways affect individual

metabolic health and how changes in the regulation of these pathways can influence major metabolic and inflammatory diseases like diabetes, cardiovascular and inflammatory diseases and obesity<sup>[2]</sup>. The new analytical capacity of lipidomics as a branch of metabolomics can increase our understanding of lipid biology, improve the characterisation of global lipid profiles and result in the identification of previously unknown changes in lipid metabolism<sup>[3]</sup>.

One study has evaluated the transgenomic metabolic effects of two probiotic lactobacilli in mice<sup>[4]</sup>, but as far as we know, the effects of probiotics on global lipidomic profiles in humans have not been characterised before. Previously, probiotics have been shown to possess immunomodulatory effects in *in vitro* assays, animal models and clinical trials<sup>[5,6]</sup>, and their effects have been studied mainly in specific conditions such as allergy<sup>[7,8]</sup> and inflammatory diseases<sup>[9]</sup>.

In the present study, we characterised the effect of the probiotic *Lactobacillus rhamnosus* GG (LGG) on global serum lipidomic profiles and investigated whether the changes in inflammatory variables (CRP, TNF- $\alpha$  and IL-6) are reflected in the lipidomics profiles of healthy adults.

## MATERIALS AND METHODS

### Subjects

The subjects were healthy adults ( $n = 26$ , 14 females, 12 males) with a mean age of 42 years (range 23–55) and a mean BMI of 24 kg/m<sup>2</sup> (range 20–30). The subjects were recruited to the study by an advertisement in the Helsinki area. The inclusion criteria were being healthy (no chronic illnesses), taking regular exercise (at least three times per week), and not participating in any other clinical trial. The exclusion criteria were milk allergy (due to the nature of the study products), use of antibiotics during the 2 mo before the study, acute gastrointestinal disorders during the 2 mo before the study, gastrointestinal diseases and related medication, pregnancy, and lactation. Before entering the study, the subjects gave their written informed consent. The study protocol was approved by the Ethics Committee of the Hospital District of Helsinki and Uusimaa.

### Intervention

The present study was a substudy of a randomised, double-blind and placebo-controlled parallel group intervention study investigating the immunomodulatory effects of probiotic bacteria with four treatment groups; placebo, LGG, *Bifidobacterium animalis* ssp. *lactis* Bb12 and *Propionibacterium freudenreichii* ssp. *shermanii* JS<sup>[10]</sup>. Only the placebo ( $n = 15$ ) and LGG ( $n = 11$ ) groups were included in the present pilot study since the LGG exhibited the best anti-inflammatory potential in the original study. Prior to the intervention period, there was a 3-wk run-in period during which no probiotic-containing products were allowed. For 3 wk thereafter, the subjects consumed either a 250 mL milk-based fruit drink containing LGG bacteria (ATCC 53103,  $6.2 \times 10^7$  cfu/mL) or a similar

placebo drink without probiotic bacteria daily. A list of probiotic-containing products was given to the subjects, and they were asked not to consume any other probiotic-containing products at any point during the study. Otherwise they were allowed to eat freely. Venous blood samples from the antecubital vein were taken at baseline and after the 3-wk intervention. The blood samples were stored at -70°C for global lipidomic analyses.

### Inflammatory variables and serum lipids

Serum levels of C-reactive protein (CRP) were measured by a high-sensitivity particle-enhanced immunoturbidimetric CRP assay using a Tina-quant CRP (latex) high-sensitivity reagent and a Roche Hitachi 912 analyser (Roche Diagnostics GmbH, Mannheim, Germany) with a detection limit of 0.04 mg/L. All samples were over the detection limit. Cytokine levels (TNF- $\alpha$ , IL-6) in serum were determined using Quantikine HS, Human TNF- $\alpha$ /TNFSF1A (Catalog Number HSTA00D) and IL-6 (HS600B) immunoassays purchased from R&D Systems (Minneapolis MN, USA) according to the manufacturer's instructions. The detection limit was 0.5 pg/mL for TNF- $\alpha$  and 0.16 pg/mL for IL-6. Serum total cholesterol, high-density lipoprotein (HDL) cholesterol and triglyceride concentrations were measured with their respective enzymatic kits from Roche Diagnostics using an autoanalyser (Roche/Hitachi 912 Automatic Analyzer). Low-density lipoprotein (LDL) cholesterol concentrations were calculated using Friedewald's equation<sup>[11]</sup>.

### Sample preparation for global lipidomic analysis

An aliquot (10  $\mu$ L) of an internal standard mixture containing 11 lipid classes and 0.05 mol/L sodium chloride (10  $\mu$ L) was added to the serum samples (10  $\mu$ L). The lipids were extracted with chloroform/methanol (2:1, 100  $\mu$ L). A standard mixture containing 3 labelled standard lipids was added (10  $\mu$ L) to the extracts. The sample order for LC/MS analysis was determined by randomization.

### Global lipidomics analysis by UPLC/MS

Lipid extracts were analysed on a Waters Q-ToF Premier mass spectrometer combined with an Acquity Ultra Performance LC<sup>TM</sup> (UPLC). The column, which was kept at 50°C, was an Acquity UPLC<sup>TM</sup> BEH C18 10 mm  $\times$  50 mm with 1.7  $\mu$ m particles. The binary solvent system included (A) water (1% 1 mol/L NH<sub>4</sub>Ac, 0.1% HCOOH) and (B) LC/MS grade (Rathburn) acetonitrile/isopropanol (5:2, 1% 1 mol/L NH<sub>4</sub>Ac, 0.1% HCOOH). The gradient started from 65% A/35% B, reached 100% B in 6 min and remained there for the next 7 min. The total run time including a 5 min re-equilibration step was 18 min. The flow rate was 0.200 mL/min and the injected amount 0.75  $\mu$ L. The temperature of the sample organiser was set at 10°C.

The lipid profiling was carried out on Waters Q-ToF Premier mass spectrometer using ESI+ mode. The data were collected at mass range of  $m/z$  300–1200 with a scan duration of 0.2 s. The source temperature was

set at 120°C, and nitrogen was used as desolvation gas (800 L/h) at 250°C. The voltages of the sampling cone and capillary were 39 V and 3.2 kV, respectively. Reserpine (50 µg/L) was used as the lock spray reference compound (5 µL/min; 10 s scan frequency).

Data were processed using MZmine software, version 0.60<sup>[12]</sup>. Lipids were identified using an internal spectral library or by tandem mass spectrometry using UPLC/MS/MS as described previously<sup>[13]</sup>. The normalisation of lipidomic data was performed as follows: All monoacyl lipids except cholesterol esters, such as monoacylglycerols and monoacylglycerol-PL, were normalised with GPCho (17:0/0:0); diacyl lipids except ethanolamine PL were normalised with GPCho (17:0/17:0); ceramides with Cer (d18:1/17:0); the diacyl ethanolamine phospholipids with GPEtn (17:0/17:0); and the TG and cholesterol esters with TG (17:0/17:0/17:0). Other (unidentified) molecular species were calibrated with GPCho (17:0/0:0) for a retention time of < 300 s, GPCho (17:0/17:0) for between 300 s and 410 s, and TG (17:0/17:0/17:0) for higher retention times. Only the identified lipid molecular species were included in further data analyses.

### Lipid nomenclature

Lipids from the global lipidomic analysis were named according to Lipid Maps (<http://www.lipidmaps.org>). For example, lysophosphatidylcholine (LysoGPCho) with 16:0 fatty acid chain was named monoacyl-glycerophosphocholine GPCho (16:0/0:0). In cases where the fatty acid composition could not be determined, the total number of carbons and double bonds was marked. For example, a phosphatidylcholine species PCho (16:0/20:4) is represented as GPCho (36:4). However, GPCho (36:4) could also represent other molecular species, for example, GPCho (20:4/16:0) or GPCho (18:2/18:2).

### Statistical analysis

Principal component analysis (PCA) and partial least squares discriminant analysis (PLS/DA) were utilised as modelling methods for clustering and discrimination<sup>[14]</sup>. PLS/DA is a pattern recognition technique that correlates variation in the dataset with class membership. The resulting projection model gives latent variables (LVs) that focus on maximum separation ("discrimination"). The random subsets cross-validation method<sup>[15]</sup> and Q2 scores were used to develop the models. The VIP (variable importance in the projection) values<sup>[16]</sup> were calculated to identify the most important molecular species for the clustering of specific groups. PLS/DA and PCA analyses were performed using Matlab, version 7.2 (Mathworks, Natick, MA, USA) and PLS Toolbox, version 4.0, of the Matlab package (Eigenvector Research, Wenatchee, WA, USA). All other analyses were performed using R statistical language (<http://www.r-project.org/>).

Comparisons between the levels of selected molecular species were performed using the paired Wilcoxon test. For the PLS/DA analyses as well as paired univariate analyses, the data were first log-transformed for

each lipid so that  $X = \log(z_2/z_1)$ , where  $z_2$  was the lipid concentration at 21 d and  $z_1$  at baseline. With such transformation, the distribution of data was closer to normal and the within-person changes could better be analysed. Chance detection plotting was used to account for multiple hypothesis testing in univariate comparisons. The chance detection plot described how many lipids show more significant differences at random than those actually observed.

In order to assess whether any of the inflammatory variables were explained by global lipidomic profile data, we regressed global lipidomic profile data on selected inflammatory variables using an elastic net method<sup>[17]</sup>. The method selects an optimal subset of lipids, based on predictive performance of the regression model using extensive bootstrap-based cross-validation. The model is selected by minimum cross-validation-error criterion, which balances the bias against the variance of the estimates. For these analyses, the data were first log-transformed for each lipid/clinical variable so that  $X = \log(z_2/z_1)$ .

## RESULTS

### Serum lipids

The mean (SD) baseline value (mmol/L) for total cholesterol was 5.1 (1.1), for LDL cholesterol 3.1 (1.0), for HDL cholesterol 1.5 (0.4) and for triglycerides 1.0 (0.4) in the placebo group and, in the LGG group, 5.4 (1.2), 3.3 (1.0), 1.5 (0.4) and 1.4 (1.1), respectively. The mean (SD) change (mmol/L) during the 3-wk intervention in total cholesterol was 0.2 (0.5), in LDL cholesterol 0.1 (0.5), in HDL cholesterol 0.1 (0.2) and in triglycerides 0.0 (0.5) in the placebo group and 0.0 (0.4), 0.1 (0.3), 0.0 (0.2) and 0.0 (0.6) in the LGG group, respectively. There were no significant differences in serum lipids during the intervention.

### Global lipidomic analysis

The global lipidomic analysis led to 407 identified lipid species, corresponding to 13 different lipid classes. PCA analysis revealed that no major outliers exist in the data, thus confirming that any changes detected in further analyses would not be due to specific outliers. PLS/DA analysis revealed that the LGG and the placebo groups differed at baseline, and therefore only the within-person changes were utilised in the later statistical analyses. PLS/DA analysis on log-transformed data indicated that the global lipidomic profiles of the groups were separable (Figure 1A). In the LGG group, significant changes ( $P < 0.05$ ) in lipids were observed during the intervention using paired Wilcoxon test, although when accounting for multiple hypothesis testing by using the chance detection plot, no lipid changes were found to be significant within the 95% confidence interval. However, the VIP analysis revealed some common trends in the lipidomic profile data. Decreased LysoGPCho and sphingomyelins (SM), mainly decreased glycerophosphatidylcholines (GPCho) and mainly increased triacylglycerols (TAG) were among the most important

**Figure 1** A: Partial least squares discriminant analysis (PLS/DA) of global serum lipidomic data during the probiotic intervention in healthy adults. The labels in the picture indicate subject ID numbers; B: Fold changes for the top 30 ranking lipids contributing to the PLS/DA model based on VIP analysis (variable important in the projection) (<sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.001$ ).

variables contributing to the separation between the LGG and the placebo groups (Figure 1B).

### Associations between global lipidomics profiles and inflammatory variables

In order to investigate whether the changes in inflammatory variables during the 3-wk intervention were reflected in global lipidomic profiles, we regressed the lipidomic profile data on measured serum TNF- $\alpha$ , IL-6, and CRP values (Figure 2). The results revealed that a reasonably good model based on global lipidomic profiles was found for the proinflammatory cytokine IL-6, while the regression model was poor for CRP and TNF- $\alpha$ . The top-ranking lipid associated with the changes in IL-6 was the proinflammatory LysoGPCCho (20:4) (Figure 2).

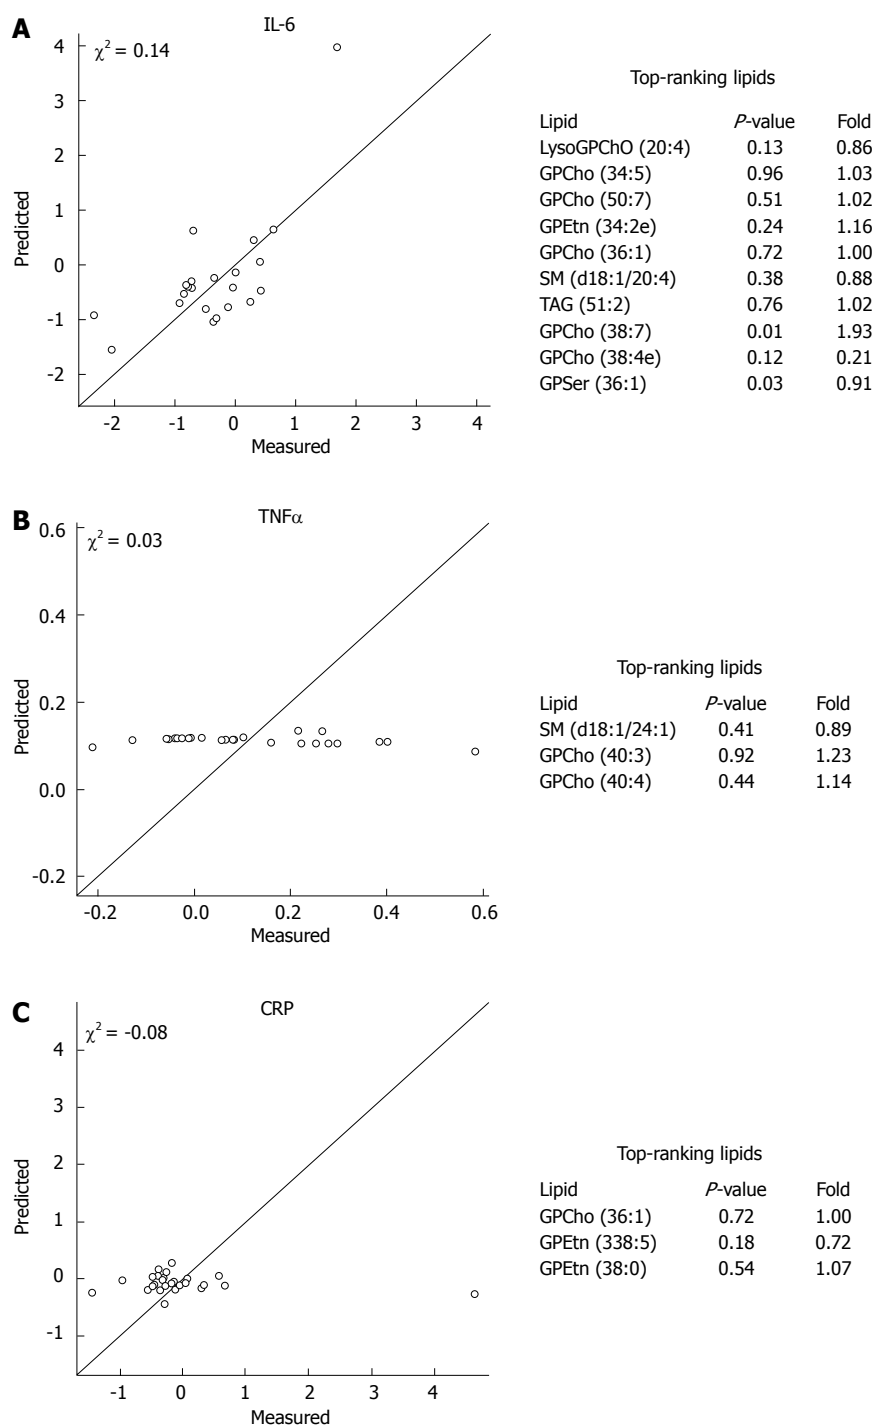

## DISCUSSION

This study is the first to apply lipidomic techniques to analyse the global lipidomic profiles of healthy adults after a probiotic intervention. The lipidomic platform has already been applied in multiple studies investigating the pathophysiology of different diseases<sup>[18–21]</sup>. In the present study, we characterised the effect of probiotic LGG on global serum lipidomic profiles and investigated whether the changes in inflammatory variables (CRP, TNF- $\alpha$  and IL-6) were reflected in global lipidomic profiles in healthy adults. We observed that the probiotic LGG intervention may lead to changes in global lipidomic profiles.

We found a trend towards decreased LysoGPCCho after the probiotic LGG intervention. LysoGPCCho, derived from phosphatidylcholines, are mediators that affect numerous functions in many types of cells, from proliferation and survival to migration and secretion. They are also involved in oxidative metabolism, angiogenesis, and carcinogenesis<sup>[22]</sup>. LysoGPCCho is a

major atherogenic lipid of oxidised LDL<sup>[23]</sup>, and it has been associated with vascular inflammation, endothelial dysfunction and coronary atherosclerosis<sup>[24]</sup>. LysoGPCCho induces an increase in several inflammatory cytokines (IL-1 $\beta$ , IL-6, TNF- $\alpha$ ) in human peripheral mononuclear cells (PBMCs)<sup>[25]</sup>. Therefore, the reduction of LysoGPCCho in the present study could be related to our, and previous, results showing a decreased production of TNF- $\alpha$  in PBMCs in healthy adults<sup>[10,26]</sup>. Interestingly, a high LysoGPCCho level has been connected also to inflammatory bowel disease (IBD)<sup>[27,28]</sup>, impaired mucosal barrier function and increased gut permeability<sup>[29–32]</sup>. LGG has not been effective in treating Crohn's disease<sup>[33,34]</sup>, but it has been shown to maintain remission in patients with ulcerative colitis<sup>[35]</sup>. In addition, LGG normalises gut permeability<sup>[36,37]</sup> and enhances mucosal integrity and epithelial cell survival<sup>[38,39]</sup>. Taken together, the decrease in LysoGPCCho after LGG intervention observed in the present study may be one of the metabolic events behind the beneficial clinical effects of LGG seen in ulcerative colitis and in normalised gut permeability.

In the present study, we also observed a decrease in SM after the LGG intervention. SM is a major membrane sphingolipid and the precursor of important signalling molecules like ceramide and sphingosine<sup>[40]</sup>. Recent studies reveal that metabolites of SM are critically important for the initiation and maintenance of diverse aspects of immune cell activation and also function as regulators of inflammatory responses<sup>[41–43]</sup>. High concentrations of sphingolipids and lipids of the SM/ceramide pathway have been connected to inflammatory processes in the development of atherosclerosis<sup>[44]</sup> and IBD<sup>[45,46]</sup>. The harmful effects of these lipids may be partly mediated via the production of reactive oxygen species in cells<sup>[42,47]</sup>. As in the case of LysoGPCCho, the generation of ceramide by sphingomyelinases from SM and epithelial oxidative stress might contribute to

**Figure 2** Cross-validated regression model prediction for IL-6 (A), TNF- $\alpha$  (B) and CRP (C) based on the global lipidomic profile data with the top-ranking lipids explaining the changes in inflammatory variables during the probiotic intervention.

the disturbed barrier function seen in diseases such as IBD<sup>[45]</sup>. Therefore, the decrease in SM seen after LGG intervention in the present study may also contribute to the beneficial effects on gut barrier function seen in the previous intervention studies with LGG<sup>[36-39]</sup>.

Although we observed some common trends in the global lipidomic profiles after LGG intervention, one should notice that, when accounting for multiple hypothesis testing using the chance detection plot, no lipid changes were found to be statistically significant. This suggests that the study was either underpowered for investigations of global lipidomic profile changes in the described setting, or the observed baseline differences in the global lipidomic profiles dominated over responses

to the intervention, masking potential effects of the LGG intervention. One thus cannot exclude the possibility that some of the significant changes were detected by chance. Furthermore, this pilot study was conducted with healthy individuals alone, whereas the effect of LGG intervention on global lipidomic profiles should also be investigated in subjects suffering from inflammatory conditions or disturbed gut barrier function before further conclusions can be drawn.

In conclusion, there are indications that probiotic LGG intervention may lead to changes in global lipidomic profiles reflected in decreased LysoGPCho and SM, mainly decreased GPCho and mainly elevated TAG. These changes may contribute, for example, to the

metabolic events behind the beneficial effects of LGG on gut barrier function seen in previous studies. IL-6 was moderately associated with the changes in lipidomic profiles. Lipidomics may provide powerful tools for identifying new biomarkers behind the clinical effects of probiotic intervention trials and for establishing relationships between molecular profiles and other known data from the same individual.

## COMMENTS

### Background

The new global metabolic profiling technique 'metabolomics' has made it possible to measure a large number of metabolites, and is currently being applied to increase the understanding of the health and disease continuum. The new analytical capacity of lipidomics as a branch of metabolomics can increase the understanding of lipid biology, improve the characterisation of global lipid profiles and result in the identification of previously unknown changes in lipid metabolism. Probiotics have been mostly studied in the prevention and treatment of different gastrointestinal diseases and allergy, but the mode of action of probiotics is poorly understood.

### Innovations and breakthroughs

This study is the first to apply lipidomic techniques to analyse the global lipidomic profiles of healthy adults after a probiotic intervention. Lipidomic analysis showed that there were decreases in the levels of lysophosphatidylcholines (LysoGPCCho), sphingomyelins (SM) and several glycerophosphatidylcholines (GPCCho), and increases in triacylglycerols (TAG) in the probiotic LGG group. These changes may contribute, for example, to the metabolic events behind the beneficial effects of LGG on gut barrier function seen in previous studies.

### Applications

Metabolomics and lipidomics may help to understand the action mechanisms of different agents, such as probiotics.

### Terminology

Lipidomics is a branch of metabolomics which enables identification of lipids in a large scale. Probiotic bacteria are defined as living microorganisms that have beneficial effects on human health.

### Peer review

This was an interesting paper and overall it was well written and well-presented. However, this is a small study. One good point is the randomized cohort. The study population was healthy individuals and the results may not be applicable to a population with lipid-related disease states. There were multiple comparisons and one thus cannot exclude the possibility that some of the significant changes were detected by chance.

second IT in 66.7% (OF 100%). Follow-up mortality rate was 0.

**CONCLUSION:** Presence of symptoms, elevated AP, and CC are associated with IT requirement. HRT is associated with presence of symptoms and IT requirement. Patients with BMI > 25 have a trend to be susceptible to IT complications. The proportions of complications are higher in FHR and second IT groups. RS is more frequent after OF.

### Abstract

**AIM:** To evaluate the factors that influence outcome of both non-invasive and invasive treatment of polycystic liver disease.

**METHODS:** Analysis of clinical files of patients with complete follow-up from July 1986 to June 2006.

**RESULTS:** Forty-one patients (male, 7; female, 34), 47.8 ± 11.9 years age, and 5.7 ± 6.7 years follow-up, were studied. Alkaline phosphatase (AP) elevation (15% of patients) was associated with the requirement of invasive treatment (IT,  $P = 0.005$ ). IT rate was higher in symptomatic than non-symptomatic patients (65.4% vs 14.3%,  $P = 0.002$ ), and in women taking hormonal replacement therapy (HRT) ( $P = 0.001$ ). Cysts complications (CC) were more frequent (22%) in the symptomatic patients group ( $P = 0.023$ ). Patients with body mass index (BMI) > 25 (59%) had a trend to complications after IT ( $P = 0.075$ ). Abdominal pain was the most common symptom (56%) and indication for IT (78%). Nineteen patients (46%) required a first IT: 12 open fenestration (OF), 4 laparoscopic fenestration (LF) and 3 fenestration with hepatic resection (FHR). Three required a second IT, and one required a third procedure. Complications due to first IT were found in 32% (OF 16.7%, LF 25%, FHR 66.7%), and in the

### INTRODUCTION

Polycystic liver disease (PLD) is an autosomic dominant disease related to chromosome 19 alterations in patients with hepatic involvement alone and in chromosomes 4 and 16 in those with renal cysts<sup>[1]</sup>. At autopsy, the prevalence appears to be 0.13%-0.6%, and the association to renal cysts about 30%<sup>[2-4]</sup>. PLD is generally asymptomatic and incidentally diagnosed. Abdominal pain, distension, early satiety, nausea and vomiting are common and hepatic function is rarely affected. Ultrasound (US) and computed tomography (CT) are common diagnostic methods. PLD is considered when more than 5 cysts are observed in the liver that typically appear anechoic, round and smooth-walled with distal echo enhancement in the US<sup>[5]</sup> (Figure 1A); and in CT with homogeneous fluid density and without wall or content enhancement after contrast administration<sup>[6]</sup>

(Figure 1B). Invasive treatment (IT) such as cyst aspiration with sclerotherapy, open fenestration (OF), laparoscopic fenestration (LF), fenestration plus hepatic resection (FHR), and hepatic transplantation in selected cases are preferred<sup>[1,4,7-10]</sup>. Symptoms are controlled with surgical liver volume reduction<sup>[11]</sup>. In a Mexican population, surgery for PLD has shown to modify quality of life<sup>[12]</sup>. We report a descriptive analysis of 41 patients with clinical and imaging diagnosis of PLD that have a complete follow-up during July 1986 to June 2006, making special emphasis on factors that influence outcome of both non-invasive and invasive treatment.

## MATERIALS AND METHODS

### Materials

This is a descriptive study of all patients diagnosed with PLD diagnosis from July 1986 to June 2006 at the National Institute of Health Sciences and Nutrition "Salvador Zubirán". Forty-nine clinical records with PLD diagnosis were reviewed; however, 8 patients were excluded from the analysis because the follow-up was not completed.

### Methods

Variables as gender, age at diagnosis, time of diagnosis delay, BMI, symptoms, diagnosis method, cyst diameter, cyst complications (CC), liver function tests (LFT: bilirubin, transaminases, AP, lactic dehydrogenase, gamma glutamyl transpeptidase, albumin, prothrombin time, glucose and complete blood count at diagnosis, 1 and 6 months, and at 1, 5, 10, 15 and 20 years), comorbidity, extrahepatic cysts, hormonal replacement therapy (HRT) intake, IT requirement, IT complications, recurrence of symptoms (RS), and follow up procedures and outcome were analyzed.

### Statistical analysis

Statistical data are expressed as mean  $\pm$  SD. Numerical variables were analyzed by *t*-test and the categorical with  $\chi^2$  test or Fisher's exact test. A *P* value  $\leq 0.05$  was accepted as being statistically significant. The SPSS 13.0 software (SPSS Inc., Chicago, Illinois, 2004) statistical program was used for the analysis.

## RESULTS

### Demographical data

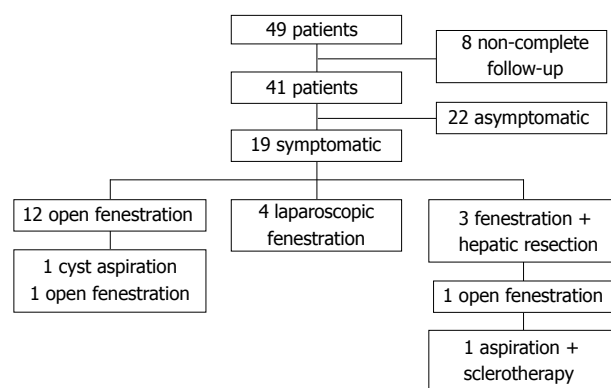

A total of 49 patients with PLD were evaluated in our institution. Eight patients lost follow-up and were not included for the analysis. Forty-one (male 7, female 34) complete patients files were included (Figure 2). The mean age at diagnosis was  $47.8 \pm 11.9$  years (range 27-82) and the mean follow-up time was 5.7 years. Eighteen (44%) patients had familiar history of PLD. Demographical data is shown in Table 1.

### Hormonal replacement therapy is associated with symptoms occurrence

We found that 23.8% of postmenopausal women

**Figure 1** US (A) and CT (B) images showing numerous hepatic cysts in a 47-year-old asymptomatic male patient.

**Figure 2** Clinical course and interventions of 49 PLD patients (July 1986-June 2006).

were taking HRT. In those patients the prevalence of symptoms at diagnosis was significantly higher than those without HRT (100% *vs* 43.8%, *P* = 0.039; OR = 2.286; 95% CI, 1.311-3.984). The requirement of IT also was higher in the HRT group than in non-HRT (80% *vs* 6.3%, *P* = 0.001; OR = 20; 95% CI, 35-115). The size of the major cyst was not associated with HRT (*P* > 0.05). The oral contraceptive intake was not associated with occurrence of symptoms (*P* > 0.05).

### Symptoms, diagnosis, and PLD complications

Based on the initial symptoms the mean time of diagnosis delay was 2.8 (range 0-9) years. We found that 65.4% of the symptomatic *versus* 14.3% of non-symptomatic patients at diagnosis required IT (*P* = 0.002, OR = 11.333, 95% CI, 2.068-62.105). The symptoms described were abdominal pain 56%, early satiety 42%, increase of the abdominal perimeter 34%, and nausea 12%. Two patients

**Table 1** Demographical data, extrahepatic cysts and comorbidity

N (Male/Female)	41 (7/34)
Age at diagnosis (range, yr)	47.8 ± 11.9 (27-82)
Mean diagnosis retard time (range, yr)	2.8 (0-9)
Mean follow up time (yr)	5.7
Familiar history of PLD	44%
Body mass index at diagnosis	
≤ 25	41%
> 25-≤ 30	44%
> 30	15%
Largest cyst diameter (range, cm)	8.2 ± 4.9 (2-25)
Extrahepatic cysts	
Renal cysts	68%
Pancreatic cysts	15%
Spleen cysts	8%
Ovary cysts	2%
Comorbidity	
Arterial hypertension	46%
Chronic renal insufficiency	24%
Dyslipidemia	15%
Hypothyroidism	7%
Type 2 diabetes	5%
Gastroesophageal reflux	5%

(4.9%) had portal hypertension manifested by esophageal varices and splenomegaly, and none of them was found with ascites or encephalopathy.

During the follow up time, symptomatic patients at diagnosis developed more CC than non-symptomatic (29.6% *vs* 0,  $P = 0.023$ ). At this time, nine (22%) patients had CC: cyst infection 5 (55.6%), cyst bleeding 3 (33.3%), and cholangitis 1 (11.1%), at a mean time of 4 months (range 0-9, Table 2). In this group of patients, four (44.4%) had a complication at the time of diagnosis (cyst infection 2, cyst bleeding 2).

Renal cysts were present in 68% of PLD patients (Table 1). Liver CC were seen in 25% of patients with renal cysts, and in 7.7% of patients without them ( $P > 0.05$ ).

At diagnosis, overweight (BMI > 25 but ≤ 30), was found in 44%; and obesity (BMI > 30), in 15%. Patients with BMI > 25 had a trend to develop surgical complications ( $P = 0.075$ ) such as abdominal pain, bleeding or infection (Table 1), and no significant association was found with the presence of symptoms, largest cyst diameter, CC, or IT requirement ( $P > 0.05$ ).

Diagnosis was achieved by US in 78% and by CT in 22%. The largest cyst mean diameter was  $8.2 \pm 4.9$  cm (range 2-25) and no association to symptoms or requirement of IT ( $P > 0.05$ ) were found. The largest cyst mean diameter was  $12.3 \pm 8.8$  cm in postmenopausal women taking HRT *vs*  $8.3 \pm 3.9$  cm in those without HRT ( $P > 0.05$ ).

#### **Elevated alkaline phosphatase at diagnosis is associated with IT requirement**

No significant alterations in bilirubin, transaminases, lactic dehydrogenase, gamma glutamyl transpeptidase, albumin, prothrombin time, glucose, and in complete blood count, were found at diagnosis or during follow up.

**Table 2** Outcome of PLD patients

Symptomatic patients at diagnosis	27 (66%)
Abdominal pain	15
Early satiety	12
Increase of abdominal perimeter	9
Nausea	3
Complications during follow up	9 (22%)
Cyst infection	5
Cyst hemorrhage	3
Cholangitis	1
Invasive treatment patients	19 (46%)
Open fenestration	12
Laparoscopic fenestration	4
Fenestration + hepatic resection	3
Overall symptoms recurrence	4 (17%)
Open fenestration	3
Laparoscopic fenestration	0
Fenestration + hepatic resection	1
Surgery complications	6 (32%)
Bleeding	3
Infection	2
Pain	1

Because we considered IT requirement as an end point in PLD patients, we studied its association with elevated levels of LFT at diagnosis, finding that AP was elevated ( $\geq 132$  IU/mL) in 15.5% of patients. During follow-up, 100% of patients in the elevated AP group required IT *versus* 35.5% in the normal AP group ( $P = 0.005$ , OR = 2.818, 95% CI, 1.753-4.530).

#### **Invasive treatment and complications**

Abdominal pain was the most common indication for surgery (78%). Other indications were satiety (10%), cyst hemorrhage (5%), and cyst infection (5%).

Nineteen patients (46%) required IT (OF 12, LF 4, FHR 3) to control symptoms (Figure 2), at a mean time of 19 months (range 0-85) after PLD diagnosis. Mean age for the first IT was  $47 \pm 10$  years.

Because of RS, 3 patients required a second IT at a mean time of 19 months (range 8-24): 2 (16.7%) in the OF group (cyst aspiration 1, OF 1) and 1 (33.3%) in the FHR group (OF 1). The last patient required a third IT (aspiration + sclerotherapy) 6 months later. None of the patients in the LF group showed RS.

Complications due to the first IT were found in 6 (32%) patients. Three (16.7%) patients had complications in the OF group (bleeding 3), 1 (25%) in the LF group (severe abdominal pain 1), and 2 (66.7%) in the FHR group (bleeding 1, infection 1; Table 2). No significant difference in complications between OF and LF was found.

Two (66.7%) patients after a second IT (OF 2) developed important complications (hemorrhage 1, pleural effusion 1), and the one who required a third IT had severe abdominal pain. Follow up mortality rate was 0.

## **DISCUSSION**

This is one of the largest series published to date and includes a large follow-up time in both symptomatic and non-symptomatic patients with a detailed description

and associations to anthropometric and biochemical data, HRT intake, CC, IT requirement, IT complications, and outcome.

As in other case series<sup>[1,9,10]</sup>, female gender predominated (83%), suggesting a possible role of estrogens in the development of liver cysts.

Data shows selective increase in liver cyst and parenchymal volume in female patients receiving postmenopausal estrogen therapy<sup>[13]</sup>, but it is not clear if it correlates with symptoms and IT requirement. The association found between HRT, the presence of symptoms and IT requirement supports that HRT has an important role in the development of symptoms and so in the requirement of IT in PLD patients. Interestingly HRT was not associated to the size of the major cyst, suggesting that symptoms are not due to the size of cysts but maybe to the number of cysts or the liver volume occupied by them. As in other liver diseases, PLD may contraindicate HRT. Further and prospective studies are recommended to confirm such associations.

As others centers that inform that the diagnosis is more common during the fourth and the fifth decade of life<sup>[9,14]</sup>, in Mexican patients seems to be equal.

No other series report the time evolution of PLD patients. We found a diagnosis delay time near to 3 years. This data may indicate that symptoms at the beginning of the disease are absent or mild and appear or increase as time advances, so patients search for medical attention.

Symptoms predicted IT requirement and were associated to a higher incidence of CC (bleeding, infection, *etc*). Most of the series report that the majority of patients are asymptomatic at diagnosis<sup>[1]</sup>, but we found a high prevalence of symptoms (66%) in Mexican patients. We found a higher prevalence of abdominal pain (56%) than reported in other studies (36.5%)<sup>[9]</sup>.

Hepatic failure in PLD patients is rare and few cases have been reported<sup>[15,16]</sup>. We found 2 (4.9%) cases of portal hypertension and none with ascites or encephalopathy. The cause of portal hypertension in these patients is not clear, but might be due to the mass effect that comprises vessels of the portal circulation. A reported rate of 2.5% for portal hypertension has been described<sup>[9]</sup>. Despite hepatomegaly, portal hypertension and its complications (ascites, variceal bleeding, *etc*) remain quite rare<sup>[1]</sup>, interestingly; we report a higher rate of portal hypertension in our patients, maybe due to a longer follow-up time.

In our knowledge this is one of the largest follow-up in a PLD case series (5.7 years). Bistriz *et al*<sup>[9]</sup> reported that in 40 patients with a follow-up time of 4.69 years, 22.5% had cyst bleeding, 12.5% cyst rupture, 12.5% cyst infection, and 2.5% developed portal hypertension. During follow-up symptomatic patients of our study developed similar incidence of CC. We found a significant association between prevalence of symptoms and the development of CC during follow-up ( $P = 0.023$ ). It suggests that symptomatic patients have increased risk factors that predispose CC. The presence of renal cysts did not significantly increase the incidence of liver CC ( $P > 0.05$ ).

The association between anthropometric data and symptoms in PLD has not been studied. We found a trend to surgical complications in patients with BMI  $> 25$  ( $P = 0.075$ ), and no significant association with symptoms, largest cyst diameter, CC, or IT requirement. The BMI is not a reliable data because it is influenced by the large amount of hepatic weight in PLD patients, so other anthropometric measurement must be achieved in future studies, especially to quantify fat tissue. It is known that fat tissue is a hormonal-active tissue, though may influence the clinical presentation and outcome of PLD patients, as happens with HRT.

By far, US is reported as the most used method for diagnosis<sup>[1]</sup>. Our finding supports that US is a good and reliable method to achieve PLD diagnosis and brings important data such as number of cysts, cyst diameter and cyst complications. It is unclear if the cyst diameter is associated to symptoms or IT requirement. We found that despite a large cyst diameter, symptoms or requirement of IT are not related to it. It suggests that what determines the occurrence of symptoms or indicates surgical therapy is not the cyst diameter, but the number of cysts or the liver volume occupied by them. Further studies are necessary to determine the clinical value of these measures, including measure of liver volume.

The LFT in our patients usually were normal and were not associated to symptoms or outcome. We did not find significant alterations at diagnosis or during follow up. In his review, Arnold<sup>[1]</sup> described that LFT are often normal, but in symptomatic patients, AP levels may be elevated in 30%-47%, GGT in 60%-70%, aspartate aminotransferase in up to 27%, and bilirubin in 17%. We studied those variables, and only the elevation of AP ( $\geq 132$  mg/dL) at diagnosis was significantly associated with requirement of IT. This association suggests that elevated AP may be an important serological marker of disease activity and could be used to indicate IT to control symptoms.

Symptoms and complications are reported indications for IT. According to Chen<sup>[4]</sup> and Que *et al*<sup>[17]</sup> these indications include abdominal distention, abdominal pain, early satiety, fatigue, supine dyspnea, infected cysts, dialysis hypotension, bile duct obstruction, severe ascites and uterine prolapse. We found similar indications in our patients, being pain the most frequent.

RS is frequent with the majority of IT modalities. The reported rate of RS for cyst aspiration is up to 100% and probably does not provide definitive therapy<sup>[18]</sup>. The RS for OF is less common. One of the largest series is the one reported by Koperna *et al*<sup>[19]</sup> who described a RS rate of 21%, but also rates between 11%-33% had been reported<sup>[20-23]</sup>. For LF, a recent case series of 6 PLD patients reported by Garcea *et al*<sup>[24]</sup> showed 16% of RS, but also has been reported in up to 4.5%-71%<sup>[22,25]</sup>. In our patients, the RS after a first IT was low (16.7% for OF, 0% for LF, and 33.3% for FHR). The RS rate for OF and for FHR was as expected, interestingly the non-RS after LF is much lower than reported<sup>[23,24,26]</sup>. We think those findings may be due to patient selection criteria.

For OF the reported morbidity rate is 0%-56%<sup>[21,27]</sup>,

for LF 0%-54%<sup>[21,28]</sup>, and for FHR varies from 20% to 100%<sup>[29,30]</sup>. The higher rate of complications in the LF group compared to the OF group may be due to procedure selection criteria. The rate of complications after FHR was high but as expected. Randomized studies are necessary to know the real rate of complications and RS with each procedure, but as the prevalence of the disease is low, studies are difficult to perform.

In summary, the presence of symptoms at diagnosis, and CC during follow-up time is associated with IT requirement. The HRT is associated to the presence of symptoms and IT requirement. The prevalence of symptoms in PLD patients is high and abdominal pain is the most common. Patients with BMI > 25 have a trend to suffer from complications after IT. Cyst diameter is not associated with the presence of symptoms or need for IT. The AP elevation was associated with IT requirement, suggesting that AP may be a marker of disease severity. In near half of the patients, a first IT is performed and complications are frequent, especially in the FHR group, but the proportion of complications due to the second IT is higher. The RS is more frequent after OF, but this fact may be due to patient selection bias.

## COMMENTS

### Background

Polycystic liver disease (PLD) is generally asymptomatic and incidentally diagnosed. For symptomatic patients invasive treatment (IT) such as cyst aspiration with sclerotherapy, fenestration with or without hepatic resection, and hepatic transplant are options of treatment. There are no known associations that could help clinicians to determine the outcome of invasive or non-invasive treatment.

### Research frontiers

Larger and prospective studies are required in order to find other variables that may affect outcome. It is important to evaluate the physiological basis of the impact of hormonal replacement therapy (HRT) on the outcome of PLD patients.

### Innovations and breakthroughs

Knowledge of factors associated with IT requirement, complications, and recurrence of symptoms.

### Applications

Helpful to determine outcome in both invasive and non-invasive treatment of PLD patients.

### Peer review

This is a retrospective study investigating the association for invasive or noninvasive treatment of polycystic liver disease and biochemical abnormalities. It is a well-written and well-designed paper.

### Abstract

**AIM:** To evaluate the prevalence of hepatitis B virus (HBV) infection in inflammatory bowel disease (IBD) patients that followed up in our hospital and try to identify the possible risk factors involved in this infection transmission.

**METHODS:** This was a cross-sectional study for which 176 patients were selected according to their arrival for the medical interview. All these patients had already IBD diagnosis. The patient was interviewed and a questionnaire was filled out.

**RESULTS:** In the group of 176 patients whom we examined, we found that 17% (30) were anti-HBc positive. Out of 30 patients with positive anti-HBc, 2.3% (4) had positive HBsAg and negative HBV-DNA. In an attempt to identify the possible HBV infection transmission risk factors in IBD patients, it was observed that 117 patients had been submitted to some kind of surgical procedure, but only 24 patients had positive anti-HBc ( $P = 0.085$ ). It was also observed that surgery to treat IBD complications was not a risk factor for HBV infection transmission, since we did not get a statically significant  $P$  value. However, IBD

### INTRODUCTION

The hepatitis B virus (HBV) infection is a worldwide public health problem. There are two billion people infected by HBV, and among these more than 350 million have chronic infection. Patients with chronic infection have a high death risk for hepatic cirrhosis or liver cancer. These two diseases are responsible for about 1 million people dying every year, in spite of the infection incidence falling recently<sup>[1-4]</sup>.

In developed countries the sexual route is responsible for 30% of infections and is the main route of HBV transmission<sup>[3-5]</sup>.

Health professionals, such as surgeons, pathologists, dialysis and chemotherapy technicians, have a high risk of acquiring HBV infections through small skin lesions or through accident with instruments that cut or perforate<sup>[6]</sup>.

Patients with inflammatory bowel disease (IBD)

have high risk of infection by hepatitis viruses B or C<sup>[7]</sup> because during the course of their disease, they need blood transfusions, and sometimes surgical and endoscopic procedures for diagnosis and treatment<sup>[8-10]</sup>. Biancone *et al* observed that in Crohn's disease (CD), 2/3 of the patients will need an intestinal resection and almost 50% will need multiple surgeries<sup>[11]</sup>. It is important to confirm this data to alert health professionals about prevention and early diagnosis of HBV infection, because the steroids and immunosuppressant drugs used in IBD treatment worsen the HBV liver disease. Few studies exist to verify if these drugs influence HBV infection in IBD patients<sup>[12-15]</sup>.

The Clementino Fraga Filho University Hospital is a reference center for IBD diagnosis and treatment. As it is not known exactly what the HBV infection rate in this group of patients in this institution, we decided to do this study.

The first aim of this study was to evaluate the prevalence of HBV infection in IBD patients that followed up in the hospital. The second aim is to evaluate the possible risk factors involved in HBV infection transmission in this patients group.

## MATERIALS AND METHODS

This study was carried out between May 2002 and November 2004, for which 176 patients were recruited. All these patients had clinical, laboratory, radiological, endoscopic and histopathological IBD diagnosis. Included were patients of both sexes, at least 18 years old, for whom medical records were kept by the hospital and who live in Rio de Janeiro State. Patients with infectious, ischemic, actinic, and uncertain colitis were excluded.

The patients were selected, weekly, according to their order of arrival for the medical interview in the hospital IBD ambulatory. After, if the patient allowed us to include him/her in the study, he/she signed an informed consent term. Next, the patient was interviewed and during this interview, a questionnaire was filled out to obtain identification data such as age, sex and IBD type.

In order to identify possible risk factors for HBV infection transmission in this population, the patients were questioned about blood transfusion histories, surgical and endoscopic interventions, dialysis<sup>[16]</sup>, use of endovenous illicit drugs<sup>[17]</sup>, acupuncture treatment, the presence of tattoos<sup>[7]</sup> or "piercings" and if they engaged in promiscuous sex (defined as more than 3 sexual partners in a year or sexual intercourse with prostitutes)<sup>[18]</sup>.

After the interview, 25 mL of blood were obtained from the patient and the material was submitted to the following analyses: qualitative test for total core antibodies; anti-HBc (Kit Diasorin S.p.A.-Italy); qualitative test for HBV antigen; HBsAg (Kit ELISA-Diasorin S.p.A.-Italy) and qualitative PCR-DNA for HBV (which can detect up to 10 particles/serum milliliter), this last analysis being only for patients with positive anti-HBc, patients with positive HBsAg, and for 14 (8%) patients with negative anti-HBc and HBsAg chosen at random.

Table 1 HBV infection transmission risk factors

Risk factors (n = 176)	n (%)
Blood transfusion	47 (26.7)
Surgery	117 (66.5)
Dialysis	0
Endovenous drug use	8 (4.5)
Tattoo	4 (2.3)
Acupuntura	7 (4.0)
"Piercings"	1 (0.6)
SPL	3 (1.7)
Digestive endoscopes	175 (99.4)

Table 2 Anti-HBc and HBsAg result distribution according to IBD type (n = 176)

	Anti-HBc	HBsAg
Positive	17 UC (56.7%) 13 CD (43.3%)	4 (2.3%)
Negative	146 (83%)	172 (97.7%)

Statistical analysis was processed by the SAS<sup>®</sup> software system. Differences were considered significant for an alpha risk of 5%.

Our objective was to verify if there is a significant association between a positive anti-HBc result and any of the risk factors analyzed. For this purpose the following methods were applied: for proportions comparison (qualitative variables) the chi-square test was used ( $\chi^2$ ) or the exact Fisher test. For numeric variables comparison (quantitative) between two groups, the *t*-test was used for independent samples or the Mann-Whitney test, when the variable did not present normal distribution due to great dispersion or for the ordinal nature of the data.

## RESULTS

In our sample there were 68 (38.6%) men and 108 (61.4%) women. There were 102 (58.0%) CD patients and 74 (42.0%) UC patients.

There were surgical procedure histories in 117 patients (66.5%). Blood transfusion was reported by 47 patients (26.7%). Eight patients (4.5%) confirmed the use of endovenous illicit drugs. None of the patient had undergone dialysis treatment and only 3 patients affirmed having a promiscuous sexual life (Table 1).

Forty-nine patients were without treatment; 7 patients used immunosuppressant drugs; 74 used steroid drugs; while 46 patients used both.

Table 2 shows that among the 176 patients, 30 patients (17%) had positive anti-HBc: 17 (56.7%) with UC and 13 (43.3%) with CD.

Among the 30 patients with positive anti-HBc, 4 had positive HBsAg.

The 30 patients with positive anti-HBc and the 14 patients with negative anti-HBc randomly selected were submitted to the PCR HBV-DNA qualitative test. All of these patients had negative PCR HBV-DNA results. The four patients with positive HBsAg were also

**Table 3** Risk factors according to anti-HBc result-frequency and percentile

Risk factors		Anti-HBc				P
		Positive		Negative		
		n	%	n	%	
Sex	Men	12	40.0	56	38.0	0.86
	Women	18	60.0	90	61.6	
Digestive endoscopy	Yes	16	53.3	91	62.3	0.35
	No	14	46.7	55	37.7	
Retosigmoidoscopy	Yes	13	43.3	50	34.0	0.34
	No	17	56.7	96	65.8	
Blood transfusion	Yes	10	33.3	37	25.3	0.36
	No	20	66.7	109	74.7	
Surgery	Yes	24	80.0	93	63.7	0.085
	No	6	20.0	53	36.3	
Surgery to treat IBD complications	Yes	8	33.3	47	50.5	0.13
	No	16	66.7	46	49.5	

**Table 4** Non-numeric variables risk factors for HBV transmission

Variable	Anti-HBc	n	Mean	SE	Minimum	Maximum	P
Age (yr)	Positive	30	47.7	11.9	26	78	0.001
	Negative	146	39.0	13.9	18	84	
Diagnose time (mo)	Positive	30	114.1	109.3	8	372	0.37
	Negative	146	89.9	90.4	1	600	
Colonoscopy number	Positive	30	2.3	1.9	0	10	0.52
	Negative	146	2.1	1.6	1	8	

submitted to qualitative PCR HBV-DNA tests and they also had negative results. Among these patients, those with positive anti-HBc and HBsAg tests are considered inactive HBV bearers.

Table 3 supplies the frequency (*n*) and the risk factor percentile (%) according to anti-HBc results and the corresponding *P* value. The statistical analysis was accomplished by the  $\chi^2$  test or by the exact Fisher test.

It was observed that sex, digestive endoscopy, retosigmoidoscopy, and blood transfusions were not considered probable risk factors in HBV infection transmission.

When we calculated surgery only, we observed that 24 patients (80%) with positive anti-HBc were submitted to some type of surgical intervention while the other 20% (6 patients) with positive anti-HBc did not undergo any surgical intervention (*P* = 0.085). We also tried to stratify patients submitted to surgery into two groups: those who underwent surgery to treat IBD complications and those who underwent other surgeries. The *P* value was not significant (*P* = 0.13). Dialysis, endovenous illicit drug use, tattoos, acupuncture, piercing and a sexual promiscuous life style, were not analyzed due to low frequency of observed cases.

Table 4 shows that patients with positive anti-HBc have an average age significantly older (*P* = 0.001) than patients with negative anti-HBc. A significant difference was not observed for disease diagnosis time (*P* = 0.37) neither for number of colonoscopies (*P* = 0.52) among both positive and negative anti-HBc groups.

One hundred and seventeen patients were submitted

**Figure 1** Blood transfusion need according to surgery complexity.

to some form of surgery. We analyzed the relationship between blood transfusion and surgery carried out to treat IBD complications, and it was observed that patients submitted to surgeries to treat IBD complications needed more transfusions (*P* = 0.015) than patients submitted to other types of surgery, as illustrated in Figure 1.

## DISCUSSION

In this study we observed that positive anti-HBc prevalence was 17% (30 patients) in a sample of 176 patients. This data shows that positive anti-HBc prevalence in IBD patient groups is larger when compared with the overall Brazil population (7.9%) and with the Rio de Janeiro state population (2.5%) figures<sup>[18]</sup>.

In the literature, we found only one case-control study that evaluated the HBV prevalence in IBD patients. In that study, the anti-HBc prevalence was larger in CD (10.9%) and ulcerative colitis patients (11.5%) when compared with control group individuals (5.1%)<sup>[11]</sup>. Our study had very similar results for CD and ulcerative colitis for positive anti-HBc prevalence. These results are probably because IBD patients are frequently exposed to surgical interventions and/or endoscopies as well as necessary blood transfusion that can be a means of transmitting HBV<sup>[19,20]</sup>.

Among 30 patients with positive anti-HBc result, 2.3% (4) had positive HBsAg with negative HBV-PCR DNA, patients that are considered HBV inactive bearers. This prevalence is considered high when we compare it with a Brazil Health Ministry study in 2006 in the central west, Northeast and Brasília regions that shows an HBsAg prevalence of 0.5%.

In addition to identifying HBV prevalence, we also tried to identify the possible risk factors for HBV transmission that could increase HBV infection prevalence among IBD patients. Considering 5% to be a significant threshold, we found that such factors as: (1) Sexual activity; (2) Digestive endoscopy; (3) Retosigmoidoscopy and (4) Blood transfusion were ruled out as possible risk factors for HBV infection of IBD patients.

Despite the fact that our sample contained 108 female patients corresponding to 61.4% of the total

sample, when we compared the positive anti-HBc percentile in women and in men, we did not obtain  $P$  value with statistical significance ( $P = 0.86$ ), even when we separated the male and female group according to IBD type, both groups being very similar in this respect. Biancone had a different result in his study. He demonstrated that female status was an important factor to be considered in HBV infection in CD patients<sup>[11]</sup>.

Studies in the last 5 years have verified the possibility of HCV and HBV transmission mainly through endoscopic procedures during therapeutic interventions. Studies demonstrated the presence of HBV-DNA in endoscopic channels that were not submitted to appropriate disinfection processes<sup>[20]</sup>. In our sample procedures, such as digestive endoscopy and retosigmoidoscopy, we did not discover any evidence of HBV transmission risk factors (digestive endoscopy  $P = 0.35$  and retosigmoidoscopy  $P = 0.34$ ).

Considering blood transfusion is an important viral hepatitis transmission route<sup>[7,21]</sup>, it has already been demonstrated by Long *et al* in 2000 and Biancone *et al* in 2001 that blood transfusion was an important risk factor in HCV transmission among IBD patients<sup>[11,22]</sup>. However, we were not able to demonstrate that blood transfusion was a risk factor for HBV infection transmission in our group because in our sample only 10 out of 47 patients with positive anti-HBc received blood transfusions while the other 20 with positive anti-HBc did not have blood transfusion histories ( $P = 0.36$ ).

When we analyzed surgery as a possible risk factor, despite of the fact of not having a  $P$  value smaller than 0.05, we observed that 80% (24) of patients with positive anti-HBc had been submitted to some surgical procedure while the other 20% (6) did not undergo any surgical procedures ( $P = 0.085$ ).

Biancone *et al* showed that surgery, and mainly surgical procedures to treat IBD complications, were an important risk factor in HCV transmission among IBD patients<sup>[11]</sup>. We can try to explain the Biancone *et al* discoveries if we take into consideration that gastrointestinal surgeries to treat IBD complications are high complexity operations<sup>[10]</sup> and probably need blood transfusions during surgical procedure, which could cause a bias in the statistical analysis because the surgery itself was not the cause of transmission but the transfusion. The possible risk factor for HCV infection transmission in these cases was blood transfusion that patients received during these procedures. In our study we separated patients according to surgery type: group 1-patients submitted to surgery to treat IBD complications, and group 2-patients submitted to other surgical interventions; we did not find a significant  $P$  value ( $P = 0.13$ ). However, as can be seen in Figure 1, our hypothesis that patients submitted to surgeries to treat IBD complications received more blood transfusions than patients submitted to other surgical interventions was confirmed ( $P = 0.015$ ).

When we compare our results with Spijkerman *et al*'s study, our data is divergent because according to that study high complexity surgeries (i.e. surgeries with more than one hour of duration, surgeries with a larger

incidence of postoperative complications and those with a higher risk of complication requiring further surgery or more blood transfusions) are associated with a higher risk of HBV infection transmission<sup>[19]</sup>. However, in this study it was demonstrated that the HBV infection was transmitted through an HBV infected surgeon during surgery.

For the other qualitative variables: dialyses, endovenous illicit drug use, tattoos, acupuncture, "piercings" and sexually promiscuous lifestyle, the associations were not analyzed because we had low frequencies of observed cases.

In quantitative-variable analysis (age, disease diagnosis time and number of colonoscopies), the  $P$  value results have statistical significance ( $P = 0.001$ ). The average age of patients with positive anti-HBc was higher (47.7 years) than patients with negative anti-HBc (39.0 years). In the literature, the positive anti-HBc prevalence was associated with ages older than 50 years in CD and in UC<sup>[11]</sup>. These data were found, we believe, because older patients probably have a longer disease duration time and therefore have had more time to develop complications requiring surgical and endoscopic interventions. However, we were not able to prove the veracity of these assumptions.

Biancone *et al* have shown ( $P = 0.37$ ) that disease duration time (number of months since IBD diagnosis) is associated with incidence of positive anti-HBc in UC patients<sup>[1]</sup>.

Steroids, immunosuppressant drugs and the anti-TNF antibodies (anti-necrosis tumor antibodies-Infliximab<sup>®</sup>) in IBD patients<sup>[23,24]</sup>, as some studies have demonstrated, can influence the course of hepatic disease when used in HBV infected patients, mainly patients with positive HBsAg and anti-HBc and negative HBV-DNA (called inactive bearers)<sup>[12-14]</sup>. It is also important to note that in patients with positive anti-HBc and negative HBsAg, the HBV can replicate because the virus stays inside the hepatocytes although there is an apparent serologic cure<sup>[23]</sup>. These studies show that immunological suppression caused by these drugs could cause viral replication and spread infection inside hepatocytes. When these drugs were suspended and the immunological reaction was restored, the infected hepatocytes were destroyed quickly and there was an increase in the transaminases levels ("flare") and an accentuated viremia reduction<sup>[15,25]</sup>. Two cases of fulminant hepatitis were identified after use of Infliximab<sup>®</sup> in rheumatoid arthritis patients infected by HBV<sup>[26]</sup> and one case of hepatic insufficiency and death in a CD patient treated with Infliximab<sup>®</sup><sup>[27,28]</sup>. The reactivation of HBV can happen also to inactive bearers submitted to transplants or in cancer patients who are submitted to chemotherapy. Such patients need higher immunosuppressant drug doses than do IBD patients<sup>[12]</sup>.

Patients with positive HBsAg and anti-HBc and negative HBV-PCR DNA have increased risk of reactivating their HBV infections. Therefore, the use of lamivudine is recommended before immunological suppression therapies<sup>[29]</sup>. Lau and collaborators demon-

strated that patients with lymphoma infected by HBV who were submitted to chemotherapy did not have HBV infection reactivated when they used lamivudine one week before chemotherapy was begun<sup>[30]</sup>.

In conclusion, our study demonstrated that there were high incidences of positive anti-HBc (17%) and positive HBsAg (2.3%) in IBD patients in Clementino Fraga Filho University Hospital when compared with the overall population (7.9%).

These data show that it is important to have an early diagnosis of HBV infection in diagnosed IBD patients before any IBD treatment is initiated using steroids, immunosuppressant drugs, or anti-TNF antibodies, as that IBD treatment may worsen quiescent HBV hepatic disease. We also recommend HBV vaccination in this group of patients.

## COMMENTS

### Background

Hepatitis B virus (HBV) infection is considered a worldwide public health problem. Inflammatory bowel disease (IBD) patients have a high risk of acquiring HBV infection because they sometimes need blood transfusions, invasive surgical and endoscopic procedures. The objective of this study is to verify the seroprevalence of HBV infection and to identify the infection transmission risk factors in IBD patients at Clementino Fraga Filho University Hospital.

### Innovations and breakthroughs

The statistical analysis cannot identify one possible risk factor for HBV transmission but the study found among the IBD patients 4 persons with positive HBsAg who were called inactive bearers. Studies show that immunological suppression caused by steroids, immunosuppressant drugs and the anti-TNF antibodies (anti necrosis antibodies-Infliximab) in IBD patients can influence the course of hepatic disease once used in HBsAg positive patients. These drugs would take a viral replication and infection spread inside hepatocytes. It has already been related to 1 case of hepatic insufficiency and death in a Crohn's disease (CD) patient and 1 case of fulminant hepatitis in rheumatoid arthritis patient, both with positive HBsAg and treated with these drugs. In patients with positive HBsAg lamivudine use would be recommended before immunological suppression.

### Applications

After this study, we recommend HBV vaccination for IBD patients that have never been infected by HBV and also recommend lamivudine for patients with positive anti-HBc and needs to use steroids and immunomodulators.

### Peer review

This article did not identify one risk factor for HBV infection transmission in IBD patients but it shows us that these patients have high risk of acquiring this infection because they need invasive procedures. IBD patients that have been infected already must receive lamivudine before immunological suppression. It is very interesting.

### Abstract

**AIM:** To find occult metastases during hepatectomy in patients with colorectal cancer liver metastases (CRCLM), contrast-enhanced intraoperative ultrasonography (CE-IIOUS) was performed using a new microbubble agent, sonazoid, which provides a parenchyma-specific contrast image based on its accumulation in the Kupffer cells.

**METHODS:** Eight patients with CRCLM underwent CE-IIOUS using sonazoid before hepatectomy. The liver was investigated during a late Kupffer-phase imaging, which is a valuable characteristic of sonazoid.

**RESULTS:** CE-IIOUS using sonazoid provided the early vascular- and sinusoidal-phase images for 10 min followed by the late Kupffer-phase image up to 30 min after the injection of sonazoid. IIOUS did not provide new findings of metastatic lesion in the 8 patients. However, during the late Kupffer-phase image of sonazoid, a metastatic lesion was newly found in two of the 8 patients. These newly detected lesions were removed by an additional hepatectomy and histopathologically diagnosed as a metastasis.

**CONCLUSION:** CE-IIOUS using sonazoid can allow surgeons to investigate the whole liver with enough time and to find new metastases intraoperatively.

### INTRODUCTION

Hepatic resection is the only treatment offering a chance of long-term survival to patients with colorectal cancer liver metastases (CRCLM)<sup>[1-4]</sup>. However, a total of 75% of patients with CRCLM who undergo liver resection will develop recurrence and the main site of recurrence is the liver<sup>[5]</sup>. In addition, 65% to 85% of all recurrences appear within the first 2 years<sup>[5]</sup>. Therefore, occult liver metastases may present at the time of hepatectomy and can be undetected preoperatively by computed tomography (CT), magnetic resonance image (MRI), or positron emission tomography (PET)<sup>[6]</sup>.

Intraoperative ultrasound (IOUS) is now considered as a standard method to determine the resection margin or to find preoperatively undetected tumors<sup>[7,8]</sup>. Recently some authors reported that a contrast-enhanced IOUS (CE-IIOUS) was more sensitive than conventional IOUS to identify new lesions and subsequently to influence surgical management<sup>[9,10]</sup>.

Sonazoid (perfluorobutane, GE Healthcare, Oslo, Norway) is a new microbubble agent<sup>[11]</sup> that provides a parenchyma-specific contrast image based on its accumulation in the Kupffer cells in the liver<sup>[12-14]</sup>. Sonazoid was

recently approved for clinical use in Japan, and it presents with a late Kupffer-phase image with a long duration following a vascular- and a sinusoidal-phase images<sup>[14]</sup>. SonoVue (Bracco SpA, Milan, Italy) has been already used as a microbubble agent in CE-IUS<sup>[9,10]</sup>, but it does not have the Kupffer-phase image<sup>[13]</sup>. The present brief clinical report shows our experience of CE-IUS using sonazoid in patients with CRCLM.

## MATERIALS AND METHODS

Examination of IUS and CE-IUS was performed using an Aplio-XV (Toshiba, Tokyo, Japan) and a micro-convex probe (PVT-375BT, 3.5 MHz, Toshiba). CE-IUS was performed under a pulse inversion harmonic (PIH) imaging capability (Toshiba). A bolus intravenous injection of sonazoid [0.015 mL/kg body weight (0.12  $\mu$ L microbubble/kg body weight as perflubutane microbubble)] was performed *via* the peripheral venous line followed by 10 mL of normal saline flush. Immediately after the administration of sonazoid, the portal veins, hepatic veins, and the normal liver parenchyma were uniformly enhanced. Hepatic metastases were identified as a dark contrast free filling defect during an early vascular phase image lasting 3 min after the injection of sonazoid. Approximately 10 min after the injection, the liver was scanned again to observe a late Kupffer-phase image. The hepatic metastases were identified as filling defects clearer than those observed at the vascular phase (Figure 1). The late Kupffer-phase image lasted at least for 30 min.

Eight patients with CRCLM underwent CE-IUS in addition to IUS. The number and size of metastases identified on preoperative CT, MR, and percutaneous contrast-enhanced ultrasonography (CE-US) were compared with those detected by IUS and CE-IUS.

## RESULTS

CE-IUS using sonazoid provided the early vascular- and sinusoidal-phase images for 10 min followed by the late Kupffer-phase image up to 30 min after the injection of sonazoid. Figure 1 shows IUS and CE-IUS images of a metastasis at the Segment 8. The lesion was detected as an unclear slightly hypoechoic mass by IUS (Figure 1A), but the lesion was shown as a clear hypoechoic mass during the late Kupffer-phase (Figure 2B).

Between December 2007 and February 2008, eight patients underwent CE-IUS. Preoperatively detected sites of liver metastases by CT, MRI, and CE-US were listed, and some differences among CT, MRI and CE-US existed as shown in Table 1. Preoperative CT seemed superior to MRI (patient No. 1 and 4). In addition, preoperative CE-US did not seem useful for finding metastases at the Segment 7 (patient No. 1, 2, and 5). Mainly based on the preoperative findings of CT, surgical methods were planned preoperatively in the eight patients (Table 2). IUS did not provide new findings of metastatic lesion in the eight patients. Indeed, IUS could not show some metastatic lesions detected by CT or

MRI (Table 1, patient No. 1 and 2). However, CE-IUS confirmed all hepatic lesions detected by CT or MRI. In addition, metastatic lesions were newly found by CE-IUS in two of the eight patients. These newly detected lesions were removed by an additional hepatectomy and histopathologically diagnosed as a metastasis.

In the patient No. 1 (Table 1), a small hypoechoic lesion with 6 mm in diameter at the Segment 4 was newly detected by the CE-IUS at the late Kupffer-phase view (Figure 2A) although IUS did not show this lesion. This small lesion was resected and histopathologically confirmed as a metastatic nodule (Figure 2C).

In the patient No. 2 who preoperatively presented with liver metastases at the Segment 3 (Table 1), another lesion at the Segment 7 was pointed out as a metastasis with an ill-defined mass by preoperative CT and MRI (Figure 3A and B). Preoperative percutaneous CE-US using sonazoid could not show the lesion at the Segment 7 because of the attenuation of echogenicity. During the surgery, IUS did not show the metastasis at the segment 7, but CE-IUS showed a well-demarcated mass at the Segment 7 (Figure 3C). This lesion was resected by a partial hepatectomy and histopathologically confirmed as a metastasis. In addition, CE-IUS detected a new small lesion at the Segment 6 which was not pointed out by CT or MRI preoperatively (Figure 4). This lesion at the Segment 6 was also removed and histopathologically confirmed as an occult metastasis.

## DISCUSSION

The importance of CE-IUS in patients with CRCLM has been shown by two recent studies<sup>[9,10]</sup>. Indeed, Torzilli *et al* reported that new metastatic lesions, which were not detected by preoperative examinations and IUS, were detected in 5 out of 24 patients (21%) using CE-IUS<sup>[9]</sup>. They also reported that the modification rate of hepatectomy by CE-IUS alone was 21% in the patients with CRCLM. Leen *et al* showed that additional new hepatic metastases were detected in 11 out of 57 patients (19%) and the planned surgical methods were converted in these patients<sup>[10]</sup>. In the present study, an occult metastatic lesion was newly detected in two of the eight patients using CE-IUS and removed by an additional hepatectomy. These metastatic lesions were not detected by preoperative CT, MRI, preoperative percutaneous CE-US, or IUS.

Sonazoid is a novel microbubble-based ultrasound contrast agent, and is classified as a second-generation agent in which the perfluorocarbon gas has enough intravascular stability *in vivo*<sup>[15,16]</sup>. Watanabe *et al* showed that microbubbles of sonazoid were taken up by Kupffer cells immediately after intravenous injection and existed as microbubbles for 30 min within Kupffer cells, and that the hepatic parenchyma-specific contrast by sonazoid was due to the distribution of the microbubbles in Kupffer cells<sup>[14]</sup>. Therefore, sonazoid has a unique "late Kupffer-phase image" in addition to "early-vascular phase image" and "sinusoidal-phase image". This late Kupffer-phase image can provide high echogenic contrast

**Figure 1** IOUS and CE-IOUS views of a metastasis at the Segment 8. **A:** The metastatic lesion was unclearly detected as a slightly hypoechoic mass; **B:** CE-IOUS view of the same lesion. The metastatic lesion was shown as a distinct hypoechoic mass at the late Kupfer-phase.

**Figure 2** An occult metastasis. **A:** An occult metastasis at the segment 4 only detected by CE-IOUS. A clear hypoechoic mass (approximately 6 mm in diameter; black arrow) was newly detected at the delayed Kupfer phase. This metastatic lesion could not be found by CT, MRI, and IOUS. **B:** Macroscopic view of this metastasis (arrow).

enhancement in the liver parenchyma<sup>[14]</sup>. On the other hand, other microbubble contrast agents such as Imavist and SonoVue provide parenchyma-specific contrast by transient mechanical slowdown of microbubbles within the sinusoid, and these two contrast agents are hardly phagocytosed by the Kupffer cells<sup>[10,13,17]</sup>. Therefore, Imavist and SonoVue cannot provide the late Kupffer-phase image, and the parenchyma-specific contrast image of these two microbubble agents can be seen during only

3 min to 5 min after the injection. Therefore, as previously described, SonoVue needs repeated injections during CE-IOUS to perform a whole liver examination<sup>[9,10]</sup>. Therefore, sonazoid seems a superior microbubble contrast agent for CE-IOUS in patients with CRCLM since a whole precise liver investigation by CE-IOUS, in which determination of surgical margin and examination of occult metastases should be investigated. Therefore, CE-IOUS needs more than 5 min, and the present brief

**Figure 3** Preoperative CT and SPIO-MRI, and CE-IIOUS. **A:** An enhanced-CT view and an ill-defined low density mass was detected at the segment 7 (arrow); **B:** A SPIO MRI view and an ill-defined high intensity mass was detected at the segment 8 (arrow); **C:** CE-IIOUS view at the delayed Kupffer phase and a well-demarcated hypoechoic mass was detected by CE-IIOUS.

**Figure 4** Preoperative CT and SPIO-MRI, and CE-IIOUS. **A:** An enhanced-CT could not detect any lesion at the Segment 6 (arrow); **B:** A SPIO MRI view could not detect any lesion at the Segment 6 (arrow); **C:** CE-IIOUS view at the delayed Kupffer phase and a small hypoechoic mass partially containing an isoechoic lesion was detected by CE-IIOUS.

clinical experience of CE-IIOUS confirmed the usefulness of sonazoid during surgery in patients with CRCLM. In addition, the duration of the approximately 30 min of the late-Kupffer phase image using sonazoid seems useful to perform preoperative percutaneous CE-US compared to SonoVue because the limiting time of SonoVue image (5 min) does not seem convenient to perform preoperative CE-US. Indeed, a routine preoperative CE-US in our institution, in which only the late Kupffer-phase image is performed, can be performed between 10 min and 30 min after the injection of sonazoid. However, based on our experience, small metastases at the Segment 7 seem hardly visualized by percutaneous CE-US using sonazoid because of the attenuation of echogenicity as shown in the present case No. 2.

Sonazoid has been reported as a safe medicine. Indeed, the incidence of adverse effects of sonazoid was shown in 25 out 397 patients (6.3%) in a clinical phase II study performed in Japan. The main side effects were headache (1.0%) and diarrhea (1.0%), but no anaphylactic shock due to sonazoid was reported unlike with contrast-enhanced CT. The image mechanism of CE-IIOUS using sonazoid seems similar to superpara-magnetic iron oxide-enhanced magnetic resonance image (SPIO-MRI) because both images are based on the phagocytosis by Kupffer cells. However, sonazoid is much less expensive compared to SPIO-MRI. Regardless of sensitivity rate of sonazoid for detecting small metastases compared to SPIO-MRI, CE-IIOUS is useful to perform intraoperative liver biopsy of newly detected lesions and to determine an additional hepatectomy.

In conclusion, CE-IIOUS using sonazoid can allow

surgeons to investigate the whole liver with enough time (at least 30 min of the late Kupffer-phase image) and to find new metastases intraoperatively.

## COMMENTS

### Background

Contrast-enhanced intraoperative ultrasonography (CE-IIOUS) seems more sensitive than conventional IIOUS to identify new occult lesions during hepatectomy in patients with colorectal cancer liver metastases (CRCLM). Sonazoid (perfluorobutane, GE Healthcare, Oslo, Norway) is a new microbubble agent that provides late Kupffer-phase image, which cannot be obtained by conventional contrast mediums.

### Research frontiers

No study has investigated the intraoperative efficacy of the late Kupffer-phase image of sonazoid in patients with CRCLM.

### Innovations and breakthroughs

CE-IIOUS using sonazoid enabled whole liver investigation at least for 30 min of the late Kupffer-phase image. Occult metastases, which had not been detected preoperatively, were newly found in some patients and removed by an additional hepatectomy.

### Applications

CE-IIOUS using sonazoid can reduce intrahepatic recurrence after hepatectomy in patients with CRCLM.

### Peer review

This article presented the clinical significance of CE-IIOUS using sonazoid during hepatectomy for colorectal cancer liver metastases. CE-IIOUS for detection of liver metastases requires stable image for enough time to perform repeated whole liver scans. Sonazoid seems to be suitable for this purpose. This article is worthy for publication in *WJG* with minor revision.

### INTRODUCTION

At present, the frequency of lifestyle-related illnesses such as diabetes mellitus and obesity is increasing due to the westernization of the Japanese diet. Diabetic patients are now estimated at 7 400 000 in Japan<sup>[1]</sup> and diabetes is showing a world-wide tendency to increase<sup>[2]</sup>.

In gastroesophageal reflux diseases (GERD), frequent gastroesophageal acid reflux causes such symptoms as heartburn, water brash, chest pain, and esophageal discomfort, lowering the quality of life of patients. Also, GERD damages the esophageal mucosa through erosion and the development of ulcers, mainly in the lower esophagus, leading to reflux esophagitis (RE). The incidence of RE has been on the rise in recent years, and today, it is one of the most common chronic diseases for adults in Europe and the United States<sup>[3]</sup>. While the incidence of RE in Japan is considered low as compared with Europe and the United States, the incidence of RE in Japan has increased due to the westernization of the Japanese diet, the rapidly growing elderly population, and lower *H pylori* infection rates<sup>[4]</sup>.

Some investigators have reported that the incidence of RE is high in diabetic patients<sup>[5,6]</sup>, although few reports have examined the incidence of RE in diabetic patient in Japan. There are some reports that hiatal hernia, age, *H pylori* infection and body mass index (BMI) are considered to affect the outbreak of RE<sup>[7,8]</sup>. Recent studies have reported that *H pylori* infection was less prevalent in patients with RE than those without RE, and was considered to suppress the onset of RE by inducing gastric mucosal atrophy and lowering gastric acid secretion<sup>[9,10]</sup>.

Some investigators have reported that the incidence of *H pylori* infection in diabetic patients is higher than controls<sup>[11-14]</sup>, though other investigators have reported

### Abstract

**AIM:** To investigate the incidence of reflux esophagitis (RE) and *H pylori* infection in the diabetic patient.

**METHODS:** The incidence of RE and *H pylori* infection were investigated in 85 patients with diabetes mellitus and the results were compared with controls.

**RESULTS:** The incidence of RE in diabetic patients was 17.6%. Although this tended to be higher in diabetic patients, there were no statistically significant differences between diabetic patients and controls. The incidence of *H pylori* infection in diabetic patients was 53.7% but no statistically significant difference was seen between diabetic patients and controls in the incidence of *H pylori* infection.

**CONCLUSION:** No significant differences could be seen between diabetic patients and controls in the incidence of RE and *H pylori* infection.

**Key words:** Diabetes mellitus; Reflux esophagitis; *Helicobacter pylori*

**Peer reviewer:** Dino Vaira, Professor, Department of Internal Medicine and Gastroent, University of Bologna, S. Orsola-

no such significant differences between these groups<sup>[15,16]</sup>.

The objective of the present study is to examine the incidence of RE and *H pylori* infection in diabetic patients.

Patient demographics, incidence of GERD, incidence of columnar lined esophagus (CLE), serum gastrin concentration, and pepsinogen (PG) I / II (an index of gastric mucosal atrophy based on serologic finding) were also evaluated.

## MATERIALS AND METHODS

### Study design

A total of 85 consecutive patients with diabetes mellitus who visited the Department of Diabetes and Metabolic Diseases at Tohoku University Hospital from December 2002 to September 2003 were included in the present study. Patients who had other severe complications, had taken PPI or H<sub>2</sub> receptor antagonists within four wk, or had undergone esophagogastrectomy were excluded from the present study. Nine hundred and forty four patients who had undergone endoscopy at the same period and another 67 age and sex-matched non-diabetic subjects without upper GI tract disorders were also included. Informed consent was obtained from each patient. The study protocol was approved by the ethical committee of the Tohoku University Graduate School of Medicine.

The subjects were divided into two groups, a well glycemic controlled group and a poorly controlled group. Patient demographics, incidence of RE, incidence of GERD, incidence of CLE, incidence of *H pylori* infection, severity grade of RE, serum gastrin concentration and PG I / II were investigated between the good glycemic controlled and poorly controlled group. The incidence of RE, GERD, CLE and the severity grade of RE were compared with 944 patients who had undergone endoscopy at the same study period as controls.

The incidence of RE and GERD were assessed due to HbA1c, disease duration, diabetic complications, and BMI. *H pylori* infection status was investigated between DM patients and 67 age and sex-matched non-diabetic subjects without upper GI tract disorders.

### Patient demographics

The following factors were investigated: gender, age, height, body weight, BMI, type of DM [insulin dependent DM (IDDM) or non insulin dependent DM (NIDDM)], duration of DM, presence of hiatal hernia, with insulin therapy, with calcium antagonists, with complications (retinopathy, nephropathy and neuropathy). All patients were examined by an ophthalmologist for retinopathy. Nephropathy was diagnosed if albuminuria was > 0.3 g/L or there was evidence of chronic renal failure. Neuropathy was diagnosed if the patients had sensory abnormalities, vibration hyposensitivity, orthostatic hypotension, or impotence.

**Good and poorly glycemic controlled groups:** The

good glycemic controlled group had hemoglobin A1c (HbA1c) 6.4% or less, and the poorly controlled group had an HbA1c value of 6.5% or more.

**Assessment of RE:** Subjects were diagnosed as having RE of grade A to D by the Los Angeles Classification<sup>[17]</sup>.

**Diagnosis of hiatal hernia:** In the present study, hiatal hernia was defined as a hernia in which the gastric mucosa could be seen by endoscopy circumferentially from the esophageal hiatus.

**Diagnosis of CLE:** CLE was defined as the replacement of the normal squamous lining of the lower esophagus by columnar epithelium.

**Assessment of *H pylori* infection:** In the present study, patients were diagnosed as having *H pylori* infection if they tested positive to at least one of the following tests: biopsy of the mucosa of the gastric body and gastric antrum along the greater curvature during endoscopy, rapid urease test, and serum *H pylori* antibody test. Patients were diagnosed as being free of *H pylori* infection if they tested negative to all tests.

**PG I / II and gastrin level:** PG I / II<sup>[18]</sup> and gastrin level<sup>[19]</sup> were measured to assess gastric mucosal atrophy. Each blood sample was centrifuged, and the sera were stored frozen at -20°C until testing.

**Diagnosis of GERD, incidence of reflux symptoms:** GERD was diagnosed with a self-administered questionnaire (QUEST). When the sum of the scores was 4 or more, the patient was considered as having GERD<sup>[20,21]</sup>. All patients were interviewed by investigators regarding their symptoms related to RE such as heartburn, burning in the upper abdomen, gastro-esophageal regurgitation, fullness, abdominal distension, anorexia, nausea, abdominal pain, and difficulty in swallowing food.

### Statistical analysis

Of the various patient background factors, gender, type of DM, presence of hiatal hernia, with insulin therapy, with calcium antagonists, with diabetic complications, incidence of RE, reflux symptoms, GERD, CLE and *H pylori* infection status were compared between diabetic patients and controls by a chi-square test. Age, height, body weight, BMI, duration of DM, sum of the QUEST score, PG I / II and gastrin level were expressed as mean  $\pm$  SD, and a one-way ANOVA test was used to compare these parameters between diabetic patients and controls. The Mann-Whitney's *U* test was used to compare RE severity. The significance level was set at < 5%.

## RESULTS

Of the 85 diabetic patients, there were 79 NIDDM and 6IDDM patients, 45 (52.9%) men and 40 (47.1%)

Table 1 Patient characteristics

	Well controlled group (%)	Poorly controlled group (%)	P
Gender (Male/Female)	(20/16)	(25/24)	0.84
Type of DM (IDDM/NIDDM)	(1/35)	(5/43)	0.36
Age (yr)	65.9 ± 10.3	60.0 ± 11.9	0.02
Height (cm)	160.3 ± 8.7	156.9 ± 17.6	0.29
Body weight (kg)	61.4 ± 16.5	61.1 ± 17.9	0.93
BMI	23.5 ± 5.6	23.3 ± 3.1	0.77
Duration of DM (yr)	12.9 ± 10.5	16.7 ± 10.3	0.10
Hiatal hernia	33.3 (12/36)	22.4 (11/49)	0.38
Insulin therapy	33.3 (12/36)	61.2 (30/49)	0.02
Calcium antagonist	13.9 (5/36)	24.5 (12/49)	0.35
Retinopathy	16.7 (6/36)	32.7 (16/49)	0.16
Nephropathy	2.3 (1/36)	8.2 (4/49)	0.56
Neuropathy	13.9 (5/36)	20.4 (10/49)	0.45

Table 2 Comparison between diabetic patients and controls

	Diabetic patients (%)	Controls (%)	P
RE	17.6 (15/85)	10.3 (97/944)	0.056
Los angeles classification			
A	80.0 (12/15)	44.3 (43/97)	0.01
B	20.0 (3/15)	48.5 (47/97)	
C	0	6.2 (6/97)	
D	0	1.0 (1/97)	
Incidence of CLE	32.9 (28/85)	37.7 (356/944)	0.45

CLE: Columnar lined esophagus.

women. The mean age ± SD was 62.5 ± 11.5 years (range 28-85 years, median 64 years). The mean durations of DM was 15.1 ± 10.5 years (range 0-44 years, median 14 years).

Thirty-six patients comprised the well glycemic controlled group and 49 patients comprised the poorly controlled group. In the poorly controlled group, age and the number of patients with insulin therapy were higher than in the well controlled group. Among each group, there were no significant differences in gender, type of DM (IDDM or NIDDM), height, body weight, BMI, duration of DM, presence of hiatal hernia, with calcium antagonists, or diabetic complications (Table 1).

In the diabetic patients, the incidence of RE was 17.6% (15/85), and in the 944 controls who had undergone endoscopy at the same period in our division, the incidence of RE was 10.3% (97/944). Though the incidence of RE tended to be higher in diabetic patients, the difference was not significant between diabetic patients and controls ( $P = 0.056$ ). Under the Los Angeles classification, all diabetic patients were grade A or B, and the severity grade of RE was statistically lower in diabetic patients than controls. The incidence of GERD and reflux symptoms in the diabetic patients were 32.9% (28/85) and 36.6% (31/85), respectively. The incidence of CLE was 32.9% (28/85), and the length all were less than 3 cm long. In the 944 controls, the incidence of CLE was 37.7% (356/944) (more than 3 cm: 11 patients, less than 3 cm: 345 patients) (Table 2).

Table 3 Comparison between good and poorly glycemic controlled groups

	Well controlled group (%)	Poorly controlled group (%)	P
RE	19.4 (7/36)	16.3 (8/49)	0.93
Incidence of GERD	25.0 (9/36)	38.8 (19/49)	0.27
Symptoms	30.1 (11/36)	41.3 (20/49)	0.46
QUEST score	2.06 ± 3.16	3.37 ± 4.22	0.12
Los angeles classification

B	14.3 (1/7)	25.0 (2/8)	
C	0	0	
D	0	0	
Incidence of CLE	27.8 (10/36)	36.7 (18/49)	0.52
PG I / II	4.07 ± 2.61	4.94 ± 2.31	0.19
Gastrin	166.0 ± 126.9	137.6 ± 122.8	0.40

CLE: Columnar lined esophagus.

### Comparison between well and poorly glycemic controlled groups

The incidences of RE in the well glycemic controlled group and poorly controlled group were 17.6% (15/85) and 10.3% (97/944), respectively. The incidences of RE in patients with HbA1c under 5.7, 5.8 to 6.4, 6.5 to 7.9, and higher than 8.0 were 27.3% (3/11), 16% (4/25), 14.6% (6/41), and 25% (2/8), respectively. The incidences of GERD for the same patient groups were 36.4% (4/11), 20% (5/25), 34.1% (14/41), and 62.5% (5/8), respectively. The incidence of RE and GERD did not show any particular tendency.

Among the well and the poorly glycemic controlled groups, there were no significant differences in the frequency of RE, GERD, reflux symptoms, CLE, sum of the QUEST score, severity grade of RE, PG I / II or gastrin level (Table 3).

### Comparison between groups receiving and not receiving calcium antagonists

The incidences of RE in patients with and without calcium antagonists were 23.5% (4/17) and 16.2% (11/68), respectively. The incidences of GERD for the same groups were 29.4% (5/17) and 33.8% (23/68), respectively. There were no significant differences between patients receiving and not receiving calcium antagonists. The incidences of RE in the well and poorly glycemic controlled groups were 16.7% (6/36) and 18.3% (9/49), respectively. The incidences of GERD were 25.0% (9/36) and 38.8% (19/49), respectively. There were no significant differences between the well and the poorly glycemic controlled groups.

### The incidence of RE and GERD in patients according to disease duration

The incidences of RE in patients with disease durations of less than 6 years, 6 to 11 years, 11 to 16 years, and more than 16 years were 11.8% (2/17), 10.5% (2/19), 21.4% (3/14) and 22.9% (8/35), respectively. The incidences of GERD for the same durations were 23.5% (4/17) 42.1% (8/19), 42.9% (6/14) and 28.6% (10/35),

respectively. The incidence of RE tended to rise with increased duration of the disease. The incidence of GERD did not show any particular tendency.

#### **The incidence of RE and GERD with and without complications**

Of the diabetic patients, 22 had retinopathy, 5 had nephropathy and 15 had neuropathy. The incidences of RE in DM patients with and without complications were 20% (6/30) and 16.5% (9/55), respectively. The incidences of GERD were 33.3% (10/30), and 32.7% (18/55), respectively. There were no significant differences between patients with and without diabetic complications.

#### **The incidence of RE and GERD in non-obese and obese patients**

The incidences of RE in non-obese (BMI less than 25) and obese patients (BMI higher than 25) were 17.2% (10/58) and 18.5% (5/27), respectively. The incidences of GERD were 29.3% (17/58) and 40.7% (11/27), respectively. There were no significant differences between non-obese and obese patients. There were also no BMI-related differences between patients with and without RE ( $23.3 \pm 2.8$  vs  $23.4 \pm 4.5$ ) and between those with GERD and without GERD ( $23.8 \pm 6.4$  vs  $23.2 \pm 2.7$ ).

#### ***H. pylori* infection**

Of the 85 diabetic patients, measurement of their *H. pylori* infectious status could be performed in 67 patients, of whom 53.7% (36/67) had *H. pylori* infection. Of the age and sex-matched controls, 68.7% (46/67) had *H. pylori* infection, with no significant differences seen in *H. pylori* infection status between diabetic patients and controls ( $P = 0.11$ ).

The incidences of RE in *H. pylori* (+) and *H. pylori* (-) patients were 19.4% (7/36) and 9.7% (3/31), respectively. The incidences of GERD in *H. pylori* (+) and *H. pylori* (-) patients were 27.8% (10/36) and 35.5% (11/31), respectively. No significant differences in the incidence of RE and GERD could be demonstrated between *H. pylori* (+) and *H. pylori* (-) patients.

## **DISCUSSION**

The incidence of RE has been on the rise in recent years, and today, it is one of the most common chronic diseases for adults in Europe and the United States<sup>[22]</sup>.

Today, the incidence of RE is reported to be 10%-20% in Europe and the United States<sup>[23-25]</sup>, and 14%-16% in Japan<sup>[26-28]</sup>. While the incidence of RE in Japan is considered low as compared to Europe and the United States, the incidence of RE in Japan has increased due to the westernization of the Japanese diet, the rapidly growing elderly population, and lower *H. pylori* infection rates<sup>[26-28]</sup>.

Parkman<sup>[5]</sup> has reported that the incidence of RE in patients was 20% (4/20). Antwi<sup>[6]</sup> reported an incidence of 40.7% (22/54), though in these reports, glycemic control in many of the patients was poor and many had neuropathy. In the present study, the incidence of RE in

diabetic patients was 17.6% (15/85), and the incidence of RE in the 944 controls was 10.3% (97/944). The incidence of RE tended to be higher in diabetic patients, there were no significant differences between diabetic patients and controls.

In Japan, with respect to the severity of RE, most patients are reported to have mild esophagitis (Grade A or B under the Los Angeles classification<sup>[26,27]</sup>). In the present study, all patients had mild esophagitis.

In Japan, Nishida has previously reported that the incidence of GERD diagnosed with the QUEST questionnaire in diabetic patients was 25.3%, and significantly higher than that of controls<sup>[29]</sup>. In this previous study, they used the QUEST questionnaire to investigate GERD, though they did not perform gastrointestinal endoscopy to investigate RE. In the present study, we used the QUEST questionnaire and additionally performed gastrointestinal endoscopy to investigate GERD and RE. To the best of our knowledge, the present study is the first study to investigate both GERD and RE at the same time for diabetic patients in Japan. In the present study, the prevalence of GERD was 32.9%.

HbA1c is an index of DM control over some months beforehand. Complications of DM such as retinopathy, nephropathy and neuropathy occur as a result of poor control of diabetes for several years. So it is conceivable that DM-related complications are more appropriate than HbA1c as an index of the diabetic control. In the present study, there were no significant differences between patients with and without complications in the incidence of RE and GERD.

Some patients with DM, particularly those with NIDDM, are obese, which increases the intra-abdominal pressure, and may worsen RE<sup>[30]</sup>. In the present study, there were no significant differences between obese patients and non-obese patients in the incidence of RE or GERD. There were also no BMI-related differences between patients with and without RE and those with and without GERD. In the present study, obesity was not a risk factor for RE or GERD in the diabetic patient.

DM induces complications such as retinopathy, nephropathy and neuropathy. Diabetic neuropathy occurs in all sensory, motor and autonomic nerves. Some investigators have reported that in diabetic patients, RE can be induced in the presence of lowered LES pressure, abnormal esophageal motility, increased transient lower esophageal sphincter relaxation (TLESR), lowered acid clearance of the esophagus and prolonged gastric emptying time due to the dysfunction of autonomic nerves or the vagal nerve<sup>[31-35]</sup>. Prolonged gastric emptying time sometimes induces an unexpected hyper or hypoglycemic status, especially in the patients using insulin or oral hypoglycemic agents. Disorder of the sensory nerves raises the perception threshold level, and some patients cannot feel reflux symptoms, possibly leading to stricture of the esophagus. In some patients, RE can be discovered for the first time during routine endoscopy. In the present study, the incidence of RE tended to be higher in diabetic patients, although the differences between diabetic patients and controls were not significant.

It would be important to test for the presence of RE in diabetic patients during the daily examination.

The incidence of *H pylori* infection in diabetic patients has attracted some controversy. Some investigators have reported that the incidence of *H pylori* infection in diabetic patients is higher than controls<sup>[9-13]</sup>. Some investigators have reported that in DM patients, due to impaired immune function and impaired gastrointestinal motility, they were prone to *H pylori* infection<sup>[36-38]</sup>. On the other hand, some previous studies show a lower incidence of *H pylori* in diabetic patients than controls<sup>[39]</sup>, whereas in other studies, there was no difference in the prevalence of *H pylori* infection between diabetic patients and controls<sup>[11,14]</sup>. In some studies, *H pylori* infection was assessed by only one or two methods taken from among a biopsy of the mucosa, the rapid urease test, and the presence of serum *H pylori* antibodies. In the present study, *H pylori* infection was investigated by all three methods, so the incidence of *H pylori* infection in DM patients the present study is considered to be accurate, being recorded as 53.7%, but with no significant differences between diabetic patients and controls.

In conclusion, our results indicated that there were no differences in the incidences of either RE or *H pylori* infection between diabetic patients and controls.

## COMMENTS

### Background

Some investigators had reported that the incidence of reflux esophagitis (RE) and *H pylori* infection is high in diabetic patients. Only a few reports, however, have examined the incidence of RE and *H pylori* infection in diabetic patients in Japan. The present study was designed to investigate the incidence of RE and *H pylori* infection in the diabetic patient.

### Research frontiers

We investigated the incidence of gastroesophageal reflux diseases (GERD), RE and *H pylori* infection in the diabetic patient. The present study is the first study to investigate both GERD and RE at the same time for diabetic patients in Japan.

### Innovations and breakthroughs

We used the questionnaire (QUEST) questionnaire to investigate GERD and performed gastrointestinal endoscopy to investigate RE at the same time for diabetic patients.

### Applications

In the present study, the incidence of RE tended to be higher in diabetic patients. It would be important to test for the presence of RE in diabetic patients during the daily examination.

### Peer review

This manuscript indicated that there were no differences in the incidences of either RE or *H pylori* infection between diabetic patients and controls. The study was well performed and the conclusion was clinically useful.

### Abstract

**AIM:** To determine the role of inflammatory cytokines and reactive oxygen species (ROS) in childhood reflux esophagitis.

**METHODS:** A total of 59 subjects who had complaints suggesting GERD underwent esophagogastroduodenoscopy. Endoscopic and histopathologic diagnosis of reflux esophagitis was established by Savary-Miller and Vandenplas grading systems, respectively. Esophageal biopsy specimens were taken from the esophagus 20% proximal above the esophagogastric junction for conventional histopathological examination and the measurements of ROS and cytokine levels. ROS were measured by chemiluminescence, whereas IL-8 and MCP-1 levels were determined with quantitative immunometric ELISA on esophageal tissue. Esophageal

tissue ROS, IL-8 and MCP-1 levels were compared among groups with and without endoscopic/histopathologic esophagitis.

**RESULTS:** Of 59 patients 28 (47.5%) had normal esophagus whereas 31 (52.5%) had endoscopic esophagitis. In histopathological evaluation, almost 73% of the cases had mild and 6.8% had moderate degree of esophagitis. When ROS and chemokine levels were compared among groups with and without endoscopic esophagitis, statistical difference could not be found between patients with and without esophagitis. Although the levels of ROS, IL-8 and MCP-1 were found to be higher in the group with histopathological reflux esophagitis, this difference was not statistically significant.

**CONCLUSION:** These results suggest that the grade of esophagitis is usually mild or moderate during childhood and factors apart from ROS, IL-8 and MCP-1 may be involved in the pathogenesis of reflux esophagitis in children.

### INTRODUCTION

Gastroesophageal reflux disease (GERD) is one of

the most frequently encountered gastrointestinal pathologies in children with a prevalence of 8% during infancy. When the presence of heartburn as a presenting symptom was considered, the prevalence rises up to 40% among adults<sup>[1-4]</sup>. Early diagnosis and treatment is of importance as GERD results in serious problems that have negative influences on the quality of life. Since there is a wide range of symptoms regarding GERD and the results of GER questionnaires (GERQ) are controversial together with the incoherencies among other investigative methods; diagnosis of the disease is difficult<sup>[5]</sup>.

Oxidative stress has been associated with several disease states like atherosclerosis, pulmonary fibrosis, cancer, neurodegenerative diseases and aging<sup>[6-7]</sup>. Furthermore, reactive oxygen species (ROS) are reported to play a role in the pathogenesis of several gastrointestinal diseases such as inflammatory bowel disease and peptic ulcer<sup>[8-11]</sup>. In studies carried out on animal models of esophagitis as well as those on human esophageal tissue, ROS that are generated in the process of reflux esophagitis were found to be responsible for the esophageal tissue damage, and this finding was further supported by the studies showing that tissue damage could be prevented with the use of antioxidants<sup>[12-19]</sup>.

Several chemokines have been shown to increase significantly in inflammatory disease states like pulmonary diseases, viral meningitis, asthma, rhinitis, a topical dermatitis, ulcerative colitis and Crohn's disease<sup>[20-24]</sup>. While IL-8 has chemotactic activity for neutrophils, monocyte chemoattractant protein-1 (MCP-1) is effective in the activation of monocytes, macrophages as well as lymphocytes<sup>[25]</sup>. In studies conducted in adults, chemokine levels were found to be significantly high in the esophageal tissues of the patients with esophagitis as compared to controls; furthermore a significant correlation was reported between the severity of the reflux esophagitis and chemokines levels<sup>[26-30]</sup>. However, there is only limited data on the levels of ROS and tissue cytokines in the pathogenesis of reflux esophagitis in children. In a study including 10 children with reflux symptoms, IL-6 levels of the esophageal tissue was found to be higher than that of the normal resulting in a claim by the researchers that cytokines could be important in the pathogenesis of the reflux disease<sup>[31]</sup>.

The aim of this study is to investigate the roles of chemokines and ROS in reflux esophagitis in children by measuring the levels of ROS, IL-8 and MCP-1 in the esophageal tissues of children having endoscopic and histopathological esophagitis.

## MATERIALS AND METHODS

### *Patient selection, endoscopy and histopathology*

Consecutive children who underwent upper gastrointestinal endoscopy between September 2005 and January 2006 were prospectively considered for the study. Patients who had complaints related to GER such as vomiting, epigastric pain, regurgitation, retrosternal pain, dysphagia and persistent wheezing were included

in this study. Patients with a history of non-steroidal anti-inflammatory drug, proton pump inhibitor, H2 receptor antagonist or antibiotics use or those having severe chronic co-morbidities like diabetes mellitus, renal diseases or neurological diseases were excluded from the study. The study was approved by the local ethics committee of Marmara University School of Medicine, and informed consent forms were obtained from first degree relatives of all the patients.

Same endoscopy team performed the upper gastrointestinal system endoscopy in all patients with a pediatric fiberoptic gastroscope having an inner diameter of 2.8 mm (Fujinon EG 200 HR, Japan). Following an appropriate fasting time based on age of the patients, sedation was established by iv administration of meperidine (2-4 mg/kg) and midazolam (0.2-0.4 mg/kg) and endoscopy was performed. The degree of endoscopic esophagitis was evaluated according to Savary-Miller classification<sup>[32]</sup>. Patients with and without endoscopic esophagitis formed the first group (Group I). During endoscopy, 4 esophageal biopsy samples were obtained from 20% proximal part of esophagogastric junction for conventional histopathological examination and the measurements of ROS and cytokine levels. At the end of the study, histopathological examination of the biopsy samples was carried out at the same time by the same pathologist who was blind for the clinical and laboratory findings of the patient. The diagnosis of histopathological esophagitis was based on the classification by Vandenplas<sup>[33]</sup> and the cases with or without histopathological esophagitis formed the second group (Group II). For simplifying histopathological evaluation; Stage 1a, 1b and 1c were grouped as mild, Stage 2 and 3 as moderate and finally Stage 4 and 5 as severe esophagitis.

The third tissue sample was rinsed with 0.9% physiological saline and placed in eppendorf tubes for measurement of ROS levels in fresh tissues in the biochemistry laboratories. Other tissue samples were stored at -80°C for the measurement of tissue IL-8 and MCP-1 at the end of the study.

For conventional histopathological examination, 3 samples from the antrum, 2 from the corpus and 2 from the duodenum were obtained from all patients, and these were placed in 10% formaldehyde and sent to pathology for examination. The presence of *H. pylori* was confirmed with a positive rapid urease test and histopathological identification of *H. pylori*. Gastric biopsy samples were evaluated with a modified Sydney scoring system that allowed for identifying the presence of gastritis, its severity and the density of *H. pylori*.

### *Biochemical measurements*

For the measurement of free oxygen radicals on esophageal tissue, chemiluminescence method was employed. The measurements were carried out with Mini Lumat LB 9506 Luminometer (EG&G, Berthold, Germany) at room temperature on fresh tissue samples. In the method employed, lucigenin corresponds to superoxide radical, whereas luminol identifies the total

value for hydroxyl radical (OH $\cdot$ ), hydroperoxyl radical (HO $_2\cdot$ ) and peroxy (RO $_2\cdot$ ) radical. The tissues were first placed into 3 mL of PBS solution, on top of the tissues luminol or lucigenin (Sigma Chemicals, USA) were added at a concentration of 4 mmol/L as enhancers and measurements were obtained.

IL-8 and MCP-1 levels were measured by the quantitative immunometric sandwich enzyme linked-immunosorbent assay (ELISA) method. For IL-8 (Diacclone Research, France) and MCP-1 (Biosource, California, USA) measurements, the tissue samples were placed into eppendorf tubes and kept at -80°C. Cytokine measurements were performed on the same day with IL-8 and MCP-1 from the same samples. The tissues obtained were homogenized with phosphate buffered physiological saline to prepare 10% homogenates. After the homogenates were centrifuged at 1000  $\times g$  for 10 min, the supernatant obtained was used for measuring IL-8 and MCP-1 levels. As IL-8 and MCP-1 levels were to be calculated based on total amount of tissue protein, protein measurements were also performed on biopsy samples. The measurement of protein in esophageal homogenates was performed according to the "Bicinchoninic acid" method. For the procedure; bicinchoninic acid solution (Sigma B 9643, Sigma Chemicals) and 4% CuSO $_4$ , protein coloring reagent (0.2 mL 4% CuSO $_4$  on 10 mL bicinchoninic acid solution) were used. Ten  $\mu$ L of homogenate was added onto 200  $\mu$ L of protein coloring reagent. After mixing, the tube was kept at 37°C for 30 min. It was brought back to room temperature and the absorbance of the coloured complex was measured at 562 nm. The values were expressed as pg/mg tissue protein. IL-8 and MCP-1 measurements were carried out with EL  $\times$  800 BIO-TEK Instruments, Inc./USA brand ELISA device in line with the instructions provided in the commercial kits.

### Statistical analysis

In the statistical evaluation of the findings obtained from the study SPSS (Statistical Package for Social Sciences) for Windows 10.0 program was used. The Kolmogorov Smirnov test was used to compare the distributions of luminol, lucigenin, MCP-1 and IL-8 to parameters with normal distribution. As IL-8 and MCP-1 parameters had limit values, logarithmic conversion was used and the values were identified accordingly. In the comparisons of two groups with normal distributions, Student-*t* test was used. In the evaluation of the parameters that do not have a normal distribution, the Kruskal Wallis test was used. Chi-square test, McNemar test, Kappa analysis and diagnostic screening tests (sensitivity, specificity) were used to compare qualitative data. *P* level of < 0.05 was evaluated as being statistically significant.

## RESULTS

A total of 152 children underwent endoscopy during the study period and 59 out of 152 subjects who had complaints suggesting GERD included in the study.

ROS levels were measured in 54 and cytokine levels in 55 out of 59 patients. Mean age of the patients in the study was  $8.9 \pm 4.4$  years (age range 1.5-17 years). Of 59 patients 28 (47.5%) had normal esophagus whereas 31 (52.5%) had endoscopic esophagitis according to Savary Miller classification. In histopathological evaluation, 80% of the cases had mild or moderate degree of esophagitis. Of 31 patients having endoscopic esophagitis, 29 (93.5%) also had histopathological esophagitis whereas of 28 patients not having endoscopic esophagitis 18 (64.3%) had histopathological esophagitis. The sensitivity of endoscopic esophagitis for prediction of histopathological esophagitis was significantly high (93.6%, *P* = 0.0083). However, endoscopy had a low specificity in the diagnosis of histopathological esophagitis in children. Kappa correlation rate between the 2 methods was 30.1%: PPV, 61.7% and NPV, 83.3%.

When esophageal tissue ROS and chemokine levels were compared among groups with and without endoscopic esophagitis, statistical difference could neither be found between the stages of endoscopic esophagitis nor between the patients with and without esophagitis (Table 1).

When a comparison was made in terms of luminol and lucigenin levels of cases with and without histopathological esophagitis, there was a difference of statistical significance between the two groups (*P* = 0.049 and *P* = 0.044, respectively). While luminol levels did not differ among normal and patients with mild esophagitis, luminol levels of patients with moderate esophagitis were significantly higher than the normal patients (Table 2). Since there was not a statistically significant difference in luminol levels between children with mild and moderate esophagitis, two groups were combined, however, groups with and without histopathological esophagitis did not differ for either luminol or lucigenin measurements (*P* > 0.05).

Patients with histopathological esophagitis and normal were compared for MCP-1 and IL-8 levels. The highest cytokine levels were identified in patients with moderate esophagitis while lowest levels were found in normal children. However, this difference did not reach a statistical evaluations (*P* > 0.05, Table 3).

In order to investigate the effect of presence of *H. pylori* gastritis, the patients having esophagitis were classified and patients with and without *H. pylori* gastritis were compared. Patients with *H. pylori* gastritis and those not having gastritis did not show any statistically significant difference between their levels of ROS and chemokines.

## DISCUSSION

Gastroesophageal reflux when untreated in children may be related to some serious complications such as esophagitis, failure to thrive, esophageal strictures, Barrett esophagus and adenocarcinoma<sup>[54]</sup>. Delineation of the pathogenesis of GERD will allow for the development of more effective treatment strategies while making it possible to prevent complications. In

recent years, the role of ROS and chemokines in the pathogenesis of GERD and reflux esophagitis are being investigated both in experimental esophagitis models and in humans<sup>[12,17,19,27,29,35]</sup>.

The relationship between reflux esophagitis and free oxygen radicals was elaborated in this study, no statistical difference could be identified between normal cases and those having different degrees of endoscopic and histopathologic esophagitis. However, although it was statistically not significant, ROS levels were found to be increased in patient groups compared to the normal group.

Free oxygen radicals in general and superoxide radical in particular were shown to increase in animals with esophagitis and it was claimed that free radical scavengers like SOD and DA-9601 as well as anti-inflammatory agents like ketotifen could prevent the tissue damage<sup>[12,13,15,17,35]</sup>. However, in the study by Soterias *et al*<sup>[36]</sup> free oxygen radicals were found to play a role mostly in severe esophagitis and it was concluded that free oxygen radicals did not increase in the mild histopathological esophagitis model and thus ROS might not be influential on the pathogenesis of mild esophagitis. Studies performed in adults with reflux esophagitis are in support

of the experimental esophagitis models showing that free oxygen radicals do play a role in the pathogenesis of reflux esophagitis<sup>[18,19]</sup>. Olyae *et al*<sup>[37]</sup> have identified a significant correlation between the degree of esophagitis and the levels of free oxygen radicals in the tissue; under the light of this finding they stipulated that in mucosal epithelial cells affected by the injury, the production of ROS was increased. After examining mucosal biopsies of cases with erosive gastritis and Barrett esophagus; another group of researcher reported that the main oxidant product responsible for the development of reflux esophagitis was superoxide anion<sup>[38]</sup>.

Although there are no studies investigating the role of free oxygen radicals in children with reflux esophagitis, our findings are different than the results obtained from adult patients with reflux esophagitis. In our study, neither lucigenin which showed superoxide radical production nor luminol reflecting the productions of other free radicals were found to be increased in children with esophagitis compared to controls. Despite not reaching the level of statistical significance, free oxygen radical levels were found to be higher in children with esophagitis when compared to the controls. The reason behind not identifying a statistically significant difference between the cases of esophagitis and normal may be attributed to the fact that in most of the cases with histopathological reflux esophagitis was of mild degree.

Likewise, the levels of IL-8 and MCP-1 that are chemokines in relation with neutrophil and mononuclear cell migration were found to be higher in the group with histopathological reflux esophagitis compared to normal, however this difference did not reach a level of statistical significance either. In studies performed in adults, tissue chemokine levels are reported to be higher in cases with esophagitis than normal and the increase is reported to be in parallel with the severity of the histopathological esophagitis concerned. Fitzgerald *et al*<sup>[26]</sup> have identified 3-10 fold higher levels of tissue cytokines in the esophageal mucosa of adults with esophagitis when compared to patients with Barrett esophagus and normal controls. Furthermore, adult patients with nonerosive esophagitis were reported to have higher levels of tissue cytokines when compared to normal<sup>[27-30]</sup>. Similarly, in a study comparing 10 children with reflux esophagitis to normal patients, esophageal tissue IL-6 levels were reported to be significantly higher in patients with esophagitis<sup>[31]</sup>. In our study, the lowest levels were measured in normal cases whereas the highest levels were identified in patients with a moderate degree of esophagitis. The difference between these two groups was not statistically significant, this can be explained by the fact that the number of individuals who were normal and who had mild and moderate esophagitis were quite different from each other.

In *H pylori* gastritis, it has been shown that levels of IL-8, MCP-1 and other cytokines increased in gastric mucosa but we do not know the effect of this infection on esophageal tissue which is not normally colonized by the bacteria<sup>[39-41]</sup>. In our study, we could not identify any

effects of *H pylori* gastritis on esophageal tissue ROS and chemokine levels.

One drawback of this study is the lack of a true control group. All the study group was selected from the patients who had GER symptoms. The subjects who had either endoscopic or histopathological reflux esophagitis were compared to their nonreflux counterparts. The subjects who were included in the normal group according to the endoscopic findings might have a nonerosive reflux disease. Similarly, the subjects included in the normal group according to the histopathological examination might have an increased tissue level of proinflammatory substances before the establishment of the well-known histopathological changes. This might be another explanation for the lack of a clear cut statistical significance between the groups. However it is not possible to find a true control group for these kind of studies because it is not ethical and possible to perform endoscopy in totally normal children.

In parallel with the results of the studies on adult GERD or esophagitis, the patients in our study had higher levels of tissue ROS and chemokines; however, this increase did not reach a level of statistical significance. The number of studies aiming at identifying the pathogenesis of reflux esophagitis in children is very limited. Studies to be performed with higher numbers of patients with the aim of identifying the pathogenesis will allow for the development of further diagnostic and therapeutic opportunities for GERD which is a significant cause of morbidity.

## COMMENTS

### Background

Gastroesophageal reflux disease (GERD) is one of the most frequently encountered gastrointestinal pathology not only in adults but also in children. Since it may be related to some serious complications such as esophagitis, failure to thrive, esophageal strictures, Barrett esophagus and adenocarcinoma, early diagnosis and treatment of reflux disease is crucial. In recent years, it has been reported that reactive oxygen species (ROS) and inflammatory chemokines play an important role in the pathogenesis of GERD in adults but there is scarce data regarding children with reflux esophagitis.

### Research frontiers

Inflammatory chemokine levels were found to be significantly high in the esophageal tissues of the patients with esophagitis and a significant correlation was found between the severity of the reflux esophagitis and chemokines levels in adults. The aim was to investigate the role of chemokines and ROS in children with reflux esophagitis. Since the duration of reflux disease might be shorter in children compared to adults, the potential role of chemokines and ROS was interrogated in early or mild cases of reflux esophagitis.

### Innovations and breakthroughs

In this study we showed that the level of ROS and chemokines in esophageal tissue were higher in children with esophagitis compared to the subjects without esophagitis. However the difference was not statistically significant. Hence, factors apart from ROS, IL-8 and MCP-1 might be important in the pathogenesis of reflux esophagitis in children.

### Applications

It was found that ROS and chemokines increased in children with reflux esophagitis. Opposite to the adults, the exposure of the noxious agents to the esophagus is not long enough in children, endoscopic or histopathological esophagitis might be obscure. Hence tissue level of ROS or/and chemokines might be an important finding in early diagnosis of childhood esophagitis. Furthermore, the use of antioxidants or antiinflammatory agents might be alternative treatment modalities to the established treatment regimens.

## Peer review

This manuscript showed that ROS and chemokines are increased in esophageal tissue in children with reflux esophagitis, though not statistically significant. This finding might be important for the delineation of the pathogenesis of reflux esophagitis in children, and therapeutic alternatives targeting these chemokines or ROS could be an option in the future.

Prognostic factors in patients with advanced cholangiocarcinoma: Role of surgery, chemotherapy and body mass index. *World J Gastroenterol* 2008; 14(20): 3224-3230 Available from: URL: <http://www.wjgnet.com/1007-9327/14/3224.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.3224>

### Abstract

**AIM:** To study the factors that may affect survival of cholangiocarcinoma in Lebanon.

**METHODS:** A retrospective review of the medical records of 55 patients diagnosed with cholangiocarcinoma at the American University of Beirut between 1990 and 2005 was conducted. Univariate and multivariate analyses were performed to determine the impact of surgery, chemotherapy, body mass index, bilirubin level and other factors on survival.

**RESULTS:** The median survival of all patients was 8.57 mo (0.03-105.2). Univariate analysis showed that low bilirubin level (< 10 mg/dL), radical surgery and chemotherapy administration were significantly associated with better survival ( $P = 0.012$ , 0.038 and 0.038, respectively). In subgroup analysis on patients who had no surgery, chemotherapy administration prolonged median survival significantly (17.0 mo vs 3.5 mo,  $P = 0.001$ ). Multivariate analysis identified

### INTRODUCTION

Cholangiocarcinoma is a rare and highly fatal neoplasm that arises from biliary epithelium. It constitutes approximately 2% of all reported cancer<sup>[1]</sup>, and accounts for about 3 percent of all gastrointestinal malignancies<sup>[2]</sup>. Up to date, radical surgery remains the optimal therapy for cholangiocarcinoma offering a potential for cure<sup>[1,3,4]</sup>. In surgical patients with negative margins, five-year survival rates approach 20%-35% as compared to zero in those with positive margins<sup>[5]</sup>. However, most patients present with advanced disease precluding surgery<sup>[6-8]</sup>. Overall prognosis in these patients is poor and survival is limited to a few months<sup>[9]</sup>. Thus, it is crucial to identify factors that would improve survival in such patients.

The role of chemotherapy in cholangiocarcinoma is yet to be determined, with conflicting data regarding its effect on survival. This is due to lack of randomized clinical trials, and absence of a standard chemotherapeutic

regimen<sup>[10]</sup>. While some authors believe that chemotherapy prolongs survival in cholangiocarcinoma<sup>[11,12]</sup>, others deny this survival benefit<sup>[13-15]</sup>.

The impact of excess body weight on survival in patients with different cancers is variable. While it is associated with improved survival in patients with cancers of the gastric cardia<sup>[16]</sup>, less aggressive disease in renal cell cancers<sup>[17]</sup>, and lower malignant potential in ovarian tumors<sup>[18]</sup>, it was found to increase mortality in early stage breast cancers<sup>[19]</sup>, cancer of the esophagus, colon and rectum, liver, gallbladder, pancreas, and kidney<sup>[20]</sup>. However, the relationship of increased body mass index (BMI) and survival in cholangiocarcinoma has not been thoroughly investigated.

Many factors are well known to increase the risk of cholangiocarcinoma; these include age, primary sclerosing cholangitis (PSC), hepatolithiasis, and liver flukes<sup>[6]</sup>.

Several studies have provided evidence that excess body weight and obesity increase the risk of overall cancers. In a study by Lee *et al.*, overweight people had a one and a half times increased risk of cancer compared to those with normal weight in both sexes<sup>[21]</sup>. Similarly, obese people had a 33% increase in overall cancer incidence<sup>[22]</sup>. In cancers of the biliary tract, cancer of the gall bladder was linked previously with increased BMI in women<sup>[23,24]</sup>, whether increased BMI is a risk factor for cholangiocarcinoma is not known yet. In our study, the effect of increased BMI was given special emphasis to investigate its role as a risk factor and as a prognostic indicator.

In this study, we sought to determine the clinicopathologic characteristics of patients with cholangiocarcinoma. We also tried to identify the determinants of prognosis and survival in those patients with special emphasis on the role of surgery, chemotherapy and BMI.

## MATERIALS AND METHODS

Patients diagnosed with cholangiocarcinoma at the American University of Beirut-Medical Center during the 15 year period between 1990 and 2005 were identified. Patients' demographics, clinical data, radiological and histopathologic findings, surgical intervention, chemotherapy administration, and survival data were obtained retrospectively from hospital medical charts and by contacting patients or their family members. All histopathology slides and radiographic studies were reevaluated by a pathologist and a radiologist to obtain data about tumor location, grade, stage, lymphatic spread, vascular invasion and metastasis.

Tumors were classified as intrahepatic if originating from intrahepatic ductules (proximal to the bifurcation of the right and left hepatic ducts), and extrahepatic if perihilar (involving the confluence of the right and left bile ducts) or distal (if originating distal to the confluence of hepatic ducts).

AJCC 2003 criteria were used for TNM staging of the tumor<sup>[25]</sup>.

The impact of high bilirubin level at presentation, tumor location, size, grade, metastasis, presence of

vascular or perineural invasion, positive surgical margins, type of treatment including palliative stenting, surgery and chemotherapy on survival was examined.

Parameters examined as possible risk factors for cholangiocarcinoma were age, gender, diabetes, BMI, history of cholelithiasis, Hepatitis B and C infection, smoking, alcohol consumption, presence of cirrhosis, inflammatory bowel disease (IBD), PSC, and parasitic infestations.

To determine if increasing BMI is a risk factor for cholangiocarcinoma, patients were compared to controls of the same age groups that were selected from a large study about obesity in the Lebanese population<sup>[26]</sup>. According to WHO standards<sup>[27]</sup>, subjects were categorized according to their body mass index (normal: < 25, overweight: 25-30, and obese:  $\geq 30$  kg/m<sup>2</sup>).

All data was coded and entered using SPSS 14.0 computer program. The Kaplan-Meier method was used to estimate survival which was measured from time of presentation to AUB-MC to the date of death or date of last follow up. Differences in survival between subgroups were compared using the log-rank test. Univariate analysis was performed using the chi-squared testing. Multivariate analysis was performed with the Cox proportional hazards model. A *P*-value of less than 0.05 was considered statistically significant.

## RESULTS

### Demographics and clinical data

During the 15-year period, a total of 55 patients diagnosed with cholangiocarcinoma were studied. The demographic and clinical data of all patients are listed in Table 1. There were 34 males (60.7%) and 22 (39.3%) females. The mean age for all patients was  $62.6 \pm 13.0$  years and ranged from 28 years to 91 years. Seventeen patients were older than 70 years (11 females and 8 males). In males, the incidence of the tumor was highest in the age group of 50-59 years, while in females it was in the older than 70 years age group.

The most common presenting symptoms were jaundice (72.7%), dark urine (61.8%), weight loss (43.6%), abdominal pain (43.6%), pruritus (36.4%), and fever (10.9%).

### Risk factors

None of the patients had primary sclerosing cholangitis or any evidence of parasitic infestation on histological examination. One patient had inflammatory bowel disease (1.8%). One patient had a history of hepatitis B infection and two had liver cirrhosis of unknown etiology (3.6%). Ten patients had a history of cholecystectomy (17.8%) and 17 had a history of cholelithiasis (30.9%). Fifteen patients had a history of diabetes mellitus (25.5%) and one third (33%) were obese (BMI  $\geq 30$  kg/m<sup>2</sup>). One patient had a family history of cholangiocarcinoma (1.8%).

### Microscopic and macroscopic appearance

Tissue diagnosis was obtained on 30 patients (54.5%). Histopathologic findings are listed in Table 2. Tumors

larger than 3 cm, as measured in resected specimens and by radiology, comprised 34.5%, compared to 23.6% for those less than 3 cm. The most common morphological type was intraductal growing ( $n = 34$ , 61.8%) followed by mass forming ( $n = 21$ , 38%). Mass forming morphology was present in 63% and 35% of intrahepatic and extrahepatic tumors, respectively, with periductal infiltrating morphology comprising the rest of the patients.

Tumor grade was available on 27 patients. They were mostly moderately (55.6%) and poorly differentiated (29.6%). Vascular involvement on histology was evident in 12 patients (21.8%), while perineural invasion was found in 10 patients (18.2%).

Tumors presented at stage IV in 49 out of 55 patients (89%).

Distribution of tumor could be obtained on 48 patients (Table 2). Thirty-seven tumors (67.2%) were extrahepatic *versus* 11 intrahepatic (20%).

Of the extrahepatic tumors, 19 were distal (34.5%) and 18 were perihilar (32.7%). Nineteen patients had metastatic disease. The most common sites of metastases were the liver (25.4%,  $n = 14/55$ ), followed by the peritoneum (10.9%,  $n = 6/55$ ). Two patients had lymph node metastasis. One patient had brain metastasis and another had bone metastasis.

### Treatment

The resection rate of the tumor was low (21/55, 31.8%).

Rate of radical operation was only 11% (6/55). Extrahepatic tumors were more resectable ( $n = 13$ , 23.6%) as compared to intrahepatic tumors ( $n = 6$ , 10.9%). In 2 surgical patients, location of tumor could not be ascertained.

Of the twenty one patients who underwent surgery: 6 had Whipple procedure, 6 hepatic resection, and 9 en bloc resection of bile ducts and gall bladder. Two patients had positive lymph nodes. Surgical margins were positive in 7 patients ( $n = 7/21$ , 33%). Thirty-four patients had unresectable disease because of gross vascular involvement, locally advanced disease, or peritoneal metastasis discovered by imaging or during surgical exploration.

Twenty-four patients underwent palliative stenting, 9 had endoscopic stenting (37.5%), 14 had percutaneous radiological stenting (58.3%), and only one patient underwent surgical stenting (4.2%).

Fourteen patients received chemotherapy in the form of postoperative chemotherapy ( $n = 6$ ) or as palliative in the setting of non-resectable disease ( $n = 8$ ). Chemotherapy regimens consisted of gemcitabine or 5-Fu. Gemcitabine was given mainly as a single agent. As part of combination therapy, it was co-administered with other drugs such as oxaliplatin, 5-Fu, or CPT-11. 5-Fu was given as part of combination therapy at all times.

### Factors influencing survival in cholangiocarcinoma

The median survival for all patients was 8.57 mo (0.03-105.2), with 1-year, 3-year and 5-year survival rates of 10.8%, 5.4%, and 5.4%, respectively.

The longest survival time among all patients was 103 mo.

Multiple clinical, tumor-related and treatment parameters were evaluated by univariate analysis to determine their impact on survival in cholangiocarcinoma (Table 3).

**Table 3** Association between clinical variables and survival in patients with cholangiocarcinoma

Variable (n)	Median survival (mo)	P (Univariate)
Age

Parameters that did not influence survival were age, gender, diabetes, history of cholelithiasis, type of operation, resection margin status, presence of metastasis, and stenting. Tumor size, grade, location, vascular and perineural invasion also did not impact survival (Table 2). Increasing BMI was associated with a non-significant decrease in survival.

On univariate analysis, parameters that did influence survival included bilirubin level less than 10 mg/dL at presentation, surgical resection, and chemotherapy administration (Table 3). Since 49 out of 55 patients were stage IV, only these patients were included in Kaplan Meier survival (Figure 1) and multivariate analysis. Using Cox regression, a multivariate analysis was performed and only two were identified as independent predictors of increased survival: bilirubin level less than 10 mg/dL (Figure 1A) and chemotherapy administration (Figure 1B). Compared to patients with bilirubin levels less than 10 mg/dL, patients with higher bilirubin levels had a more than 2-fold increase in death risk from cholangiocarcinoma ( $P < 0.05$ ). Although the risk of dying was less in patients who underwent surgery, results did not attain statistical significance. On the contrary, patients who received chemotherapy had better survival ( $P < 0.05$ , Table 4).

## DISCUSSION

**Figure 1** A: Bilirubin level  $\geq 10$  mg/dL at presentation was associated with decreased survival as compared to lower levels; B: Chemotherapy administration prolonged survival in cholangiocarcinoma patients; C: Surgery added survival benefit in patients with cholangiocarcinoma.

This is the first report of cholangiocarcinoma from Lebanon, a small country in the Middle East, with a population of 3.4 million people. Our study shows the positive impact of surgery, chemotherapy, and low bilirubin level on survival in patients with advanced cholangiocarcinoma.

In previous studies, variables such as low preoperative bilirubin<sup>[4,14,28,29]</sup>, radical resection<sup>[28,29]</sup>, negative resection margin<sup>[11,30]</sup> and well-differentiated tumor histology<sup>[1,31]</sup>

**Table 4** Multivariate analysis of prognostic factors in patients with advanced cholangiocarcinoma

	Hazard's ratio	95% CI	P
Bilirubin			
< 10	1	1.13-0.52	0.023
≥ 10	2.421		
Surgery			
No	1	0.27-1.38	0.238
Yes	0.611		
Chemotherapy			
No	1	0.16-0.92	0.038
Yes	0.383		

were found to be predictors of improved outcome. On the other hand, less-differentiated histology<sup>[32]</sup>, perineural involvement, positive surgical margins, vascular or lymphatic invasion were associated with worse prognosis<sup>[30,32-37]</sup>.

The findings of our study emphasize the importance of increased bilirubin level upon presentation as an independent predictor of decreased survival in cholangiocarcinoma. Due to the small number of patients, we could not confirm the impact of the previously proposed variables on survival.

Radical surgery is considered as the most effective therapy for cholangiocarcinoma<sup>[5]</sup>. Only 20% of patients present with resectable disease<sup>[1]</sup>, yet surgery remains the only potential chance of cure. Without surgery, cholangiocarcinoma is a rapidly fatal disease with 5-year survival rates of less than 5%<sup>[9]</sup>, while in curative resections 5-year survival approaches 20%-35% with negative surgical margins<sup>[5]</sup>. In our findings, we could not document an improved survival after surgical resection which can be explained by the advanced stage at which all patients presented and the small number of the study group.

The significance of chemotherapy in cholangiocarcinoma is still not clear especially with the low response rates<sup>[5]</sup>, disappointing efficacy results and lack of a superior standard chemotherapeutic regimen<sup>[7,38]</sup>. Conflicting data exist regarding the role of chemotherapy in cholangiocarcinoma. Some studies suggest that chemotherapy, whether given in a setting of non-resectable disease or postoperatively, has little or no impact on the course of the disease or on survival outcome<sup>[13-15,29,39-41]</sup> and is therefore considered palliative more than curative<sup>[42]</sup>. Other studies report survival benefit from chemotherapy<sup>[11,12,43]</sup>. Recently, a pooled analysis of all clinical trials from 1985 to 2007 concluded that the combination of gemcitabine with oxaliplatin or cisplatin may improve survival in cholangiocarcinoma<sup>[10]</sup>.

Our study adds further evidence to the previously published reports showing that chemotherapy improves survival in cholangiocarcinoma. We found that chemotherapy markedly improves survival in patients with either resected or unresected cholangiocarcinoma (17.0 mo *vs* 6.0 mo;  $P < 0.01$ ). Additionally, chemotherapy prolonged survival significantly in patients with unresectable tumors (17.0 mo *vs* 3.5 mo;  $P = 0.001$ ). Thus, in patients with advanced cholangiocarcinoma who are not surgical

candidates, Gemcitabine and/or 5-Fu based chemotherapy might offer a survival advantage.

Our results also show a non-significant decrease in survival with increasing BMI. The median survival for patients with BMI < 25 was 17.0 mo (8.5-17.6), 7.0 mo (3.2-10.8) for patients with BMI 25-29.99, and 4 mo (0.5-7.6) for patients with BMI ≥ 30 ( $P = 0.412$ ). The fact that these results did not attain statistical significance may be attributed to the small sample size. Further prospective studies are needed to determine the effect of increased body mass index on prognosis in cholangiocarcinoma.

In line with other reports, cholangiocarcinoma in Lebanon affected older patients<sup>[44,45]</sup> and more males than females<sup>[44-46]</sup>, except in the above 70-year-old group where females were more commonly affected. However, the mean age of our patients was higher than that of patients in the USA<sup>[47]</sup>. The clinical symptoms and signs observed in Lebanese patients with cholangiocarcinoma were mostly of biliary obstruction and abdominal pain, as was previously reported<sup>[28]</sup>.

Most of the tumors in our study were distal extrahepatic lesions, whereas perihilar lesions are the most common type usually reported<sup>[5,6,48]</sup>. A moderate degree of differentiation was noted in the majority of tumors in our patients, while well-differentiated histology is more commonly reported<sup>[5,6]</sup>.

Similar to other reports<sup>[4]</sup>, this series did not identify any risk factors associated with cholangiocarcinoma, which is different from reports of biliary tract cancers elsewhere. In Asian countries, well-established risk factors are hepatolithiasis and liver fluke infestations<sup>[49]</sup>, while in western countries hepatitis B and C infection, HIV, cirrhosis, diabetes, alcohol consumption, and IBD were recently implicated as potential risk factors for cholangiocarcinoma<sup>[44,47,50]</sup>.

Our patients might have had some of the known risk factors for cholangiocarcinoma that might have been missed at the time of patient presentation. Therefore, absence of those risk factors can not be ascertained due to the retrospective design of our study.

The prevalence of diabetes in our patients was 33% with the highest incidence being observed in patients over the age of 65, which was very close to the 29% prevalence rate of diabetes in the general Lebanese population older than 65 years<sup>[51]</sup>. Therefore, diabetes can not be considered a risk factor for cholangiocarcinoma in our population, unlike other populations where diabetes increased the risk 2-3 folds<sup>[44,50,52]</sup>.

Cholelithiasis was present in 30% of our patients. Prevalence of cholelithiasis in cholangiocarcinoma patients was previously reported to fall in the 30% to 48% range<sup>[53]</sup>. It was described as a risk factor for cholangiocarcinoma in a number of studies<sup>[50,53,54]</sup>. However, a definitive cause-effect relationship has not been established yet.

Few reports addressed the association between BMI and bile duct cancer; Samonic *et al* showed that obese black men are at a significant risk of extrahepatic bile duct cancers<sup>[55]</sup>. On the other hand, Welzel *et al* showed

that obesity was not a risk factor for intrahepatic cholangiocarcinoma<sup>[50]</sup>. Others suggested that increased body mass index was associated only with cancer of the extrahepatic duct<sup>[54]</sup>. Furthermore, in a large Korean cohort, a significant positive linear relationship was found between increasing BMI and risk of cholangiocarcinoma<sup>[56]</sup>. The risk of cholangiocarcinoma increased approximately 1.6 folds in patients with BMI > 30 kg/m<sup>2</sup><sup>[56]</sup>. In our study, 68% of all patients with cholangiocarcinoma had excess BMI (median BMI was 26.9 kg/m<sup>2</sup>). In the Lebanese adult population, 53% are overweight (BMI ≥ 25), 17% are obese (BMI ≥ 30) and the mean BMI is estimated to be 25.9 kg/m<sup>2</sup><sup>[26]</sup>, which is comparable to the mean BMI of our study group.

There are several limitations in our study. The first is the small sample size, which is due to the rarity of the disease under investigation. Second, the study represents cases seen at a single tertiary care center, which may limit its utility in patients with cholangiocarcinoma in general. Third, our study is limited by its retrospective design; a key limitation resulting from such a design is the missing data, which may result in fewer patients included in multivariable models, generally increasing the risk for both type one and type two errors. Fourth, our study is non-randomized and lacks a control group. Despite the limitations of retrospective studies, absence of prospective and controlled data in the current literature makes the results of our study of more interest.

In conclusion, bilirubin levels less than 10 mg/dL at presentation and chemotherapy administration both in advanced disease and in postoperative adjuvant settings are associated with better prognosis and prolonged survival in patients with cholangiocarcinoma. None of the well-established or the potential risk factors for cholangiocarcinoma could be identified in the Lebanese population due to the above mentioned limitations. High body mass index was not found to be a risk factor for cholangiocarcinoma; however, increments were associated with a trend towards a decrease in median survival.

## COMMENTARY

### Background

Cholangiocarcinoma is an infrequent malignancy that involves the biliary epithelium. It has a poor prognosis with a survival less than 5% at five years. Radical surgery is the only potentially curative treatment modality, while the impact of chemotherapy on survival remains controversial. Due to small number of patients, determinants of prognosis in cholangiocarcinoma are not well characterized.

### Research frontiers

A retrospective review of the medical records of 55 patients diagnosed with cholangiocarcinoma at the American University of Beirut between 1990 and 2005 was conducted. Univariate and multivariate analysis were performed to determine the impact of surgery, chemotherapy, body mass index, bilirubin level and other factors on survival.

### Innovations and breakthroughs

Bilirubin levels less than 10 mg/dL at presentation and chemotherapy administration both in advanced disease and in postoperative adjuvant settings are associated with better prognosis and prolonged survival in patients with cholangiocarcinoma. High body mass index was not found to be a risk factor for cholangiocarcinoma; however, increments were associated with a trend towards a decrease in median survival.

### Applications

Palliative and postoperative chemotherapy as well as a bilirubin level < 10 mg/dL are independent predictors of a significant increase in survival in patients with cholangiocarcinoma. Large prospective controlled studies are needed to verify these results.

### Peer review

This article reports interesting epidemiological data on cholangiocarcinoma in Lebanon and the effects of surgical resection and chemotherapy on survival. Multivariate analysis identified only a bilirubin level < 10 mg/dL and chemotherapy as independent predictors of better survival.

## Abstract

**AIM:** To sum up the recent 30-year experience in the prevention and treatment of gastrointestinal dysfunction in severe burn patients, and propose practicable guidelines for the prevention and treatment of gastrointestinal (GI) dysfunction.

**METHODS:** From 1980 to 2007, a total of 219 patients with large area and extraordinarily large area burns (LAB) were admitted, who were classified into three stages according the therapeutic protocols used at the time: Stage 1 from 1980 to 1989, stage 2 from 1990 to 1995, and stage 3 from 1996 to 2007. The occurrence and mortality of GI dysfunction in patients of the three stages were calculated and the main causes were analyzed.

**RESULTS:** The occurrence of stress ulcer in patients with LAB was 8.6% in stage 1, which was significantly lower than that in stage 1 ( $P < 0.05$ ). No massive hemorrhage from severe stress ulcer and enterogenic infections occurred in stages 2 and 3. The occurrence of abdominal distension and stress ulcer and the mortality in stage 3 patients with extraordinarily LAB was 7.1%, 21.4% and 28.5%, respectively, which were significantly lower than those in stage 1 patients

( $P < 0.05$  or  $P < 0.01$ ), and the occurrence of stress ulcer was also significantly lower than that in stage 2 patients ( $P < 0.05$ ).

**CONCLUSION:** Comprehensive fluid resuscitation, early excision of necrotic tissue, staged food ingestion, and administration of specific nutrients are essential strategies for preventing gastrointestinal complications and lowering mortality in severely burned patients.

Prevention and treatment of gastrointestinal dysfunction following severe burns: A summary of recent 30-year clinical experience. *World J Gastroenterol* 2008; 14(20): 3231-3235 Available from: URL: <http://www.wjgnet.com/1007-9327/14/3231.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.3231>

## INTRODUCTION

Gastrointestinal dysfunction is a common complication of severe burns. Injury to GI function, especially to GI barrier function, is an important initiator as well as a stimulator for occurrence of systemic inflammatory response syndrome (SIRS), sepsis and multiple organ dysfunction syndrome (MODS) following severe burns<sup>[1]</sup>. With the deeper understanding of GI function and changes in the stereotype of clinical treatment in recent 30 years, a series of new therapies including fluid resuscitation, early escharectomy, continuous renal replacement therapy, and use of glutamine and growth factor has been adopted in the treatment of severe burns<sup>[2,3]</sup>. Although animal experiments have shown that these new therapies do play a positive role in the prevention and treatment of GI dysfunction following severe burns, there has been a lack of convincing clinical

data to confirm the outcome<sup>[4-6]</sup>. The present study reviewed the clinical data of 219 patients with large area burns (LAB) in recent more than 20 years, who were classified into different stages according to the therapeutic protocols used at the time. Based on the review, the outcomes of GI function protection and treatment were compared, analyzed and summarized in an attempt to propose some practicable guidelines for the effective prevention and treatment of GI dysfunction.

## MATERIALS AND METHODS

### *Clinical data*

This study included 219 patients with severe burns who were admitted to this burn center from January 1980 to August 2007. They were classified as LAB patients (50%-79% TBSA, or degree III burn area > 20%) and extraordinarily large area burn (ELAB) patients (80%-100% TBSA, or degree III burn area > 50%). According to the therapeutic protocols used at the time, they were assigned to three stages: stage 1 from 1980 to 1989, stage 2 from 1990 to 1995, and stage 3 from 1996 to 2007. The occurrence of GI dysfunction and mortality were analyzed statistically.

**Stage 1 (1980-1989):** Limited fluid resuscitation was advocated during the shock phase of burn patients. In other words, the total fluid input was minimized as long as the vital signs were stably maintained, and the urine output was controlled at a level of 0.5 mL/h per kg body weight. The first escharectomy was usually done 4-7 d after burn injury, and the operation area was 20%-30% TBSA in most cases. Patients were mostly starved in the early stage of burn and relied on intravenous nutrition. To prevent stress ulcer, gastric mucosal protection agents and anti-acid drugs were administered routinely.

**Stage 2 (1990-1995):** The major therapeutic changes were advancing the first escharectomy to 3-4 d after burn injury, expanding the operation area as much as possible, and excising the necrotic tissue as early as possible. When bowel sounds recovered 2-4 d after burn injury, food intake was started gradually through the gastric tube and patients were encouraged to take food orally, with administration of appropriate amounts of gastrokinetic drugs such as domperidone to promote gastrointestinal peristalsis. Oral norfloxacin and nystatin were administered routinely within 2 wk after burn. Selective decontamination of the digestive tract (SDD) was also recommended.

**Stage 3 (1996-2007):** The comprehensive resuscitation strategy was advocated for shock burn, which includes sufficient resuscitation and maintenance of urine output at 1-1.5 mL/h per kg BW; routine intravenous instillation of vasoactive drugs such as small doses of dopamine; adjustment of the gastrointestinal tract and renal blood perfusion; and use of antioxidants such as large doses of Vitamin C and E to eliminate free oxygen radicals. In addition, antibiotics were used prudently,

including shortening the duration of antibiotic administration and reducing the variety of antibiotics. So far as gastrointestinal nutrition is concerned, staged food ingestion was advocated, where small amounts of light fluids (20-40 mL/h) were instilled through the gastric tube 2 h after burn to stimulate gastrointestinal peristalsis. Once bowel sounds recovered, the amount of food was increased gradually. Usually the amount of enteral nutrition fed through the gastric tube was increased to 2000-2500 Kcal/d 3-6 d after burn. Specific nutrients were used such as oral glutamine, L-arginine, dietary fiber and subcutaneous growth factor.

Since 2003, early administration of continuous renal replacement therapy (CRRT) for 5-8 consecutive days has been advocated in patients with GI failure accompanied with sepsis. The content of endotoxin, IL-1 $\beta$ , IL-6 and IL-8 in plasma were analyzed before and after CRRT treatment. TNF- $\alpha$  content was measured by radioimmunoassay. The activity of diamine oxidase (DAO) in plasma was tested according to the previous report<sup>[7]</sup>.

### *Indexes for assessing GI function*

There was no uniformed criterion for assessing GI dysfunction<sup>[8]</sup>. Based on the diagnostic criteria for MODS and GI symptoms commonly seen in burned patients, GI dysfunction is summarized as follows: (1) abdominal distension: bowel sound was reduced and food intolerance exceeded more than 5 d; (2) stress ulcer: gastric fluid aspirated from the gastric tube appeared bloody macroscopically and gastric mucosa was erosive and ulcerative gastroendoscopically; (3) severe stress ulcer: blood loss exceeded 800 mL within 24 h; (4) alteration of intestinal microbiota: Gram-negative *E.coli* was amplified, and the bacillus/coccus ratio was greater than 10:1; and (5) enterogenic infection: highly suspected systemic infection occurred after ruling out wound surface, pulmonary and indwelling catheter infections<sup>[9,10]</sup>.

### *Statistical analysis*

Data were testified by Pearson's Chi-square test, and Fisher's two-tail exact test.

## RESULTS

Of the 219 severe burn cases analyzed (Table 1), 89 cases were LAB and 130 cases were ELAB. There was no significant difference in age distribution and burn area between the three stages of patients.

Table 2 shows that the occurrence of stress ulcer in LAB patients of stage 3 was 8.6%, which was significantly lower than 30.3% of stage 1 patients ( $P < 0.05$ ). No hemorrhage from severe stress ulcer and enterogenic infection occurred in the patients of stage 2 and 3.

Compared with LAB patients, the occurrence of gastrointestinal complications and mortality in ELAB patients were significantly higher, indicating that occurrence of gastrointestinal complications was closely

associated with the severity of burn. Table 3 shows that the occurrence of abdominal extension and stress ulcer and mortality in the stage 3 ELAB patients were 7.1%, 21.4% and 28.5%, respectively, which were significantly lower than those of stage 1 (*P* < 0.05 or *P* < 0.01), and the occurrence of stress ulcer in the stage 3 ELAB patients was also significantly lower than that of stage 2 patients (*P* < 0.05).

In the 5 patients with GI failure accompanied with severe sepsis, endotoxin, IL-1β, IL-6, IL-8 and TNF-α levels and plasma DAO activity were decreased significantly after CRRT (Table 4) (*P* < 0.01).

## DISCUSSION

Timely and effective fluid resuscitation is the basis and guarantee of curing severely burned patients<sup>[11]</sup>. Before the 1990s, the therapeutic concepts were limited to such that excessive fluid infusion would aggravate edema so that limited resuscitation was addressed. Under the bunker of stable vital signs lies the problems of GI hypoxia and ischemia, or occult GI shock<sup>[12,13]</sup>. Since the mid and late 1990s, comprehensive resuscitation strategies for maintaining the stability of vital signs and splanchnic resuscitation to restore GI blood supply as early as possible and reduce hypoxic and ischemic injuries as much as possible have been recommended<sup>[14]</sup>. It is suggested that small doses of dopamine should be administered to dilate the renal and GI vessels<sup>[15]</sup>, and free oxygen radical clearing agents to attenuate ischemia/reperfusion injury in the process of resuscitation<sup>[16,17]</sup>. These comprehensive resuscitation measures played an important role in protecting GI function, helping resume bowel sound earlier and digestive function<sup>[18]</sup>. No stress ulcer occurred during the shock phase, which laid a sound foundation for future treatment.

It has been generally accepted that early enteric nourishment plays an essential role in preventing GI dysfunction following severe burns<sup>[19,20]</sup>. But as LAB often causes serious edema of GI mucosa, there is a

Table 3 GI complications and mortality in ELAB patients (%)

Stage	<i>n</i>	AE	SU	SSU	FA	EI	Mortality
1	45	24.4	60.0	11.1	20.0	15.5	55.6

Table 4 Endotoxin, IL-1β, IL-6, IL-8 and TNF-α levels and plasma DAO activity before and after CRRT

	Endotoxin (Eu/mL)	TNF-α (pg/mL)	IL-6 (pg/mL)	IL-8 (pg/mL)	DAO (U/mL)
Before CRRT	0.76 ± 0.13	272 ± 28	518 ± 64	583 ± 51	2.98 ± 0.94
After CRRT	0.045 ± 0.017 <sup>b</sup>	57 ± 15 <sup>b</sup>	98 ± 25 <sup>b</sup>	105 ± 31 <sup>b</sup>	1.27 ± 0.54 <sup>b</sup>

Compared with before CRRT, <sup>b</sup>*P* < 0.01.

concern that early food intake would give additional burden to the GI tract or even cause acute gastric dilation, resulting in vomiting and aspiration. For this reason, there is controversy over when and how to take food. Before the 1990s, food intake was usually started when patients resumed bowel sound. After the mid and late 1990s, the idea of staged food intake was advanced: a small amount of light fluid is started several hours after burn so as to not only supplement nutrition but stimulate GI peristalsis and improve GI blood supply. Once bowel sound resumes, the amount of food can be increased. Using immunoregulatory nutrients such as oral glutamine, L-arginine and dietary fiber promoted post-burn repair of GI mucosa, maintained GI barrier function, and reduced translocation of enterogenic bacteria and endotoxins<sup>[21,22]</sup>.

The microenvironment formed by GI resident bacteria forms an ecologic barrier in the intestinal lumen, preventing intestinal pathologic bacteria from colonization and substantial proliferation<sup>[23]</sup>. To maintain normal intestinal microbiota, we paid special attention to the followings: prudent use of antibiotics and routine use of SDD. In earlier treatment of severe burns, a variety of broad-spectrum antibiotics were often used concomitantly. But our clinical experiences showed that mere use of antibiotics failed to control infections effectively in severely burned patients; instead it often caused alteration of bacterial flora, resulting in superinfection. Since the mid and late 1990s, the principle of “bold use of antibiotics and bold discontinuation of them” has been advocated. In other words, the duration and variety of antibiotics should be minimized, and the use of antibiotics should be enhanced properly during the edema reabsorption phase and the perioperative period. By doing so, the incidence of systemic infection was lowered, and furthermore it avoided alteration of intestinal microbiota effectively. The use of SDD within two weeks of burn injury inhibited the growth of Gram bacteria and fungi and maintained the stability of intestinal microbiota, which may also be beneficial to reducing superinfection

of intestinal bacteria<sup>[24]</sup>.

Early excision of necrotic tissue and closure of the wound surface are essential in the treatment of severe burns<sup>[25]</sup>. Positive surgical treatment has become a generally accepted idea. Our practice is that surgery is started 3-4 d after burn injury and the area of escharectomy at a time is much larger than before, usually reaching 60%-75% TBSA. The wound surface is covered with heterogeneous skin, which plays an important role in preventing systemic inflammatory reaction and protecting organ functions<sup>[26]</sup>.

In some patients in whom fluid resuscitation was not implemented effectively for various reasons, wound surface infection often caused severe injury to the GI function, or even toxic paralytic ileus palsy, greatly increasing toxin absorption and bacterial superinfection. Toxins absorbed in the blood act on the GI tract, which in turn lowers the GI kinetics, resulting in a vicious cycle<sup>[27]</sup>. Treatment of this kind of critically severely burned patients is a real challenge, in whom the mortality rate is usually high. Apart from the above mentioned routine treatments, we also used CRRT to filtrate inflammatory mediators and toxins in the body, which significantly lowered the content of endotoxins and inflammatory factors and DAO activity. As the vicious cycle was broken off, the therapeutic outcome was usually good<sup>[28]</sup>.

In summary, post-burn GI dysfunction is caused by multiple factors, and therefore maintaining GI function is a systematic engineering project. The therapeutic strategy should not rely on a single treatment or a single drug<sup>[29,30]</sup>. Furthermore, as severe burn itself may cause serious injury to various functions of the body, prevention of multi-organ functions should be addressed. Clinical experiences in recent 30 years have demonstrated that comprehensive fluid resuscitation, early excision of necrotic tissue, staged food ingestion, and administration of specific nutrients are essential strategies for preventing gastrointestinal complications in severely burned patients. Once severe GI dysfunction and sepsis occur, individualized comprehensive treatment should be implemented without delay. CRRT developed in recent years appears to be a promising strategy in the treatment of severe burns<sup>[31]</sup>.

## COMMENTS

### Background

Gastrointestinal dysfunction is a common complication of severe burns. Injury to GI function, especially to GI barrier function, is an important initiator as well as a stimulator for occurrence of systemic inflammatory response syndrome (SIRS), sepsis and multiple organ dysfunction syndrome (MODS) following severe burns.

### Research frontiers

The study analyzed and summarized the authors' clinical experiences in recent 30 years in the prevention and treatment of gastrointestinal dysfunction in severely burned patients in an attempt to propose some practicable guidelines for the effective prevention and treatment of GI dysfunction following severe burns.

### Innovations and breakthroughs

Comprehensive fluid resuscitation, early excision of necrotic tissue, staged food ingestion, and administration of specific nutrients are essential strategies for

preventing gastrointestinal complications and lowering the mortality in severely burned patients.

### Applications

The study provided some practicable guidelines for the effective prevention and treatment of GI dysfunction following severe burns.

### Peer review

The paper analyzed and summarized some practicable experience for the effective prevention of GI dysfunction. It is valuable to see the actual results from the therapies by the authors over the last 30 years.

revealed acute tubular necrosis and interstitial nephritis. Significant differences in preexisting severe hepatitis, ascites, renal disease, and diuretic therapy were found between groups. Prior to diethylene glycol injections, the mean values for neutral granular cells, BUN, Cr, calcium and phosphorous ions differed significantly between groups.

**CONCLUSION:** Venous diethylene glycol poisoning is characterized by oliguric acute renal failure, metabolic acidosis, digestive symptoms, nervous system impairment, and a high probability of anemia and WBC proliferation. Mortality is high. Correlative factors include preexisting severe liver disease, renal disease, and infection.

### Abstract

**AIM:** To analyze the clinical presentation of venous diethylene glycol (DEG) poisoning in patients with preexisting severe liver disease and factors that correlate with DEG poisoning.

**METHODS:** Retrospective chart review was performed to analyze the epidemiology, clinical presentation, hepatorenal functions, hemodynamics and pathological characteristics of 64 patients with severe liver disease who received intravenous armillarisin-A, the solvent of which was DEG. Comparative analyses of correlating factors and causes for poisoning were based on the presence or absence of poisoning.

**RESULTS:** Of the 64 patients who received armillarisin-A, 15 were found to have DEG poisoning. Twelve poisoned patients died. After a mean of 5 d, the poisoned patients displayed acute renal failure. Metabolic acidosis occurred in 13 cases. BUN, Cr, and CO<sub>2</sub> values were significantly elevated and exacerbation of digestive tract symptoms and/or symptom was noted in 11 cases. Neurological system impairment was observed in 10 cases after 2 wk. Compared to the 49 non-poisoned patients, the poisoned patients exhibited significantly lower RBC and Hb values and higher WBC count. Renal biopsy from the poisoned patients

### INTRODUCTION

Diethylene glycol (DEG) is a chemical substance used primarily for industrial purposes. Tested in animals, DEG induces liver impairment and kidney toxicity presenting as acute renal failure (ARF)<sup>[1,2]</sup>. In 1937, 358 human cases of ARF resulting in 107 deaths were described following ingestion of sulfanilamide dissolved in DEG in America<sup>[3]</sup>. Similar reports of DEG poisoning appeared subsequently in the other countries<sup>[4-10]</sup>, with most cases involving pediatric poisoning through oral ingestion and with fundamentally milder complications.

On April 22th 2006 and April 24th 2006, two patients in the Department of Infectious Diseases, Third Affiliated Hospital of Sun Yat-Sen University, with severe liver disease developed ARF. On April 29th

2006 and April 30th 2006, another six patients in this department with severe liver disease also developed ARF. Upon further investigation, armillarisin-A<sup>[11]</sup>, a drug produced by the Qiqihar No. 2 Pharmaceutical Co. Ltd, for treatment of gall-bladder disease, was found to have been administered to all patients who developed ARF. Administration of the drug was immediately suspended. Subsequently, the situation was reported to the relevant pharmacy. All preparations of armillarisin-A were sealed and forwarded to the Guangdong Drug Examination Center for investigation. Findings revealed that DEG was present in these preparations at a concentration of 30%. Subsequent judiciary investigation disclosed that the Qiqihar No. 2 Pharmaceutical Co. Ltd, selected DEG to serve as an economic substitute for trimethylene glycol in armillarisin-A preparations.

Review of 64 patients who received armillarisin-A in the hospital during the relevant time period was therefore undertaken, and findings were described in the present report. Of the 15 patients subsequently died, 12 were diagnosed with DEG poisoning. No other patients with similar complications have been reported since May 2nd 2006. The investigation described in the present report has the following features: (1) all subjects were adults who received armillarisin-A with DEG intravenously; (2) clinical presentation was recorded before and after DEG poisoning, and the exact injection volumes and DEG concentrations in the preparations were recorded; (3) the majority of patients presented with concurrent severe liver disease. In the present report, the clinical presentation of venous diethylene glycol poisoning and the pathological characteristics of renal tissue of poisoned patients were described and factors that correlate with this form of poisoning were identified.

## MATERIALS AND METHODS

### Subjects

The 64 patients enrolled in the present study were treated with armillarisin-A in the Third Affiliated Hospital of Sun Yat-Sen University in Guangzhou between April 19th 2006 and May 1st 2006. All the patients, including 49 (76.6%) males, were diagnosed with severe liver diseases. Of these 64 patients, 14 had severe hepatitis, 16 had liver cirrhosis caused by hepatitis B virus, 21 had chronic active hepatitis, 6 had primary hepatocellular carcinoma, 2 underwent liver transplantation, 2 had biliary cirrhosis, and 1 had hepatolenticular degeneration and liver impairment due to malignant lymphoma and cholangiocarcinoma.

### Diagnostic methods

Based on the published findings long before and the consensus of experts, the Department of Health of Guangdong Province established the criteria for clinical diagnosis of DEG poisoning. The following three criteria are considered essential: (1) a history of DEG prescription (oral/venous injection), (2) acute renal impairment or renal failure characterized by oliguria or anuria occurring within 2 wk of the last ingestion/injection, and (3) elimination of all other causes of

acute renal impairment or renal failure.

Diagnosis of viral hepatitis was based on the standardized "viral hepatitis prevention study" performed in 2000 by the Society of Infections Diseases and Society of Liver Diseases of the Chinese Medical Association<sup>[12]</sup>.

### Research methods

Retrospective chart review was applied to all 64 patients who received DEG intravenously. These patients were assigned to either the poisoned group or the non-poisoned group. For each poisoned patient, analyses of epidemiology, clinical symptoms, prognosis, hepatorenal functions, hemodynamics and pathology of renal tissue were performed before and after poisoning for comparison purposes. Analyses were also performed for the poisoned group as compared to the non-poisoned group prior to receipt of DEG to identify factors predisposing to DEG poisoning.

Renal tissues from poisoned patients were examined with several methods. Ten or more renal corpuscles were extracted and subjected to HE and PASH staining followed by microscopic observation. The nature and degree of corpuscular and tubular-interstitial pathologies were evaluated. Immunofluorescence staining of frozen sections was performed to observe the deposition sites and degree of deposition of immune-complex compounds. Electron microscopy was performed to identify the ultrastructural changes in renal tissue.

Liver function and biochemical parameters were detected using an automatic chemistry analyzer. The concentration of DEG in armillarisin-A was determined by spectrophotometry.

### Statistical analysis

Normality distribution was analyzed for the continuous variables. The *t*-test was performed to detect significant differences between groups with normality. The data are presented as mean  $\pm$  SD. Group comparison for data without a normal distribution involved evaluation by independent nonparametric testing. Findings were presented as the medians. The Chi-square test was performed to examine numerical data.  $P < 0.05$  was considered statistically significant. SPSS13.0 for windows was used for all statistical analyses.

## RESULTS

### Basic information concerning patients who received DEG intravenously

Sixty-four patients who received intravenous injections of armillarisin-A were observed. On June 30th 2006, DEG poisoning was present in 15 patients and absent in 49 patients. Comparative statistics was performed based on the presence or absence of DEG poisoning, and findings are listed in Table 1. The DEG concentration in the patients ranged from 1.2% to 6%, with a cumulative dosage volume of 2.4-114 mL, but no statistical differences in these values were observed between the poisoned and non-poisoned groups. Liver impairment was more severe in the DEG-poisoned group than in

TLD: Terminal liver disease, including severe hepatitis, liver cirrhosis, recurrence of post liver transplantation; ALT: alanine aminotransferase; CH: Chronic hepatitis; TB: total bilirubin; WBC: White blood cells; RBC: Red blood cells; NEUT: Ratio of neutral leucocyte; BUN: Blood urea nitrogen. <sup>1</sup>Fisher's exact test; <sup>2</sup>Pre-existing renal diseases, including kidney stones, proliferative renal cysts and urinary tract infections. One case of renal carcinoma was observed in the non-poisoned group.

the non-DEG-poisoned group. Of the 15 poisoned patients, 12 had terminal liver disease. Data analyses revealed significant differences between the poisoned and non-poisoned groups with respect to the severity of pre-injection liver conditions, presence of ascites and renal diseases, use of diuretics, pre-injection neutral granular cell count, serum BUN, serum Cr, calcium and phosphate ion (IP) concentrations. Death occurred in 12 patients of the poisoned group and 8 patients of the non-poisoned group. Hepatic failure and multiple organ dysfunction syndromes (MODS) were identified as the main causes of death.

#### **Clinical presentation of patients with DEG poisoning**

Oliguric ARF was present for a mean of 5 d in 15 patients with intravenous DEG poisoning. The clinical characteristics of these 15 patients are presented in Table 2. The urine volume decreased rapidly. The majority of poisoned patients developed digestive tract symptoms,

such as nausea, vomiting and bloating, or exhibited an increase in the severity of these symptoms. Half of the patients exhibited concomitant mild pyrexia. Ten patients displayed nervous system impairment involving the cranial nerves, including the facial, optic, oculomotor and glossopharyngeal nerves, at an average of 14 d after the initial injection. A few patients exhibited peripheral nerve involvement presenting as limb tremor and paralysis. Respiratory muscle paralysis might have been present in some patients, leading inevitably to respiratory failure. DEG poisoning was also associated with an increase in the severity of hepatic encephalopathy among patients previously exhibiting this complication. Retrospective analyses of 13 patients before and after DEG poisoning revealed that all patients experienced metabolic acidosis at an average of 9 d after injection and 4 d following development of ARF. The most severe manifestations of metabolic acidosis occurred on d 10 after initial ingestion of DEG. Twelve of the 15 patients diagnosed with DEG poisoning died. Death generally occurred 1 wk following the initial signs of renal failure. Among the 3 patients who survived the poisoning, however, urine volume was observed to recover 3 wk after poisoning and urine volume was normal 1 mo after poisoning. One of the three patients who survived underwent combined liver-kidney transplantation 16 d after exhibiting DEG poisoning.

#### **Hepatorenal functions and peripheral blood cell count before and after DEG poisoning**

When the liver function, renal function and peripheral blood cell counts before DEG poisoning were compared

**Figure 1** Pathological changes in renal tissue of patients with DEG poisoning. **A:** Glomerulus of a patient poisoned by intravenously administered DEG revealing no remarkable changes (HE, × 200); **B:** Tubular necrosis and interstitial inflammatory response in renal tissue following poisoning by intravenously administered DEG (HE, × 100); **C:** Microscopic observation of tubular vacuolation and interstitial inflammatory response in renal tissue following poisoning by intravenously administered DEG (× 6000).

BP: The last values before DEG poisoning; AP: The peak values after DEG poisoning; GGT: Gamma-glutamyl transpeptidase; ALP: Alkaline phosphatase.

with the peak value after DEG poisoning: (1) the patients' blood urea nitrogen (BUN), creatinine (Cr), and phosphate (P) concentrations increased significantly after DEG poisoning, while serum CO<sub>2</sub> concentration dropped significantly, but serum calcium had no remarkable change; (2) DEG did not cause aggravation of liver function, while serum total bilirubin level, GGT, ALP and prothrombin time did not change significantly; (3) the peripheral blood cell counts increased significantly after DEG poisoning, while the red blood cell counts and hemoglobin value dropped significantly, but platelet counts did not change obviously (Table 3).

**Pathological changes in renal tissue from patients with DEG poisoning**

Renal tissues were taken from two patients with DEG poisoning on the third and forth days after ARF, respectively. Biopsies of renal tissue indicated significant tubular pathological changes, partial dissolution and necrosis of epithelial cells, and interstitial inflammatory cell infiltration (Figure 1). No pathological changes in the glomerular basement membrane of these patients were observed.

**DISCUSSION**

In 1937, the Massengill Company (USA) developed an “elixir of sulfanilamide”, a preparation of 9-10 g of sulfanilamide dissolved in 100 mL of DEG. Other cases of DEG poisoning have been largely associated with foul play or deliberate consumption of alcoholic mixtures containing DEG<sup>[3-10,13]</sup>. In this study, injection of armillarisin-A produced by the Qiqihar No. 2 Pharmaceutical Co. Ltd. resulted in events similar to those described previously in response to DEG poisoning. Sixty-four patients with severe liver disease received venous armillarisin-A injections containing high concentrations of DEG (325.9 mg/mL and 30% concentration as reported by the Heilongjiang Province Drug Inspection Center and the Guangdong Province Drug Inspection Center, respectively). Fifteen patients were diagnosed with DEG poisoning. The rate of poisoning was 23.4%.

Liver impairment was more severe in the DEG-poisoned group than in the non-DEG-poisoned group. Metabolism of DEG involves the actions of alcohol dehydrogenase and aldehyde dehydrogenase<sup>[1]</sup>. Alcohol dehydrogenase ordinarily converts DEG to an aldehyde and aldehyde dehydrogenase ordinarily converts this

aldehyde to certain acids. As alcohol dehydrogenase and aldehyde dehydrogenase are mainly restricted to the liver, loss of these enzymes as a consequence of severe liver disease may significantly impair DEG metabolism. Furthermore, secondary infection is a common complication in patients with terminal liver disease. Peritonitis caused by Gram-negative bacilli and hepatobiliary infection are the most prevalent complications. Data also indicate that the pre-injection rate of neutral granular cells in the poisoned group was significantly higher than that in the non-poisoned group. Infection-induced endotoxemia increases alcohol dehydrogenase activity<sup>[14]</sup>, and accumulation of the aldehyde intermediate can provoke DEG poisoning. Concurrently, serious liver diseases often produce massive ascites requiring diuretic therapy. Resultant renal hemodynamic changes occurring in response to such therapy may inevitably lead to exacerbation of renal damage. Therefore, lower dosages and concentrations of DEG can provoke poisoning *via* the intravenous route in patients with severe liver disease as compared to the oral route in patients without severe liver disease.

In the present study, the poisoned patients had a significantly higher incidence of renal disease and significantly higher serum BUN and Cr concentrations than the non-poisoned patients, suggesting that patients with renal disease are more susceptible to DEG poisoning than those without renal disease.

Currently available information about DEG indicates that this glycol induces acute poisoning, but no chronic poisoning. This apparent discrepancy can be explained by the short half-life of DEG (approximately 3 h)<sup>[15]</sup>. DEG poisoning was previously considered similar to ethylene glycol poisoning, which is associated with renal impairment attributable to renal accumulation of calcium ions and to the final product, oxalic acid, with resultant accumulation of calcium oxalates. Recent findings show that the final product of DEG metabolism is a 2-hydroxy-ethoxyacetic acid rather than an oxalic acid. DEG-induced pathological changes and necrosis of tubular epithelial cells are attributable to a metabolic intermediate that poisons tubular epithelial cells rather than to deposition of calcium oxalates<sup>[16-19]</sup>. Renal impairment is observed at early stages of poisoning and is prominent in all cases of poisoning, as was observed in the present study.

The clinical characteristics of patients poisoned by intravenous DEG were similar to those of patients poisoned following oral ingestion of DEG in the present study. It was reported that renal impairment occurs at early times following ingestion, with metabolic acidosis and delayed neurological impairment mainly involving the cranial and peripheral nerves commonly observed<sup>[20-24]</sup>. Poisoning *via* the intravenous route differs notably from poisoning *via* the oral route in that exhibition of mild fever and an increase in severity of digestive tract symptoms before occurrence of renal failure, along with a later occurrence of organ impairment, is specific for intravenous poisoning. This finding may be attributable to the age of patients in the present study and to their preexisting severe liver disease which could have limited

the actions of alcohol and aldehyde dehydrogenases. Prospective research is warranted for further clarification. Due to the scarcity of DEG poisoning survivors, it is difficult to evaluate the process of systematic recovery. While previous reports indicate that recovery of the nervous system after oral DEG poisoning requires 4-6 mo<sup>[25]</sup>, the present findings disclose that nervous system recovery occurs 1 mo following intravenous poisoning.

In the present study, 80% mortality was observed in the poisoned patients. Seven died of MODS, 4 died of severe infection, and 1 died of severe digestive tract bleeding. The lethal dose of DEG varies with species<sup>[26]</sup>. It was reported that DEG at a cumulative dosage of 0.22-4 mL/kg with a concentration of 17.5%-72% in humans can lead to death<sup>[6,7]</sup>. The DEG concentration in the present study ranged from 3% to 6%, with a cumulative dosage volume of 9-72 mL, but no statistical differences in these values were observed between the poisoned and non-poisoned groups, indicating that the severity of preexisting liver disease leading to loss of alcohol and aldehyde dehydrogenase activities constitutes a primary important predisposing factor for poisoning.

In the present study, the patients with DEG poisoning had higher serum calcium values and lower serum IP values than the non-poisoned patients, the serum IP concentrations were significantly increased after intravenous DEG poisoning. The importance of calcium and phosphates in DEG poisoning remains to be determined.

Although the DEG-poisoned patients described in the present study presented with concomitant severe liver diseases, no exacerbating degenerative features of general liver function (no changes in bilirubin, aldehyde dehydrogenase, albumin, and hemostatic function) were found. Furthermore, no significant increase in gamma-glutamyl transpeptidase or alkaline phosphatase was noted, indicating that venous injections of DEG do not directly affect the hepatobiliary system and drug-induced liver damage is absent. These observations may be attributable to the fact that, in contrast to oral ingestion of DEG<sup>[27]</sup>, venous injection of this glycol does not participate in liver metabolism.

Additional analyses indicated that DEG-poisoned patients might present with anemia characterized by decreased red blood cells and hemoglobin. A similar form of anemia was observed in ethylene glycol poisoning. The DEG-poisoned patients described in the present study also presented with an increase in white blood cell count, with a significant increase in neutral granular cells but no remarkable changes in eosinophils. This phenomenon can be attributed to an increase in the severity of infection in patients with severe liver disease and is indicative of acute renal failure as a result of DEG poisoning rather than allergen induction.

Renal biopsy findings revealed that DEG induced tubular epithelial cell dissolution and necrosis and renal interstitial inflammatory cell infiltration, but no pathological changes in the glomerulus. These alterations differ from those associated with the hepatorenal complications and glomerulonephritis induced by severe

liver disease and are therefore important in differential diagnosis.

In conclusion, venous diethylene glycol poisoning is characterized by oliguric acute renal failure, metabolic acidosis, digestive symptoms, nervous system impairment, and a high probability of anemia and WBC proliferation. Mortality is high, and correlative factors include preexisting severe liver disease, renal disease, and infection.

## COMMENTS

### Background

Diethylene glycol (DEG) is a chemical substance used primarily for industrial purposes. DEG induces kidney toxicity presenting as acute renal failure (ARF) and has been used as a chemical substance for industrial purposes in many countries since 1937. In 2006, 64 patients with severe liver disease received venous armillarisin-A injections containing high concentrations of DEG, and 15 were diagnosed with DEG poisoning in Guangzhou, China. In the present report, the clinical presentation of venous diethylene glycol poisoning and the pathological characteristics of renal tissue from poisoned patients were described and factors that correlate with this form of poisoning were identified.

### Research frontiers

All the clinical researches about DEG poisoning based on events of herbal toxicity, have been limited in oral DEG intake and normal persons.

### Innovations and breakthroughs

The investigation described in the present report was characterized by the following features: (1) all subjects were adults who received armillarisin-A with DEG intravenously, (2) clinical presentation was recorded before and after DEG poisoning and the exact injection volumes and DEG concentrations in the preparations were recorded, (3) the majority of patients presented with concurrent severe liver diseases.

### Applications

This work may help to know the clinical presentation of venous diethylene glycol (DEG) poisoning in patients with preexisting severe liver disease and factors that correlate with this form of poisoning.

### Peer review

This is a nice report on an outbreak of IV DEG poisoning. Authors analyzed the features of venous DEG poisoning and serious consequences to remind government of paying attentions to drug safety and supervising.

in the gastric mucosa of animals subjected to ethanol treatment for 7 days was significant increased (increased to 290% for PCNA density  $P < 0.05$ , increased to 150 for Cyclin D1 density  $P < 0.05$  and  $21.6 \pm 0.8$  vs  $42.3 \pm 0.7$  for PCNA positive cells per view field), accompanied by an increase in ROS generation ( $1.298 \pm 0.135 \mu\text{mol}$  vs  $1.772 \pm 0.078 \mu\text{mol}$  for TBARS  $P < 0.05$ ;  $4.36 \pm 0.39 \text{ mmol}$  vs  $7.48 \pm 0.40 \text{ mmol}$  for carbonyl contents  $P < 0.05$ ) and decrease in NO generation ( $11.334 \pm 0.467 \mu\text{mol}$  vs  $7.978 \pm 0.334 \mu\text{mol}$   $P < 0.01$  for NOx;  $8.986 \pm 1.351 \mu\text{mol}$  vs  $6.854 \pm 0.460 \mu\text{mol}$  for nitrotyrosine  $P < 0.01$ ) and nNOS activity (decreased to 43%  $P < 0.05$ ). This function was abolished by the co-administration of quercetin.

**CONCLUSION:** The antioxidant action of quercetin relies, in part, on its ability to stimulate nNOS and enhance production of NO that would interact with endogenously produced reactive oxygen to inhibit hyper-proliferation of gastric mucosal cells in rats treated with chronic oral ethanol.

### Abstract

**AIM:** To investigate the effect of quercetin (3,3',4',5,7-pentahydroxy flavone), a major flavonoid in human diet, on hyper-proliferation of gastric mucosal cells in rats treated with chronic oral ethanol.

**METHODS:** Forty male Sprague-Dawley rats, weighing 200-250 g, were randomly divided into control group (tap water *ad libitum*), ethanol treatment group (6 mL/L ethanol), quercetin treatment group (intragastric gavage with 100 mg/kg of quercetin per day), and ethanol plus quercetin treatment group (quercetin and 6 mL/L ethanol). Expression levels of proliferating cell nuclear antigen (PCNA) and Cyclin D1 were detected by Western blot to assay gastric mucosal cell proliferation in rats. To demonstrate the influence of quercetin on the production of extra-cellular reactive oxygen species/nitrogen species (ROS/RNS) in rats, changes in levels of thiobarbituric acid reactive substance (TBARS), protein carbonyl, nitrite and nitrate (NOx) and nitrotyrosine (NT) were determined. The activity of inducible nitric oxide synthase (NOS) including iNOS and nNOS was also detected by Western blot.

**RESULTS:** Compared to control animals, cell proliferation

### INTRODUCTION

Chronic ethanol consumption is a major risk factor for oropharyngeal, esophageal, and rectal cancer<sup>[1]</sup>. Chronic ethanol consumption resulting in gastric mucosal lesions might thus be expected to influence the kinetic balance between cell proliferation and cell death. Because hyper-

regenerative gastrointestinal mucosa has an increased susceptibility to chemical carcinogens and thus influences carcinogenesis. Various studies have been performed to evaluate the effect of chronic ethanol consumption on gastric mucosal cell turnover<sup>[2,3]</sup>. However, the role of ethanol in the altered cell proliferation in rat stomach remains poorly understood. There is evidence that alcohol is involved in gastric mucosa oxidant injury as studies showed that ethanol-induced damage can be prevented if antioxidant treatment or therapy is given concurrently or prior to alcohol exposure<sup>[4-6]</sup>. Previous studies in our laboratory found that cell proliferation is enhanced in gastric mucosa of rats treated with ethanol in a dose- and time-dependent manner<sup>[7]</sup>. These findings indicate that ethanol-associated gastric cell proliferation may involve oxidative stress<sup>[8]</sup>.

Oxidative stress occurs when there is a significant imbalance between generation of reactive oxygen species (ROS) and nitrogen species (RNS) and its clearance by antioxidant defenses<sup>[9]</sup>. 3, 3', 4', 5, 7-pentahydroxy flavone (quercetin) is a potent bioflavonoid widely distributed throughout vegetables and fruits. It was reported that quercetin has many beneficial effects on human health, including cardiovascular protection, anticancer activity, anti-ulcer effects, anti-allergy activity, cataract prevention, antiviral activity and anti-inflammatory effects<sup>[10,11]</sup>. These effects of quercetin due to its antioxidant properties of potent anti-oxidant, scavenge free radicals directly<sup>[12]</sup>, inhibit xanthine oxidase and lipid peroxidation<sup>[13,14]</sup>, and alter the anti-oxidant defense pathway *in vivo* and *in vitro*<sup>[15]</sup>. It was recently reported that quercetin inhibits oxidative damage in ethanol-induced gastric lesions of rats<sup>[16]</sup>.

In light of these findings, we hypothesized that quercetin has an effect on gastric mucosa cell proliferation in rats that chronically administer ethanol involving inhibition of the ROS-nitric oxide (ROS-NO) pathway. To establish the potential antiproliferative mechanism of quercetin, we detected the expression levels of proliferating cell nuclear antigen (PCNA) and Cyclin D1, which are significantly associated with gastric mucosal cell proliferation in rats. To demonstrate the influence of quercetin on the production of extra-cellular ROS/RNS, changes in thiobarbituric acid reactive substance levels (TBARS) as an index of lipid peroxidation, protein carbonyl content as a marker of free radical-mediated modification of proteins, nitrite and nitrate (NOx) and nitrotyrosine (NT) levels as the marker of NO production, were also determined.

## MATERIALS AND METHODS

### Animals and treatment protocol

Male Sprague-Dawley rats, weighing 200-250 g, were used in this study. Twenty-four rats were housed in plastic cages in an air-conditioned and light controlled room at  $24 \pm 2^\circ\text{C}$  and  $60\% \pm 5\%$  humidity. The study protocol was approved by the Nanjing Medical University Animal Care and Use Committee. After a 3 d adaptation period, the rats were randomly divided into

four groups (6 in each group). Group 1 had free access to tap water, group 2 had drinking water containing 6 mL/L ethanol as previously described<sup>[7]</sup>, group 3 was given 50 mg/kg quercetin (Sigma, St Louis, MO, USA) by intragastric gavage twice a day, group 4 was given 50 mg/kg quercetin by intragastric gavage twice a day and 6 mL/L ethanol. Quercetin was dissolved using DMSO as the vehicle and diluted in PBS to 2 mL, with the maximum concentration of DMSO being 0.1%. As controls, animals in groups 1 and 2 were also treated with 2 mL 0.1% DMSO, twice a day. The time and doses of ethanol and quercetin treatment were determined on the basis of results from our preliminary experiment. The mean ethanol consumption was 6.52 g/kg body weight per day, the mean plasma ethanol concentration at the time of stomach excision was 18.47 mmol/L in animals of groups 3 and 4. The rats were anesthetized with urethane and sacrificed after 7 d. Their stomachs were dissected and used for this study.

### Cell proliferation assay

Nuclear extracts from gastric mucosa were prepared using a nuclear extract kit (Active Motif Japan, Japan) following the instructions of its manufacturer. PCNA and Cyclin D1 detected by Western blot were applied to determination of gastric mucosal cell proliferation in rats.

### Lipid peroxidation

To evaluate the extent of lipid peroxidation, the amount of thiobarbituric acid reactive substances (TBARS) in gastric tissue, a measurement of the extent of lipid peroxidation, was detected with the modified thiobarbituric acid (TBA) method<sup>[17,18]</sup>. Each sample was homogenized in a 1.15% KCl solution containing 10 mmol/L deferoxamine, 0.04% butylated hydroxytoluene (BHT), and 2% ethanol. Each homogenate was incubated for 60 min at  $95^\circ\text{C}$  in an oil bath with a stock TCA-TBA-HCl reagent consisting of 15% (w/v) trichloroacetic acid, 0.375% (w/v) thiobarbituric acid, 0.25 mol/L hydrochloric acid and 2% BHT. After cooling, the precipitate was removed by centrifugation, and the extinction coefficient of the supernatant at 535 nm was determined spectrophotometrically and compared with a known TBARS standard.

### Protein oxidation

Protein carbonyls in gastric tissues were determined by spectrometric DNPH assay according to Fagan *et al* with minor modifications<sup>[19]</sup>. Briefly, gastric tissues were homogenized by sonication in a lysis buffer containing PBS (pH 7.2), 1% Triton X-100, 1 mmol/L EDTA and 1X protease inhibitor cocktail and removal of insoluble cellular debris was performed by centrifugation. Aliquots in protein samples were precipitated with 10 volumes of HCl-acetone (3:100) and washed with 5 mL of 10% TCA solution. Pellets were re-suspended in 500  $\mu\text{L}$  buffer solution and reacted with 500  $\mu\text{L}$  of 10 mmol/L DNPH (in 2 mol/L HCl) by vortexing for 15 min. To remove the un-reacted DNPH, the centrifuged pellets were washed with 5 mL of 20% TCA and 5 mL of ethanol: ethylacetate mixture (v/v = 1:1). The

final precipitate was resolved in 1 mL of 6 mol/L guanidine HCl, and the absorbance at 380 nm was determined for the sample treated with DNPH and HCl, which was subtracted as a background and compared with a known protein carbonyl standard.

#### **Nitric oxide (NO) assay**

The amount of stable nitrite (nitrite and nitrate), the end product of NO in gastric mucosa, was determined by colorimetric assay as described previously<sup>[20]</sup>. Briefly, 50  $\mu$ L of gastric mucosa homogenate was mixed with an equal volume of Griess reagent consisting of 1% sulfanilamide, 0.1% naphthyl ethylenediamine dihydrochloride and 2.5%  $\text{H}_3\text{PO}_4$ , and incubated at room temperature for 10 min. The absorbance was read at 540 nm on a microplate reader (Elx800, Bio-TEK Ins, USA). The amount of nitrite was calculated from a  $\text{NaNO}_2$  standard curve.

#### **Measurement of nitrotyrosine (NT) levels**

Gastric mucosa was homogenized on ice in the prepared solution (20 mmol/L Tris-HCl containing 1% NP-40, 100 mmol/L NaF, 137 mmol/L NaCl, 5 mmol/L EDTA, 0.1 mol/L PMSF, 1% proteinase inhibitor, and 10% glycerol, pH 7.5) for 30 min at 4°C. The homogenate was centrifuged at 12000 r/min for 20 min to remove cellular debris. Protein concentration was determined using a BCA protein assay reagent kit.

Nitrotyrosine levels were quantified as previously described<sup>[21]</sup>. In short, assay was performed in 96-well plates coated with 5 mg/L of nitrotyrosine-BTG conjugate, which was blocked with gelatin to prevent non-specific binding. A standard curve was plotted by incubating serial dilutions of NT with biotin labeled anti-nitrotyrosine Fab' in PBS containing 0.1% gelatin for 1 h. Subsequently, plates were incubated with a streptavidin peroxidase conjugate followed by o-phenylenediamine (OPD). The reaction was terminated after 20-30 min by addition of 4 mol/L  $\text{H}_2\text{SO}_4$ . Data on the standard curve were fitted to a logistic plot and the levels of NT were measured. All samples and standards were assayed in triplicate.

Anti-nitrotyrosine monoclonal antibody used in ELISA was a kind gift from Dr. Yang TB (Institute of Space Medico-Engineering, Beijing, China). The study of cross-reaction with nitrotyrosine-like compounds showed that the antibodies have a high specificity for NT<sup>[21]</sup>.

#### **Measurement of neuronal and inducible NO synthase (nNOS and iNOS) levels**

The stomach was homogenized on ice in a buffer containing 50 mmol/L Tris-Cl, 150 mmol/L NaCl, 0.02%  $\text{NaN}_2$ , 100 mg/L phenylmethanesulfonyl fluoride, 1 mg/L aprotinin, and 1% Triton X-100. Lysates were centrifuged at 12000 r/min for 25 min at 4°C. The supernatant was used for nNOS and inducible NOS (iNOS) determined by Western blot analysis.

#### **Western blot analysis**

Proteins were detected by the Bradford method using

bovine serum albumin as a standard. An equal amount of 40  $\mu$ g protein from each sample was run per lane on 10% sodium dodecyl sulphate polyacrylamide gel electrophoresis (SDS-PAGE) and electroblotted to nitrocellulose membranes. The membranes were blocked by overnight incubation in 5% dry milk at 4°C, and thereafter incubated with primary antibodies (1:200-1000 dilution) for 3 h at room temperature. Each blot was probed with monoclonal anti-PCNA, anti-Cyclin D1 (Santa Cruz Biotech, USA), polyclonal anti- $\beta$ -actin (Upstate, USA), anti-nNOS, and anti-iNOS (Santa Cruz Biotech, USA). The membranes were washed and incubated with horseradish peroxidase-conjugated goat anti-mouse or anti-rabbit IgG (1:2000 dilution) (Upstate, USA) for 1 h. Immune complexes were visualized with an ECL kit (Pierce; Rockford, IL, USA) according to the manufacturer's protocol. Signal intensity was quantified using a Bio-Rad image analysis system and the results were normalized to the signal intensity of  $\beta$ -actin for each blot.

#### **Immunohistochemical analysis**

Stomachs were excised from three rats in each group and fixed in 10% neutral buffered formalin, embedded in paraffin and sectioned at 5  $\mu$ m for immunohistochemical staining. Staining was performed according to the routine standard procedures. Briefly, the sections were deparaffinized in xylene, cleared in graded ethanol to PBS, then quenched in 3% hydrogen peroxide ( $\text{H}_2\text{O}_2$ ) containing 0.1% sodium azide to suppress the endogenous peroxidase activity and placed in 10 mmol/L citrate buffer (pH 6.0) for 15 min at 100°C for antigen retrieval. A routine streptavidin-biotin protocol using the DAKO LSAB + kits (Dako Japan, Kyoto, Japan) was applied. The tissue sections mounted on glass slides were incubated in PBS containing 0.5% BSA to reduce nonspecific protein binding, and sequentially incubated to react with monoclonal anti-PCNA primary antibody overnight at 4°C. The antibody was then linked with streptavidin conjugated to horseradish peroxidase (HRP). HRP sites were visualized with 3,3'-diaminobenzidine (DAB) and  $\text{H}_2\text{O}_2$ , counterstained with hematoxylin. The presence of PCNA was detected by light field microscopy as a dark brown reaction product in cell nuclei. Some sections were reacted with normal mouse IgG instead of the specific antibody as a negative control. An image analysis system (NYD100) was used for quantitative analysis of cell density (cell number/view field) of the PCNA-positive cells in the rat stomach. Four sections from four rats were used. PCNA-positive cells per section were counted in five randomly selected view fields at a magnification of  $\times 400$ . At least, 20 fields in each group were analyzed.

#### **Statistical analysis**

All experiments were done in triplicate and stomach tissues were excised from three rats in each group. One-way analysis of variance was used to estimate the overall significance followed by *post hoc* Tukey's test corrected for multiple comparisons. Data are presented as mean  $\pm$  SD.  $P < 0.05$  was considered statistically significant.

## RESULTS

### **Quercetin treatment could partially prevent ethanol-induced cell proliferation in gastric mucosa**

PCNA is a polypeptide that specifically increases in nuclei during G1 and S phases of the cell cycle. It is considered to be an essential cofactor for the activation of DNA polymerase during DNA replication. Therefore, PCNA-positive nuclei indicate that cells replicate DNA and undergo proliferation. It is well known that Cyclin D1 promotes G1 phase progression. The levels of PCNA and Cyclin D1 were higher in gastric mucosa exposed to 6% ethanol for 7 d than in normal control rats, while the expression of PCNA and Cyclin D1 was reduced after treatment with quercetin in this study (Figure 1). PCNA immunohistochemistry and computer image analysis showed, a significantly increased number of PCNA positive cells in the fundic gland of rats treated with ethanol for 7 d. The number of PCNA positive cells in ethanol + quercetin and quercetin treated rats was very analogous to that in the control rats (Figure 2, Table 1).

### **Quercetin treatment could prevent ethanol-induced lipid peroxidation and protein oxidation in gastric mucosa**

As TBARS shown in Figure 3, ethanol-induced ROS may increase lipid peroxidation. Quantitative measurement of TBARS in gastric mucosa revealed a significant effect of ethanol treatment on ethanol-induced lipid peroxidation and protein oxidation in gastric mucosa ( $1.772 \mu\text{mol/g protein}$ ) compared to the normal control rats ( $1.298 \mu\text{mol/g protein}$ ), which was reduced to  $1.500 \mu\text{mol/g protein}$  ( $P < 0.05$ ). TBARS was slightly decreased in the rats treated with quercetin (Figure 3A), suggesting that quercetin can decrease lipid peroxidation in gastric mucosa. The mean values of carbonyl contents in gastric tissue are shown in Figure 3B, revealing a similar pattern of TBARS in each group of rats.

### **Quercetin treatment could prevent ethanol-induced decrease in nitrite/nitrate content in gastric mucosa**

The nitrite/nitrate content in gastric mucosa was determined using the Griess method. As shown in Table 1, the nitrite/nitrate content in the group treated with 6% ethanol for 7 d was significantly lower than that in the control group ( $P < 0.01$ ) and significantly higher in rats treated with combined ethanol and quercetin than that in rats treated with ethanol only ( $P < 0.01$ ). The gastric nNOS level was slightly increased in rats treated with quercetin, suggesting that quercetin treatment can prevent ethanol-induced decrease of nitrite/nitrate content in rat gastric mucosa.

### **Quercetin treatment could prevent ethanol-induced decrease in nNOS levels**

NO produced by nNOS was detected by Western blot in gastric mucosa (Figure 4). Quantitative analysis revealed a significant effect of ethanol treatment on ethanol-induced decrease in nNOS levels. The gastric nNOS level

**Figure 1** Immunoblotting of nuclear extracts from gastric mucosa with antibodies to PCNA and Cyclin D1 in the 4 groups as indicated in lanes 1-4 (A) and values normalized by arbitrarily setting the densitometry of control to 1.0 (B).  $\beta$ -actin staining was performed to ensure an equal loading. The results indicated are in percentage above the control value and are representative of four independent experiments.  $^aP < 0.05$  vs control animals,  $^cP < 0.05$  vs ethanol-treated animals.

in rats treated with combined ethanol and quercetin was significantly higher than that in rats treated with ethanol only. The gastric nNOS level was slightly increased in rats treated with quercetin, suggesting that quercetin can prevent ethanol-induced decrease in nNOS, which is in agreement with the data on nitrite/nitrate (Table 1) in rat gastric mucosa. No iNOS expression was detected in each group.

### **Quercetin treatment could prevent ethanol-induced decrease in protein-bound 3-NT**

Ultimately, increased NO, nitrite/nitrate, and peroxynitrite resulted in production of protein-bound 3-NT in gastric mucosa (Table 1). Quantitative analysis revealed a significant effect of ethanol on ethanol-induced decrease in protein-bound 3-NT. Gastric 3-NT levels in rats treated with combined ethanol and quercetin were significantly higher than those in rats treated with ethanol only. The level of 3-NT was slightly increased in rats not treated with ethanol, suggesting that quercetin treatment can prevent ethanol-induced decrease in 3-NT, which is in agreement with the data on nitrite/nitrate (Table 1) and nNOS level in rat gastric mucosa (Figure 4).

**Figure 2** Staining of PCNA from rats in the 4 groups, respectively (A-D). Stem cells at the neck position were positively stained, while other cells were negatively stained. A significantly increased number of PCNA positive cells were observed in the fundic gland of rats treated with ethanol for 7 d. **A:** Control; **B:** Ethanol; **C:** Ethanol + Quercetin; **D:** Quercetin.

## DISCUSSION

ROS, such as superoxide anion radical ( $O_2^{\cdot-}$ ), hydroxyl radical ( $OH^{\cdot}$ ), lipid peroxidation and nitric oxide (NO), are involved both in the regulation of cell proliferation and apoptosis and in macromolecular damage to gastric cells, leading to increased oxidative stress and stress-induced senescence<sup>[22,23]</sup>. ROS are oxygen-containing

**Figure 4** Immunoblotting of gastric homogenate with the antibody to nNOS in different treatment groups as indicated in lanes 1-4 (A) and values normalized by arbitrarily setting the densitometry of actin (B). The results indicated are in percentage above the control value and are representative of the four independent experiments. <sup>a</sup>*P* < 0.05 vs control animals, <sup>c</sup>*P* < 0.05 vs ethanol-treated animals.

molecules having either unpaired electrons or ability to abstract electrons from other molecules. Lipids are modified by ROS and visualized as a thiobarbituric acid-reactive substance (TBARS). Oxidative damage to proteins generates increased carbonyl groups due to oxidation of sensitive amino acids, such as histidine, proline, arginine and lysine<sup>[24]</sup>. We measured the TBARS and protein carbonyls to serve as an indicator for intracellular oxidation in gastric mucosa. NO formation in cells is rapidly converted to nitrite. After reducing nitrate to nitrite with bacterial nitrate reductase, nitrite levels can be determined as an indicator for NO synthesis based on the Griess reaction<sup>[20]</sup>.  $O_2^{\cdot-}$  reacts with NO to produce peroxynitrite ( $ONOO^{\cdot}$ ), which is considered a more powerful oxidant than  $O_2^{\cdot-}$ <sup>[25]</sup>, entering the cells rapidly. A variety of nitrate macromolecules are chiefly at the aromatic rings<sup>[26]</sup>. The nitration of tyrosyl residues on proteins is considered the stable “foot print” of RNS stress both *in vitro* and *in vivo*<sup>[27]</sup>. In this study, we also measured the levels of  $NO_x$  and 3-NT to provide an index of NO in gastric mucosa. Using these indicators, the effect of quercetin on chronic ethanol-induced generation of ROS and NO was detected.

The present study demonstrated a clear enhancement of cell proliferation in gastric mucosa of animals subjected to ethanol treatment for 7 d, which is similar to that in our previous studies<sup>[7]</sup>. Since PCNA and Cyclin D1 were strongly up-regulated (Figure 1), and the number of PCNA positive cells was increased in gastric mucosa (Figure 2 and Table 1). This enhancement function was accompanied with an increase in ROS generation and abolished by co-administration of quercetin and ethanol, which was accompanied with a decrease in ROS level. Quercetin has the ability to directly block the cell cycle at the G1/S transition in colon and gastric cancer cells<sup>[28]</sup> as well as in human leukemic T cells<sup>[29]</sup>. However, the protein levels of PCNA and Cyclin D1 were similar to the control values irrespective of quercetin administration alone in our study. These results show that an excessive amount of ROS can induce enhanced cell proliferation in gastric mucosa of rats *in vivo*.

In addition to ROS, RNS in the form of NO has also been implicated in regulation of cellular proliferation, but its role as a proliferative signal is not well defined, because it appears to depend on the cell type responsible for its release and the NOS isoforms within cells, as well as on the concentration of released NO and the composition of intracellular milieu<sup>[30,31]</sup>. The neuronal and endothelial isoforms are thought to be responsible for production of low levels of NO<sup>[32]</sup> and both isoforms have been identified in gastric mucosa<sup>[33,34]</sup>. NO is a lipophilic radical, which can exert beneficial effects by reacting with O<sub>2</sub> when produced in a small amount and, in this manner, behaves as an antioxidant. A low level of NO could protect against ROS and inhibit gastric cancer cell proliferation<sup>[23]</sup>. NO donors retard gastric wound healing by inhibiting cell migration and proliferation and inducing cell apoptosis in a dose- and time-dependent manner<sup>[35]</sup>. However, excess NO produced by inducible NOS (iNOS) plays a potent role as a cytotoxic agent during infection and inflammation, with essential involvement of chronic inflammation, especially increased rates of cell proliferation, in *H pylori*-associated glandular stomach carcinogenesis<sup>[36]</sup>. Suppression of NO generation by iNOS inhibitors (aminoguanidine, AG) could also suppress cancer cell proliferation in gastric cancer xenografts<sup>[37]</sup>.

In the present study, iNOS expression was not detectable in gastric mucosa. After treatment with 6% ethanol for 7 d, the expression of nNOS and the levels of NOx (nitrite/nitrate) and NT in gastric homogenates were decreased, suggesting that the nNOS activity is decreased. These results are consistent with the reported data<sup>[38]</sup>. Surprisingly, the decreased nNOS activity could be abolished by co-administration of quercetin and ethanol. Without further examination, we cannot rule out the mechanism of quercetin-enhanced activity of nNOS. It was reported that resveratrol, another kind of flavonoids, can inhibit gastric cancer cell proliferation by stimulating the activity of NOS *in vitro*<sup>[23]</sup>, suggesting that quercetin may play a role as resveratrol in the inhibition of gastric cell proliferation *in vivo*.

In conclusion, our findings indicate that the antioxi-

dant action of quercetin resides depends in part, on its ability to stimulate nNOS and increase production of NO that would interact with endogenously produced reactive oxygen to inhibit hyper-proliferation of gastric mucosal cells in rats that have chronic ethanol consumption.

## COMMENTS

### Background

Chronic ethanol consumption resulting in hyper-regenerative gastrointestinal mucosa has an increased susceptibility to chemical carcinogens and thus influences carcinogenesis. Some studies indicate that ethanol-associated gastric cell proliferation may involve oxidative stress. It was reported that quercetin, a 3,3',4',5,7-pentahydroxy flavone, has effects on oxidative damage to ethanol-induced gastric lesions due to its antioxidant properties of potent anti-oxidant. We hypothesized that quercetin has an effect on gastric mucosal cell proliferation in rats that have chronic ethanol consumption, thus inhibiting gastric cancer.

### Research frontiers

In this study, we developed an animal model by continuous ethanol ingestion for 7 d. By using this model, we investigated the relationship between chronic ethanol intake and gastric mucosal cell proliferation, which is related to reactive oxygen species (ROS) and reactive nitrogen species (RNS).

### Innovations and breakthroughs

Our findings indicate that the antioxidant action of quercetin resides, depends in part, on its ability to stimulate nNOS and increase production of NO that would interact with endogenously produced reactive oxygen to inhibit gastric mucosal cell proliferation in rats that have chronic ethanol consumption.

### Applications

This animal model established by continuous ethanol ingestion for 7 d is a useful tool for studying the mechanism of gastric mucosal cell proliferation *in vivo*. We will investigate the signal transduction of ROS in gastric mucosal cell proliferation.

### Terminology

ROS are oxygen-containing molecules having either unpaired electrons or ability to abstract electrons from other molecules. Reactive RNS are forms of NO.

### Peer review

This is an interesting paper, in which the authors showed that ethanol could induce gastric mucosal cell proliferation in their animal model. The ROS/RNS pathway may be involved. Further study is needed to show signal transduction of ROS in gastric mucosal cell proliferation.

## Abstract

**AIM:** To observe the effect of proteasome inhibitor MG-132 on severe acute pancreatitis (SAP) and associated lung injury of rats.

**METHODS:** Male adult SD rats were randomly divided into SAP group, sham-operation group, and MG-132 treatment group. A model of SAP was established by injection of 5% sodium taurocholate into the biliary-pancreatic duct of rats. The MG-132 group was pretreated with 10 mg/kg MG-132 intraperitoneally (ip) 30 min before the induction of pancreatitis. The changes in serum amylase, myeloperoxidase (MPO) activity of pancreatic and pulmonary tissue were measured. The TNF- $\alpha$  level in pancreatic cytosolic fractions was assayed with an enzyme-linked immunosorbent assay (ELISA) kit. Meanwhile, the pathological changes in both pancreatic and pulmonary tissues were also observed.

**RESULTS:** MG-132 significantly decreased serum amylase, pancreatic weight/body ratio, pancreatic TNF- $\alpha$  level, pancreatic and pulmonary MPO activity ( $P < 0.05$ ). Histopathological examinations revealed that pancreatic and pulmonary samples from rats pretreated with MG-132 demonstrated milder edema, cellular damage, and inflammatory activity ( $P < 0.05$ ).

**CONCLUSION:** The proteasome inhibitor MG-132 shows a protective effect on severe acute pancreatitis and associated lung injury of rats.

## INTRODUCTION

Acute pancreatitis (AP) is a common clinical disease and its incidence has been increasing in recent years. Although most patients experience mild and self-limited AP, some patients have severe acute pancreatitis (SAP)<sup>[1-3]</sup>. Abnormal activation of digestive enzymes within pancreatic acinar cells is thought to be a critical initiating event<sup>[4]</sup>. Pancreatic injury leads to a localized and a subsequent systemic inflammatory response which determines the severity of pancreatitis. It may lead to the development of multiple organ dysfunction syndrome (MODS), which is responsible for the mortality rate associated with this disease. The major component of MODS is lung injury, clinically manifested as acute respiratory distress syndrome<sup>[5]</sup>. So how to ameliorate the injury of pancreatic acinar cells and downstream events is the way to influence the severity of pancreatitis.

MG-132 (Z-Leu-Leu-Leu-aldehyde) is a member of the peptide aldehyde proteasome inhibitors, including calpains, cathepsins and the proteasome<sup>[6,7]</sup>. Both calpain I and proteasome can degrade I $\kappa$ B and enhance the activity of NF- $\kappa$ B<sup>[8]</sup>. Cathepsins, especially cathepsin B, has been confirmed to be a key agent for the abnormal activation of digest enzymes within pancreatic acinar cells<sup>[9]</sup>. MG-132 can also inhibit the activation of NF- $\kappa$ B by blocking I $\kappa$ B degradation and enhance the expression of heat shock proteins (HSP) that suppress the inflammatory response<sup>[10]</sup>. In the present study, we used a model of severe acute pancreatitis (SAP) established

by retrograde injection of 5% sodium taurocholate (1 mL/kg) into the pancreatic duct to observe the effect of the proteasome inhibitor MG-132 on severe acute pancreatitis and associated lung injury of rats.

## MATERIALS AND METHODS

### *Animals and materials*

Male Sprague-Dawley rats, weighing 250-300 g, were obtained from Experimental Animals Center of Medical College of Xi'an Jiaotong University. The animals were fasted overnight with free access to water and standard rat chow diet before the experiment. Five percent sodium taurocholate was purchased from Sigma, USA. MG-132 was purchased from Calbiochem, Germany. TNF- $\alpha$  ELISA kit was obtained from Genzyme, USA. Serum amylase kit and MPO kit were purchased from Nanjing Jiancheng Company, China.

### *Induction of acute pancreatitis*

The rats were randomly divided into control group, SAP group and MG-132 treatment group (SAP + MG-132), 10 in each group. The animals were anesthetized with ketamine and subjected to a midline laparotomy. A blunt needle was inserted transduodenally into the common biliary-pancreatic duct as previously described<sup>[11]</sup>. The hepatic duct was closed at the hilum of the liver with a bulldog clamp to prevent backflow. Sodium taurocholate (5% in saline) was infused using a fine needle inserted into 5 mm of the common biliary-pancreatic duct and each rat received a total volume of 1 mL/kg body weight for 1 min. After 5 min, the needle and clamp were removed, and the laparotomy incision was closed. Animals in the treatment group were injected intraperitoneally (ip) with 10 mg/kg MG-132 dissolved in 0.25 mL dimethyl sulfoxide (DMSO). Thirty minutes later, pancreatitis was induced as above. Animals in the control group underwent a sham operation consisting of laparotomy and puncture of the duodenum, under an identical anesthesia. Six hours after duct infusion or sham operation, the animals were killed by depletion and samples were taken for study. Blood was collected by cardiac puncture using heparinized syringes, centrifuged at 4000 r/min for 10 min, and stored at 4°C for further analysis. The pancreas and lungs were carefully isolated and weighed for subsequent experiments. Tissues for histological examination were isolated, fixed in 10% formalin and embedded in paraffin for sectioning.

### *Measurement of the ratio of pancreas weight to body weight*

Changes in pancreatic weight were assessed for pancreatic interstitial edema. The whole pancreas was removed and weighed. Weight of each pancreatic sample was used to estimate the water content in pancreas as previously described<sup>[12]</sup>, which was presented as a ratio of pancreas/body weight for evaluating the consequence of pancreatic edema.

### *Water content in lung*

For quantification of lung edema, the left lung was resected,

blotted dry, and weighed (wet weight). Thereafter, the left lung was desiccated for 24 h at 80°C and weighed again (dry weight). Water content in the lung was determined by calculating the wet weight/dry weight ratio as previously described<sup>[13]</sup>.

### *Serum amylase and MPO activity*

Serum amylase was assayed with an amylase kit with a kinetic spectrophotometric method according to the manufacturer's instructions. Briefly, the methodology is based on the enzymatic degradation of ethylidene-*p*-nitrophenol-G7 by amylase coupled with glucosidase, thus producing *p*-nitrophenol which exhibits strong absorbance at 405 nm. Enzymatic activity was expressed as units/liter.

Pancreatic and lung myeloperoxidase (MPO) activity, a quantitative indicator of neutrophil infiltration, was assessed according to the instructions from Nanjing Jiancheng Company. Briefly, tissues were thawed, homogenized in a 20 mmol/L phosphate buffer (pH 7.4), centrifuged at 13000 r/min for 10 min at 4°C. The resulting pellet was re-suspended in 50 mmol/L phosphate buffer (pH 6.0) containing 0.5% hexadecyl trimethylammonium bromide. The suspension was subjected to four cycles of freezing and thawing. The sample was then centrifuged at 10000 r/min for 5 min at 4°C. The supernatant was used for MPO assay. The absorbance at 450 nm of the resulting mixture was determined. The MPO activity was expressed as U/g tissue.

### *TNF- $\alpha$ level in pancreas*

TNF- $\alpha$  level in pancreatic cytosolic fractions was measured with a commercial ELISA kit according to the instructions of its manufacturer. The absorbance was read on a microplate reader and concentrations were calculated according to the standard curve.

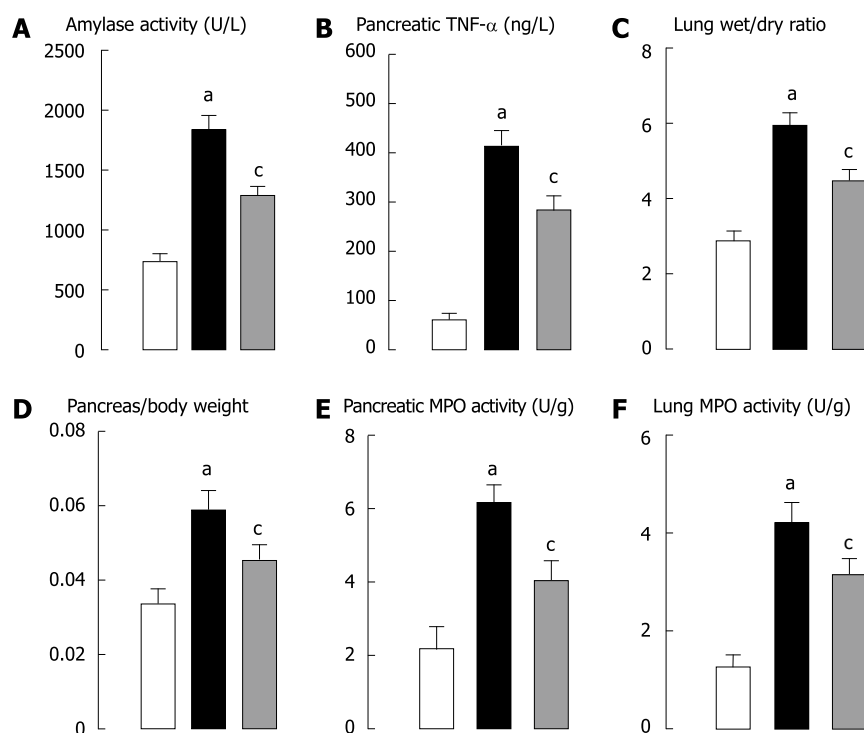

### *Histological examination*

Paraffin-embedded tissues were sectioned, stained with hematoxylin and eosin, and assessed by two different attending physicians unaware of the experimental protocol, at Department of Pathology of Xi'an Jiaotong University. The pancreas damage evaluation system was used as previously described<sup>[14]</sup>, the sections were examined and scored on a scale of 0-3 with 0 being normal and 3 being severe. Six characteristics were included, namely the presence of edema, acinar necrosis, inflammatory infiltrate, hemorrhage, fat necrosis, and perivascular inflammation. Five parameters were used as criteria for lung injury, manifested as alveolar thickening, vascular congestion, hemorrhage, edema, and leukocyte infiltration. Each observer was required to give a score from 0 to 2 for each slide according to the criteria mentioned above. A score of 0 indicates that there was no histological damage. A score of 1 indicates only mild or intermediate histological damage in the slides, and a score of 2 was given to the tissue sections with severe morphological deterioration in most of the areas observed.

### *Statistical analysis*

All results are expressed as mean  $\pm$  SE. Statistical

**Figure 1** Effect of MG-132 on serum amylase level (A), pancreatic TNF- $\alpha$  level (B), lung water content (C), pancreas/body weight ratio (D), and MPO activity in pancreas (E) and lung (F). White bars represent the control group (a sham operation consisting of laparotomy and puncture of the duodenum), black bars represent the SAP group (with retrograde injection of sodium taurocholate into pancreatic duct) and grey bars represent the MG-132 group (10 mg/kg MG-132 ip 30 min before the induction of pancreatitis). <sup>a</sup> $P < 0.05$  vs sham group, <sup>c</sup> $P < 0.05$  vs SAP group.

analysis of data was accomplished by analysis of variance (ANOVA).  $P < 0.05$  was considered statistically significant.

## RESULTS

### Effect of MG-132 on serum amylase activity

Serum amylase activity, a most common indicator for assessing pancreatitis, was markedly increased in the SAP animals (Figure 1A). The effect of MG-132 on pancreatitis was statistically significant.

### Effect of MG-132 on pancreatic TNF- $\alpha$ level

In the SAP animals, the concentration of TNF- $\alpha$  was increased (Figure 1B), which could be ameliorated in rats treated with MG-132, showing that TNF- $\alpha$  could improve pancreatitis.

### Effect of MG-132 on lung wet/dry weight ratio

The ratio of lung wet/dry weight, a commonly used indicator for estimating the water content in acute lung injury was significantly increased in the SAP group compared with the sham group (Figure 1C). Treatment with MG-132 could reduce the water content lung.

### Effect of MG-132 on the ratio of pancreas to body weight

Pancreatic edema, one of the major criteria for assessing pancreatitis was found in our experiment. Injection of 5% sodium taurocholate into the biliary-pancreatic duct of rats could significantly increase the ratio of pancreas to body weight (Figure 1D). Treatment with MG-132 showed a beneficial effect on pancreatic edema.

### Effect of MG-132 on pancreatic and lung MPO activity

SAP is associated with a rise in both pancreatic and lung MPO activity, indicating the presence of sequestered

neutrophils<sup>[15]</sup>. Pre-treatment of the animals with MG-132 significantly reduced the MPO activity both in pancreas and in lung (Figure 1E and F).

### Effect of MG-132 on pancreatic and lung histology

To assess the effects of MG-132 on local pancreatic injury, the morphology of pancreas was examined and compared with the treatment group. The results showed that the SAP group exhibited severe edema and a high degree of destruction of histoarchitecture of the acini cells. The architecture and integrity of acini cells were improved in the MG-132 group.

Normal lung tissue morphology (Figure 2A) was observed in the sham group. Histological examination of the sections confirmed lung injury with significant alveolate thickening, vasocongestion and infiltration with leukocytes observed in the SAP group (Figure 2B). In contrast, the lung injury was significantly ameliorated in the animals treated with MG-132 (Figure 2C). The scores of histological evaluation of pancreatitis and lung injury are summarized in Table 1.

## DISCUSSION

Acute pancreatitis is a life-threatening disease with a high mortality rate, especially in the setting of systemic inflammatory response and multiple organ failure when severe infection of necrosis occurs<sup>[16]</sup>. Under physiological conditions, digestive enzymes are synthesized by and stored in pancreatic acinar cells as inactive proenzymes known as zymogens which are secreted into the duodenum where enterokinase initiates their activation. The pathogenesis of acute pancreatitis remains obscure. However, it is believed that the premature activation of zymogens within acinar cells is a critical initiating event,

**Figure 2** Representative images illustrating histologically observed morphology of pancreas in pulmonary sections (HE, × 200).

**Table 1** Effect of MG-132 on histological damage to pancreas and lung

	Sham	SAP	MG-132
Pancreas	0.36 ± 0.04	13.82 ± 1.12 <sup>a</sup>	8.33 ± 0.52 <sup>c</sup>
Lung	0.23 ± 0.05	7.63 ± 0.65 <sup>a</sup>	4.46 ± 0.31 <sup>c</sup>

<sup>a</sup>*P* < 0.05 vs sham group, <sup>c</sup>*P* < 0.05 vs SAP group.

thus leading to auto-digestion of the gland. Afflicted acinar cells release factors that lead to recruitment of inflammatory cells and generation of multiple mediators, such as reactive oxygen species and cytokines<sup>[17]</sup>. Two potential key elements involved in this process are cathepsin B and NF-κB.

Cathepsin B is a lysosomal hydrolase, which activates human trypsinogen *in vitro* and is redistributed in a zymogen-granule enriched subcellular compartment during the early course of experimental pancreatitis<sup>[18,19]</sup>. It was reported that inhibition of lysosomal protease cathepsin B can suppress pancreatic inflammation<sup>[20,21]</sup>. Studies in cathepsin B gene knocked-out mice showed that the premature and intracellular activation of trypsinogen largely depends on the presence of cathepsin B<sup>[22]</sup>.

NF-κB is a member of the transcription factors which, under normal conditions, are coupled to an inhibitor (IκB) in cytoplasm<sup>[23,24]</sup>. In response to stress, a cascade of phosphorylation events results in IκB phosphorylation and degradation by proteasome. NF-κB with subsequent up-regulation of the expression of genes coding for a variety inflammatory factors including cytokines and chemokines such as TNF-α, IL-1, IL-6, IL-8. In acute pancreatitis<sup>[25]</sup>, NF-κB activation can be inhibited by blocking the degradation of IκB, which has been shown to ameliorate the severity of pancreatitis<sup>[26]</sup>.

During acute pancreatitis, lung injury is associated with the accumulation of neutrophils within the interstitial and alveolar spaces. Leukocyte sequestration within an inflamed area is a multistep process that begins with leukocyte activation<sup>[27]</sup>, followed by the rolling of inflammatory cells and the adhesion of circulating activated inflammatory cells to the endothelium via adhesion molecules, such as intercellular adhesion molecule-1 (ICAM-1)<sup>[28]</sup>. Cytokines, such as IL-1 and TNF-α, can also increase lung injury and spread to other

distant organs, indicating that NF-κB plays key role in this proinflammatory process<sup>[29-31]</sup>.

MG-132 is a cell-permeable aldehyde proteasome inhibitor, which has been shown to suppress the inflammatory cascade by decreasing NF-κB activity through blocking IκB degradation and increasing cellular HSP level<sup>[32]</sup>. MG-132 can also suppress pancreatic inflammation by inhibiting calpains and cathepsin B.

Since the SAP model established by injecting sodium taurocholate is most similar to the situation in human severe acute pancreatitis<sup>[33]</sup>, we chose it to examine the effect of proteasome inhibitor MG-132 on pancreatitis and lung injury in order to simulate the situation in humans.

In the present study, administration of MG-132 significantly suppressed the elevation of serum amylase, TNF-α and pancreatic MPO activity. Significant improvements were also observed in pancreatic histology after treatment with MG-132. Edema, acinar cell and fat necrosis, perivascular inflammation occurring in almost all inflammatory processes in any organ, were resolved in pancreatic tissues from the animals treated with MG-132.

The group pre-treated with MG-132, as compared with the sham and SAP groups, showed a significant reduction in the lung water content and MPO activity. These results are in close agreement with the histological analysis, suggesting that alveolar thickening, vasocongestion and recruitment of leukocytes in lung tissue can be suppressed with MG-132.

In conclusion, MG-132, a proteasome inhibitor, can ameliorate sodium taurocholate-induced SAP and its associated lung injury.

## COMMENTS

### Background

Severe acute pancreatitis (SAP) is still a fatal disease and its pathogenesis has not been fully understood. Pathological activation of digestive zymogens within pancreatic acinar cells is considered the key initiator of AP. The effect of MG-132 was investigated in experimental severe acute pancreatitis in the present study.

### Research frontiers

Proteasome inhibitors have a broad inhibitory action on pancreatic enzymes and production of proinflammatory cytokines. Therefore, they are expected to prevent necrotic changes in the pancreas and reduce the mortality rate.

### Innovations and breakthroughs

The SAP model established by retrograde injection of 5% sodium taurocholate (1 mL/kg) into the pancreatic duct was used to observe the effect of the

proteasome inhibitor MG-132 on severe acute pancreatitis and its associated lung injury of rats. Taurocholate-induced pancreatitis is a reliable model of severe acute pancreatitis rats with significantly greater pancreatic damage and systemic inflammatory response in comparison with cerulein-induced pancreatitis. Pancreatic and lung injury was a distant organ injury which is the key determinant of mortality in AP patients.

### Applications

MG-132 shows its protective effect on SAP induced by sodium taurocholate and its associated lung injury of rats. Moreover, proteasome inhibitors may promote further studies on the treatment of AP.

### Peer review

This paper describes the effect of MG-132 (carbobenzoxy-L-leucyl-L-leucyl-L-leucinal), a proteasome inhibitor, on SAP and its associated lung injury of rats. The model selected is appropriate and induces SAP and lung injury. Further researches are needed to explore its mechanism.

### Abstract

**AIM:** To explore the change of intestinal mucosa barrier function in the progress of non-alcoholic steatohepatitis (NASH) in rats.

**METHODS:** Thirty-two Sprague-Dawley (SD) rats were randomly divided into control group and model group. Rats in the control group were given normal diet, and rats in the model group were given fat-rich diet. Eight rats in each group were killed at end of the 8th and 12th wk, respectively. The levels of endotoxin, D-xylose, TG, TC, ALT and AST, intestinal tissue SOD and MDA as well as intestinal mucus secretory IgA (sIgA) were measured. The pathology of liver was observed by HE staining.

**RESULTS:** At end of the 8th wk, there was no marked difference in the levels of endotoxin, D-xylose and sIgA between the two groups. At end of the 12th wk, rats in the model group developed steatohepatitis and had a higher serum level of endotoxin ( $P = 0.01$ ) and D-xylose ( $P = 0.00$ ) and a lower serum level of sIgA ( $P = 0.007$ ).

**CONCLUSION:** Intestinal mucosa barrier malfunction may exist in NASH rats and may be an important promoter of NASH in rats.

### INTRODUCTION

Non-alcoholic steatohepatitis (NASH) is a type of non-alcoholic fatty liver disease (NAFLD), and may progress to hepatic fibrosis and cirrhosis<sup>[1-3]</sup>. The pathogenesis of NASH remains unclear. Nowadays, lipid metabolism abnormality, insulin resistance and oxidative stress and lipid peroxidation reaction<sup>[4-8]</sup> are thought to play an important role in the pathogenesis of NASH<sup>[9,10]</sup>. It was reported that the change of intestinal environment may play a role in NASH, which may be a cause of enterogenous endotoxemia<sup>[11,12]</sup>. Since the relationship between intestinal mucosa barrier function and NASH is uncertain, we established an animal model of NASH by giving fat-rich diet to explore the change of intestinal mucosa barrier function in the progress of NASH.

### MATERIALS AND METHODS

#### Materials

Thirty-two healthy female mice, provided by Nanjing Qinglongshan Experimental Animal Center, were used in this study. D-xylose, SOD and MDA kit were purchased from Nanjing Jiancheng Bioengineering Institute (NJBI). Quantitative chromogenic end-point tachyplesus amebocyte lysate kit was purchased from Xiamen Houshiji, Ltd. Secretory IgA (sIgA) kit was purchased from Beijing North Institute of Biological Technology (BNIBT).

#### Methods

**Establishment of animal mode:** 32 female Sprague-Dawley (SD) rats, weighing 130-150 g, after a week of adaptive feeding, were randomly divided into model group and control group (16 in each group). Rats in the control group were given normal diet and rats in the model group ( $n = 16$ ) were given fat-rich diet containing 88% normal diet, 10% lard and 2% cholesterol. All rats were maintained at controlled room temperature in a

**Key words:** Non-alcoholic steatohepatitis; Intestinal mucosa barrier; Endotoxin; Secretory IgA

**Peer reviewer:** Anthony J Bauer, PhD, Department of Medicine/Gastroenterology, University of Pittsburgh, 3550 Terrace Street, S-849 Scaife Hall, Pittsburgh 15261, United States

12-h light/dark cycle with free access to laboratory feed and water. Eight rats in each group were killed at wk 8, 12 respectively during the study. All rats had no access to food and water for 12 h, but received intra-gastric 5% D-xylose (0.5 mL/100 g, BW) and 0.3% pentobarbital (0.15-0.2 mL/kg) *via* abdominal cavity, 25 min and a short wile, respectively, before they were killed.

**Histological evaluation:** Liver specimen was obtained from the central part of liver, observed by HE staining, and evaluated according to the guidelines for diagnosis and treatment of nonalcoholic fatty liver diseases revised by Fatty Liver and Alcoholic Liver Study Group of the Chinese Liver Disease Association<sup>[13]</sup>.

**Measurement of ALT, AST, TG and TC:** Two milliliters blood was taken from abdominal aorta and serum was taken after centrifugation at 4000 r/min for 10 min. The levels of ALT, AST, TG and TC were measured with an automatic biochemical analyzer.

**Measurement of D-xylose:** Two milliliters blood was taken from abdominal aorta, and collected into a tube (containing heparin) immediately and plasma was taken after the blood was centrifuged at 4000 r/min for 10 min. The Level of D-xylose in plasma was measured with a D-xylose kit.

**Measurement of endotoxin:** One milliliter blood was taken from portal vein and collected into an apyrogenic tube (containing heparin) immediately. Plasma was taken after the blood was centrifuged at 3000 r/min for 10 min (environmental temperature: 0°C). The levels of endotoxin were measured by limulus amebocyte lysate test.

**Detection of sIgA:** sIgA was detected as previously described<sup>[14]</sup>. A 10 cm long tissue was obtained from the small intestine, dissected and washed with normal saline carefully. Intestine mucus was collected into an Eppendorf tube, and centrifuged at 3000 r/min for 10 min (environmental temperature: 0°C) after 1 mL 0.01 mol/L PBS was added. The supernatant was harvested. The level of sIgA was measured by double antibody sandwich immunoradiometric assay. The total protein of intestine mucus was assayed by Bradford brilliant blue method simultaneously. The sIgA content in total protein of one milligram small intestine mucus was detected.

**Detection of SOD and MDA in small intestine tissue:** The small intestine tissue was weighed to prepare 10% tissue homogenate by adding normal saline according to weighing ratio. The homogenate was centrifuged at 3000 r/min for 10 min (environmental temperature: 0°C). The supernatant was harvested to make 1% tissue homogenate by adding normal saline. The levels of SOD and MDA in tissue homogenate were measured.

### Statistical analysis

All statistical analyses were performed using SPSS 11.5

**Table 1** Level of serum TG, TC, ALT and AST (mean  $\pm$  SD,  $n = 8$ )

Group	Time (wk)	TG (mmol/L)	TC (mmol/L)	ALT (U/L)	AST (U/L)
Control	8	0.72 $\pm$ 0.17	1.21 $\pm$ 0.29	39.00 $\pm$ 7.46	134.88 $\pm$ 35.11
Model	8	0.79 $\pm$ 0.20	1.78 $\pm$ 0.35 <sup>a</sup>	61.75 $\pm$ 15.85 <sup>a</sup>	96.63 $\pm$ 52.80 <sup>a</sup>
Control	12	0.76 $\pm$ 0.17	1.26 $\pm$ 0.25	41.88 $\pm$ 6.27	138.00 $\pm$ 36.70
Model	12	0.85 $\pm$ 0.18	1.99 $\pm$ 0.26 <sup>a</sup>	87.75 $\pm$ 26.89 <sup>a</sup>	248.88 $\pm$ 53.09

<sup>a</sup> $P < 0.05$  vs control group.

software package. All data were expressed as mean  $\pm$  SD. Group comparison was done by one-factor analysis of variance.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Liver histology

The structure of hepatic lobules and the morphology of liver cells were normal in the control group. Lipid droplets were observed in 50%-75% of hepatic cells in the model group after 8 wk of fat-rich diet, predominantly bullules, consistent with the diagnostic criteria for simple fatty liver disease. Fatty degeneration in hepatic cells exceeded 75% and patch necrosis, mild to moderate chronic inflammation could be seen after 12 wk of fat-rich diet, consistent with the diagnostic criteria for steatohepatitis.

### Contents of serum TG, TC, ALT and AST

Serum TC, ALT and AST levels were higher in the model group than in the control group in the 8th, and 12th wk. There was a statistical difference between the two groups ( $P < 0.05$ ). The serum TG level was slightly higher in the model group than in the control group, but there was no statistical difference between the two groups (Table 1).

### Level of serum D-xylose, endotoxin and intestine mucus sIgA

At end of the 8th wk, there was no significant difference in the levels of endotoxin, D-xylose and sIgA between the two groups. At end of the 12th wk, rats in the model group developed steatohepatitis and had a higher serum level of endotoxin and D-xylose ( $P < 0.05$ ), but a lower level of sIgA ( $P < 0.05$ ) (Table 2).

### Level of SOD and MDA in small intestine tissue

The level of SOD in small intestine tissue was lower in the model group than in the control group in the 8th and 12th wk. There was a statistical difference between the two groups ( $P < 0.05$ ). The level of MDA in small intestine tissue was higher in the model group than in control group in the 8th and 12th wk. There was a statistical difference between the two groups ( $P < 0.05$ ) (Table 3).

### Correlation analysis of serum D-xylose, endotoxin and intestine mucus sIgA

A line tendency could be observed in scatter plots bellow. The serum level of endotoxin in portal vein was positively

**Table 2** Level of serum D-xylose, endotoxin and intestine mucus sIgA (mean  $\pm$  SD,  $n = 8$ )

Group	Time (wk)	D-xylose (mmol/L)	sIgA ( $\mu$ g/mg)	Endotoxin (EU/mL)
Control	8	0.65 $\pm$ 0.21	1.72 $\pm$ 0.67	0.267 $\pm$ 0.022
Model	8	0.71 $\pm$ 0.17	1.55 $\pm$ 0.58	0.272 $\pm$ 0.021
Control	12	0.72 $\pm$ 0.23	1.64 $\pm$ 0.60	0.270 $\pm$ 0.023
Model	12	1.33 $\pm$ 0.37 <sup>a</sup>	0.78 $\pm$ 0.27 <sup>a</sup>	0.302 $\pm$ 0.020 <sup>a</sup>

<sup>a</sup> $P < 0.05$  vs control group.**Table 3** Level of SOD and MDA in small intestine tissue SOD and MDA (mean  $\pm$  SD,  $n = 8$ )

Group	Time (wk)	SOD (U/mgprot)	MDA (nmol/mgprot)
Control	8	83.29 $\pm$ 10.56	0.55 $\pm$ 0.06
Model	8	71.61 $\pm$ 9.28 <sup>a</sup>	0.72 $\pm$ 0.05 <sup>a</sup>
Control	12	80.79 $\pm$ 7.76	0.59 $\pm$ 0.04
Model	12	61.26 $\pm$ 7.01 <sup>c</sup>	0.93 $\pm$ 0.08 <sup>c</sup>

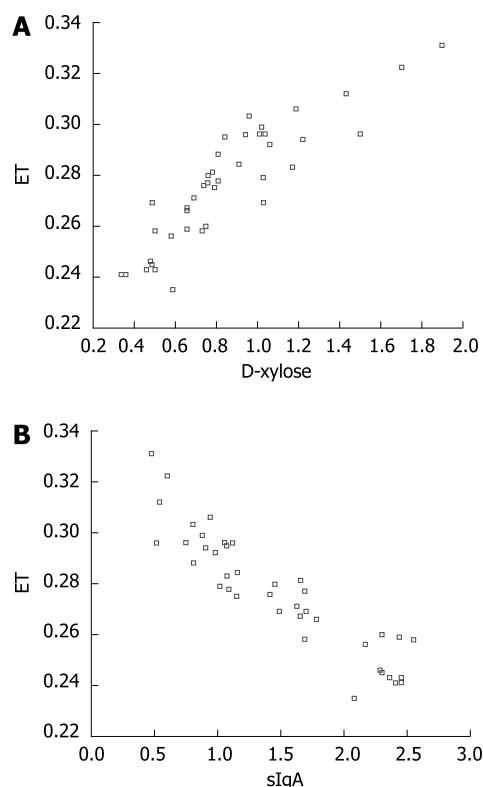

<sup>a</sup> $P < 0.05$ , <sup>c</sup> $P < 0.05$  vs control group.

correlated with that of D-xylose in abdominal aorta ( $r = 0.846$ ,  $n = 8$ ,  $P < 0.01$ ) and negatively correlated that of sIgA in intestine mucus ( $r = -0.873$ ,  $n = 8$ ,  $P < 0.01$ ) (Figure 1A and B).

## DISCUSSION

At present, the specific pathogenesis and progress of NASH remain unclear. It was reported that there is enterogenous endotoxemia in NASH, suggesting that NASH is closely related to endotoxin<sup>[15-17]</sup>. Wigg *et al*<sup>[11]</sup> reported that small intestinal bacterial overgrowth is present in 50% of patients with non-alcoholic steatosis not accompanying increased intestinal permeability or elevated endotoxin levels. Brun P *et al*<sup>[12]</sup> showed that obese mice with NASH have higher intestinal mucosa permeability and circulating level of endotoxemia in portal vein than the control mice, suggesting that genetically obese mice display an enhanced intestinal permeability, leading to severe endotoxemia in portal vein. Therefore, whether there is an increased intestinal permeability and a change in intestinal mucosa barrier function in NASH patients needs to be further explored.

Intestinal mucosa barriers include mechanical barrier, chemical barrier, immunologic barrier and biology barrier<sup>[18-21]</sup>, any damage of these barriers will damage intestinal mucosa barrier function. In this study, we used plasma D-xylose, endotoxin and intestine mucus sIgA to evaluate the intestinal mucosa barrier function in rats with NASH and to observe its change in NASH rats. Intestine mucus sIgA is a major ingredient of intestinal immunologic barrier, mostly secreted by plasmocytes of intestinal mucosa, and may restrain intestinal bacteria to adhere to intestinal mucosa surface, to counteract toxin, enzyme and virus in the intestinal tract, thus playing an important role in intestinal immunity<sup>[22-24]</sup>. SOD is the most important anti-oxidation enzyme in anti-oxidation defense system and MDA is the end product

**Figure 1** Relationships scatter plot. A: ET and D-xylose; B: ET and sIgA.

of lipid peroxidation, which can cause tissue injury. SOD activity and MDA level can reflect the degree of lipid peroxidation and oxidative stress. It was reported that NASH is closely related to lipid peroxidation and oxidative stress<sup>[25-27]</sup>. In the present study, we successfully established the NASH model by giving fat-rich diet, and observed the change of intestinal mucosa barrier function in simple fatty liver disease and NASH. The results showed that there was no statistical difference in serum D-xylose, endotoxin and intestine mucus sIgA between the two groups at the 8th wk, suggesting that there might be no damage to the intestinal mucosa barrier at the stage of simple fatty liver disease. However, the SOD activity was decreased in intestinal tissue, while the level of MDA was increased, suggesting that lipid peroxidation and anti-oxidation are imbalanced. There was a significant difference in serum D-xylose, endotoxin and intestine mucus sIgA between the two groups ( $P < 0.05$ ) at the 12th wk. Serum D-xylose and endotoxin levels were higher in the model group than in the control group, while the intestine mucus sIgA levels were lower in the model group, suggesting that the intestinal mucosa barrier is damaged at the stage of NASH and that the SOD activity is further decreased in the intestinal tissue while MDA level is further elevated and lipid peroxidation reaction is further aggravated. The fact that serum endotoxin level in portal vein was positively correlated with that of serum D-xylose in abdominal aorta, but negatively correlated with that of sIgA in intestine mucus, suggesting that the damage to intestinal mucosa barrier may cause enterogenous endotoxemia.

In our study, no damage to intestinal mucosa barrier occurred at the early stage of nonalcoholic fatty liver disease. With the progress from simple fatty liver disease to NASH, severe damage to intestinal mucosa barrier occurred. The pathogenesis of intestinal mucosa barrier damage is unclear. It may be due to the increased lipid peroxidation reaction in intestinal tissue and intestinal mucosa damage caused by endotoxin<sup>[28]</sup>. It needs to be further studied. Increased sIgA levels in intestine mucus would lead to the ability of intestinal bacterium to inhibit adherence to intestinal mucosa surface and decrease counteracting toxin, so bacteria and endotoxin are increased in the intestinal tract. Wigg *et al*<sup>[11]</sup> reported that bacteria grow in small intestine of patients with non-alcoholic steatosis, suggesting that and decreased sIgA promotes overgrowth of bacteria in small intestine. We suppose that small intestinal bacterial overgrowth in small intestine can produce more endotoxin in enteric cavity, thus damaging intestinal mucosa barrier and absorbing more endotoxin, finally leading to enterogenous endotoxemia. It was reported that endotoxin can not only injure hepatic cells but also activate Kupffer cells by combining receptor CD14 and signal receptor TLR4. The activated Kupffer cells release a series of bioactive substances, such as TNF- $\alpha$ , causing hepatic injury, thus aggravating the effect of endotoxin and promoting development of NASH<sup>[29-31]</sup>.

## COMMENTS

### Background

The pathogenesis of non-alcoholic steatohepatitis (NASH) remains unclear. Insulin resistance, obesity-related inflammation, oxidative stress, microcirculation disturbance, and malnutrition are thought to play a key role in the pathogenesis of NASH. Studies have also demonstrated that change in intestinal environment may also play a role in the pathogenesis of NASH, and may be a cause of enterogenous endotoxemia. It has been found that a higher intestinal permeability may also play a role in the process of NASH. However, it is not accepted that there exists enterogenous endotoxemia in NASH.

### Research frontiers

Great effort has been made to clarify the pathogenesis of NASH. The source and pathogenesis of endotoxin in the process are two hot spots.

### Innovations and breakthroughs

In this study, the relationship between intestinal mucosa barrier function and NASH was studied.

### Applications

The intestinal mucosa barrier malfunction may lead to NASH. There might be a vicious circle between intestinal mucosa barrier malfunction and NASH.

### Terminology

NASH is a kind of liver disease which resembles alcoholic liver disease accompanying steatosis, inflammation, necrosis, and fibrosis. Intestinal mucosa barriers include mechanical barrier, chemical barrier, immunologic barrier and biology barrier.

### Peer review

This paper explores the change of intestinal mucosa barrier function in the progress of NASH in rats. The well designed study demonstrated that the intestinal mucosa barrier malfunction may exist in NASH rats, and may be an important promoter of NASH in rats.

### Abstract

Small bowel diverticulosis represents an uncommon disorder (except for Meckel diverticulum) often misdiagnosed since it causes non-specific gastrointestinal symptoms. Most of times the diagnosis is carried out in case of related complications, such as diverticulitis, hemorrhage, perforation or obstruction. Intestinal obstruction can be caused by inflammatory stenosis due to repeated episodes of diverticulitis, volvulus, intussusception or jejunal stones. Herein we report a case of multiple jejunal diverticula causing chronic gastrointestinal obstruction.

### INTRODUCTION

Multiple diverticulosis of the foregut is uncommon<sup>[1]</sup>. Although it is often asymptomatic, it can lead to severe complications, such as obstruction, hemorrhage, diverticulitis and perforation. Obstruction can be caused by inflammatory stenosis due to repeated episodes of diverticulitis, volvulus or intussusception, voluminous jejunal stones or dyskinesia of the small bowel<sup>[2-4]</sup>. We herein report a case of chronic gastrointestinal obstruction in a patient with a previous diagnosis of jejunal multiple giant diverticula.

### CASE REPORT

A 49-year-old woman was admitted to our department, because of abdominal pain and vomiting together with a history of repeated episodes of obstructive gastrointestinal symptoms in the last two years.

In a previous diagnostic work out, she underwent contrast barium that showed multiple giant diverticula in the proximal small bowel tract (Figure 1).

At physical examination, she was dehydrated and her abdomen was distended but soft. A plain X-ray abdominal film showed distended small bowel loops and multiple gas-fluid levels

The actual clinical condition, the long duration of symptoms and the previous diagnosis were all considered indications for surgery.

At the operation, diffuse giant diverticula were observed in the duodenum (Figure 2) and proximal jejunum so that duodenal diverticulectomy and jejunal resection were performed.

No postoperative complication was observed. During the 4-mo follow-up, the patient remained free of GI symptoms.

### DISCUSSION

Jejunal diverticulosis is a rare entity with an incidence rate ranging from 0.3%-1.3% in autopsy series to 2.3% of radiographic findings<sup>[1]</sup>.

Like colonic diverticula, small bowel diverticula other than Meckel's, are false diverticula resulting from mucosal herniation at the point where blood vessels penetrate the intestinal wall. This also explains their

**Figure 1** Contrast barium study showing multiple giant jejunal diverticula.

**Figure 2** All diverticula arising at the mesenteric border.

typical location at the mesenteric side<sup>[2]</sup>.

Aetiology of jejunal diverticula is still unclear since an anatomic wall defect seems not to be the only factor. Increased intraluminal pressure can play a main role as happens in case of colonic diverticulosis. Small bowel diverticula in fact can be seen in patients older than 50 years with peristaltic disorders, such as progressive systemic sclerosis, visceral myopathy and visceral neuropathies leading to increase of intraluminal pressure<sup>[3]</sup>.

This condition is often misdiagnosed as it is often asymptomatic or causes minor, non-specific gastrointestinal symptoms. Nevertheless, it could lead to severe complications, such as hemorrhage, diverticulitis, perforation and obstruction.

The small number of symptomatic patients may explain chronic post prandial abdominal pain, nausea and vomiting, borborygmi, alternating diarrhea and constipation, and weight loss, and present with anemia, steatorrhea, tenderness, and fever<sup>[1,4]</sup>. All these symptoms reflect inflammation, malabsorption, hemorrhage or mechanical obstruction.

Hemorrhage and perforation are the consequence of progressive ulceration in case of acute diverticulitis. While perforation is the result of progressive ulceration in case of acute diverticulitis, hemorrhage could be caused by diverticulitis with ulceration, or diverticulosis associated with trauma and irritation, or congenital arteriovenous malformations<sup>[5]</sup>.

Obstruction can be caused by inflammatory stenosis due to repeated episodes of diverticulitis, volvulus or

intussusception and voluminous jejunal stones. The latter seem to be caused by the intradiverticular milieu including alteration of the chemical environment and malabsorption, both of which are related to intestinal stasis and stagnant diverticula. Dyskinesia of the small bowel, in fact, causes an intraluminal stasis with bacterial overgrowth leading to deconjugation of bile acids. Deconjugated bile acid, together with cholic acid formed from bile salts and precipitate in aggregates, starts enterolith formation<sup>[6,7]</sup>.

In our patient, intermittent occlusive symptoms were probably caused by hyperdistension of the voluminous diverticula (Figure 2), resulting in external obstruction of jejunal loops.

Asymptomatic diverticula are found only in case of radiography or surgery performed for unrelated causes.

The diagnostic work up in symptomatic patients can start with plain abdominal X-ray film that could show distension of jejunal loops and gas-fluid levels into voluminous diverticula. Upper gastrointestinal X-ray study by barium contrast clearly shows the presence of multiple diverticula.

In case of acute abdomen due to diverticular perforation or intestinal obstruction, X-ray studies show typical signs of these conditions giving no information about the cause that will be recognized at surgery.

The treatment of choice for jejunal diverticulosis, often performed emergently, is resection of all the affected jejunum even in case of perforation or peridiverticular stenosis, in order to avoid further complications<sup>[4,8]</sup>.

In case of obstruction due to an enterolith, some authors suggest conservative management by performing the manual breakage of all stones, intradiverticular and blocking ones, pushing their fragments to the colon<sup>[1,4,8,9]</sup>.

This treatment is to be discouraged because of the persisting risk of stone formation and diverticular complications.

In contrast to jejunal diverticulosis, duodenal diverticula have been treated with simple diverticulectomy. The decision to operate a duodenal diverticulum, however, should be made with great caution because postoperative complications such as fistula formation and pancreatitis are not rare given the peripapillary location of many of these diverticula.

## INTRODUCTION

Diving is a difficult underwater activity in which environmental conditions can affect body structure and function. Barotrauma is caused by compression during descent or expansion during ascent, of the gas filled spaces of the body and it may be associated with pneumothorax, pneumomediastinum and embolism. Decompression sickness may occur when gas, which has dissolved in tissues at depth, eventually produces bubbles which occasionally result in severe cardiorespiratory and neurological emergencies<sup>[1]</sup>.

Approximately 13% of divers complain of gastrointestinal disturbances upon ascent, while most of them present as aerophagy<sup>[2]</sup>. Rarer, more severe diving-associated gastrointestinal manifestations have been reported in the literature, including a few cases of gastrointestinal barotraumas, mainly gastric rupture<sup>[3-6]</sup> and a case of small bowel infarction due to thrombosis of mesenteric veins<sup>[7]</sup>. We describe a clinical case of ischemic colitis in a 27-year-old male admitted to our emergency department, who manifested abdominal pain while he was in the process of scuba diving 20 meters undersea, followed by bloody diarrhoea as soon as he ascended to sea level. Taking into account his past medical history, the thorough impeccable clinical and laboratory examinations and presence of no other factors predisposing to ischemia of the colon, we assume that a possible relationship between the diving conditions and the pathogenesis of ischemic colitis may exist. This case, is as far as we know, the first report relating scuba diving with acute ischemic colitis.

## Abstract

The presentation of clinical symptoms due to decompression during diving, varies significantly, as mainly minor disturbances for the gastrointestinal tract in particular have been reported. The following case debates whether diving can cause severe symptoms from the gastrointestinal system. We describe a clinical case of ischemic colitis presented in a 27-year-old male, who manifested abdominal pain while in the process of scuba diving 20 meters undersea, followed by bloody diarrhoea as soon as he ascended to sea level. Taking into account his past medical history, the thorough, impeccable clinical and laboratory examinations and presence of no other factors predisposing to ischemia of the colon, we assume that a possible relationship between diving conditions and the pathogenesis of ischemic colitis may exist. This unusual case might represent a hematologic manifestation of decompression sickness, due to increased coagulability and/or transient air emboli, occurring during a routine scuba diving ascent to sea level.

## CASE REPORT

A 27-year-old male novice scuba diver came to the emergency department of our hospital, accompanied by his father, suffering from lower abdominal pain with concurrent bloody diarrhoea. He reported that 2 h earlier, he was submerged for approximately 5 min at a depth of 20 meters when he experienced an acute and intense lower abdominal pain with a simultaneous urge to defecate. Further, he insisted that although under stress, his ascent had been completely normal, under control and in accordance with a scheduled dive plan. Immediately after reaching the surface, he had two loose bowel movements followed by bloody diarrhoea and tenesmus. Our patient was a non-smoker, was taking no medication, and his past medical history was limited to a known Gilbert's syndrome. When admitted to the accident and emergency department his vital signs were: blood pressure of 120/80 mmHg, pulse rate of 72 bpm and respiratory rate of approximately 12 breaths/min. Physical examination revealed a moderate abdominal tenderness at the left lower quadrant and a mild abdominal distention, while per rectum examination confirmed the presence of fresh blood in the lumen with no other apparent physical signs of clinical importance detected.

Laboratory results were: Hematocrit (HCT): 47.1%, white cell counts (WCC): 7.800/ $\mu$ L with 63%

**Figure 3** Immunohistochemistry for CD31 revealing lack of staining in the areas of air bubbles in the lamina propria (arrows).

neutrophils, 27% lymphocytes, 7% monocytes and 3% eosinophils, platelet (PLT): 236.000/ $\mu$ L, total-bilirubin: 2.73 mg/dL, Direct-bilirubin: 0.25 mg/dL and serum lactic dehydrogenase: 223 U/L. Coagulation tests including prothrombin time (PT), international normalized ratio (INR), activated partial thromboplastin time (APTT), fibrinogen, protein S, protein C, antithrombin III and V leiden factor were in the normal range. Urea and electrolytes, antiphospholipid antibodies, serum amylase, blood gases and all other tests including urine analysis were also normal. Chest and abdominal X-rays plus ultrasound examination of both upper and lower abdomen did not reveal any pathological findings. Colonoscopy, with inspection of the terminal ileum, performed 24 h later, revealed an edematous mucosa of the sigmoid colon in extent of 20 cm, with redness, superficial ulcerations and submucosal haemorrhages (Figure 1). The histological study of specimens taken from the affected area showed findings compatible with ischemic colitis, while the pathologist noticed presence of air in the lamina propria but not intravascularly (Figures 2 and 3). No air was detected in the colon wall by magnetic resonance tomography performed 2 d after admission.

The patient recovered uneventfully with bloody diarrhoea ceasing a few hours after admission and abdominal pain progressively diminishing till disappearance in 48 h. The patient was discharged with complete comeback 4 d after admission. The follow-up colonoscopy two mo later showed complete endoscopic and histologic healing of the mucosa (Figure 4) with the patient free of any clinical symptoms.

## DISCUSSION

Abdominal discomfort and belching due to air swallowing are quite frequent manifestations during diving, with more severe gastrointestinal complications scarcely described. Gastric rupture due to expansion of intra-gastric air during a quick ascent to sea level has been described in a few case reports<sup>[3-6]</sup>. Massive pneumoperitoneum without rupture of an abdominal hollow viscous organ, possibly caused by lung

**Figure 4** HE staining of normal histologic appearance of our patient's colonic mucosa, 2 mo after the ischemic colitis episode.

barotrauma has also been reported<sup>[8]</sup>. Gertler *et al* have presented a case of mesenteric vein thrombosis as a unique complication of decompression sickness<sup>[7]</sup>. Finally, we must emphasize that a confirmed case of acute ischemic colitis in association with scuba diving has never been reported.

In our case, the patient's clinical manifestations of ischemic colitis initiated with acute abdominal pain while at a depth of 20 meters under sea, progressing to bloody diarrhoea on the surface. Several environmental parameters during diving can alter body function and structure<sup>[1]</sup>, as for approximately every 10 meters of descent in sea water ambient pressure increases by 100 kPa (1 bar). The air trapped in body cavities including the gastrointestinal tract, is therefore subjected to compression during descent and expansion during ascent to sea level, which may lead to tissue damage such as gastric rupture<sup>[3-6]</sup>. Decompression sickness occurs when the partial pressure of gas trapped in the hollow cavities of the body raises in direct proportion to the increase in ambient pressure. This leads to large volumes of inert gas, mainly nitrogen, which dissolve in tissues while at depth transforming to bubbles during ascent to sea level. In addition breathing workload increases due to a combination of increased gas density, increased hydrostatic pressure and altered respiratory mechanisms. Finally, a number of unpredictable events such as malfunction of a diving equipment or technical issues, as well as panic attacks or hypothermia of the diver, may increase the existing physical and/or psychological stress. In our case, except for the arduous and stress inducing conditions during underwater activity, other factors predisposing to ischemic colitis were not identified.

Our patient's past medical history was free of thrombotic events whilst complete examination and evaluation of the patient, including specific blood tests, did not reveal any type of coagulopathy. On the other hand, the pathophysiologic mechanism of decompression sickness could predispose to vascular obstruction and venous infarction<sup>[9]</sup>. The partial pressure of body gases increases during a scuba dive, resulting in a time-dependent concentration of mainly nitrogen in body fluids and tissues. Bubbles can be formed during

ascent due to rapid decrease of barometric pressure. Bubbles are formed predominately in the venous circulation, although in overwhelming decompression sickness they can be found in the arterial circulation also<sup>[10]</sup>, causing vascular obstruction due to coalition. Although bubble formation is considered as the causative mechanism of decompression sickness, a series of hematological disorders leading to a hypercoagulable state have been described<sup>[9,11]</sup>. *In vitro* experiments concluded that increased vascular permeability, vascular obstruction due to fat emboli and interaction of the bubble surface with the cellular elements of the blood, may contribute to the pathogenesis of decompression sickness<sup>[9,12]</sup>. Mesenteric vein thrombosis<sup>[7]</sup>, retinal artery occlusion<sup>[13]</sup> and vascular obstruction due to fat emboli<sup>[14]</sup>, have previously been reported as unique complications of decompression sickness. The presence of trapped air in the lamina propria, likely of intravascular origin, demonstrated in biopsies taken from the colonic area with ischemic lesions, supports the thesis that decompression sickness was the main cause of our patient's colonic ischemia. Vascular bubbles and bowel wall congestion are the visceral changes described in decompression sickness<sup>[15]</sup>. It has recently been reported that magnetic resonance imaging (MRI) may be superior to autopsy in the demonstration of gas in intraparenchymal blood vessels of internal organs<sup>[16]</sup>. Our patient's MRI scan didn't reveal any intravascular air bubbles, which can be attributed to the 48 h delay between the scan and the onset of the acute episode. Finally, a procedure that may lead to rapid alleviation of decompression sickness symptoms<sup>[3,6,8]</sup> is recompression, which in our case was not implemented due to the rapid clinical improvement and complete recovery of the patient.

In conclusion, this unusual case emphasizes the probability that scuba diving can cause colonic ischemia, even in young patients with no known coagulation disorders or other factors predisposing to colonic ischemia.

A symptomatic cyst of the ligamentum teres of the liver: A case report. *World J Gastroenterol* 2008; 14(20): 3266-3268 Available from: URL: <http://www.wjgnet.com/1007-9327/14/3266.asp>

DOI: <http://dx.doi.org/10.3748/wjg.14.3266>

## INTRODUCTION

Ligamentum teres (or round ligament) of the liver is a cord-like ligament found within the falciform ligament on the inner surface of the anterior abdominal wall and represents a remnant of the umbilical vein, which is a connecting venous structure between the placenta and the umbilical portion of the left portal vein. It is located at the dorsal free margin of the falciform ligament.

Lesions of the liver ligaments are extremely rare and cysts of the falciform ligament have been previously reported<sup>[1-3]</sup>.

The aetiology of these cysts is not well understood yet and their clinical manifestations vary a lot. They may appear completely asymptomatic or may produce palpable masses and pain. The differential diagnosis in such cases includes benign or malignant tumors arising from the liver ligaments or the abdominal wall, fatty masses, disseminated cancer and hepatic lesions.

CT scan, although necessary, may not well define the nature and origin of these masses. Definite diagnosis is made based on laparotomy and pathologic examination of the surgical specimen.

We report a case of a symptomatic patient with a cyst of the ligamentum teres of the liver treated with total excision. The pathologic features of this cyst are also presented.

## CASE REPORT

A 57-year old woman was referred to our department due to right upper quadrant pain and episodes of vomiting during the last 2 years. The pain was mild, experienced at irregular periods of time and had no relation to meals. The patient did not have any previous medical history. She was a non-smoker and did not receive any medication in a regular basis. Physical examination was unremarkable. Complete blood cell count, electrolytes,

## Abstract

Cysts of the liver ligaments are extremely rare and cysts of the ligamentum teres of the liver have been sporadically reported in the literature during the last century. The present report describes a case of a symptomatic patient with a cyst of the ligamentum teres of the liver. The patient presented with right upper quadrant pain and indigestion during the last 2 years. Ultrasound and computed tomography scans revealed a water-density mass attached to the anterior abdominal wall, but definite diagnosis could not be reached. The cyst was completely excised during laparotomy. Cysts of the ligamentum teres of the liver, although infrequent, may produce clinical symptoms and require excision. Ultrasound and computed tomography scan preoperatively cannot rule out malignancy, thus exploratory laparotomy and total resection of these lesions are necessary.

**Figure 1** Ultrasound appearance of the cystic abdominal mass.

**Figure 2** Abdominal CT scan with intravenous contrast media used showing a water-density mass attached to the anterior abdominal wall. A well circumscribed area of low attenuation in contact with the abdominal wall is identified.

eosinophil count, serum biochemistry and urinalysis were within normal limits. Levels of serous neoplastic markers, such as carbohydrate antigen 19-9 (CA 19-9), carcinoembryonic antigen (CEA), carbohydrate antigen 125 (CA 125), and  $\alpha$ -fetoprotein (AFP) were normal as well. Anti-echinococcal IgM and IgG antibodies and viral markers for hepatitis B and C were negative. Chest X-ray was normal. Plain radiographs of the abdomen did not reveal any pathological entity. The patient underwent ultrasound examination (US) that showed a 4.7 cm  $\times$  3.5 cm cystic mass on the anterior surface of the liver (Figure 1). CT scanning demonstrated the presence of a 5 cm  $\times$  4 cm  $\times$  7 cm solitary water-density mass, in contact with the right rectus abdominis muscle, showing no enhancement after intravenous contrast media injection (Figure 2). No ascites, lymphnodes or other intra-abdominal masses were found either in the liver or in the peritoneum.

The cyst was removed without rupture by a midline abdominal incision (Figure 3). The cyst's origin was at the attachment between the ligamentum teres and the anterior abdominal wall. It was neither drained nor aspirated during the procedure. An appropriate dissection plane between the cyst and the ligament could easily be found as it was not hard and adhesive. The exploration of the rest of the peritoneal cavity did not reveal any other lesions. Macroscopic examination showed a circumscribed serous cyst, 5 cm in diameter, with a thick fibrous wall of 1 mm. Microscopically, the wall of the

**Figure 3** The cyst is shown originating from the ligamentum teres.

**Figure 4** Hematoxylin-eosin staining of the cyst wall shows the single layered cuboidal epithelium ( $\times$  40).

lesion was composed of a single layered cuboidal epithelium. No signs of malignancy were identified (Figure 4). The patient's postoperative course was uneventful. The patient was discharged on the second postoperative day. After 6 mo, the patient was well and in good condition with no further symptoms.

## DISCUSSION

Unusual lesions reported in the falciform ligament and ligamentum teres of the liver are lipoma<sup>[4-6]</sup>, paraganglioma<sup>[7]</sup>, lymphangioma<sup>[8]</sup> and leiomyosarcoma<sup>[9-14]</sup>.

Moreover, simple serous cysts of the falciform ligament<sup>[1-3,15]</sup> and the ligamentum teres of the liver have been sporadically reported in the literature<sup>[16-20]</sup>.

The etiology of liver ligament cysts is diverse and the causes have been classified into primary and secondary<sup>[1]</sup>. Primary cysts arise during development from congenital defects of mesenteric origin<sup>[21]</sup>. Secondary cysts are the result of infections (echinococcus, abscesses), trauma (hematomas and biliary leaks) and neoplasms with cystic degeneration. Partial obliteration of the umbilical veins has also been reported to cause falciform ligament cysts<sup>[20]</sup>. Pathology report suggested the congenital origin of the cyst in our case.

The main symptoms of these patients are unclear and have been reported to include vague abdominal pain and indigestion. Physical examination may sometimes demonstrate a palpable right upper quadrant mass as well.

Our patient was treated with laparotomy to reach a definite diagnosis. Intraoperative findings included a solitary cyst, 5 cm × 5 cm in size, originating from the round ligament of the liver, which was attached to the right rectus abdominis muscle. It was easily dissected since it contained no hard adhesions to the abdominal wall and totally removed. Laparotomy allowed complete inspection of the abdomen to exclude other intra-abdominal masses or lymphnodes.

Ultrasound and computed tomography scans are essential to identify the solid or cystic nature of such lesions but cannot provide a definite diagnosis. In a similar previous report, a falciform ligament cyst has been suggested at CT by a water-density mass at the caudal aspect of the left intersegmental fissure<sup>[3]</sup>. Nevertheless, a significant number of other benign or malignant lesions have been previously presented as mentioned above.

As a result, the differential diagnosis of a right upper quadrant mass includes several clinical entities and radiological findings can only imply but not ensure a definite diagnosis.

### Abstract

We described a patient with adenocarcinoma of the stomach combined with choriocarcinoma and neuroendocrine cell carcinoma. An 85-year-old man visited our hospital because of appetite loss. Gastric fiberoscopy revealed a large tumor occupying the cardinal region and anterior wall of the gastric body. The patient underwent total gastrectomy with lymphnode dissection and partial resection of the liver. Choriocarcinoma, small cell carcinoma and tubular adenocarcinoma existed in the gastric tumor. The choriocarcinomatous foci contained cells positive for beta-subunit of human chorionic gonadotropin (B-hCG) and human placental lactogen mainly in syncytiotrophoblastic cells. The small cell carcinomatous foci contained cells positive for synaptophysin, neuron-specific enolase (NSE), and chromogranin A. The prognosis for gastric adenocarcinoma with choriocarcinoma and neuroendocrine cell carcinoma is exceedingly poor. This patient died about 2 mo after the first complaint from hepatic failure. This is the first reported case of gastric cancer with these three pathological features.

### INTRODUCTION

Primary carcinoma of the stomach is almost always adenocarcinoma or signet ring cell carcinoma and there have been few reports of choriocarcinoma<sup>[1-5]</sup> or neuroendocrine cell carcinoma<sup>[6-9]</sup>. We report a patient with adenocarcinoma of the stomach combined with choriocarcinoma and neuroendocrine cell carcinoma. This is the first reported case of gastric cancer with these three pathological features.

### CASE REPORT

An 85-year-old man was admitted to Kouseiren Takaoka Hospital because of appetite loss in March 2004. He had been treated for hypertension and gout in another hospital. His family history was negative for family and hereditary disease. On examination, the patient was pale because of severe anemia, and had an ill-defined mobile left hypochondrial mass, approximately 10 cm in size. Findings for the chest and heart were normal. Lymphadenopathy, hepatomegaly, and splenomegaly were not observed and the testes and breasts were normal. Blood examination showed severe anemia, leukocytosis, and platelet count was increased. The level of serum carcinoembryonic antigen (CEA) was slightly elevated (Table 1). Radiographic examination of the

upper gastrointestinal tract demonstrated a Borrmann type 1 tumor in the cardia. Gastric fiberoscopy revealed a large tumor occupying the cardial region and anterior wall of the gastric body accompanied by areas of hemorrhage. Tumor invasion to the esophagus was highly suspected. Biopsy specimens were interpreted as showing adenocarcinoma without features of choriocarcinoma or neuroendocrine cell carcinoma. Contrast-enhanced computed tomography (CT) of the abdomen showed a 7-cm low-density tumor suspected to be regional lymph node metastasis. Liver and lung metastases and abnormality with his testes and breast were not detected radiologically. The patient underwent total gastrectomy on March 15, 2004, with the preoperative diagnosis of primary gastric carcinoma. Liver metastasis, peritoneal dissemination, and ascites were not investigated, and distant metastasis to other organs was not present. There was an invasive tumor encircling the gastric body and cardia and this tumor was invading the liver. Total gastrectomy with lymphnode dissection and partial resection of the liver were performed. The Roux-en-Y method of reconstruction was performed after resection.

### Gross findings

The resected specimen included an elevated tumor with

Figure 1 Cut surfaces of the tumor demonstrate two different features, a hemorrhagic brown area and a whitish-yellow area.

Figure 2 A: The hemorrhagic brown area is composed of choriocarcinoma; B: The whitish-yellow area contains small cell carcinoma.

ulcer measuring 12.0 cm  $\times$  11.5 cm in the cardia, the body of the stomach, and abdominal esophagus, and the tumor had invaded the liver. Cut surfaces of the tumor showed two different features, a hemorrhagic brown area and a whitish-yellow area. Most of the tumor was composed of the hemorrhagic brown area (Figure 1).

### Histopathological findings

The hemorrhagic brown area was composed of choriocarcinoma, and consisted mostly of clusters of cytotrophoblastic cells separated by steaming masses of syncytiotrophoblasts (Figure 2A). Cytotrophoblastic cells were small cells with large, oval nuclei, and syncytiotrophoblasts were large cells with bizzare nuclei. The whitish-yellow area contained small cell carcinoma, consisting of small amounts of cytoplasm with large nuclei (Figure 2B) and tubular adenocarcinoma.

**Figure 3** A: The choriocarcinomatous foci contain cells positive for B-hCG; B: The small cell carcinomatous foci contain cells positive for chromogranin A.

### Immunohistochemical findings

The choriocarcinomatous foci contained cells positive for beta-subunit of human chorionic gonadotropin (B-hCG) and human placental lactogen mainly in syncytiotrophoblastic cells (Figure 3A). These findings enabled us to diagnose these cells as choriocarcinoma. The small cell carcinomatous foci contained cells positive for synaptophysin, neuron-specific enolase (NSE), and chromogranin A (Figure 3B). From these results, we diagnosed them as neuroendocrine cell carcinoma.

### Outcome

The patient was discharged uneventfully 3 wk after surgery. He presented to our hospital with general malaise 2 wk after discharge. CT revealed multiple liver tumors, and his serum hCG level was 67 000 IU/mL. The liver tumor progressed, the patient died eventually from hepatic failure 6 wk after operation.

## DISCUSSION

Choriocarcinoma can be gonadal or extragonadal in origin, and most often arises in the uterus in association with pregnancy<sup>[10]</sup>. The most common sites for extragonadal tumors are the mediastinum, ovary and testis<sup>[11]</sup>. There are many reported cases with metastatic choriocarcinoma to the stomach<sup>[12]</sup>, but primary choriocarcinomas of the stomach are extremely rare. Primary neuroendocrine carcinomas are known to arise in the stomach, although they are also rare. Motoyama *et al.*<sup>[13]</sup> reported a case of combined choriocarcinoma, hepatoid carcinoma, small cell carcinoma, and tubular

adenocarcinoma in the esophagus in 1995, but there has been no reported case of combined choriocarcinoma, neuroendocrine carcinoma and tubular adenocarcinoma in the stomach in the English-language literature.

There are several theories of the histopathogenesis of primary choriocarcinoma of the stomach. These hypotheses include origin from a gonadal angle displaced in the abdomen<sup>[14]</sup>, histological resemblance to choriocarcinoma<sup>[10]</sup>, origin from an underlying gastric teratoma<sup>[15]</sup>, and the retrodifferentiation or opisthoplatia of carcinoma cells to the level of the embryonal ectoderm with the ability to form trophoblasts<sup>[16]</sup>. The finding that gastric choriocarcinomas are frequently accompanied by adenocarcinoma is supported by this retrodifferentiation theory. In the present case, choriocarcinomas, neuroendocrine carcinomas and tubular adenocarcinoma existed in the same tumor of the stomach, and this finding suggests that choriocarcinoma and neuroendocrine carcinoma represent aberrant differentiation in common adenocarcinoma.

In the present case, we failed to diagnose adenocarcinoma combined with choriocarcinoma and neuroendocrine carcinoma before operation based on pathological examination of biopsy specimens. Therefore, larger biopsy specimens from the whole tumor should be taken when encountering large and hemorrhagic tumors so that pathologic components are not missed.

It is well known that choriocarcinomas and neuroendocrine carcinomas readily metastasize to distant organs and carry a poor prognosis because effective regimens have not been established. Further studies to establish new regimens are required.

Pneumatosis cystoides intestinalis after fluorouracil chemotherapy for rectal cancer. *World J Gastroenterol* 2008; 14(20): 3273-3275 Available from: URL: <http://www.wjgnet.com/1007-9327/14/3273.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.3273>

### INTRODUCTION

Fluorouracil (FU) is one of the most commonly used chemotherapeutic agents in clinical oncology regimens. With regard to colorectal cancer, treatment involving FU with leucovorin (LV) can improve the survival, tumor response and quality of life<sup>[1]</sup> of patients. We report a case of pneumatosis cystoides intestinalis (PCI) in a patient who received adjuvant chemotherapy with 5-FU and l-LV<sup>[2]</sup>. To our knowledge, FU-related or FU-induced PCI has not been reported previously. This case will add to the reported series of patients with FU-induced small bowel toxicity<sup>[3,4]</sup> and chemotherapy-related PCI<sup>[5-9]</sup>.

### CASE REPORT

A 76-year-old male underwent anterior resection for stage III rectal cancer. He received an adjuvant chemotherapy protocol comprising intravenous bolus injection of 600 mg/m<sup>2</sup> 5-FU at 1 h after the initiation of 2 h-long 250 mg/m<sup>2</sup> l-LV infusion, once a week for 6 wk, followed by 2 wk of rest<sup>[2]</sup>. After 1 cycle of this treatment, the patient presented with diarrhea and abdominal pain. Although his abdomen was distended, he did not exhibit any peritoneal signs. He was afebrile and had no neutropenia. His stool culture was negative. An abdominal radiogram revealed the presence of free air under the diaphragm and intramural gas in the entire intestine (Figure 1). Abdominal computed tomography (CT) revealed the presence of free air in the intestinal wall, retroperitoneal space (Figure 2A), and falciform ligament (Figure 2B). Since bowel perforation was strongly suspected, an emergency operation was performed. Laparotomy revealed pneumatosis of the intestine (Figure 3) and colon, and pneumoretroperitoneum without evidence of perforation. Therefore, gastrostomy was performed to reduce the pressure in the bowel. PCI was

### Abstract

Pneumatosis cystoides intestinalis (PCI) is a relatively rare condition characterized by intraluminal gas in the gastrointestinal tract. Several chemotherapeutic agents have been reported to be associated with PCI, although fluorouracil-related PCI is extremely rare. We report a case of a 76-year old man who received adjuvant chemotherapy for rectal cancer with fluorouracil (FU) and leucovorin (LV). After 1 cycle of the treatment, he presented with diarrhea and abdominal pain. Abdominal radiogram revealed the presence of free air under the diaphragm and intramural gas in the intestine. Laparotomy was performed, showing a suspected diagnosis of perforation in the gastrointestinal tract. Intraoperative findings revealed pneumatosis of the intestine without evidence of perforation. He was treated supportively and his symptoms improved. In conclusion, we should consider the possibility of PCI occurring in patients with malignancies during chemotherapy treatment.

disappeared within 2 wk after parenteral nutrition, antibiotic treatment and oxygen therapy. Enema showed no

incidence of anastomotic stenosis and he administered oral uracil-ftorafur, and no recurrence of PCI was observed during the 1-year follow-up.

## DISCUSSION

PCI is relatively rare condition characterized by multiple intraluminal gases existing in any part of the gastrointestinal tract. The mechanism and etiology of PCI are not fully understood. According to most hypotheses, mechanical and bacterial factors are the predominant causes for PCI<sup>[10-12]</sup>. However, in this present case, no mechanical or bacterial factors, including bowel ischemia, bowel obstruction<sup>[13,14]</sup>, inflammatory bowel disease and infectious colitis, for the gas production in the intestinal wall were observed.

Several chemotherapeutic agents have been reported to be associated with PCI, including cyclophosphamide, cytarabine, vincristine, doxorubicin, daunorubicin, etoposide, docetaxel, irinotecan and cisplatin<sup>[5-9]</sup>. Although fluorouracil-related PCI has not been previously described, the cytotoxic effect of chemotherapy on the epithelial bowel can also play a role in the pathogenesis of PCI<sup>[7]</sup>. Because the intestinal mucosa is highly proliferative, mucosal damage occurs easily during chemotherapy<sup>[6]</sup>. Moreover, the chemotherapeutic agent might interfere with the mucosal integrity of the intestinal tract, resulting in extensive intramural air<sup>[8]</sup>. Tamura *et al*<sup>[15]</sup> reported that PCI following chemotherapy might be due to depletion of submucosal lymphoid tissue or leukemic infiltrates, such as denuded Peyer's patches producing mucosal defects, thereby permitting entry of gas into the bowel wall. It was reported that chemotherapy-related PCI occurs due to immunosuppressive treatment for hematological malignancies<sup>[5,6]</sup>. Neutropenia is an important factor for the development of PCI<sup>[5-9]</sup>. However, the current patient did not suffer from neutropenia before or when PCI was diagnosed.

Several studies have reported severe erosion and superficial ulceration in the ileum after chemotherapy comprising 5-FU and LV in colon cancer patients<sup>[3,4]</sup>. The mechanisms are thought to be multifactorial, including alteration in the local mucosal blood flow and thrombogenic and vasospastic effects of 5-FU on the vascular epithelium<sup>[5]</sup>. The mechanism underlying 5-FU-induced PCI is thought to be multifactorial, including bowel toxicity caused by 5-FU itself.

In conclusion, although PCI is a rare complication of chemotherapy, the possibility of PCI occurring in patients undergoing chemotherapy should be kept in mind.

## ACKNOWLEDGMENTS

The written consent was obtained from the patient for publication of this case report.

### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (*World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly open access peer-reviewed journal supported by an editorial board consisting of 1215 experts in gastroenterology and hepatology from 60 countries. The aim of the journal is to deliver the most clinically relevant original and commentary articles to readers, and to make the full text publicly available to all clinicians, scientists, patients and biomedical students on an unrestricted platform, so that they can access and learn about the most recent key advances in the field.

In addition to the open access nature, another key characteristic of *WJG* is its reading guidance for each article which includes background, research frontier, related reports, breakthroughs, applications, terminology, and comments of peer reviewers for the general readers.

*WJG* publishes articles on esophageal, gastrointestinal, hepatobiliary and pancreatic tumors, and other esophageal, gastrointestinal, hepatic-biliary and pancreatic diseases in relation to epidemiology, immunology, microbiology, motility & nerve-gut interaction, endocrinology, nutrition & obesity, endoscopy, imaging and advanced hi-technology.

The main goal of *WJG* is to publish high quality commentary articles contributed by leading experts in gastroenterology and hepatology and original articles that combine the clinical practice and advanced basic research, to provide an interactive platform for clinicians and researchers in internal medicine, surgery, infectious diseases, traditional Chinese medicine, oncology, integrated Chinese and Western medicine, imaging, endoscopy, interventional therapy, pathology and other basic medical specialties, and thus eventually improving the clinical practice and healthcare for patients.

### Indexed and abstracted in

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, Index Medicus, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology and Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

### Published by

The WJG Press

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjgnet.com>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjgnet.com](mailto:submission@wjgnet.com), or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was carried out; author contributions; disclosure of any financial support for the research; and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (remove all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s), and full family name.

**Author contributions:** The format of this section should be like this: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed research; Wang CL, Zou CC, Hong F and Wu XM performed research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed data; and Wang CL, Liang L and Fu JF wrote the paper.

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

#### Abstract

An informative, structured abstract of no more than 350 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipment, and the experimental procedures should be included. RESULTS: The observed and experimental results, including data, effects, outcome, *etc.* should be included. Authors should present *P* value where necessary, and also include any significant data. CONCLUSION: Accurate view and the value of the results should be included.

The format for structured abstracts can be found at: <http://www.wjgnet.com/wjg/help/11.doc>.

#### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

#### Text

For articles of these sections, original articles, rapid communication

and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, should be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

### Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ... *etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

### Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  should be noted ( $P > 0.05$  should not be noted). If there are other series of  $P$  values, <sup>c</sup> $P < 0.05$  and <sup>d</sup> $P < 0.01$  are used. A third series of  $P$  values can be expressed as <sup>e</sup> $P < 0.05$  and <sup>f</sup> $P < 0.01$ . Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

### PMID requirement

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information for journal citations is very important. Using the reference testing system, the authors and editor should check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in an ASP file so that the readers can immediately access the abstract of the citations online.

### DOI requirement

A CrossRef DOI® (Digital Object Identifier) name is a unique string created to identify a piece of scholarly content in the online environment. The author should supply the DOIs for journal citation (doi:10.3748/wjg.13.6458). This link (<http://www.crossref.org/SimpleTextQuery/>) allows you to retrieve Digital Object Identifiers (DOIs) for journal articles, books, and chapters by simply cutting and pasting the reference list into the box. You may use the form with any reference style, although the tool works most reliably if references are formatted in a standard style such as shown in this example: Assimakopoulos SF, Scopa CD, Vagianos CE. Pathophysiology of increased intestinal permeability in obstructive jaundice. *World J Gastroenterol* 2007; 13(48): 6458-6464

The accuracy of the information of journal citations is very important. We will interlink all references with DOI in ASP file so that readers can access the abstracts of cited articles online immediately.

### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

## Electronic journal (list all authors)

Morse SS. Factors in the emergence of infectious diseases. *Emerg Infect Dis* serial online, 1995-01-03, cited 1996-06-05; 1(1): 24 screens. Available from: URL: <http://www.cdc.gov/ncidod/EID/eid.htm>

## Patent (list all authors)

- 16 Pagedas AC, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

## Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those linked with a hyphen when the difference between the two numbers is greater than five. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered inappropriate references. Authors should not cite their own unrelated published articles.

## Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

## Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as *v* (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

## Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6  $24.5 \mu\text{g/L}$ ; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: <http://www.wjgnet.com/wjg/help/15.doc>.

## Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of

Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

## Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gvrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindIII*, *BamHI*, *KhoI*, *KpnI*, etc.

Biology: *H pylori*, *E coli*, etc.

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

## Editorial Office

### World Journal of Gastroenterology

Editorial Department: Room 903

Ocean International Center, Building D

No. 62 Dongsihuan Zhonglu

Chaoyang District, Beijing 100025, China

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

Telephone: +86-10-59080039

Fax: +86-10-85381893

## Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

## Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/9.doc>.

## Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/10.doc>.

## Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

## Links to documents related to the manuscript

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

## Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

## Publication fee

Authors of accepted articles must pay a publication fee.

EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

Surgical treatment for rectal cancer: An international perspective on what the medical gastroenterologist needs to know. *World J Gastroenterol* 2008; 14(21): 3281-3289 Available from: URL: <http://www.wjgnet.com/1007-9327/14/3281.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.3281>

## Abstract

Rectal cancer accounts for one third of all colorectal cancers. The age adjusted death rates from colorectal cancer have declined over recent decades due to a combination of colorectal cancer screening, improved diagnostic tests, improved standardized surgical technique, improved medical support, neoadjuvant chemotherapies and radiation treatment or combinations of these. Because of complex treatment algorithms, use of multidisciplinary teams in the management of rectal cancer patients has also been popularized. Medical gastroenterologists performing colonoscopies are frequently the first health care provider to raise the suspicion of a rectal cancer. Although the diagnosis depends on histological confirmation, the endoscopic presentation is almost diagnostic in many cases. In order to meet the patient's immediate needs for information, it is important that the endoscopist has knowledge about the investigations and treatment options that will be required for their patient. The aim of this paper is to describe the modern preoperative investigations and operative procedures commonly offered to rectal cancer patients taking into account perspectives of three colorectal surgeons, practicing in the USA, Europe and Asia.

## INTRODUCTION

Rectal cancer accounts for one third of all colorectal cancers and in the USA 41 420 new rectal cancer cases were estimated in 2007<sup>[1]</sup>. The age adjusted death rate from colorectal cancer has declined over recent decades due to a combination of colorectal cancer screening, improved diagnostic tests, improved standardized surgical technique, improved medical support, neoadjuvant chemotherapies and radiation treatment or combinations of these<sup>[2]</sup>. Because of complex treatment algorithms, use of multidisciplinary teams in the management of rectal cancer patients has also been popularized<sup>[3]</sup>.

Medical gastroenterologists performing colonoscopies are frequently the first health care provider to raise the suspicion of a rectal cancer. Although the diagnosis depends on histological confirmation, the endoscopic presentation is almost diagnostic in many cases. In order to meet the patient's immediate needs for information, it is important that the endoscopist has knowledge about the investigations and treatment options that will be required for their patient.

The aim of this paper is to describe the modern preoperative investigations and operative procedures commonly offered to rectal cancer patients taking into account perspectives of three colorectal surgeons, practicing in the USA, Europe and Asia.

## PREOPERATIVE INVESTIGATION AND STAGING

Perhaps the most basic and informative test in patients with low rectal cancer is a digital examination. For many tumors, this will immediately give the experienced surgeon enough information to determine what treatment will be required. As well as a general health evaluation, such as appropriate cardiopulmonary investigations, the preoperative evaluation includes rigid proctoscopy, endoscopic rectal ultrasound, total colonoscopy, pelvic MRI, CT-scans of the abdomen, liver and lungs. These investigations will help the surgeon and his multidisciplinary team to determine: (1) The patient's health condition and comorbidities; (2) The stage of the rectal cancer; and (3) Which treatment option is best suited to meet the patient's preferences and at the same time be oncologically appropriate.

## MEDICAL HISTORY AND PHYSICAL EXAMINATION

The three decisions that should be made initially include: whether the tumor is suitable for local therapy; whether preoperative therapy is required; and whether a permanent stoma is necessary. Severe comorbidities and poor health status can be a relative contraindication to abdominal surgery, whether open or even laparoscopic. A local or palliative approach may then be more reasonable. Accurate preoperative tumor staging is of extreme importance as it determines the indications for neoadjuvant therapy and the possibilities for a local resection versus a radical abdominal procedure. This must be balanced against the patient's preferences while at the same time giving the patients and their family the option to choose an individualized treatment plan with optimal chance for cure.

A patient history of previous pelvic or abdominal surgery will increase the difficulty of a laparoscopic approach, and thereby increases the likelihood of a decision for open rectal surgery. Abdominal wall scars should be noted as they might preclude the optimal stoma placement. Morbid obesity, especially in males, because of more intra-abdominal fat and narrow pelvis compared to females, will also favor open rectal surgery compared to laparoscopic surgery.

If the patient has a low rectal cancer, careful palpation of the groin lymph nodes is mandatory. Finding of one or several enlarged, hard and painless lymph nodes in the groin will ultimately lead to focus on palliative treatment once the finding is verified by MRI or biopsy. Excision (removing whole lymph nodes) should be considered after preoperative irradiation therapy including the affected groin.

Information about the benefits and limitations of the various surgical methods available, including the laparoscopic approach compared to the open operation should be given by the operating surgeon. However, most patients would also expect the medical endoscopist

to have a brief overview and knowledge of the most common preoperative investigations and operative procedures performed in the treatment of rectal cancer. Frequently, the endoscopist receives questions about chemoradiation therapy or is involved in the diagnosis and treatment of its side-effects.

## DIGITAL RECTAL EXAMINATION (DRE)

Despite the limited sensitivity and specificity of DRE, until recently the whole treatment plan was based upon its performance. Important information can still be gained from a correctly performed digital examination. What is the condition of the anal sphincters? Can the tumor be reached? If yes, is it occlusive? How much of the circumference is involved? Is it fixed to the surrounding tissue or can it be freely moved? What is the distance from the dentate line to the lower border of the tumor? Can the upper edge be reached?

By this simple examination the size, mobility and location of the cancer can be assessed. Before any decisions about treatment are made, the information gathered from DRE has to be confirmed by more objective means.

## ENDOSCOPIC INVESTIGATIONS

A colonoscopy is used to rule out the presence of synchronous polyps and cancers in the rest of the colon with a reasonably high accuracy<sup>[4]</sup>. The findings of multiple polyps in a patient under the age of 50 should alarm the endoscopist of a hereditary colorectal cancer. A detailed family history of cancer is warranted and referral to genetic consultation should be considered. In patients with familial cancer syndromes, the planned operation is a total colectomy. A colectomy with ileorectal anastomosis is used for patients with hereditary non-polyposis colon cancer (HNPCC), and those with familial adenomatous polyposis (FAP) and fewer than 20 rectal polyps. Patients with FAP and more than 20 rectal polyps should undergo proctocolectomy and ileoanal anastomosis.

When the patient with rectal cancer meets the surgeon at the outpatient clinic, both transanal endoscopic rectal ultrasound (TRUS) and rigid proctoscopy will be performed. The diagnostic accuracy for TRUS is dependant on the experience of the operator, and the stage and location of the tumor. Because of limited reach, large tumors in the upper rectum are not suitable for rectal ultrasound. Occluding tumors that cannot be passed with the transducer are also not amenable for this examination. TRUS is most accurate for early rectal cancers in the distal half of the rectum, and is particularly valuable in assessing the T-stage. The limited penetration depth of 7 MHz ultrasound waves makes it difficult to access the N-stage with high precision, with most studies showing accuracy of 70%-75%<sup>[5]</sup>. Three dimensional rectal ultrasound imaging seems to improve the staging properties<sup>[5]</sup>. Thus, for making a decision about whether local resection is possible the results of TRUS are of significant importance.

## MRI OF PELVIS

Because standard protocols can be used, and because it is less operator dependent, MRI has become the standard for preoperative stage assessment of rectal tumors<sup>[5]</sup>. With its high resolution and accuracy MRI can give information about T-stage and N-stage as well as distance to planned resection margins, especially lateral or circumferential margins within the pelvic cavity. MRI may also be used for the assessment of response to preoperative neoadjuvant chemoradiation treatment (CRT).

## CT SCAN OF LIVER AND LUNGS

CT scans of liver and lungs are performed to rule out the presence of metastatic disease. Resectable liver metastasis can be removed in a one stage operation or as a second operation 3 mo after the primary rectal cancer surgery. Multiple metastases in both liver lobes or hilar lymph node involvement are signs of incurable disease. However, some of the new forms of chemotherapy have such excellent response rates that these patients may become surgical candidates after reassessment.

## BLOOD TESTS

After the diagnosis of colorectal cancer, the carcinoembryonic antigen (CEA) level is measured in a simple blood test. The result of the CEA does not have any implications for the treatment, but increased levels are associated with poorer prognosis<sup>[6]</sup>. After resection of the cancer, elevated CEA levels should return to normal or metastatic disease should be suspected. CEA levels > 50 are very suggestive of liver metastases. In the surveillance program a three-fold increase in CEA level should alert the surgeon to search for local recurrence or metastatic disease<sup>[7]</sup>.

Other blood tests such as electrolytes, hemoglobin, and albumin are frequently taken to assess the patient's general condition. A low serum albumin indicates poor nutritional status or deranged liver function and is associated with increased frequency of postoperative complications including anastomotic leaks.

## MULTIDISCIPLINARY TEAMS

The complexity of individualized and highly specialized preoperative investigations and neoadjuvant treatment plans has evolved into the need for multidisciplinary teams. These teams are now being used in many institutions to ensure patients are appropriately placed on multidisciplinary care pathways. The results of the preoperative investigations and the clinical information about the patient are reviewed in the presence of dedicated specialists in medical oncology, gastrointestinal radiology and colorectal surgery. In the same meeting the pathology report of previous cases can be presented by a pathologist. The accuracy of the preoperative investigations, critical reevaluation of indications for adjuvant treatment, adjuvant treatment response as well as a judg-

ment of the quality of the surgery performed can be discussed in relation to the pathological TMN stage and resection margins presented in the pathology report.

## NEOADJUVANT TREATMENT

There is an important debate going on among surgical and oncological experts in rectal cancer treatment regarding the use of pre- or post operative radiation with or without chemotherapy in order to reduce rates of local recurrence and improve survival. Best evidence seems to support preoperative radiation in order to reduce local recurrence and at the same time reduce the side effects of radiation<sup>[8-10]</sup>. Adding chemotherapeutic agents to increase tumor radiosensitivity has been shown to be beneficial in improving local control, but was reported to have no effect upon survival<sup>[11]</sup>. Most centers nowadays have included preoperative chemoradiation therapy in their multimodality treatment options. However, there are still discussions about what gives best oncological results: short term radiation with 25Gy given in daily fractions of 5Gy and surgery the following week, or long term radiation treatment with chemotherapy in daily fractions of 1.8Gy five days per week, 50.4Gy in total, followed by surgery 4 to 6 wk later<sup>[12]</sup>. The latter treatment option probably has the advantage of down staging of the tumor and thereby increases the possibilities of a sphincter saving procedure, particularly in advanced low rectal cancers<sup>[13]</sup>. The connection between preoperative chemoradiation and achievement of uninvolved circumferential resection margin (CRM) is uncertain<sup>[14,15]</sup>.

The long term follow up of the European Organisation for Research and Treatment of Cancer (EORTC) trial 22921 that compared adjuvant fluorouracil-based chemotherapy to no adjuvant treatment in patients with resectable T3-4 rectal cancer, reported no beneficial effects of adjuvant chemotherapy if the cancer did not respond to the preoperative radiation or chemoradiation therapy<sup>[16]</sup>.

The role of postoperative radiation has recently been limited to inadvertent tumor perforations intraoperatively or involved resection margins if irradiation treatment was not given preoperatively. Intraoperative radiation therapy (IORT) can be given in cancers locally invading the pelvic side walls<sup>[17]</sup>. The definite role of postoperative chemotherapy for rectal cancer remains unclear<sup>[10]</sup>.

However, the situation is even more complicated. Current discussion is not just about which is the best treatment, but also which patients should receive such treatment. Generally accepted international treatment guidelines are yet to be developed. Some countries recommend preoperative radiation or chemoradiation to almost all rectal cancer patients<sup>[11,18]</sup>, whereas others recommend neoadjuvant chemotherapy to all patients with stage II and III rectal cancer<sup>[19]</sup>. Finally, others argue for a more selective neoadjuvant treatment policy offering it only to patients with preoperative MRI showing threatened CRM (nearest tumor tissue < 3 mm from predicted CRM) or for tumors in the lower half of the rectum<sup>[3,20-22]</sup>.

## SURGICAL TREATMENT OF RECTAL CANCER

Surgery is the only method to offer cure for rectal cancer. Rectal cancer surgery performed either as a minimally invasive or as an open procedure has four goals<sup>[23]</sup>: (1) To cure the patients and give long term survival; (2) To give local control and avoid local recurrence; (3) To preserve normal defecation-, bladder- and sexual functions when possible; (4) To maintain or improve the patients quality of life.

The best way to achieve goal number 1-cure and long term survival; and goal number 2-local control and avoidance of local recurrence, is by means of major surgery. However, this has its price and considerable efforts have been made to reduce the negative impact of rectal resections upon goals number 3-to preserve normal defecation-, bladder- and sexual functions and goal number 4-to maintain or improve the patients quality of life.

Functional disturbances such as impotency, retrograde ejaculation, urinary retention or disturbed urinary bladder function as well as defecational problems or formation of a stoma have negative impact on quality of life after surgical treatment. One of the main steps during the dissection of the mesorectum is to identify and preserve the hypogastric and parasympatic pelvic nerves and thereby preserve functions. Functional disturbances are still a problem after rectal cancer surgery in about 20% of the patients<sup>[24]</sup>. Table 1 shows a summary of abbreviations that are commonly used in the surgical treatment of rectal cancer.

### Local resections

Local resections are performed transanally using both specially developed instruments and sutures to expose the rectal mucosa (transanal excision, TAE), or the operation might be performed endoscopically using a microscope to improve visualization through a specially designed proctoscope to secure access and instrumentation of the tumor (transanal endoscopic microsurgery, TEM). Local resections would be the operation of choice if only goals 3 and 4 were to be considered. Early rectal cancers treated with local resections have been reported to be associated with unacceptably high local recurrence rates of up to 40%<sup>[25]</sup>, and should only be offered to carefully selected patients, or to those who otherwise would need a permanent end stoma<sup>[26]</sup>. For patients with severe comorbidities or with extremely high risk from anesthesia and abdominal surgery, a local resection procedure can be the optimal solution despite its limitations regarding local recurrences. Studies are underway in which the results of combining chemoradiation therapy and TEM will be determined<sup>[27]</sup>.

Studies of the mesorectum in rectal cancer have shown that 10% of early rectal cancer (T1) has micrometastasis in mesorectal lymph nodes, and close to 20% have local lymph node metastasis in T2 cases<sup>[28]</sup>. Performing local resections that leave metastatic lymph nodes is undoubtedly likely to increase local recurrence rates, although the exact risk has yet to be evaluated and

Table 1 Vocabulary for rectal cancer treatment

	Treatment
Anterior resection	Resection of rectum with an anastomosis above the pelvic peritoneal reflection.
Low anterior resection	Resection of rectum with an anastomosis below the pelvic peritoneal reflection.
TME	Total mesorectal excision. The fatty tissue which contains the draining lymph nodes surrounding the lateral and posterior part of the rectal tube, are dissected down to the pelvic floor and resected. The hypogastric nerves are preserved.
PME	Partial mesorectal excision. The mesorectum is divided 5 cm below the cancer and rectum transected. PME is performed for cancers located in the upper rectum and rectosigmoid junction.
TEM	Transanal endoscopic microsurgery. A specially constructed proctoscope with an attached microscope permits local resection of premalignant lesions and selected cases of early rectal cancer up to 20 cm from the anal verge.
TAE	Transanal excision. Lesions in the lower third of rectum can be resected transanally.
APR	Abdominoperineal resection. Low rectal cancers that cannot be resected with a sphincter-saving procedure are resected with perianal tissue and the anal channel en block with the whole rectum and mesorectum.
Adjuvant	Additional treatment (chemotherapy, radiation therapy or chemoradiation) given after surgical resection.
Neoadjuvant CRT	Preoperative treatment. Chemoradiation treatment. Chemotherapeutic drugs, typically 5'-fluorouracil and/or leucovorin are given in order to increase cancer cells sensitivity to the radiation. CRT is frequently offered to patients preoperatively (neoadjuvant) in order to reduce the chances for local recurrence and improve survival.
Intersphincteric resection	The upper part of the internal anal sphincter muscle is resected continuously with the lower rectum in order to preserve anal function and avoid colostomy in cases of ultralow rectal cancer.
CRM	Circumferential resection margin is the distance in mm from the mesorectal fascia (the resection plane) to the nearest tumor growth.
DRM	Distal resection margin.

the risk is likely dependent on the exact individual tumor stage biology.

### Total mesorectal excision (TME)

Heald and coworkers standardized the approach to rectal cancer by performing a TME with sharp dissection in the avascular plane surrounding the mesorectum with preservation of the hypogastric and parasympathetic pelvic nerves<sup>[29]</sup>. They reported a 5-year recurrence rate of 5%-7% or lower, depending on the cancer stage, without the use of neoadjuvant treatment, showing the importance of adequate surgical quality upon local recurrence. By contrast, traditional rectal cancer surgery with blunt dissection and ignoring the importance of an intact mesorectum with adequate tumor resection margins,

has yielded local recurrence rates of 30% or higher<sup>[30]</sup>. The benefits of the mesorectal dissection technique have been confirmed in several European countries after introduction of training programs and national consensus of TME as the standard operation method for rectal cancer<sup>[11,18,31]</sup>. It has been documented that cancers located in the upper rectum do not need to be removed along with all the fatty tissue surrounding the rectum (mesorectum) down to the pelvic floor<sup>[32]</sup>. They do need a TME-like radial margin, but can be resected with a 5-cm distal margin to the cancer, ie a partially mesorectal excision (PME), without compromising the oncological result. This helps minimize some of the functional disturbances seen after a coloanal anastomosis.

The development of suturing devices with stapled circular anastomosis has also made the formation of anastomoses in the lower pelvis feasible, reducing the need for permanent stomas. However, the reported rates of anastomotic complications still vary considerably between surgeons<sup>[33]</sup>. It is common practice to protect the lowest anastomosis, especially after radiation treatment, with a temporary diverting loop ileostomy. The ileostomy is normally closed after 8 to 12 wk.

The low anterior syndrome describes the functional disturbances that may be seen after rectal cancer surgery. Improved defecation function can be achieved by anastomosing a colon J pouch to the top of the anal channel or to the top of a short rectal remnant<sup>[34]</sup>.

### **Laparoscopic mesorectal excision**

Laparoscopic resection of the rectum has not gained the same international acceptance as laparoscopic colon surgery. However, it has proven to be technically feasible and safe with no more or perhaps fewer complications than after open rectal surgery<sup>[35,36]</sup>. Low anterior resection (LAR) technically performed as laparoscopic TME or PME has the same oncological outcome when compared to traditional open rectal surgery<sup>[37-40]</sup>. For patients, laparoscopic surgery gives benefits regarding reduced postoperative pain, shortened postoperative ileus with faster bowel recovery after surgery, improved abdominal cosmesis, fewer wound infections, less postoperative small bowel obstruction and ventral hernias<sup>[41,42]</sup>. For the health care providers the benefits are shorter hospital stay and reduced overall costs<sup>[43]</sup> and thereby more effective use of health care resources.

Because of the technical challenges of laparoscopic pelvic surgery a standardization of the technique is important to reduce the rate of conversion and improve the operating team performance. The learning curve for laparoscopic mesorectal resection is higher than commonly stated for other laparoscopic procedures<sup>[44]</sup>. This has probably contributed to the centralization of laparoscopic rectal resections to high volume hospitals with trained and experienced surgeons.

### **Abdominoperineal resection (APR)**

About one third of rectal cancers are located in the distal third of the rectum. Traditionally this tumor location has led to an APR and a permanent colostomy. A frequency

of 30% or more of APR has therefore been reported in many series<sup>[45]</sup>. However, improved surgical technique and neoadjuvant CRT have made it possible to perform low resections and stapled or handsewn coloanal anastomosis<sup>[46]</sup>. For the ultralow rectal cancers, intersphincteric resection and a handsewn colonic J-pouch anastomosis can be performed with good oncological results<sup>[47]</sup>. Increased focus on sphincter saving surgery has reduced the frequency of APR to around 10% or less in some hands. Some authors even regard the frequency of APR as a surrogate marker of the surgical quality in rectal cancer treatment<sup>[48]</sup>.

### **Hartmann's procedure**

The Hartmann's procedure is a rectosigmoid resection where the bowel continuity is not restored by an anastomosis. Instead the proximal colon is diverted as an end colostomy and the distal rectum, or sometimes just the anal canal, is left behind as a pouch (Hartman's pouch). This procedure is performed in selected rectal cancer patients, such as those with preexisting fecal incontinence, or unacceptably high risk after an anastomotic complication.

### **Loop ileostomy**

A loop ileostomy can be performed to divert the flow of stool until the anastomosis has healed. The ileostomy does not reduce the rate of anastomotic leakage but it will limit the infectious consequences and mortality of the leakage<sup>[49]</sup>. In cases with obstructive symptoms from the cancer, a loop ileostomy can relieve symptoms before preoperative chemoradiation therapy is initiated, as well as reducing the risk of complications associated with emergency surgery by converting emergency cases into later elective surgery.

## **ENHANCED RECOVERY PROGRAMS**

The development of fast track surgery or enhanced recovery programs has dramatically reduced the recovery time and length of hospital stay after colorectal surgery<sup>[50,51]</sup>. By combining laparoscopic rectal surgery and enhanced recovery programs, hospital stay of 4 d or less can be expected for 90% of the patients<sup>[52]</sup>. Fast track pathways may include avoidance of preoperative mechanical bowel preparation, drinking of a carbohydrate enriched solution 2 h prior to surgery, use of total intravenous anaesthesia, early postoperative mobilization, avoidance of nasogastric tubes and abdominal drains, early postoperative intake of liquids and solid food, minimizing opiates for pain control and use of bowel stimulating drugs. Effective pain control can be achieved by patient controlled analgesia (PCA) pumps in most cases. Intravenous and urinary catheters are removed on postoperative day one. Using these strategies as a combined pathway leads to early recovery, with low risk for readmission within 30 d<sup>[53]</sup>.

## **SURGICAL QUALITY**

The aim to cure and improve survival as well as number

of lymph nodes in the specimen the surgical quality can be evaluated within a few days. Similarly, many of the important outcomes of early recovery after surgery can only be achieved in patients having high quality surgery. Tumor biology and stage are important prognostic factors, but so is the performance of the surgeon. The importance of the surgical quality can easily be obscured by focusing on short term and long term over all survival, cancer specific survival, long term and short term local recurrence rates, different radiation regimens with or without pre- or post operative chemotherapy, local versus major resections, or laparoscopic versus open technique. Overall local recurrence rates > 10% should lead to concerns about the surgical quality. However, it is rather late to change the technique, when the rates of local recurrence are commonly calculated 3-5 years after surgery.

By using the recommended pathological description<sup>[54]</sup>, TME grading, CRM, distal mesorectal and mural margins as well as number of lymph nodes in the specimen can be evaluated within a few days of surgery. If preoperative MRI showed more than 2 mm distance from tumor to the lateral resection margin, the CRM measured in the specimen should be at least 2 mm. Because of distal spread of tumor cells in mesorectum, a 5-cm distal resection margin is advocated in cases of PME. When performing a TME all the mesorectal fatty tissue is removed, and the surgeon can focus on achieving a safe distal rectal wall resection margin which is shown to be 1 cm or even less in cases with preoperative chemoradiation<sup>[55]</sup>.

If the surgeon repeatedly has tumor involvement in the CRM, too short distal mesorectal resection margins, or involved distal rectal wall resection margin, then his patients will suffer unnecessary local recurrence and shortened survival. Few, if any national colorectal associations have considered the consequences of this and started a certification program for colorectal surgeons who operate on rectal cancer. Development of centers of excellence could also help improve the quality of all aspects of rectal cancer treatment.

The complexity of individualized multimodal treatment plans and the challenges and technical difficulties of open or laparoscopic pelvic surgery, have centralized rectal cancer treatment to high volume institutions, hopefully to the benefit of the patients.

Additionally, there has been no broad discussion in the literature of possible overtreatment by giving neoadjuvant chemoradiation to all rectal cancer patients, since less than 10% of all rectal cancer patients will have local recurrence after optimal surgery alone.

## COMPLICATIONS AFTER SURGICAL TREATMENT

The narrow pelvic cavity and the close relations of the rectum to functionally important organs and structures as the hypogastric and parasympathetic nerves, the urinary tract including ureters, bladder and urethra, the seminal vesicles and prostate gland in males, uterus and

posterior vaginal wall in females, pelvic and sacral vessels, make rectal surgery technical challenging and risky. Impotency and sexual dysfunctions, bladder dysfunctions, defecational problems including evacuation difficulties, fecal incontinence and urgency significantly add to the mental stress of a recent cancer diagnosis. Stoma problems with fear of malodorous leakage can be socially crippling. An increased focus on quality of life has included preservation of normal defecation-, bladder- and sexual functions and maintaining or improvement of the patient's quality of life as main goals of the surgical therapy for rectal cancer. Still, up to 20% of the patients will experience one or more of the above-mentioned side effects of the surgical treatment<sup>[56]</sup>.

## POSTOPERATIVE SURVEILLANCE

The medical endoscopist frequently meets rectal cancer patients when they are coming in for colonoscopy, commonly at 6 mo and at 4 years in their postoperative surveillance program. The clinical benefit of a postoperative surveillance program is disputed<sup>[57]</sup>, but there are several considerations. One is to discover signs of cancer local recurrence or metastatic disease. Another is to educate the patient to recognize signs and symptoms of recurrent disease as well as to encourage the patients to cope with the sequelae of treatment. Thirdly, it is an important way to monitor the results and quality of the rectal cancer treatment.

Details of recent development of weight loss despite normal appetite, increased fatigue, changes in bowel habits and vague abdominal discomfort should be questioned at every postoperative consultation. Physical examination, including palpation of the abdomen for any possible mass, surgical scars, the lower edge of the liver and palpation around stomas will be performed. The presence of ventral or parastomal hernias should be recorded, but any suggestions about surgical treatment should be balanced against symptoms, impact on quality of life or other possible benefits and risks. The left supraclavicular fossa (Virchows lymph node) and the groins should be palpated for enlarged lymph nodes. The perineal region should be inspected and palpated and a DRE performed in all cases with a residual anal canal. During DRE the anastomosis should be palpated if within reach and any pelvic mass recognized.

As mentioned earlier, postoperative CEA level should return to normal if elevated preoperatively. In these patients elevated CEA levels can be indicative of local recurrence or metastatic disease.

Unsuspected findings should be verified by CT or MRI scans. PET scan is the most accurate method to rule out presence and the extent of local or metastatic disease<sup>[58]</sup>.

## LOCAL RECURRENCE

If a local recurrence is verified, surgical resection must be considered either with curative intent or as a palliative effort. However, the side effects and complications of

any surgery for recurrent disease must not be underestimated. The plan for the investigation is to determine resectability and to assess risks to the patient. Second line chemotherapy is an option, however it is non-curative and with considerable side effects. Most cases of recurrent disease will be discovered between the surveillance controls, and two thirds within two years after surgery.

## LIVER METASTASIS

The attitude towards liver metastasis from colorectal cancer has also changed during recent decades. An aggressive approach has been shown to prolong survival and increase chances for cure<sup>[59]</sup>. Even patients with multiple liver metastases should be considered for liver surgery because combination of surgical resection and ablation (radiofrequency ablation or cryo ablation) after downstaging chemotherapy can be a valuable option for the patient unless there is evidence of systemic cancer disease. Selective hepatic intraarterial chemotherapy and segmental liver embolization are also treatment options in selected cases.

## LUNG METASTASIS

Rectal cancer does also spread to the lungs. In an otherwise fit patient with no other signs of metastatic disease, an aggressive surgical approach will prolong survival. Segmental pulmonary resection or lobectomy is advocated for selected patients<sup>[60]</sup>. Multilobular and bilateral location is a sign of systemic disease and is a contraindication for surgical treatment.

## PALLIATIVE SURGERY FOR ADVANCED AND INOPERABLE RECTAL CANCER

Preoperative chemoradiation therapy might downstage a fixed and inoperable cancer to become resectable and even curable. All efforts should be made to resect a rectal cancer in order to avoid the painful and devastating conditions associated with an uncontrollable cancer growth inside the pelvic cavity. Stoma, intestinal bypass, stent, fulguration (burning down the cancer with diathermy) or laser evaporation can give temporary relief from an obstructing rectal cancer or its metastasis.

Large procedures as hemipelvectomy or anterior or total pelvic exenteration with or without combination with intraoperative radiation (IORT) have been performed in order to achieve a R0 resection (all cancer tissue removed) and thereby reduce the chances of local recurrence. Obviously, this has side effects for the patients.

## CONCLUSION

The medical endoscopist is not commonly involved in the multidisciplinary teams deciding the treatment plans for patients with rectal cancer. However, the endoscopist frequently is the first health care provider to meet the patient with suspected rectal cancer in the setting of

endoscopy for colorectal symptoms or screening, and is frequently the person that performs the postoperative endoscopic surveillance. By having knowledge about the complex investigation plans and treatment options available, the endoscopist can provide important information in order to help the patient to prepare for the coming meeting with the surgeon.

## Abstract

The liver was one of the earliest recognized sites among autoimmune diseases yet autoimmune hepatitis, primary biliary cirrhosis, primary sclerosing cholangitis, and their overlap forms, are still problematic in diagnosis and causation. The contributions herein comprise 'pairs of articles' on clinical characteristics, and concepts of etiopathogenesis, for each of the above diseases, together with childhood autoimmune liver disease, overlaps, interpretations of diagnostic serology, and liver transplantation. This issue is timely, since we are witnessing an ever increasing applicability of immunology to a wide variety of chronic diseases, hepatic and non-hepatic, in both developed and developing countries. The 11 invited expert review articles capture the changing features over recent years of the autoimmune liver diseases, the underlying immunomolecular mechanisms of development, the potent albeit still unexplained genetic influences, the expanding repertoire of immunoserological diagnostic markers, and the increasingly effective therapeutic possibilities.

Invernizzi P, Mackay IR. Autoimmune liver diseases. *World J Gastroenterol* 2008; 14(21): 3290-3291 Available from: URL: <http://www.wjgnet.com/1007-9327/14/3290.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.3290>

The liver is one of the earliest recognized sites among those affected by autoimmune diseases. Such diseases became recognized during the 1950s as novel pathogenetic entities in humans and, later, in laboratory animals. Today there are 80 different disorders attributable to autoimmunity. Over the past five decades, clinical awareness of autoimmune liver disease has been greatly enhanced, knowledge of pathogenesis has become more refined, laboratory diagnosis far more precise, and therapy more effective. These advances are authoritatively described by the expert contributors to this dedicated issue of the *World Journal of Gastroenterology*.

The health burden of autoimmune liver diseases, numerically not of the same magnitude resulting from liver diseases due to alcohol abuse, hepatitis virus infection or steatosis-related pathology, is still very substantial. Thus autoimmune liver diseases can affect individuals in childhood, at highly productive stages of adult life, as well as in later years; and these diseases are life long, and have degrading effects on *joie de vivre* due to distressing symptoms and complications, or side-effects of therapy. Moreover, there is an impression sometimes given by doctors that medical knowledge has not yet fully explained the exact nature or cause of autoimmune disorders. This might not be surprising because autoimmune diseases, including those affecting the liver, result from intricate derangements of immunological functions, and the idea that "immunity" can work against the well-being of the individual is counter-intuitive. Furthermore, immunology as a discipline of science is still not well accommodated in the curricula for students of medicine; it is a fast-evolving and strongly laboratory-based discipline with its own arcane terminology; and it may be disadvantaged by a still incomplete severance from microbiology in many university departments. Expectedly, clinicians may not readily engage with the theoretical pillars of modern immunology, nor fully appreciate the intimate applicability of immunology to a wide variety of chronic diseases, whether in developed or developing countries.

The autoimmune liver diseases considered among these reviews are autoimmune hepatitis (AIH), primary biliary cirrhosis (PBC), and primary (autoimmune) sclerosing cholangitis (PSC). AIH and PBC are very well proved in terms of an autoimmune background whereas PSC, as readers will discern, fits less readily into this category. Nevertheless, the evidence in PSC for some forms of immune derangement is quite impressive, and we can reasonably attribute "guilt by association" with, for example, ulcerative colitis, as pointed out by our authors

on this topic.

We have made special provisions in this series of articles on the etiopathogenesis for each of the three autoimmune liver diseases. We often read that “such-and-such” a disease is “an autoimmune disorder of unknown etiology”. We would contend that autoimmunity, synonymous with tolerance deficit, should be regarded as aetiology in its own right, meaning that failure of natural immune tolerance itself can be pathogenic even in the absence of any overt environmental provocation. The regular and predictable occurrence of autoimmunity in certain tolerance-deficient inbred and genetically tilted strains of mice (NOD, NZB) is an ample witness to this. Among the autoimmune liver diseases, an environmental provocation is seldom discernible for AIH except for some “transient” examples after exposure to particular sensitizing medications, such as minocycline, whereas for PBC, there are a great variety of agents or processes claimed to act as “initiators”. As for PSC, the co-morbidity with ulcerative colitis leads to an indictment of pathogenetic immune hyper-responsiveness to the normally tolerated microbial flora of the colon. Tolerance deficits in humans, as in animals, will be largely genetically based, and deciphering the nature of these errors is an urgent and exciting challenge for the future studies.

Each of the three reviews dealing with etiopathogenesis of an autoimmune liver disease has a partner article on clinical features and management, and readers will note that clinical presentations have changed compared with earlier days. For example, AIH is currently presenting more as an indolent disease with an onset in later life, in contrast to its major impact on young women in the past years. PBC occurs more often at minimally symptomatic earlier stages, with cases frequently ascertained as a result of automated laboratory screening, sometimes for unrelated purposes. It is encouraging for clinicians that both AIH and PBC are gratifyingly responsive to the current standardized treatment regimens, even though, for ursodeoxycholic acid in PBC, the undoubted therapeutic benefits are not readily explicable on theoretical grounds. Finally, some patients will still require liver transplantation for eventual end-stage disease, but readers will be glad to

learn that AIH and PBC provide liver transplantation with more satisfying results in terms of post-transplantation morbidity and mortality. And, speaking of transplantation, the inescapable complications of allograft rejection or graft-versus-host disease do exist, but are now eminently manageable. Of much interest, there are credible examples of recurrence of autoimmune liver disease, or even *de novo* autoimmune hepatitis, in an allografted liver. This puzzling immunological scenario is engaged in one of our articles. Finally, a review article focuses on the particular aspects of autoimmune liver diseases occurring during childhood.

We have included an authoritative review on diagnostic serology in autoimmune liver disease. Previously diagnostic serological tests were usually provided by “academic” laboratories in either universities or major teaching hospitals. Currently commercial sectors are providing (increasingly more efficiently) the source materials and/or assay kits for private laboratories to perform autoimmune serologic assays. However, there is still a pressing need for the standardization of the assay procedures worldwide, and for a ready availability of calibrated anti-sera with which the laboratories can evaluate and quantitate their results. Clinicians should also be fully informed about the interpretation of the assay data rather than entirely rely on the printed results from the computer. For example, the hepatologist will be confronted from time to time with what is called an “overlap syndrome”. This is a topic that has attracted the attention of authors of several recent review articles, given that the partner diseases, AIH and PBC, or AIH and PSC require different regimens of therapy. The theme is reviewed in these articles. The diagnostic serological laboratory can often help the clinicians to identify the dominant partner to which therapy should primarily be directed.

We recommend to readers this series of reviews as a timely and “state-of-the-art” outline of autoimmunity and liver, by research centres esteemed for their contributions to the science and practice of hepatimmunology. Finally, we would express our deep appreciation to the invited authors for their painstaking preparation of the highly informative articles in this issue.

## Abstract

Autoimmune hepatitis (AIH), initially known as chronic active or active chronic hepatitis (and by various other names), first came under clinical notice in the late 1940s. However, quite likely, chronic active hepatitis (CAH) had been observed prior to this and was attributed to a persistently destructive virus infection of the liver. An earlier (and controversial) designation in 1956 as lupoid hepatitis was derived from associated L.E. cell test positivity and emphasized accompanying multisystem features and immunological aberrations. Young women featured prominently in early descriptions of CAH. AIH was first applied in 1965 as a descriptive term. Disease-characteristic autoantibodies were defined from the early 1960s, notably antinuclear antibody (ANA), smooth muscle antibody (SMA) and liver-kidney microsomal (LKM) antibody. These are still widely used diagnostically but their relationship to pathogenesis is still not evident. A liver and disease specific autoantigen has long been searched for but unsuccessfully. Prolonged immunosuppressive therapy with prednisolone and azathioprine in the 1960s proved beneficial and remains standard therapy today. AIH like many other autoimmune diseases is associated with particular HLA alleles especially with the "ancestral" B8, DR3 haplotype, and also with DR4. Looking forwards, AIH is one of the several enigmatic autoimmune diseases that, despite being (relatively) organ specific, are marked by autoimmune reactivities with non-organ-specific autoantigens. New paradigms are needed to explain the occurrence, expressions and pathogenesis of such diseases.

## EARLY DAYS: 1940s-1950s

The recognition in the 1950s of the disease now known as autoimmune hepatitis (AIH) with its various guises and appellations is a richly interesting story, as hitherto recounted<sup>[1,2]</sup>. The history was recently embellished by Reuben in one of his memorable "Landmarks" published in *Hepatology*<sup>[3]</sup> (Figure 1). AIH, known in earlier days as chronic active hepatitis (CAH), was generally regarded as a "new" disease when reported in 1950 by Waldenström<sup>[4]</sup> in an out-of-the-way Conference Proceedings on nutrition. However, since it is hardly believable that any disease of autoimmune nature would have arisen then *de novo*, it is likely that it did exist but was unrecognized, for two reasons: first, autoimmunity in the 1940s had scarcely entered the medical mind and, second, most of the necessary diagnostic laboratory procedures (liver biopsy, serum aminotransferases, serum autoantibodies) were not then routinely available. The exception was the hallmark feature of hyperglobulinaemia, recognized by Waldenström<sup>[4]</sup>, and also by others writing at around the same time (see below). Indeed increased levels of serum gamma globulin, first ascertained by moving boundary electrophoresis, are well illustrated in cases of cirrhosis of the liver reported in the early 1940s<sup>[5]</sup>. In fact, early descriptions that would fit AIH are discernible under the non-committal names of subacute hepatitis or subacute hepatic necrosis: such cases were ascribed to non-healing infectious hepatitis. As one example, Himsworth<sup>[6]</sup> in his 1947 monograph alluded to:

"the form of subacute hepatitis which appears to arise as such, without the patient ever having had acute illness suggestive of liver disease... jaundice being absent or so faint as to unnoticed... the conditions affects women more often than men... the patient may date her present illness from an acute infection, such as cystitis or bronchitis, some 1 or 2 years previously... since then she has never felt really well ... rheumatic pains, without evidence of articular damage are often noticed... or she may delay attending until the condition has passed into

the next stage of post necrotic scarring... a particular problem is why do nearly all cases of sub-acute massive necrosis inevitably progress...?"

Similarly, Zimmerman *et al*<sup>[7]</sup> in 1951 described a case of subacute hepatic necrosis in a 36-year-old man with slowly developing jaundice and extreme hyperglobulinaemia (87 g/L) and in fact reached for an immunological explanation, in commenting that:

"the initial injury causes an alteration in liver protein, which stimulates the formation of anti-liver antibodies. These newly formed antibodies produce more liver injury, thus releasing more altered liver protein, which again contributes to the vicious circle of continuing necrosis."

The general interpretation in the 1940s of subacute or chronic hepatitis was that it was a sequel to, and a consequence of, an unresolved acute infectious hepatitis. For example Neefe<sup>[8]</sup>, writing from a long experience of viral hepatitis, comments in his review in 1946 on the occurrence of chronic hepatitis as a sequel of viral hepatitis. The stage was actually set for the later nomenclature of CAH in 1945 by Barker, Capps and Allen<sup>[9]</sup> who followed the course of viral hepatitis in military personnel in the Mediterranean theatre. They defined "non-recovery" as persistence of symptoms after 4 mo and applied the term chronic hepatitis "without any implications regarding the nature of the pathologic process or the eventual prognosis". Further, their cases of "chronic hepatitis" were divided into active if symptoms were present, or inactive if there were only laboratory defined abnormalities<sup>[10]</sup>. Thereafter CAH became the standard descriptor of later years, albeit for a disease quite different from that exhibited by the soldiers. Even so, there still remained the strong impression that the precursor of CAH was hepatitis virus infection, according to articles by Wood and colleagues<sup>[11]</sup> in Melbourne in 1948, Kunkel and Labby<sup>[12]</sup> in New York in 1950, and Liebowitz<sup>[13]</sup> in New York in 1950 who followed up 68 patients with presumed acute viral hepatitis and reported that seven (11%) developed CAH. Waldenstrom<sup>[4]</sup> in his 1950 report had been more circumspect in specifying that the cause of the disease was unknown, *wie wir alle wissen*, although he also speculated on persisting viral infection (see below).

In the event, the disease seen during 1948-1950 that fulfils the modern description of AIH is illustrated by key phrases reproduced from the 1950 report of Waldenstrom<sup>[4]</sup>, and by a 1951 Meeting Abstract of Kunkel and colleagues<sup>[14]</sup>. According to Waldenstrom:

"Dazu kommt bei fast allen Fällen das Auftreten von sog. Sternchen (Naevi aranei) und bei den Mädchen auch eine besondere Tendenz zur schweren Akneeruption. Eine langdauernde Amenorrhöe ist charakteristisch, die wahrscheinlich anovulatorisch ist... Es ist damit möglich, dass in der Zukunft eine Anzahl von diesen Fällen mit ACTH verbessert werden können... Die zweite Frage, ob die nachgewiesene Erhöhung des Gammaglobulins als Zeichen eines chronischen Immunisierungsprozesses aufzufassen ist, verdient meines Erachtens grösste Auf-

merksamkeit... Die Ätiologie dieser chronischen Leberleiden ist-wie wir alle wissen-immer noch unbekannt. Es werden toxische, infektiöse und Nahrungsfaktoren als Ursache angenommen... Es scheint sehr wohl möglich, dass die Gammaglobulinvermehrung als Symptom einer Immunisierung gegen das im Körper verbleibende Virus aufzufassen ist". Kunkel and colleagues<sup>[14]</sup> used the following phrases:

"Total proteins ranged from 9-13 per cent...this rise was due entirely to gamma globulin increase... eleven of these twelve patients were females... the maximum age was 32...onset of disease was insidious... course was prolonged and either stationary or downhill... frequently marked by periods of high fever, arthralgia, and arthritis ... remarkable degree of plasma cell infiltration in the liver... which diminished during the course of disease... the etiology of the syndrome remains unknown."

This apparently new liver disease came under particular scrutiny in Melbourne following the report of Wood *et al*<sup>[11]</sup> referred to above, and particularly from the standpoint of clinical and histological correlations, described by Saint *et al*<sup>[15]</sup> in 1953, who noted:

"fairly well defined clinical features, a highly characteristic pattern of biochemical tests including hypergammaglobulinaemia, and a histological picture which seems to indicate active chronic inflammatory changes... in many cases an initial history of contact or

even a history of typical acute infectious hepatitis was lacking... but little doubt existed that the liver disease was due to infection with a virus”.

This latter article followed the earlier nomenclature of Capps<sup>[10]</sup> in 1948 of active and inactive chronic hepatitis but used histological rather than clinical criteria to draw the distinction. Accordingly Saint *et al* introduced the term active chronic hepatitis<sup>[15]</sup> that for a while coexisted with CAH, although the latter eventually prevailed. The dire outcome was recorded as follows:

“the course was progressively downhill... jaundice became a permanent feature... bleeding episodes became more frequent... alternatively these patients became permanently bedridden owing to their dropsical enfeebled state, and finally lapsed into coma... the time or presentation until death has varied between six months and two years”.

Among the cases assembled by Saint *et al*<sup>[15]</sup>, one stands out. This was a 36-year-old woman, described further in 1955 in a case study by Joske and King<sup>[16]</sup> as active chronic viral hepatitis with positivity for the lupus erythematosus (L.E.) cell test. Their report includes the following:

“liver biopsy showed the typical picture of an active chronic viral hepatitis... cellular infiltration with lymphocytes and plasma cells and fibroblastic activity... fairly numerous L.E. cells present... cortisone produced a dramatic improvement in her arthralgia... we may recall that Leonie (1954) found L. E. cells in ascitic fluid from a patient with hepatic cirrhosis... we suggest that the L.E. cell and related phenomena might be based either: (1) on an abnormality of the antibody-producing mechanism... or (2) on changes in red or white cells or their constituents... which modify their characteristic “self markers”.

The latter 3-4 lines can be reasonably attributed to the pen of FM Burnet who, at this time in 1955 had already turned his mind to immunological aberrations in disease states. Also noteworthy in the report are comments on the plasma cellular content of the inflammatory infiltration into the liver, and the improvement conferred by treatment with cortisone.

The L.E. (lupus erythematosus) cell effect requires a few lines here. L.E. cells had been discovered incidentally in the 1940s by Hargraves<sup>[17]</sup> in bone marrow preparations from patients with “collagen diseases” of the lupus erythematosus type, and were modestly reported after a delay of some years in 1948 in the Mayo Clinic Proceedings. Hargraves himself was quite surprised by the interest that his report aroused<sup>[18]</sup>. This interest intensified further with the discovery that the L.E. cell effect depended on a serum factor, of gamma globulin nature<sup>[19]</sup>, which only a few years thereafter became recognized by various groups as an antinuclear autoantibody. An item of interest, unreported and transmitted as a personal comment from Hargraves to this author, was that among the initial patients in whom L.E. cells were detected was a young girl (PC) suffering from chronic hepatitis! The L.E. cell test soon became

a surrogate marker for an autoimmune basis for a given disease and, as such, was deployed in Melbourne in the early 1950s as the single available routine laboratory indicator for multisystem autoimmunity-hence its application to cases of CAH.

## LUPOID TO AIH

After my return to Melbourne from abroad in 1955, it took only a little time to identify several instances of CAH in young women with hypergammaglobulinaemia and a lymphoplasmacytic infiltration in the liver and, in each, a positive test for the presence of L.E. cells in blood. Then the case for an immunological derangement as the cause of the disease became even stronger because at the time, DC Gajdusek who was a visiting scientist to the Hall Institute was attempting to develop a diagnostic serological test for viral hepatitis based on a complement fixation (CF) reaction, using as antigen liver tissue obtained at autopsy from a patient with fatal acute viral hepatitis. However sera from cases of acute hepatitis were at most only weakly positive using this CF reaction, whereas sera from cases of CAH (inserted as disease controls) tested positive, not only using as antigen the virally infected liver tissue but also using normal liver as well<sup>[20]</sup>. We can recall that during the development of the Wassermann serological test for syphilis infection, *Spirochaeta*-infected tissue was used initially, but normal tissue was found to serve equally well to elicit a positive reaction.

The several patients with CAH and a positive L.E. cell test appeared to represent a unique disease entity since most had, additionally, extrahepatic disease expressions including arthralgia, rash, haemolytic anaemia and others, typically seen in cases of systemic lupus erythematosus (SLE) wherein sera also gave a positive autoimmune CF test. In a report to *Lancet* in 1957<sup>[21]</sup>, the concept was developed thus:

“linking certain types of active chronic hepatitis and lupus erythematosus... possibly through the common factor of disturbed immunological response... this group of cases has been provisionally designated as ‘lupoid hepatitis’ since ‘lupus’ has now acquired a far broader significance than the original term suggests... we consider that immunological destruction of the host’s liver cells best explains the perpetuation of the hepatitis and progression to cirrhosis. If this is so, it would be rational to use therapeutic measures (e.g. cortisone therapy) designed to modify this process, and our experience suggests that cortisone is of benefit in this autoimmune hepatitis.”

The global response to this report was remarkable. There were journal reports of patients with lupoid hepatitis from far and wide and, as well, detailed case studies, by Bearn *et al*<sup>[22]</sup>, Reynolds *et al*<sup>[23]</sup> and others<sup>[1,2]</sup>. Thereafter there arose controversy, still not completely resolved<sup>[3,24]</sup>, as to whether “lupoid hepatitis” was intended to specify a particular form of CAH and thus a disease in the realm of hepatology, or a component of a multisystem syndrome in the realm of rheumatology.

Admittedly, this dilemma was not helped by our earlier writings which attempted to distinguish cases of “lupoid hepatitis” from those of “CAH” in which L.E. cell positivity was not demonstrable<sup>[25]</sup>. The development of the immunofluorescence test for antinuclear antibody (ANA), and its application to patients with CAH<sup>[26]</sup> soon revealed that cases of “lupoid” and “ordinary” CAH were indistinguishable on important criteria such as biochemical indices of liver dysfunction, histological abnormalities in the liver, and responsiveness to immunosuppressive therapy. Also, by the early 1960s, it was clearly evident that the disease in all its guises was best accounted for by an autoimmune reaction in the liver and thus, in 1965, we suggested that the disease be named “autoimmune hepatitis”<sup>[27]</sup>, although this appellation did not become formally endorsed until 1993<sup>[28]</sup>. Meanwhile, lupoid hepatitis lived on for quite some years, having heuristic appeal in some jurisdictions and causing semantic grievance in others, to the extent that one publication was directed to establishing that lupoid hepatitis was a “non-entity” within the disease group known as CAH<sup>[29]</sup>. Actually our Clinic had already discarded a possible association between lupoid hepatitis and SLE by showing in 1959 that liver lesions in classic instances of SLE were relatively trivial and nondescript<sup>[30]</sup>, and a serological distinction was forthcoming a few years later (see below).

## THERAPIES FOR CHRONIC ACTIVE/AIH

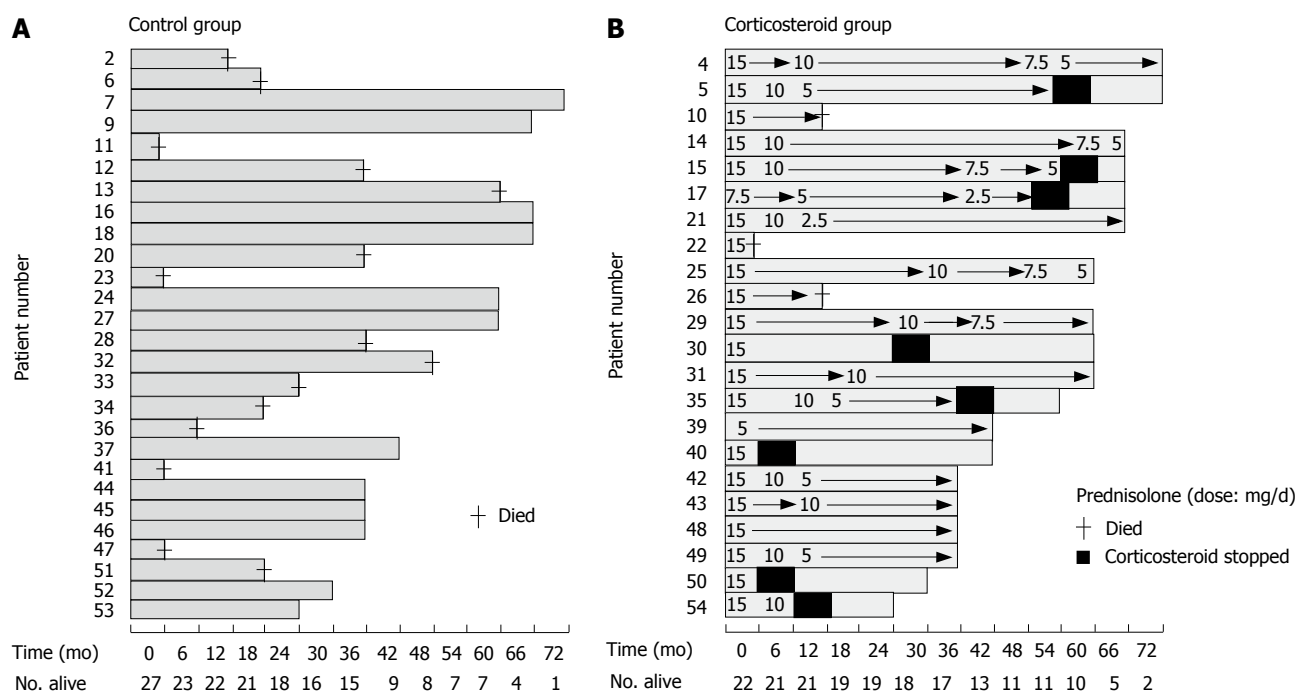

In our 1957 publication on lupoid hepatitis<sup>[21]</sup>, the notion of immunological destruction of host liver cells was seen to provide a rationale for the use of “anti-immune” therapies to modify the process. Corticosteroid therapy in fact had been used in cases of CAH in Melbourne from as early as 1953, and, although initial results were equivocal<sup>[15]</sup>, later experience proved more encouraging<sup>[31]</sup>. Also, Bearn *et al*<sup>[21]</sup> in their 1956 article that formalised observations made in the 1951 Meeting Abstract<sup>[14]</sup>, reported that cortisone induced improvement in symptoms, and in physical and biochemical expressions of disease, and that withdrawal of cortisone from two patients resulted in prompt relapse. However they did retain the proviso that “there was no conclusive evidence that cortisone modified the disease process or that it will alter the eventual outcome”. A telling observation in Melbourne, reported in 1958<sup>[32]</sup>, was that by serial daily monitoring of levels of serum aspartate transaminase after treatment was started, prompt falls in highly raised levels occurred, often within hours, and other indices of impaired liver function improved in turn. Moreover, since relapse tended to occur when cortisone was withdrawn, the need for long term maintenance therapy became evident. Hence co-therapy with a “steroid-sparing” agent was sought and, on theoretical grounds, there was chosen azathioprine, a derivative of the immunosuppressive drug 6-mercaptopurine, and this conferred added benefit<sup>[33]</sup>. However there was scepticism whether our routine prednisolone-azathioprine regimen, albeit

symptomatically beneficial, actually altered the natural history of the disease. The view in Melbourne was that a trial that included randomly allocated placebo control patients was ethically problematic. Our decision was that all trial patients would receive active therapy after a 4-8 wk non-treatment run-up with close monitoring of multiple liver functional indices, and comparison would be made of mean levels for such indices for a group of 15 patients pre- and post -therapy with prednisolone, or prednisolone plus azathioprine. The outcome, published in 1968<sup>[34]</sup>, led to the recommendation for long term (2-3 years) maintenance therapy with either prednisolone monotherapy, or combined prednisolone-azathioprine. However, conventional trials with randomly allocated non-treated controls were still called for, and these convincingly indicated survival benefits for the treated patients. The study of Cook *et al*<sup>[35]</sup> is exemplary, albeit with a substantial burden of mortality among the control group (Figure 2). Detailed studies on immunosuppressive therapy by the Mayo Clinic through the 1970s-1980s, with substantial case numbers, have shown sustained efficacy according to various criteria, survival, biochemical and histological<sup>[36]</sup>.

## PATHOLOGICAL FEATURES OF CHRONIC ACTIVE/AIH

The increasing use of percutaneous biopsy of the liver in the 1950s greatly contributed to better knowledge of the nature of chronic hepatitis, well illustrated by the description in 1958 by Klatskin<sup>[37]</sup> of nine cases bearing the pre-1950s diagnoses of subacute hepatic necrosis/post-necrotic cirrhosis, and attributed to “anicteric infections with the hepatitis virus” because histopathological appearances met existing criteria for subacute hepatic necrosis of viral origin. However scrutiny of the clinical, biochemical and histological features strongly suggests that the illness in some, perhaps most, of the nine cases was actually AIH: there was female preponderance, hyperglobulinaemia, and corticosteroid responsiveness. However the particular feature of Klatskin’s study was the introduction of, or emphasis on, detailed histological features characteristic of those associated with autoimmune (as well as with viral) hepatitis. These included extensive “bridging” hepatocellular necrosis, ballooning of hepatocytes, regenerating hepatocytes with arrangement of cells in the form of “rosettes”, intense mononuclear inflammatory reaction; regenerative nodules, and acidophilic bodies (Councilman bodies) which are rounded intensely eosinophilic homogeneous cytoplasmic masses derived from hepatic cells undergoing coagulation necrosis. These latter appearances of course represent apoptosis of hepatocytes, recognized by Kerr<sup>[38]</sup> some 30-40 years before but not widely appreciated until interest developed in the 1980s in the apoptosis process. A detailed analysis of apoptosis in the context of chronic hepatitis and liver cell degeneration is given by Searle *et al*<sup>[39]</sup>.

There were two morphological features additional

**Figure 2** Combined Figures 1 and 2 from a publication<sup>[35]</sup> on long-term prospective controlled trial of corticosteroid treatment of patients with active chronic (autoimmune) hepatitis. The graphs show duration of treatment and survival for (A), left, non-treated control group and (B), right, corticosteroid treated group, and length of time (months) that the individual patients in either group had been in the investigation at the time of assessment. Numbers indicate the sequence of entry to the trial; +, time of death. Survival was 19/22 for the treated group and 12/27 for the control group. Reproduced with permission of Oxford University Press, publishers of Quarterly Journal of Medicine.

to those described by Klatskin that deserve comment. One was the concentration of inflammatory activity and necrosis in the junctional region between the portal tract and liver lobule, initially described by Popper *et al*<sup>[40]</sup> as piecemeal necrosis, and currently referred to as interface hepatitis. The other feature was the striking accumulation among the inflammatory infiltrates of plasma cells, noted in most pathological descriptions, although not all<sup>[41]</sup>, and earlier on leading to the disease being designated as “plasma cell hepatitis”<sup>[42]</sup>. This feature of CAH, i.e. prominence of plasma cells in liver, and bone marrow as well, aligns with the characteristic hypergammaglobulinaemia, although the antigenic specificity of these plasma cells and their secreted immunoglobulins has not yet been ascertained.

Finally we can note the protracted debate on whether histological features, irrespective of clinical diagnosis, would distinguish cases of chronic hepatitis with a progressive course and cirrhotic potential-CAH-from those without such potential-chronic persistent hepatitis<sup>[43,44]</sup>. After much elaboration in the 1970s these terms slowly disappeared from the lexicon.

## HETEROGENEITY OF CAH

The term CAH used in 1950s and 1960s was generic, for what tended to be regarded as a single disease entity, with the prototypic cases being those that would fulfil criteria that presently define the autoimmune type of disease. However, impressions developed from the 1960s that CAH was not a homogeneous disease entity. Thus a collaborative study with colleagues in

Singapore ascertained that CAH seen among Caucasians in Melbourne and Chinese in Singapore differed substantially, clinically, histologically and serologically<sup>[45]</sup>. Similarly, in unpublished observations in Melbourne, features of cases of chronic hepatitis and cirrhosis among recent Southern European immigrants differed from those among Australian-born individuals, such that we spoke of “Mediterranean cirrhosis”. An explanation was soon forthcoming. This depended on the fortuitous discovery by Blumberg and colleagues of an antigenic particle in serum initially called “Australia antigen” (Au), because it was first detected in serum from an Australian aboriginal serum donor<sup>[46]</sup>. Au was later found to be a surface protein of a virus identified with as the transmissible agent responsible for infectious (serum) hepatitis type B. The particle became known as hepatitis B surface antigen-HBsAg<sup>[47]</sup>.

It became evident, as reported from several centres that cases of “CAH” segregated into those that were autoantibody positive and HBsAg negative, or vice versa and, in fact, prototypic (autoimmune) CAH became referred to as HBsAg-negative CAH<sup>[36]</sup>. Moreover, certain histological features of CAH, chiefly interface hepatitis, could be recognized in various other causally different cases chronic liver disease, whether due to viral infection, ethanol abuse, Wilson’s disease or other causes. An invitation was extended to me in 1972 to write an editorial on the “Prognosis (I changed this to Prognoses) of CAH” which led to a proposal that CAH was indeed heterogeneous in terms of aetiology, histological appearances, immunogenetic background, therapy requirements and outcome<sup>[48]</sup>. Moreover it seemed

reasonable to assume that aetiological proportions among all cases of CAH would differ according to geographic region, and this proved to be the case, as judged by differences ascertained for cases of CAH in Australia and Singapore (see above) or Yugoslavia wherein proportions of cases due to chronic hepatitis B were substantially higher<sup>[49]</sup>. Finally, there were cases regarded as cryptogenic CAH, with some perhaps resulting from infection with non-A, non-B hepatitis virus; these later became attributable to the subsequently discovered hepatitis C virus (HCV). Currently, worldwide, the proportion of cases of chronic hepatitis B, followed by that of hepatitis C, far outnumber that of all other types.

All this led to the perception of a need for a clearer definition of CAH. This was met by the convening of a widely representative expert panel of hepatologists, the International AIH Group whose consensus deliberations led to reports in 1993 and 1999 on generally acceptable diagnostic criteria<sup>[28,50]</sup>.

## GENETIC FEATURES OF CHRONIC ACTIVE/AIH

The wide regional differences in prevalence of different types of chronic hepatitis depend on differing environmental exposures and genetic composition of the particular population groups. Among the former, the endemicity of hepatitis virus infections is one important element.

The first genetic factor of interest in AIH was female predisposition, common to most autoimmune diseases, and for which the basis is still not well understood. Then, recognized in 1972, were genes that encoded for human leucocyte antigens, HLA. Cases of “classical” CAH, selected for typing for the then testable HLA alleles encoded at the HLA A and B loci, showed a significantly increased frequency of HLA-B8<sup>[51]</sup>, an allele already implicated among Caucasian subjects with certain other autoimmune diseases. This association was soon confirmed in other centres, and was followed by the finding of an increased frequency in CAH of the D-related (DR) locus allele, DR3; a family study showed the combined inheritance of HLA A1, B8 and DR3 *en bloc* (a haplotype) from one or other parent, or both<sup>[52]</sup>. Possession of HLA DR3, particularly in those homozygous for these alleles, was predictive of a severe course and lesser responsiveness to immunosuppressive therapy<sup>[53]</sup>. The culprit allele is now styled as *HLA-DRB1\*0301*. Later an additional HLA type, DR4 (*HLA-DRB1\*0401*), not evident in our earlier studies, was identified<sup>[54]</sup>. The 6-7 fold risk for disease conferred by HLA DR3/4 is substantial but not highly potent meaning that, like all other “complex” autoimmune diseases, there must exist multiple other polymorphisms in “tolerance/ autoimmunity” genes that contribute to susceptibility: these are mostly undiscerned pending application of population genetics by genome wide screening.

## IMMUNOSEROLOGICAL AND T-CELL STUDIES IN CHRONIC ACTIVE/AIH

The reactivities that initially (in the 1950s) were indicative of autoimmunity in CAH, the L.E. cell test and the AICF reaction, were soon superseded by more discriminatory and simpler laboratory assays. These are described in detail in other articles in this issue and in contemporary reviews<sup>[55-57]</sup>.

### Nuclear antigen(s)

Detection of ANA by indirect immunofluorescence (IIF) was introduced in the early 1960s<sup>[26]</sup> and remains the standard diagnostic screening procedure<sup>[57]</sup>. Superficially at least, the nuclear reactant(s) is the same as that responsible for the ANA reactivity observed in SLE i.e. the nucleosome (chromatin), although anti-DNA is much less frequent<sup>[56]</sup>. The idea that patients with AIH and SLE share one or more of the gene loci that determine ANA reactivity may be revealed by future population genome studies.

### Smooth muscle antigen(s)

In 1963 there was observed a novel reactivity with smooth muscle of rodent gastric mucosa<sup>[58]</sup>. Detection of this smooth muscle antibody (SMA) to high titre proved to have high specificity for the diagnosis of CAH and notably, in “conventional” cases of SLE in which inflammatory destruction of liver cells is not evident, the test proved negative<sup>[59]</sup>. Further observations showed that some SMA+ve sera reacted by IIF with the mesangium of renal glomeruli, indicative of a wider distribution of the antigenic reactant than merely gastric smooth muscle tissue<sup>[60]</sup>. A subsequent observation was that some positive sera gave reactivity only with blood vessel walls (SMAv), and others reacted as well with renal glomeruli and renal tubular cells (SMAgt)<sup>[61]</sup>. The recognition that SMAv pointed to non-specific reactivity, and SMAvgt to reactivity specifically associated with AIH has led laboratory serologists to retain the designations SMAv and SMAgt in their diagnostic reporting.

The first indication of the identity of a reactant for SMA+ve sera was that reactivity could be absorbed from serum by exposure to the cytoskeletal protein F-actin<sup>[62]</sup>. Further studies using IIF on cultured tissue cells revealed that SMA+ve sera stained cytoskeletal microfilaments (actin “cables”), representing polymeric F-actin, whereas SMA+ve sera from cases other than CAH stained intermediate filaments representing vimentin, desmin or others<sup>[63]</sup>. After much developmental work, there are now commercially available ELISA formats based on highly purified F-actin that have good specificity and sensitivity for the diagnosis of AIH<sup>[56]</sup>. The need at present is for better knowledge on the basis of anti-F-actin reactivity, including the significance (if any) for the pathogenesis of AIH, the epitope specificity of the antibodies, the relationship of epitopes to binding sites for the numerous F-actin binding proteins in the cell, and functional effects of anti-F-actin on cell motility<sup>[64]</sup>.

### LKM-1 antigen

In 1973, yet another serum reactant in AIH was discovered by IIF, to an antigen that was enriched in cytoplasm of liver and kidney proximal tubular cells<sup>[65]</sup>. This so-called liver-kidney “microsomal” (LKM) antigen, later designated LKM-1 because other LKM antigens became demonstrable<sup>[56]</sup>, is actually located in the endoplasmic reticulum of liver and kidney proximal tubular cells<sup>[66]</sup>. A notable feature of anti-LKM-1-positive-AIH, versus ANA/SMA positive AIH, is that the serologically defined reactivities appear mutually exclusive, providing grounds for distinguishing these serological variants of AIH as type 2 and type 1<sup>[67]</sup>; this distinction has been retained by hepatologists even though few other differences exist. The point of interest heuristically on the serological distinction is that the respective autoantibody responses (ANA/SMA, anti-LKM-1) cannot be ascribed simply to (hepato) cellular injury, an explanation often levelled for the appearance of at least for some types of autoantibody. Although cases of anti-LKM-1-positive AIH are numerically far less than the traditional type, the ratios being about 1:10 in adults and 1:4 in children, type 2 AIH has proven far more amenable to investigation, since the LKM-1 antigen has been molecularly identified by screening a gene expression library as the cytochrome P450 isoform 2D6, enabling epitopes to be mapped<sup>[68]</sup>; there is demonstrated a CD4+ T-cell responsiveness to peptide antigens of CYP450 2D6<sup>[69]</sup>; and an experimentally credible model in mice has been developed<sup>[70]</sup>.

### Soluble liver/pancreas antigen

A soluble cytoplasmic antigen was independently discovered by CF<sup>[71]</sup>, and ELISA<sup>[72]</sup>, using pancreas or liver cell extracts respectively, and the reactant was found to be identical; it is generally known as “soluble liver/pancreas antigen (SLA). Sero-positivity, initially thought to identify a type 3 AIH, occurs in cases of AIH that are negative for other reactivities, but also in sero-positive cases of type 1 AIH. SLA has been cloned, identified and purified<sup>[56]</sup>, and commercially available ELISA kits are diagnostically reliable. The pathogenetic significance of SLA is uncertain.

### A liver-specific and disease specific antigen

This has been long searched for, since AIH behaves very much like an organ-specific autoimmune disease. In earlier times much effort was put into the characterisation of a preparation called liver-specific lipoprotein (LSP)<sup>[73]</sup>, and assessment of the autoantigenic potential of this claimed liver-specific molecule<sup>[74]</sup>. Stemming from this was the recognition of the liver-specific membrane antigen, the asialoglycoprotein receptor<sup>[75]</sup>, but this has not quite fulfilled the earlier hopes<sup>[76]</sup>. The liver cell membrane has been repeatedly studied, mostly by immunoblotting using AIH sera, for a molecular signal corresponding to a specific autoantigenic moiety, with the consistent finding being that of multiple reactive components of mw ranging from 20 to > 100 kDa<sup>[77,78]</sup>, but with none of these

reaching candidate status as a liver-specific or disease-specific autoantigen.

## CONCLUSION

Despite weighty circumstantial evidence for autoimmunity as one proximal cause of chronic hepatitis, and the existence of diagnostic serological reactants of high sensitivity and specificity, there is a disconcerting lack of mechanistic immunological explanation for AIH, and particularly the more prevalent type 1. There are high expectations for “the way we hope to be”<sup>[79]</sup> but, for these to be realised, new paradigms will be needed to explain AIH as well as other examples of organ-specific autoimmunity with non-organ-specific immune-dependent accompaniments.

### Abstract

Autoimmune hepatitis (AIH) is a chronic hepatitis of unknown etiology which can progress to cirrhosis. Its clinical manifestations are highly variable and sometimes follow a fluctuating course. Diagnosis is based on characteristic histologic, clinical, biochemical and serological findings. Anti-inflammatory/immunosuppressive treatment frequently induces remission but long-term maintenance therapy is often required. Liver transplantation is generally successful in patients with decompensated cirrhosis unresponsive to or intolerant of medical therapy.

### INTRODUCTION

Autoimmune hepatitis (AIH) is chronic hepatitis of unknown etiology, which is thought to occur as a result of escape from normal suppression of self-reactivity. It occurs worldwide in children and adults. Clinical manifestations are highly variable and sometimes follow a fluctuating course. Diagnosis is based on characteristic histologic, clinical, biochemical and serological findings. Anti-inflammatory/immunosuppressive treatment induces remission but long-term maintenance therapy is often required. Liver transplantation is generally success-

ful in patients with decompensated cirrhosis unresponsive to or intolerant of medical therapy.

### HISTOLOGY

The histologic appearance of AIH is that of chronic hepatitis, and, although certain changes are characteristic, there are no findings specific to the disease. The histologic differential diagnosis of chronic hepatitis is shown in Table 1. Based on the advances in virologic studies and refinements of cholangiographic methods, exclusion of other entities has become easier, although co-existence of chronic viral hepatitis and AIH may make the diagnosis difficult.

The inflammatory component is characterized by a mononuclear cell infiltrate, which invades the sharply demarcated hepatocyte boundary (limiting plate) surrounding the portal triad and permeates the surrounding parenchyma (periportal infiltrate; piecemeal necrosis; interface hepatitis) and beyond (lobular hepatitis). It may include an abundance of plasma cells and/or eosinophils, but the portal lesion generally spares the biliary tree. In all but the mildest forms of AIH, fibrosis is present. In advanced disease, fibrosis is extensive (bridging fibrosis) and, with distortion of the hepatic lobule and appearance of regenerative nodules, cirrhosis occurs. On occasion, centrilobular disease may be present.

The histologic findings differ somewhat comparing patients with acute onset AIH to those with an insidious presentation. Patients presenting with fulminant hepatic failure have more interface and lobular hepatitis, lobular disarray, hepatocyte necrosis, central necrosis and submassive necrosis, but less fibrosis and cirrhosis compared to patients presenting with a more chronic course<sup>[1,2]</sup>. Steatosis occurs in a minority of patients, although, given the increasing prevalence of diabetes, dyslipidemia and obesity in many parts of the world, non-alcoholic fatty liver disease may be seen more often accompanying AIH. Whether the co-morbidity of steatosis and/or steatohepatitis accelerate progression of disease in AIH is unknown. The prevalence of cirrhosis in patients  $\geq 60$  years at presentation was found to be higher than that in patients  $\leq 30$  years; when comparing groups of patients  $\geq 60$  years with those  $< 60$  years, however, no differences were found<sup>[2,3]</sup>. In patients with a spontaneous or pharmacologically-induced remission, histologic findings may revert to normal; inflammation

Systemic lupus erythematosus
Graft-versus-host disease
Alcoholic steatohepatitis
Nonalcoholic steatohepatitis

may be confined to portal areas; cirrhosis may become inactive; and fibrosis may regress or disappear<sup>[4]</sup>.

## CLASSIFICATION

The most commonly accepted classification of AIH is based on patterns of circulating antibodies, although there is little evidence to support a role for these antibodies in pathogenesis (Table 2).

Type 1 AIH is most frequently characterized by antinuclear antibody (ANA), smooth muscle antibody (SMA) and anti-actin antibody (AAA). Titers of significance vary depending on the autoantibody in question and assays employed<sup>[5]</sup>. Anti-actin (IgG anti F actin) antibodies measured by ELISA appear to be more sensitive than SMA measured by immunofluorescence<sup>[6,7]</sup>.

The identification of other circulating autoantibodies, in particular anti-soluble liver antigen/liver-pancreas antigen (anti-SLA/LP) and atypical perinuclear anticytoplasmic antibody (pANCA) are sometimes helpful in diagnosing type 1 disease. Anti-SLA/LP is the most specific autoantibody detected in type 1 AIH but is found in only 10%-30% of type 1 AIH. Atypical pANCA is non-specific, but commonly present. Antimitochondrial antibodies (AMA) occur infrequently in type 1 AIH. At times AMA may be the sole antibody present and identify an entity sometimes referred to as AMA-positive AIH or the overlap syndrome<sup>[8]</sup>.

Anti-liver/kidney microsome -1 (ALKM-1) and anti-liver cytosol-1 (ALC-1) antibodies occurring alone or together characterize type 2 AIH. Anti-liver cytosol-1 generally occurs in conjunction with anti-liver/kidney microsome-1, but may be the sole autoantibody<sup>[9]</sup>.

Type 1 AIH in Caucasians is associated with the *HLA-DR3* serotype, which is found in linkage disequilibrium with *HLA-B8* and *HLA-A1* and in *HLA-DR3*-negative patients with *HLA-DR4*. *HLA-DR3*-associated disease is more commonly found in patients  $\leq 40$  years at presentation<sup>[2]</sup>. In Japan, where *HLA-DR3* is rare, the primary association is with *HLA-DR4*. Polymerase chain reaction

Table 2 Classification of autoimmune hepatitis

Disorder	Characteristic autoantibodies
Type 1	ANA (antinuclear antibody) SMA (smooth muscle antibody) AAA (anti-actin antibody) Anti SLA/LP (anti-soluble liver antigen/liver-pancreas antigen) pANCA (atypical perinuclear antineutrophil cytoplasmic antibody) AMA (antimitochondrial antibody) <sup>1</sup>
Type 2	ALKM-1 (anti-liver/kidney microsome-1) ALC-1 (anti-liver cytosol-1)

<sup>1</sup>Occurs infrequently in association with other characteristic autoantibodies. It may be the sole antibody present in AMA-negative autoimmune hepatitis, also referred to as the overlap syndrome.

studies genotyping for *HLA-DRB*, *DQA* and *DQB* have confirmed the serologic findings. In children, type 1 AIH is commonly associated with the *HLA-DRB1\*03* and *HLA-DRB1\*13* alleles. Type 2 AIH has been associated with *HLA-DRB1* as well as *HLA-DQB1* alleles<sup>[10]</sup>.

## CLINICAL FEATURES

Although there is a female predominance, AIH occurs in children and adults of both sexes in diverse ethnic groups worldwide. Type 2 disease, which is seen predominantly in children and young women, is rare in North America<sup>[9,10]</sup>. Although AIH was thought previously to be primarily a disease of the young or middle aged, it is now clear that it also occurs in the elderly (generally defined as  $\geq 60$  years of age)<sup>[2,3,11]</sup>.

The heterogeneous, sometimes fluctuating nature of AIH, leads to marked variability in clinical manifestations. Presentation may be asymptomatic or insidious, with mild non-specific symptoms only or may mimic acute viral hepatitis. Rarely, AIH presents as fulminant hepatic failure<sup>[11,12]</sup>. Patients with occult disease may have undetected cirrhosis and present only when decompensation occurs. The group of patients now labeled as cryptogenic cirrhosis, includes some patients with seronegative AIH, underscoring the possibility of the absence of circulating autoantibodies in AIH<sup>[13]</sup>.

Many patients with an acute presentation have histological evidence of chronic disease in the liver biopsy, indicating that they have had antecedent subclinical disease, although the duration of the subclinical anicteric course is generally difficult to ascertain. In retrospect, a fluctuating course, which had been thought to reflect some other diseases, can be identified occasionally. Long periods of subclinical disease may also ensue after presentation. Recent surveys of pregnancy in AIH have indicated that the initial presentations of AIH may occur not only during pregnancy but in the early post-partum period<sup>[14,15]</sup>. AIH may occur in conjunction with a variety of autoimmune disorders, including celiac disease<sup>[16,17]</sup>. Arthralgia involving small joints is common, and inflammatory arthritis may be particularly troublesome.

One presentation of AIH is in the setting of medications, or herbal agents, used for other diseases. It is not

clear if they unmask and/or induce AIH or simply result in a drug-induced hepatitis with histological findings that mimic AIH. Minocycline and, more recently, statins<sup>[18]</sup>, both of which induce other autoimmune syndromes, have been considered as drugs capable of “triggering” AIH.

Complications of AIH are those seen in any progressive liver disease and primary hepatocellular carcinoma is an expected, although uncommon, consequence<sup>[2,19,20]</sup>. There are no established guidelines for hepatocellular carcinoma screening in cirrhosis associated with AIH. A reasonable approach would be surveillance with an ultrasound and alpha feta-protein every 6-12 mo.

## DIAGNOSIS

In the presence of a compatible histologic picture, the diagnosis of AIH is based on characteristic clinical and biochemical findings, circulating autoantibodies and abnormalities of serum globulins. A scoring system, proposed and subsequently revised by the International AIH Group for experimental purposes to standardize diagnosis for clinical trials and population studies, has been adopted by clinicians, but found to be problematic when applied to individual patients, especially children. Thus attempts were undertaken by the International AIH Group to devise a less complicated and more accurate system for wider application in clinical practice. A scoring system, using autoantibodies, gamma globulins, absence of viral hepatitis and histologic findings from patients form a wide geographic distribution, has been proposed as a sufficiently sensitive and specific scoring system<sup>[21]</sup>.

## TREATMENT OF ADULTS WITH AIH

Appropriate management of AIH can mitigate inflammation, slow progression of disease, prolong survival, improve quality of life and delay or avoid liver transplantation. However, depending on a variety of definitions of response, success rates only range from 65% to 80%, which leaves a significant number of patients in need of other than standard treatment. Considerable challenges still exist in the areas of initial and maintenance regimens, management of relapse, non-response, drug toxicity and intolerance, and non-compliance<sup>[8,22]</sup>.

Standard medications for initial and maintenance regimens are still considered to be prednisone (or prednisolone) alone or in combination with azathioprine (or 6-mercaptopurine) (Table 3). A recent retrospective analysis of corticosteroid treatment in AIH patients with severe and fulminant AIH, suggested that steroids did not obviate the need for transplantation and may have promoted septic complications<sup>[23]</sup>.

One issue of treatment of particular concern is toxicity and/or intolerance to 6-mercaptopurine and its pro-drug azathioprine. The methylation of 6-mercaptopurine and 6-thioguanosine 5'-monophosphate is catalyzed by thiopurine methyltransferase (TPMT). The genes encoding thiopurine methyltransferase are highly polymorphic.

**Table 3** Drugs used in standard treatment of autoimmune hepatitis in adults

Regimen	Single-drug therapy	Combination therapy
Initial	Prednisone 20-60 mg/d	Prednisone 15-30 mg/d and azathioprine 50-100 mg/d
Maintenance	Prednisone 5-15 mg/d or azathioprine 50-200 mg/d	Prednisone 5-10 mg/d and azathioprine 50-150 mg/d

Homozygosity and heterozygosity for mutations in TPMT genes occur in Caucasian and other populations, and these patients may accumulate high levels of thio-guanine nucleotides in bone marrow cells. Patients who are homozygous for a mutation of TPMT are at high risk for severe toxicity, including death. Patients, who are heterozygous for the TPMT mutation, probably have an intermediate risk of toxicity. These findings have led to the suggestion that prior to placing patients on azathioprine or 6-mercaptopurine, TPMT genotyping may be appropriate. Despite reliable methods for TPMT genotyping and measurement of levels of 6-mercaptopurine metabolites, their assessment in the clinical management of AIH is not established, and must be evaluated in the context of severity of disease, as well, as advanced fibrosis has been shown to predict azathioprine toxicity<sup>[24-26]</sup>.

Although some patients will remain in remission when drug treatment is withdrawn, the majority requires long-term maintenance therapy. In general, the response is better with milder disease. Adults with cirrhosis at the time of initial biopsy and children, particularly those with type 2 disease, rarely stay in remission when treatment is withdrawn and will almost require life-long maintenance therapy.

No firm guidelines exist for decisions regarding withdrawal of medications because histologic changes may lag biochemical responses and a quiescent histologic appearance and normal biochemical findings while patients are still receiving therapy, are not necessarily predictive of continued remission once therapy is withdrawn. Although, in the past, aminotransferase levels  $\leq 2 \times$  normal were proposed as a guideline to reducing medications, relapse has been shown to be less likely in patients who achieve normal transaminase and gamma globulin (or IgG) levels<sup>[27]</sup>.

Progress in non-standard treatment for patients with inadequate responses or intolerance to therapy with glucocorticosteroids alone or in combination with azathioprine or 6-mercaptopurine (including mycophenolate mofetil, methotrexate, cyclophosphamide, tacrolimus, budesonide and ursodeoxycholic acid) has been slow. In view of the paucity of trials with non-standard forms of therapy most decisions must be based on data obtained from case reports and series of small numbers of patients. Cyclosporine, which has been used successfully in children to induce remission<sup>[28]</sup>, and tacrolimus are used occasionally to treat adults<sup>[29,30]</sup>. Off-label use of mycophenolate mofetil has become more frequently employed in intolerant or non-responsive patients<sup>[31,32]</sup>. The roles of cyclosporine, tacrolimus, mycophenolate mofetil,

methotrexate, cyclophosphamide, ursodeoxycholic acid, budesonide<sup>[33,34]</sup> and other immunosuppressive medications have not been established.

AIH patients who develop decompensated cirrhosis may require liver transplantation. Five-year patient and graft survivals range from 80% to 90%. As in other autoimmune liver diseases, recurrence and cirrhosis may occur after transplantation<sup>[35,36]</sup> and mandate modifications of the post-transplantation therapeutic regimens. So-called *de novo* AIH, also referred to as post-transplantation immune hepatitis or graft dysfunction mimicking AIH, occurs after liver transplantation for diseases other than AIH in adults and children, and may require changes in post-transplantation therapy as well<sup>[37,38]</sup>.

## Abstract

The histological hallmark of autoimmune hepatitis (AIH) is a dense portal mononuclear cell infiltrate that invades the surrounding parenchyma and comprises T and B lymphocytes, macrophages, and plasma cells. An unknown but powerful stimulus must be promoting the formation of this massive inflammatory cellular reaction that is likely to initiate and perpetuate liver damage. An autoimmune attack can follow different pathways to inflict damage on hepatocytes. Liver damage is likely to be orchestrated by CD4<sup>+</sup> T lymphocytes recognizing an autoantigenic liver peptide. To trigger an autoimmune response, the peptide must be embraced by an HLA class II molecule and presented to naïve CD4<sup>+</sup> T helper (Th0) cells by professional antigen presenting cells, with the co-stimulation of ligand-ligand fostering interaction between the two cells. Th0 cells become activated, differentiate into functional phenotypes according to the cytokines prevailing in the microenvironment and the nature of the antigen, and initiate a cascade of immune reactions determined by the cytokines produced by the activated T cells. Th1 cells, arising in the presence of the macrophage-derived interleukin (IL) -12, secrete mainly IL-2 and interferon-gamma (IFN- $\gamma$ ), which activate macrophages, enhance expression of HLA class I (increasing liver cell vulnerability to a CD8<sup>+</sup> T cell cytotoxic attack), and induce expression of HLA class II molecules on hepatocytes. Th2 cells, which differentiate from Th0 if the microenvironment is rich in IL-4, produce mainly IL-4, IL-10, and IL-13 which favour autoantibody production by B lymphocytes. Physiologically, Th1 and Th2 antagonize each other. Th17 cells, a recently described population, arise in the presence of transforming growth factor beta (TGF- $\beta$ ) and IL-6 and appear to have an important effector role in inflammation and autoimmunity. The

process of autoantigen recognition is strictly controlled by regulatory mechanisms, such as those exerted by CD4<sup>+</sup>CD25<sup>+</sup> regulatory T cells, which derive from Th0 in the presence of TGF- $\beta$ , but in the absence of IL-6. If regulatory mechanisms fail, the autoimmune attack is perpetuated. Over the past three decades different aspects of the above pathogenic scenario have been investigated. In particular, a defect in immunoregulation affecting CD4<sup>+</sup>CD25<sup>+</sup> regulatory T cells (T-regs) has been demonstrated in AIH, particularly at diagnosis or during relapse. Advances in the study of autoreactive T cells have occurred mostly in AIH type 2, since the knowledge that CYP2D6 is the main autoantigen has enabled the characterization of both CD4 and CD8 T cells targeting this cytochrome. CD4 T cells from patients with type 2 AIH positive for the predisposing HLA allele *DRB1\*0701* recognize seven regions of CYP2D6, five of which are also recognized by CD8 T cells. High numbers of IFN- $\gamma$  producing CD4 T cells and CD8 T cells are associated with biochemical evidence of liver damage, suggesting a combined cellular immune attack.

## INTRODUCTION

Autoimmune hepatitis (AIH) is an inflammatory liver disease, affecting mainly females, characterized by elevated serum transaminase activity, positive organ and non-organ specific autoantibodies, elevated IgG, and a histological picture of interface hepatitis. There are two types of AIH according to their serology: type 1 is characterized by anti-nuclear (ANA) and/or anti-smooth muscle (SMA) antibodies; type 2 by anti-liver kidney microsomal type 1 (anti-LKM-1) antibody. The aetiology of AIH is unknown, though both genetic and environmental factors are involved in its expression.

Immune reactions against host liver antigens are believed to be the major pathogenic mechanism.

## GENETICS

AIH is a “complex trait” disease, i.e. a condition not inherited in a Mendelian autosomal dominant, autosomal recessive, or sex-linked fashion. The mode of inheritance of a complex trait disorder is unknown and involves one or more genes, operating alone or in concert, to increase or reduce the risk of the trait, and interacting with environmental factors.

Susceptibility to AIH is imparted by genes within the major histocompatibility complex (MHC) - the human leukocyte antigen (HLA) region - on the short arm of chromosome 6, especially genes encoding HLA *DRB1* alleles. Since the role of class II MHC molecules is to present peptide antigens to CD4 T cells, HLA class II antigen presentation with ensuing T cell activation is likely to be involved in the pathogenesis of AIH.

In Europe and North America, susceptibility to AIH type 1 is conferred by the presence of HLA *DR3* (*DRB1\*0301*) and *DR4* (*DRB1\*0401*), both heterodimers containing a lysine residue at position 71 of the *DRB1* polypeptide and the hexameric amino acid sequence LLEQKR at positions 67-72<sup>[1,2]</sup>. In Japan, Argentina, and Mexico, susceptibility is linked to *DRB1\*0405* and *DRB1\*0404*, alleles encoding arginine rather than lysine at position 71, but sharing the motif LLEQ-R with *DRB1\*0401* and *DRB1\*0301*<sup>[3]</sup>. Thus, K or R at position 71 in the context of LLEQ-R may be critical for susceptibility to AIH, favouring the binding of autoantigenic peptides, complementary to this hexameric sequence. However, an alternative model based on valine/glycine dimorphism at position 86 of the DR- $\beta$  polypeptide has been proposed, better representing the key HLA associations in patients from Argentina and Brazil<sup>[1,2]</sup>. In a study from Japan, patients with AIH type 1 were found to have *DRB1* alleles which encode histidine at position 13<sup>[1,2]</sup>. There appears therefore to be at least three different models, suggesting that different genetic associations are present in different populations and that the peptides presented by HLA class II molecules to the T cell receptors are different and may be derived from different antigens. Thus, these HLA associations may be the molecular footprints of the prevailing environmental triggers that precipitate AIH type 1 in different environments, though at the effector level the same autoantigenic target would be recognized. In this context, it is of interest that in South America presence of the HLA *DRB1\*1301* allele, which predisposes to paediatric AIH type 1 in that population, is also associated with persistent infection with the endemic hepatitis A virus.

The lysine-71 and other models for AIH type 1 cannot explain completely the disease, since for example in European and North American patients presence of lysine-71 is associated with a severe, mainly juvenile, disease in those *DRB1\*0301* positive, but to a mild, late onset, disease in those *DRB1\*0401* positive. Other genes

within or/and without the MHC are, therefore, likely to be involved in determining the phenotype. Possible candidates are the MHC encoded complement and tumour necrosis factor  $\alpha$  genes, that are located in the class III MHC region, and the MHC class I chain-related (MICA) A and B genes.

Susceptibility to AIH type 2 is conferred by HLA *DR7* (*DRB1\*0701*) and *DR3* (*DRB1\*0301*); patients positive for *DRB1\*0701* have a more aggressive disease and worse outcome<sup>[4]</sup>.

In an attempt to define additional susceptibility genes, a genome-wide approach was applied to a Japanese cohort of patients with AIH type 1<sup>[5]</sup>. This study found that 2 microsatellite markers (on chromosomes 11 and 18) out of 400 studied are associated with AIH type 1, though no protein of clear relevance to the disease is encoded in proximity of these two markers. The use of a larger number of microsatellites may prove more informative.

A form of AIH resembling AIH type 2 affects some 20% of patients with autoimmune polyendocrinopathy-candidiasis-ectodermal dystrophy (APECED), a condition also known as autoimmune polyendocrine syndrome 1. APECED is a monogenic autosomal recessive disorder caused by homozygous mutations in the *AIRE1* gene and characterized by a variety of organ-specific autoimmune diseases, the most common of which are hypoparathyroidism and primary adrenocortical failure, accompanied by chronic mucocutaneous candidiasis<sup>[6,7]</sup>. The *AIRE1* gene sequence consists of 14 exons containing 45 different mutations, with a 13 bp deletion at nucleotide 964 in exon 8 accounting for more than 70% of APECED alleles in the UK<sup>[6]</sup>. The protein predicted to be encoded by *AIRE1* is a transcription factor. *AIRE1* is highly expressed in thymic medullary epithelial cells and thymic stromal cells involved in clonal deletion of self-reactive T cells. Studies in a murine model indicate that the gene inhibits organ specific autoimmunity by inducing thymic expression of peripheral antigens in the medulla leading to central deletion of autoreactive T cells. Interestingly, APECED has a high level of variability in symptoms, especially between populations. Since various gene mutations have the same effect on thymic transcription of ectopic genes in animal models, it is likely that the clinical variability across human populations relates to environmental or genetic modifiers. Of the various genetic modifiers, perhaps the most likely to synergize with *AIRE* mutations are polymorphisms in the HLA region. HLA molecules are not only highly variable and strongly associated with multiple autoimmune diseases, but are also able to affect thymic repertoire selection of autoreactive T cell clones. Carriers of a single *AIRE* mutation do not develop APECED. However, although the inheritance pattern of APECED indicates a strictly recessive disorder, there are anecdotal data of mutations in a single copy of *AIRE* being associated with human autoimmunity of a less severe form than classically defined APECED<sup>[6,7]</sup>. A role of the heterozygote state for mutant *AIRE1* in the development of AIH remains

to be established. *AIRE1* mutations have been reported in 3 children with severe AIH type 2 and extrahepatic autoimmune manifestations<sup>[8]</sup>.

## IMMUNE MECHANISMS

The liver is regarded as a lymphoid organ with unique immunological properties<sup>[9]</sup>. Because of its location and function, the liver is continuously exposed to a large antigenic load that includes pathogens, toxins, tumour cells, dietary, and self-antigens. The liver contains large numbers of phagocytic cells, antigen presenting cells (APC) and lymphocytes and is a site for the abundant production of cytokines, complement components and acute phase proteins. The intrinsic lymphocyte population mainly resides in the portal tracts but is also scattered throughout the parenchyma, consisting of both cells of the innate (natural killer T cells, natural killer cells, and macrophages) and the adaptive (T and B cells) arms of the immune system. The blood entering the liver from the gut is rich in bacterial and dietary antigens that intermingle with lymphocytes. Immunoregulatory mechanisms are required to determine whether an antigen encounter will result in immunological unresponsiveness (tolerance) or reactivity. Liver autoimmunity implies loss of self-tolerance. Programmed cell death - apoptosis - which is responsible for the normal turnover of hepatocytes and the elimination of liver cells and unwanted lymphocytes in inflammatory pathologies is also relevant to the breakdown and/or maintenance of liver tolerance. First, death by apoptosis allows for non-inflammatory elimination of cell components in contrast to necrosis, which is pro-inflammatory and potentially autoantigenic. Second, apoptosis is the mechanism whereby the immune system is "cleansed" of autoreactive T and B lymphocytes as illustrated by the process of "activation induced cell death".

Various mechanisms have been proposed to account for the onset of an autoimmune liver response with no single initiating event being able to explain all instances of autoimmunity. Two general conditions, however, should prevail: self reactive B and T lymphocytes must exist in the immunological repertoire and autoantigens must be presented in conjunction with MHC class II molecules by APC.

### Humoral autoimmunity

Titres of antibodies to liver specific protein (LSP), a macromolecular complex present on the hepatocyte membrane<sup>[10]</sup>, and to its well characterized components asialoglycoprotein receptor (ASGPR)<sup>[11]</sup> and alcohol dehydrogenase (ADH)<sup>[12]</sup> correlate with the biochemical and histological severity of AIH. Immunofluorescence studies on monodispersed suspensions of liver cells obtained from patients with AIH show that these cells are coated *in vivo* with antibodies reacting with antigens on the liver cell membrane<sup>[13]</sup>. A pathogenic role for these autoantibodies has been indicated by cytotoxicity assays demonstrating that autoantibody-coated hepato-

cytes from patients with AIH are killed when incubated with autologous or allogeneic lymphocytes<sup>[13]</sup>. The effector cell was identified as an Fc receptor positive mononuclear cell, presumably a natural killer (NK) cell.

In AIH type 2 the target of the disease-defining antibody, anti-LKM-1, is CYP2D6, a member of the hepatic P450 cytochrome family. Since CYP2D6 is expressed on the membrane of the hepatocytes and readily "accessible"<sup>[14]</sup>, anti-LKM-1 antibodies might well have a pathogenic effect. In AIH type 2 anti-LKM-1 antibodies recognize linear regions (autoepitopes) of CYP2D6 in a hierarchical manner. Thus, the principal linear B-cell epitope, CYP2D6<sub>193-212</sub> is recognized by 93% of patients, CYP2D6<sub>257-269</sub> by 85%, CYP2D6<sub>321-351</sub> by 53%, and two additional minor epitopes CYP2D6<sub>373-389</sub> and CYP2D6<sub>410-429</sub> are recognized by 7% and 13% respectively<sup>[15]</sup>. Intriguingly, anti-LKM-1 antibodies are also found in some 5% of patients with hepatitis C virus (HCV) infection, among whom they appear to correlate with increased disease severity and adverse reactions to interferon  $\alpha$  treatment<sup>[16]</sup>. The major CYP2D6 epitope recognized by patients with AIH type 2, CYP2D6<sub>193-212</sub>, is also recognized by 50% of patients with anti-LKM-1 positive HCV infection<sup>[15]</sup>. Interestingly, these patients have antibodies that cross-react with homologous regions of HCV (NS5B HCV<sub>2985-2990</sub>) and CYP2D6 (CYP2D6<sub>204-209</sub>), and also of cytomegalovirus (exon CMV<sub>130-135</sub>)<sup>[15]</sup>. Cross-reactive mechanisms to explain the emergence of CYP2D6 specific autoimmunity have also been suggested for other sequences of CYP2D6 which share homologies with HCV and herpes simplex virus (HSV), such as the sequence spanning aa 310-324 of E1 HCV and aa 156-170 of IE175 HSV1, which share homology with the CYP2D6 region comprising aa 254-271. As anti-LKM-1 antibodies cross-react with homologous regions of CYP2D6, HCV, HSV, and CMV, a "multi-hit" mechanism for the generation of these antibodies and possibly of AIH type 2 may be envisaged. In this model, multiple exposures to CMV or HSV, common viral pathogens, may establish permissive immunological conditions, by priming a cross-reactive subset of T cells, in a genetically predisposed host. Depending on the degree of immunological priming, i.e. level of exposure and the degree of genetic susceptibility (particularly at the HLA locus and coding regions for "innate" components of immunity), a minority of recurrently infected individuals may progress to autoimmune disease. It is therefore conceivable that an as yet unsuspected virus infection may be part of the origin of the autoimmune attack in AIH; this is to some degree in agreement with the concept expressed by Rolf Zinkernagel that an autoimmune disease is a viral disease in which the virus is unknown<sup>[17]</sup>.

### Molecular mimicry

The central function of the adaptive immune system is to generate T and B lymphocytes that can specifically recognize a potentially infinite number of non-self antigens without any prior information as to their structure. This is achieved by randomly generating a

**Figure 1** The portal and periportal inflammatory infiltrate characteristic of autoimmune hepatitis is composed by lymphocytes and plasma cells (interface hepatitis) (HE,  $\times 40$ , provided by Dr. Alberto Quaglia).

large number of T and B cell specificities (*via* their respective antigen receptors-the T cell receptor and the antibody receptor) that are then able to clonally expand and recruit effector mechanisms on recognition of their cognate antigen or epitope. It is however, becoming clear that even this versatile system cannot cope with the extent of non-self antigenic diversity, and in the past decade convincing evidence has emerged for cross reactivity as an inherent property of immune ontogeny<sup>[18]</sup>. This has been studied primarily in the context of T lymphocytes, where it is clear that altered peptide ligands (APLs) - peptides similar in structure to the peptide antigen which are initially encountered - are able to induce both stimulatory and inhibitory T cell responses and, indeed, endogenous APLs operate in selecting the T cell repertoire in the thymus. This implies that a single T cell, rather than responding to a single antigen specificity, is able to cross-reactively respond to a number of antigens, thus expanding the antigenic specificities of the immune system to a level that reflects the antigenic diversity of the external environment<sup>[19]</sup>.

This inherent potential for cross-reactivity, whilst allowing efficient responses to a vast array of pathogens also provides the immune system with the potential to cross-react with self, leading to autoimmunity. This process has been termed “molecular mimicry” as described above, whereby immune responses to external pathogens become directed towards structurally similar self components. Molecular mimicry has been shown to participate to the pathogenesis of autoimmune disease both in experimental models and in the human setting at the level of both T and B cells<sup>[18]</sup>.

### Cellular autoimmunity

The histological picture of interface hepatitis (Figure 1), with its striking infiltrate of lymphocytes, plasma cells, and macrophages was the first to suggest an autoaggressive cellular immune attack in the pathogenesis of AIH. Whatever is the initial trigger, this massive recruitment of activated inflammatory cells is likely to cause damage. Immunohistochemical studies have identified a predominance of T lymphocytes mounting the  $\alpha/\beta$  T cell receptor<sup>[20]</sup>. Amongst the

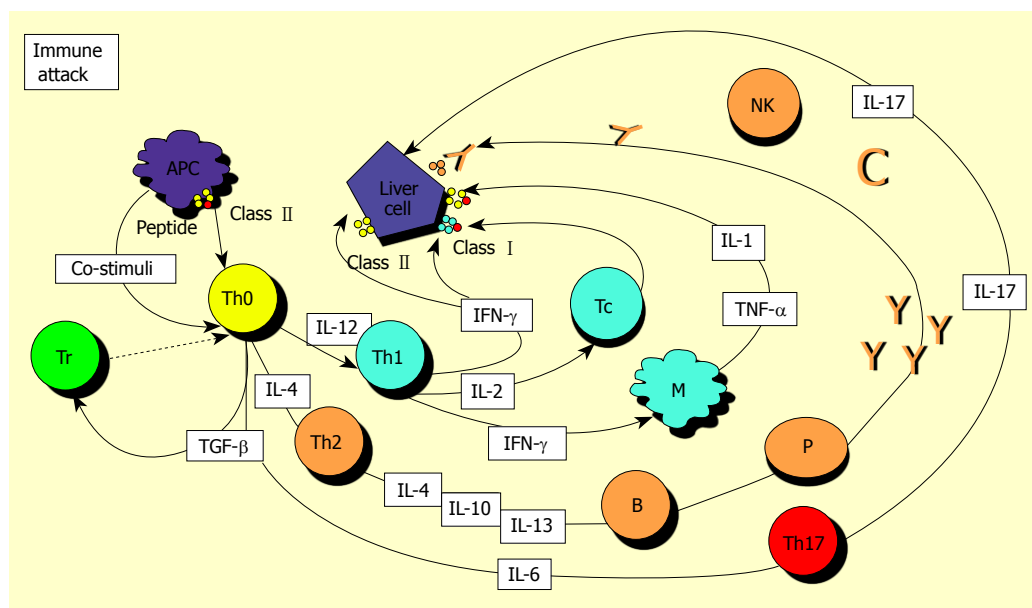

T cells, a majority are positive for the CD4 helper/inducer phenotype, and a sizeable minority for the CD8 cytotoxic phenotype. Lymphocytes of non-T cell lineage are fewer and include (in decreasing order of frequency) natural killer cells (CD16/CD56 positive), macrophages, B cells, and plasma cells. The involvement of natural killer T cells is the focus of ongoing studies.

There are different possible pathways that an immune attack can follow to inflict damage on hepatocytes (Figure 2) as discussed below.

### Impairment of T regulatory cells

An impairment of immunoregulatory mechanisms, which would enable the autoimmune response to develop, has been repeatedly reported in the setting of both human and experimental autoimmunity. Thus, in early studies it was shown that patients with AIH have low levels of circulating T cells expressing the CD8 marker<sup>[21]</sup>, and impaired suppressor cell function which segregates with the possession of the disease-predisposing HLA haplotype B8/DR3<sup>[22]</sup> and is correctable by therapeutic doses of corticosteroids<sup>[23]</sup>. Furthermore, patients with AIH have been reported to have a defect specifically in a subpopulation of T cells that control the immune response to an as yet unidentified liver-specific membrane antigen(s)<sup>[24]</sup>. Recent experimental evidence confirms an impairment of the immunoregulatory function in AIH. Thus, among recently defined T cell subsets with potential immunosuppressive function, CD4<sup>+</sup> T cells constitutively expressing the interleukin 2 receptor  $\alpha$  chain (CD25) (T-regulatory cells, T-regs) have emerged as the dominant immunoregulatory lymphocytes<sup>[25]</sup>. These cells, which in health represent 5%-10% of the total population of peripheral CD4<sup>+</sup> T cells, control the innate and the adaptive immune responses by preventing the proliferation and effector function of autoreactive T cells. Their mechanism of action involves mainly a direct contact with the target cells, and to a lesser extent the release of immunoregulatory cytokines, such as interleukin 10 and transforming growth factor  $\beta$  1 (TGF- $\beta$ ). In addition to CD25, which is also present on T cells undergoing activation, T-regs express a number of additional markers such as the glucocorticoid induced tumour necrosis factor receptor, CD62L, the cytotoxic T lymphocyte associated protein-4 (CTLA-4) and the forkhead/winged helix transcription factor FOXP3, the expression of which is closely associated with the acquisition of regulatory properties. In patients with AIH, T-regs are defective both in number and function compared to normal controls and these abnormalities relate to the stage of disease, being more evident at diagnosis than during drug-induced remission<sup>[26-28]</sup>. The percentage of T-regs inversely correlates with markers of disease severity, such as levels of antibodies to anti-soluble liver antigen<sup>[29]</sup> and anti-LKM-1 autoantibody titres, suggesting that a reduction T-regs favours the serological manifestations of autoimmune liver disease. If loss of immunoregulation was central to the pathogenesis of autoimmune liver disease, treatment should concentrate on restoring T-regs ability to expand, with consequent

**Figure 2** Autoimmune attack to the liver cell. A specific autoantigenic peptide is presented to an uncommitted T helper (Th0) lymphocyte within the HLA class II molecule of an antigen-presenting cell (APC). Th0 cells become activated and, according to the presence in the microenvironment of IL-12 or IL-4 and the nature of the antigen, differentiate into Th1 or Th2 and initiate a series of immune reactions determined by the cytokines they produce: Th2 secrete mainly IL-4, IL-10 and IL-13, and direct autoantibody production by B lymphocytes; Th1 secrete IL-2 and IFN- $\gamma$ , which stimulate T cytotoxic (Tc) lymphocytes, enhance expression of class I and induce expression of class II HLA molecules on hepatocytes and activate macrophages; activated macrophages release IL-1 and tumour necrosis factor alpha (TNF- $\alpha$ ). If regulatory T cells do not oppose, a variety of effector mechanisms are triggered: liver cell destruction could derive from the action of Tc lymphocytes; cytokines released by Th1 and recruited macrophages; complement activation or engagement of Fc receptor-bearing cells such as natural killer (NK) lymphocytes by the autoantibody bound to the hepatocyte surface. The role of the recently described Th17 cells, which arise in the presence of transforming growth factor beta (TGF- $\beta$ ) and IL-6, is under investigation.

increase in their number and function. This is at least partially achieved by standard immunosuppression, since T-reg numbers do increase during remission<sup>[26,28]</sup>.

### CD4 autoreactive T cells

To trigger an autoimmune response, a peptide must be embraced by an HLA class II molecule and presented to uncommitted T helper (Th0) cells by professional APC, with the co-stimulation of ligand-ligand (CD28 on Th0, CD80 on APC) interaction between the cells (Figure 2). Once the autoimmune response has been initiated and in the absence of effective immunosuppressive treatment, tissue damage ensues and persists. In an inflammatory milieu, hepatocytes from patients with AIH, in contrast to normal hepatocytes, express HLA class II molecules<sup>[20]</sup>, as well as class I. Although lacking the antigen processing machinery typical of APC, MHC-class II-bearing hepatocytes may present peptides through a bystander mechanism<sup>[30]</sup>. In the presence of impaired immunoregulation and inappropriate expression of HLA class II antigens on the hepatocytes, an intracellular autoantigenic peptide from intact hepatocytes could be presented to the CD4 helper/inducer T cells leading to their activation. Although no direct evidence exists as yet that an autoantigenic peptide is in fact presented by MHC-class II-bearing hepatocytes and recognized by CD4 T helper cells, activation of such cells has been documented in AIH<sup>[21]</sup>. Circulating T cells specific for liver autoantigens are found also in normal subjects, but in AIH their frequency is at least 10-fold higher<sup>[31]</sup>. This

finding suggests that the pool of liver-autoreactive T cells undergoes a significant expansion in patients with AIH and hence may be involved in the initiation and perpetuation of the immune attack to the liver.

Given that T cells recognize antigens in a precise fashion, studies in the early 1990s were conducted at a single T cell level in order to characterize antigen-specific T cell recognition. T cell clones generated from the peripheral blood were mainly CD4<sup>+</sup>  $\alpha/\beta$  T cells<sup>[32]</sup>, while a large proportion of liver-derived clones were either CD4/CD8<sup>+</sup>  $\gamma/\delta$  or CD8<sup>+</sup>  $\alpha/\beta$  T cells<sup>[31,33,34]</sup>. Both  $\alpha/\beta$  and  $\gamma/\delta$  T cell clones proliferated in the presence of a crude liver membrane preparation, liver specific protein and asialoglycoprotein receptor,  $\alpha/\beta$  being more reactive than  $\gamma/\delta$  clones. Some of the liver membrane reactive clones also proliferated in the presence of LSP and/or ASGPR, responded in an HLA class II restricted fashion and helped autologous B cells to produce immunoglobulins, and in particular autoantibodies to LSP and ASGPR<sup>[32]</sup>.

T cell ligands are best studied in AIH type 2, since the target of anti-LKM-1 has been characterized as CYP2D6. CYP2D6<sub>262-285</sub> specific T cell clones generated from liver tissue and peripheral blood express a Th1 CD4<sup>+</sup> phenotype<sup>[33,34]</sup>. In contrast to the latter study that focused on a short antigenic sequence of CYP2D6, a systematic approach based on the construction of overlapping peptides covering the whole CYP2D6 molecule was recently adopted to define the specificity of *ex vivo* CYP2D6 reactive T cells in patients with AIH type

2<sup>[4]</sup>. This study showed that T cells from patients positive for the predisposing HLA allele *DRB1\*0701* recognize in a proliferation assay seven regions of CYP2D6, four of which are also partially recognized by T cells of *DRB1\*0701* negative patients. While distinct peptides induce production of IFN- $\gamma$ , IL-4 or IL-10, peptides that induced IFN- $\gamma$  and proliferative responses overlap. There was also an overlap between sequences inducing T and B cell responses. The number of epitopes recognized and the quantity of cytokine produced by T cells are directly correlated to biochemical and histological markers of disease activity. These results indicate that the T cell response to CYP2D6 in AIH type 2 is polyclonal, involves multiple effector types targeting different epitopes, and is associated with hepatocyte damage<sup>[4]</sup>.

### CD8 autoreactive T cells

In addition to the unfolding role of CYP2D6 specific CD4 T cells in AIH type 2, there is growing evidence implicating an HLA class I restricted CD8 response in the pathogenesis of autoimmune liver damage. In the early 1990s CD8 T cell clones specific for ASGPR were described in patients with AIH<sup>[32]</sup>. Recent studies have identified CYP2D6 specific CD8 T cells capable of secreting IFN- $\gamma$  and of exerting cytotoxicity after recognition of CYP2D6 epitopic sequences in an HLA class I restricted fashion<sup>[35]</sup>.

Taken together, the data presented above suggest that a failure of immune homeostatic processes, normally keeping the response against self-antigens under control, is involved in the pathogenesis of AIH. The prime mechanism for tolerance breakdown remains to be elucidated. There is some evidence that molecular mimicry mechanisms involving viral self-mimicking and autologous sequences may be involved<sup>[36,37]</sup> and such mechanisms are the focus of ongoing studies.

### ANIMAL MODELS

Research on the pathogenesis of AIH has been hampered by the lack of animal models reproducing faithfully the human condition. The ideal model for AIH should have a well-defined initiating event followed by chronic inflammation leading to fibrosis. Recently, researchers have focused on animal models of AIH type 2, since in this condition the autoantigen is well defined. The model produced by the group of Alvarez<sup>[38]</sup> is based on immunizing every two weeks for three times C57BL/6 female mice with a plasmid containing cDNA for the antigenic region of human CYP2D6, which is the target of anti-LKM-1, and formimino-transferase cyclodeaminase, which is the target of anti-liver cytosol-1 and an additional marker for AIH type 2<sup>[39]</sup>, together with the end of the terminal region of murine CTLA-4. The latter was added to facilitate antigen uptake by antigen presenting cells. In a parallel set of experiments a plasmid containing the cDNA encoding IL-12, a Th1 skewing pro-inflammatory cytokine, was also used. When autoantigens and IL-12 were used to

break tolerance, antigen specific autoantibodies were produced, a relatively modest elevation of transaminase levels at 4 and 7 mo was observed, and a portal and periportal inflammatory infiltrate composed of CD4 and CD8 T cells and, to a lesser extent, B cells was demonstrated 8-10 mo after the third immunization. When the same immunization protocol was used in different mouse strains, either a mild hepatitis or no inflammatory changes were observed indicating the importance of a specific genetic background. Another model of AIH type 2 uses CYP2D6 transgenic mice and aims at breaking tolerance with an adenovirus-CYP2D6 vector<sup>[40]</sup>. While focal hepatocyte necrosis was seen in both mice treated with the adenovirus-CYP2D6 vector and control mice treated with adenovirus alone, only the former developed chronic histological changes, including fibrosis, reminiscent of AIH. The hepatic lesion was associated to a specific immune response to an immunodominant region of CYP2D6 and a cytotoxic T cell response to adenovirus-CYP2D6 vector infected target cells. Though these two experimental approaches provide useful information on the possible pathogenic mechanisms leading to human AIH type 2, a model that closely reproduces human AIH type 1 is still lacking, hampering the elucidation of pathogenic mechanisms in this form of AIH.

### Abstract

Primary biliary cirrhosis (PBC), which is characterized by progressive destruction of intrahepatic bile ducts, is not a rare disease since both prevalence and incidence are increasing during the last years mainly due to the improvement of case finding strategies. The prognosis of the disease has improved due to both the recognition of earlier and indolent cases, and to the wide use of ursodeoxycholic acid (UDCA). New indicators of prognosis are available that will be useful especially for the growing number of patients with less severe disease. Most patients are asymptomatic at presentation. Pruritus may represent the most distressing symptom and, when UDCA is ineffective, cholestyramine represents the mainstay of treatment. Complications of long-standing cholestasis may be clinically relevant only in very advanced stages. Available data on the effects of UDCA on clinically relevant end points clearly indicate that the drug is able to slow but not to halt the progression of the disease while, in advanced stages, the only therapeutic option remains liver transplantation.

### INTRODUCTION

Primary biliary cirrhosis (PBC) is an autoimmune liver disease characterized by progressive destruction of intrahepatic bile ducts with cholestasis, portal inflammation, and fibrosis which may lead to cirrhosis, to its complications, and eventually to liver transplantation or death. Thus, primary biliary cirrhosis is indeed a historically-based misnomer, since currently a substantial proportion of patients may not develop cirrhosis as the final event. The disease predominantly affects women who are usually diagnosed in their fifties mainly in an asymptomatic stage. The loss of bile ducts leads to the retention within the liver of detergent bile acids which contribute to parenchymal damage through interaction with cell membranes and cellular organelles. The derangement of the entero-hepatic circulation of bile acids may also induce important pathophysiological changes which may determine, if untreated, some of the extra-hepatic alterations characteristic of established disease. It is well known that both clinical features and natural history vary greatly among individual patients ranging from asymptomatic and stable or only slowly progressive to symptomatic and rapidly progressive disease. The clinical presentation has progressively changed from one characterized by a serious outcome to that of a slowly evolving disease since natural history and outcome have improved, during the last few decades, due to the recognition of earlier more indolent cases and, likely, to widespread use of ursodeoxycholic acid (UDCA).

Since aetiology and immunological aspects are reviewed separately in this series, the aim here is to review the evidence on epidemiology, diagnosis, clinical features, and treatment. Both management of the consequences of long-standing cholestasis and specific therapy for PBC will be discussed.

### EPIDEMIOLOGY

Descriptive epidemiology of a particular disease is important in order to establish the magnitude of the problem and to find clues for aetiopathogenesis. There are a number of epidemiologic studies reported among patients affected by PBC<sup>[1]</sup>. The key issue involving all these studies is that they rely upon the number of diagnoses recorded in a defined location rather than on the screening of the entire population at risk. Obviously, this latter approach

**Table 1** Epidemiology of primary biliary cirrhosis: Results from the most relevant studies<sup>[2-9]</sup>

Area	Patients (No.)	Prevalence (per million)	Incidence (per million/yr)	Age (yr)	Gender (M:F)
Europe (1984)	569	23	54	54	1:10
Northern Sweden (1990)	111	151 <sup>1</sup>	13.3	55	1:6
North East England (1990)	347	129 <sup>1</sup>	19	58	1:9

Victoria, Australia (2004)	249	51 <sup>1</sup>	-	61	1:9

<sup>1</sup>Data include survey of laboratories for antimitochondrial antibodies.

would be particularly expensive in view of the relatively low prevalence of the disease thus requiring large populations to be screened. At present, we must consider the prevalence indicated by case-finding studies as underestimates, to a degree inversely related to the accuracy of the methodology employed to identify the potential diagnoses made in the area under consideration. In Table 1, relevant data from the available epidemiologic studies are reported in chronological order<sup>[2-9]</sup>.

Several difficulties however exist when attempting to compare results of these studies among each other, and over time. Heterogeneity in the methodology of case finding and, to a lesser extent, the criteria used for the diagnosis represent the most problematic issue. In particular, only a few studies used multiple strategies to reduce selection bias by capturing the entire spectrum of illness associated with PBC, especially cases at the preclinical stage<sup>[10]</sup>. Ascertainment from laboratory determination of anti-mitochondrial antibodies (AMA), which are highly sensitive and specific markers of the disease, has been a valuable approach. Differences in estimates of incidence and prevalence of PBC among populations, coming from the earlier studies<sup>[2,11-15]</sup>, may be due to differences in diagnostic criteria and study design, as well as to the different disease awareness among physicians, and to the differing degrees of access to health care systems. Similarly the same limits may explain the lack of confirmation of preliminary observations of associations between the occurrence of PBC and environmental factors<sup>[12,16]</sup>.

The methodological quality of reported investigations has improved over time which allows some capacity to compare incidence and prevalence rates by geographic areas. Initial studies published between 1974 and 1986 described annual incidence rate of PBC ranging from 0.6 to 13.7 cases per million<sup>[2,11,13-15]</sup>. Prevalence rates from these studies varied between 23 and 128 cases per million<sup>[2,11,13-15]</sup>. The majority of data originated from the United Kingdom and Sweden. Since 1989 a larger number of studies have been reported, mainly performed in Europe but also coming from Asia, North

America, and Australia<sup>[3-10,16-31]</sup>. From these more recent studies, both the annual incidence rates and prevalence of PBC have increased<sup>[3-10,16-31]</sup>. In particular, from the United Kingdom the annual incidence rates increased from 5.8 to 20.5 cases per million between 1980 and 1999 among residents of Sheffield<sup>[12,28]</sup> and from 11 to 32 cases in Newcastle-upon-Tyne between 1976 and 1994<sup>[4,7,27]</sup>. A parallel increase of the prevalence rate occurred reaching the number of more than 200 cases per million in the middle-late nineties<sup>[4,7,27]</sup>. A similar picture has been reported by very recent studies coming from Europe<sup>[30,31]</sup>. These data may be explained by the progressively higher proportion of asymptomatic cases with early-stage disease, resulting in growing prevalence rates, and the increased use of biochemical and serologic testing leading to the increasing diagnosis of new cases per year. Interestingly the mean age at diagnosis did not change from initial to more recent studies (Table 1), thus indicating that the increasing prevalence and incidence reported by the literature is more related to wider rather than to earlier diagnoses.

Only recently, several epidemiological data are available also from the USA in full indicating an annual incidence rate of 27 cases per million with prevalence rates ranging between 160 and 402 cases per million, thus leading to an estimate of 3500 new cases each year with 47 000 prevalent cases among the white population<sup>[8]</sup>. However, these data come from specific regions and difficulties in obtaining more complete epidemiological evaluations are mainly due to two reasons: (1) the lack of an universal health care system; and (2) the large number of patients followed in secondary and tertiary centres. Lower prevalence and incidence have been reported in Canada and Australia<sup>[5,6,9,18,22]</sup>.

For PBC there is a well known high prevalence of female gender (F/M 9 to 1), and based on this observation several studies provided greater insight into the aetio-pathogenesis of the disease<sup>[32]</sup>. Little information is available regarding the influence of race or ethnicity on the descriptive epidemiology of PBC<sup>[1]</sup> indicating that host susceptibility plays a significant role in the development of the disease. PBC occurs more commonly among individuals with a family history of either PBC itself or other autoimmune disorders<sup>[33-35]</sup> and there is a high concordance rate (63%) *versus* that in other autoimmune diseases in monozygotic twins<sup>[36]</sup>. Taken altogether, these observations point towards the relevance of genetic factors in the occurrence of PBC. On the other hand, the recent finding of several clusters of PBC within defined spatial boundaries suggests that also environmental factors, such as pollution, may contribute to the development of the disease<sup>[37,38]</sup>. These associations are statistically extremely weak and may be flawed by quite a high number of biases of different types<sup>[39]</sup>. The role of a previous infection as the triggering factor for the development of PBC by the mechanism of molecular mimicry has been repeatedly suggested, in analogy with other autoimmune diseases, but data are inconsistent<sup>[40-42]</sup>.

In conclusion, data coming from more recent surveys of diagnoses performed in different geographical areas

indicate that PBC is not a rare disease and its prevalence and incidence are apparently increasing in recent years mainly due to easier recognition of the disease and improved case finding strategies. No firm suggestion on the aetiologic role of any specific environmental factors has come from epidemiology, whereas familial clustering indicates a major role for genetic background.

## DIAGNOSIS

The diagnosis of PBC is currently based on three criteria: the presence of AMA in serum which is highly specific for the disease, elevation of biochemical indices of cholestasis for more than 6 mo, and histological features in the liver that are indicative of the diagnosis. The presence of two of these criteria allows a probable diagnosis but for a definite diagnosis the occurrence of all criteria is needed<sup>[43]</sup>. However, alternative diagnoses of liver disease should be ruled out and particularly in the absence of detectable AMA, a nuclear magnetic resonance cholangiography is necessary to exclude a primary sclerosing cholangitis.

Determination of AMA using routine methods, however may lead to underestimation of their presence<sup>[44]</sup>. Up to 5% to 10% of patients have no detectable antimitochondrial antibodies, but their disease appears to be identical to that in AMA positive patients<sup>[45]</sup>.

Serum liver enzymes are the earliest biochemical indices to increase in serum: gamma glutamyl transpeptidase, alkaline phosphatase, and aminotransferases in descending order of sensitivity, but each lacks specificity, except, to some extent, alkaline phosphatase, if bone disease can be ruled out. On the other hand, serum bilirubin concentrations increase only in advanced stages of the disease, and accurate measure of serum bile acid concentrations requires state of the art methods, like gas chromatography-mass spectrometry (GC-MS), which are not available routinely<sup>[46]</sup>. In addition, serum bile acids are extremely sensitive but poorly specific and their detection by GC-MS is more useful to study derangement of the bile acid circulation or the effects of therapeutic bile acids<sup>[47]</sup>.

The utility of liver biopsy in the diagnosis of PBC has been questioned by several hepatologists<sup>[43]</sup> and even for staging purposes it is scarcely justified in patients who have obvious features of cirrhosis by clinical evaluation including imaging techniques.

## HISTOLOGICAL FEATURES

The pathological lesion typical for PBC is a chronic non-suppurative destructive cholangitis involving interlobular bile ducts of 40–80 µm in diameter<sup>[48]</sup>. Overall, coexistence of portal inflammatory infiltrate with bile duct paucity is needed for diagnosis. PBC is divided into four histological stages but the liver is not affected uniformly and even a single biopsy sample may demonstrate the presence of different stages of the disease. If this is the case, the most advanced stage of those present is assigned, according to convention<sup>[43]</sup>. Stage 1 is characterized by localization of

**Table 2** Modifications during time of the clinical spectrum of primary biliary cirrhosis at presentation<sup>[50–52]</sup>

inflammation to portal triads. Stage 2 entails extension of inflammation beyond the portal triads into the lobular parenchyma and reduction in number of normal bile ducts. Stage 3 entails fibrous septa linking adjacent portal tracts. Stage 4 is the most advanced histological stage in which liver cirrhosis has occurred<sup>[49]</sup>.

## CLINICAL FEATURES

### Symptoms

**Asymptomatic disease:** PBC is now diagnosed earlier in its clinical course and most cases are only slowly progressive in comparison with the past, and the large majority of patients are asymptomatic at diagnosis (Table 2)<sup>[50–52]</sup>. It has been suggested that symptoms develop within five years in most asymptomatic patients, although one third of patients may remain symptom-free for many years<sup>[53,54]</sup>. Pruritus and fatigue are early symptoms and occur in about 20% of the patients<sup>[53,55]</sup>.

**Fatigue:** This is reported in up to 78% of PBC patients overall and is suggested to be a significant cause of disability from numerous studies<sup>[56–59]</sup>. However, a well-preserved quality of life has been recently reported in a very large cohort of patients with PBC in the USA thus arguing against the clinical relevance of fatigue in such a population<sup>[60]</sup>. Several studies have explored the pathogenesis of this symptom and indicated heterogeneous mechanisms ranging from autonomic dysfunction<sup>[59,61,62]</sup>, to excessive daytime somnolence<sup>[63]</sup>, and to altered manganese homeostasis within the central nervous system<sup>[64]</sup>, while concomitant depression could not be ruled out<sup>[65–67]</sup>. In addition, studies aimed at demonstrating the clinical relevance of fatigue in PBC are affected by significant flaws, since the correlation of inaccurate quantification of the symptom with both scores related to quality of life and clinically relevant events appears to be inappropriate, and a possible role of concomitant diseases could not be excluded<sup>[56–59]</sup>. Therefore fatigue seems a poorly specific symptom and a predominant psychogenic component is likely, as usually occurs in carriers of a chronic progressive illness who are aware of the potential impact on their future life.

**Pruritus:** This appears to be the most typical symptom of PBC. It was reported to occur in 20% to 70% of patients and occasionally is quite distressing<sup>[68]</sup>. In latter years its frequency in PBC has been decreasing because

the disease is increasingly recognized in its asymptomatic stage. The availability of therapeutic options such as UDCA which has been widely administered during the last two decades, seems to have also modified the occurrence and intensity of this symptom. The onset of pruritus generally precedes the onset of jaundice by months to years. The cause of pruritus remains unknown. However there is consensus that in the course of cholestasis biliary excretion of several compounds is impaired, thus leading to increased systemic concentrations of a putative “pruritogenic” compound. The occurrence of pruritus would result from the interaction between these substances and nervous terminations at the skin level. The extreme variability of the degree of pruritus between patients, or even in the same patient, may have two explanations: (1) inter-individual or time variability of the systemic concentrations of the “pruritogenic” compounds, which are generally confined within the enterohepatic circulation; and (2) subjective variability of the perception of pruritus, mainly due to psycho-emotional factors. Increased serum concentrations of bile acids are associated with cholestasis by definition, and a direct causative relationship between increased bile acid concentrations and the occurrence of pruritus has been suggested<sup>[69]</sup>. Several observations support this hypothesis, including: (1) the presence of bile acids in the skin in cholestatic patients<sup>[70]</sup>; (2) the capability of bile acids to produce pruritus when injected subcutaneously<sup>[71,72]</sup>; (3) the relief of pruritus by external biliary drainage, and by cholestyramine which can bind bile acids and thus favours their fecal elimination<sup>[73-75]</sup>. However, this hypothesis has never been proven since no relationship was found between degree of pruritus and bile acid levels measured in cutaneous interstitial fluid<sup>[76-78]</sup>. In addition, it is possible that many other substances are eliminated during both biliary drainage and cholestyramine administration.

The hypothesis that pruritus in cholestatic liver disease may have a central origin has been suggested by the observation of an increased opioidergic activity in both experimental models of cholestasis<sup>[79-82]</sup> and in cholestatic patients<sup>[79-81,83]</sup>, and by the observation that opioid receptor ligands with agonist properties (morphine for example) mediate pruritus<sup>[84-86]</sup>. Therefore, there have been studies using opioid antagonists for the treatment of pruritus in cholestatic conditions with positive results<sup>[87-89]</sup>, thus confirming the hypothesis that an increased opioidergic activity plays a role in the occurrence of pruritus associated with cholestasis. In cholestatic conditions high concentrations of bile acids in the systemic circulation may alter several central regulatory systems such as the opioid-mediated system.

**Portal hypertension:** This may occur even before cirrhosis develops. However, usually, ascites, variceal bleeding, and hepatic encephalopathy complicate the course of PBC only in advanced stages. Similarly, the incidence of hepatocellular carcinoma is elevated among patients with long-standing histologically advanced PBC<sup>[90]</sup>.

### **Consequences of long-standing cholestasis**

Other common findings in advanced PBC include the consequences of long-standing cholestasis that can lead to hyperlipidemia, fat malabsorption, renal tubular acidosis, and osteopenia. However, the clinical relevance of hyperlipidemia in patients with PBC remains questionable since neither cardiovascular risk<sup>[91]</sup> nor more precocious signs of atherosclerosis<sup>[92]</sup> are associated with alterations of lipid metabolism in PBC. In addition, the wide use of therapeutic bile acids in the last decade may have modified the metabolic pattern of plasma lipids in PBC<sup>[93,94]</sup>.

Metabolic bone disease described in patients with PBC is the result of two different pathological processes: osteomalacia and osteoporosis. Osteomalacia which is a consequence of lipid malabsorption may be easily corrected by supplementation with calcium and vitamin D<sup>[95-97]</sup>. The changing spectrum of bone disease associated with cholestasis with a progressive disappearance of osteomalacic features over time may be due to the increasingly wide use of vitamin D and calcium supplementation in clinical practice<sup>[97,98]</sup>. Therefore, at present, osteoporosis is the predominant component of metabolic bone disease<sup>[98]</sup>. During end-stage liver disease, which is characterized by reduced physical activity, malnutrition, and, possibly, infectious complications, bone loss is a major clinical issue<sup>[99]</sup>. On the other hand there is no consensus on the clinical relevance of cholestasis in inducing bone loss at less advanced stages of liver disease<sup>[100]</sup>. In a recent longitudinal controlled study, we demonstrated that cholestasis was not an additional risk factor for bone demineralization in women with well-compensated PBC if adequate calcium and vitamin D supplementation had been provided<sup>[101]</sup>. These data are in accordance with several studies<sup>[102-104]</sup> but in contrast with others<sup>[105-107]</sup>. Different results may be due to: (1) the cross-sectional nature of many studies; (2) the lack of an adequate control group in the majority of the published studies so precluding the protection against confounding factors such as menopausal status, which is important in a population wherein perimenopausal women are largely represented; (3) the lack of adequate vitamin D and calcium supplementation in most of the published studies; and (4) the confounding effects of other concomitant medications.

Malabsorption, deficiencies of fat-soluble vitamins, and steatorrhea are uncommon except in the late stages of the disease<sup>[108]</sup>. Finally, the occurrence of renal tubular acidosis which was once thought to be quite frequent<sup>[109]</sup> was not found in a large population of PBC in the absence of complication of liver cirrhosis<sup>[110]</sup>, thus indicating that such a complication, if present at all, may be restricted to very late stages of the disease in association with multiorgan dysfunction.

### **Associated diseases of autoimmune type**

Symptoms of coexisting autoimmune diseases including Sjogren syndrome, scleroderma, rheumatoid arthritis autoimmune thrombocytopenia, and haemolytic anaemia may be present. Interestingly, liver disease was recently shown to have a slower progression when systemic

sclerosis is associated with PBC compared with matched patients with PBC alone<sup>[111]</sup>. Overlap syndromes with autoimmune hepatitis are described in another article in this issue.

## NATURAL HISTORY AND PROGNOSTIC MODELS

The natural history and prognosis of PBC have become more difficult to characterize given the rising number of asymptomatic cases which require long-term follow-up<sup>[1,43,109,112]</sup>. Furthermore, patients are more likely than in the past to be asymptomatic at diagnosis<sup>[1,43,112]</sup> and to receive medical treatment as soon as diagnosis is made. Hence, estimated survival has significantly improved compared to the past. Earlier data on survival suggesting a poor outcome were obtained from patients in whom the disease had been diagnosed many years ago when no effective treatment existed<sup>[1,43,112]</sup>. In addition, most of these patients were symptomatic<sup>[1,43,112]</sup>.

A different outcome of the disease has been reported for symptomatic *versus* asymptomatic patients. In 1983, the reported survival of asymptomatic PBC patients was similar to that of a normal U.S. population matched for age and sex<sup>[113]</sup>, but, when their survival data were extended for a longer duration, the asymptomatic patients had a shortened survival compared with controls<sup>[114]</sup>. In this latter study, 279 patients from the USA were observed for up to 24 years, and the median survival of asymptomatic PBC patients was significantly longer than symptomatic patients at presentation<sup>[114]</sup>. Additional studies confirmed that initially asymptomatic patients had a longer survival than symptomatic ones<sup>[109,115]</sup>. In one of these studies from Canada, asymptomatic PBC patients had a shortened survival compared with a healthy population<sup>[115]</sup>. The results described in a community-based study from the UK are at variance with all of the other reports<sup>[54]</sup>. Here 770 patients (61% asymptomatic) living in England were diagnosed between 1987 and 1994 and observed until death, transplantation, or until data were censored in January 2000. The median survival was similar in asymptomatic and symptomatic patients, and symptom development was not associated with shorter survival. However, the design of this study, in which patients were followed by regular interview and by examination of their medical records may be not as informative as a single centre cohort study to assess the natural history of PBC, even though it is sufficient for epidemiological purposes. In fact, these UK results are confounded by the fact that 45% of the deaths in asymptomatic patients occurred while these patients were remained asymptomatic, suggesting that many of these patients would have been died of non-hepatic causes and that age at diagnosis was a major determinant of survival. Since the prognostic relevance of the presence of symptoms is well documented, the higher proportions of asymptomatic patients enrolled in the more recent cohort studies explain, partly at least, the observed improvement in the natural history of PBC since 1980s.

**Table 3** Parameters independently associated with bad prognosis in different prognostic models based on a single point observation<sup>[16,113,119,121-123]</sup>

Parameters	Yale	European	Mayo	Glasgow	Oslo	London
Increase in serum bilirubin	+	+	+	+	+	+
Decrease in serum albumin		+	+			+
Increase in PT (INR)			+			
Advanced age	+	+	+	+		+
Hepatomegaly	+					+
Ascites, fluid retention			+	+		+
Esophageal varices						+
Gastrointestinal bleeding				+	+	
Cirrhosis	+	+		+		+
Cholestatic picture at histology		+		+		
Mallory bodies				+		

Most patients with PBC are now treated with UDCA<sup>[43]</sup> and the widely used administration of this drug has greatly changed the natural history of the disease<sup>[43,112]</sup>. At least 20% of patients treated with UDCA will have no histologic progression over four years, and some will have no progression over a decade or longer<sup>[116]</sup>. In a recent study, the survival rate of patients with stage 1 or 2 disease given UDCA long-term was similar to that of a healthy control population<sup>[117]</sup>. In the above-mentioned community-based study from the UK no improvement in survival was found in UDCA-treated patients<sup>[54]</sup>. We reiterate that such a study design albeit excellent for epidemiological purposes, is not adequate for the evaluation of the effects of medical treatment. In addition, there is sufficient evidence that UDCA treatment does prevent the development of esophageal varices<sup>[118]</sup>. Therefore, sufficient information is now available to indicate that, among the reasons for the improving prognosis of PBC, is the wide use of bile acid therapy. Detailed information on the effects of UDCA therapy on survival is described below.

Cox proportional hazards regression analysis has been used to develop prognostic models. There are different prognostic models for predicting survival for PBC patients. Of these models, the Mayo survival model is the most popular. The Mayo model was based on combined data from more than 400 patients who were observed at the Mayo Clinic and was then externally cross-validated using PBC patients from other medical centers<sup>[119,120]</sup>. The Mayo model uses five independent prognostic variables: age, total serum bilirubin, serum albumin, prothrombin time, and the severity of fluid retention. Serum bilirubin is the most heavily weighted among these variables, consistent with the presence of this index in all the proposed prognostic models<sup>[16,113,119,121-123]</sup> (Table 3). All these models are based on a single assessment but several have been modified to include repeated measures of prognostic indices<sup>[121,124,125]</sup>. The Mayo model has been widely used to assess the efficacy of medical treatment in clinical trials, but also serum bilirubin concentrations

have been similarly used as surrogate markers of disease improvement, due to the prognostic value of this index in PBC patients with more advanced disease<sup>[126]</sup>.

Recently, also an immune marker was shown to be of prognostic value since a particular specificity of antinuclear antibodies that directed against nuclear pore complex, identified patients destined to experience more rapid disease progression<sup>[127]</sup>.

## TREATMENT OF SYMPTOMS AND COMPLICATIONS

### Fatigue

No therapy that has been evaluated for the treatment of PBC has proven able to ameliorate fatigue<sup>[128-130]</sup>. However, this symptom is not specific, only indirect quantitative measurement is available, and there are no convincing data to support any organic pathophysiological mechanism with even a psychological basis possible in some cases<sup>[65-67]</sup>.

### Pruritus

Pruritus in several, albeit very rare, cases may severely affect the quality of life, leading to sleep disturbance and major depression. This is the reason why intractable pruritus has been considered an indication for orthotopic liver transplantation (OLT). A large number of pharmacological approaches have been tested on the basis of both pathophysiologic considerations and serendipitous observations. The heterogeneity of the treatments suggested reflects the difficulties in treating this symptom which is extremely variable in severity and type, influenced by subjective factors and not easily quantifiable. The administration of UDCA, the only approved treatment for PBC, was not associated with a consistent improvement of pruritus in most controlled clinical trials; however, since the majority of them were not designed specifically to test the effects of this drug on pruritus, no definite conclusion can be drawn. In addition, as reported above, epidemiological data indicate that the disease expression has changed during the last two decades towards less symptomatic disease<sup>[1,43,112]</sup>, and a possible effect of the widely administered UDCA in decreasing pruritus certainly cannot be ruled out.

The oral anion exchange resin cholestyramine has been the mainstay of therapy for pruritus associated with cholestasis<sup>[73-75]</sup>. The mechanism of action is related to binding of bile acids and other biliary molecules, with their subsequent fecal excretion. Dose of cholestyramine should start from 4 g daily and should be increased, in case of therapeutic failure, until a maximum of 16 g. The timing of administration is before meals. The drug is more effective in those patients with an intact gallbladder when taken before and after breakfast, because the greatest amount of bile is likely to be available for binding at this time. Since cholestyramine binds also other medications, notably UDCA, oral contraceptive hormones, digoxin and thyroxine, it is advisable that at least 4 h should elapse between the administration of cholestyramine and other medications. In the majority of cases this drug is effective within a few days from starting treatment, but in about

**Table 4 Pharmacological characteristics of the opiate antagonists investigated in clinical studies**

Pharmacological characteristics	
Naloxone	Very short half life Intravenous continuous infusion Dose: 0.2-0.4 µg/kg per minute
Nalmefene	Longer half life Oral administration 2 mg twice/d with a gradual increase until 20 mg twice/d
Naltrexone	Longer half life Oral administration 50 mg/d (in two divided doses the first day and subsequently in a unique dose)

10% to 20% of the patients it is ineffective. In addition, many patients find cholestyramine unpleasant to take and complain of dyspeptic symptoms or diarrhea or, alternatively, constipation so leading to poor compliance with treatment.

Rifampicin is an enzyme-inducing antibiotic which was serendipitously identified as an agent that improves pruritus in cholestasis<sup>[131]</sup>. A subsequent crossover trial indicated that the drug provided good control of pruritus in PBC at doses of 150 mg twice per day or three times per day<sup>[132]</sup>. In subsequent studies higher doses were used up to 600 mg/d<sup>[133]</sup> and 10 mg/kg per day<sup>[134]</sup>. Its mechanism of action remains unknown but it may alter bile acid composition<sup>[135,136]</sup> and stimulate the hepatobiliary transport systems<sup>[137,138]</sup>. When given long-term, rifampicin was shown to improve also the biochemical expression of PBC<sup>[139]</sup>. However, it is not effective in all patients and may cause side effects<sup>[140]</sup>. Two cases of acute hepatitis were reported (12.5% of treated patients) during long-term administration<sup>[139]</sup>, but this spontaneously resolved after discontinuation of treatment. In any case, the potential hepatotoxicity of rifampicin precludes long-term administration of this drug to patients with PBC.

Many studies endorse the use of opioid antagonists, given intravenously or orally, for the treatment of cholestasis-related pruritus<sup>[87-89]</sup>. The main pharmacological characteristics of the three compounds investigated clinically are reported in Table 4. Each compound was shown to be highly effective in improving pruritus, but the main limit on their use was the occurrence of withdrawal-like symptoms in several patients. In addition, after initial enthusiasm following elegant studies supporting the intriguing hypothesis of an increased opioidergic activity in cholestatic patients<sup>[79-82]</sup>, opioid antagonists have lapsed for the treatment of pruritus. Larger and longer studies are needed to fully assess the actual clinical value of opioid antagonists in controlling pruritus in PBC.

Since the serotonergic system participates in the mediation of nociception, it appears rational to use drugs acting on this system. Several studies suggested that a possible beneficial effect may be exerted by ondansetron a type III serotonin antagonist<sup>[141-143]</sup>, but subsequent studies showed only limited or no effects on pruritus<sup>[144-146]</sup>. Surprisingly, the results of a recently published small randomized, double-blind, placebo-controlled trial based

on a heterogeneous group of patients with pruritus and liver disease suggested a beneficial effect of sertraline, a serotonin reuptake inhibitor<sup>[147]</sup>. Finally, since the cannaboidergic system plays a role in the mediation of nociception, uncontrolled observations on the effects of dronabinol, a cannabinoid B1 receptor, suggested relief of pruritus in course of cholestasis<sup>[148]</sup>.

In conclusion, since UDCA is the only accepted therapy for PBC, this bile acid represents the treatment of choice for pruritus. If the symptom persists, cholestyramine be initiated. Only in the case of a lack of response to maximal doses of cholestyramine a therapeutic approach with rifampicin or opioid antagonists should be considered.

### Metabolic bone disease

Osteomalacia may be easily corrected by parenteral supplementation of vitamin D (vitamin D<sub>3</sub> 100 000 UI intramuscular monthly). Supplementation with calcium carbonate (1 g/d) has been largely recommended based on pathophysiological considerations and on data coming from experience in postmenopausal osteoporosis whereas only indirect evidence is available in PBC patients<sup>[97,149]</sup>.

As reported above, it is highly questionable whether osteoporosis during cholestatic conditions represents a separate clinical entity<sup>[100,101]</sup>. Therefore the available data on treatment of metabolic bone disease in PBC are similar to those reported for postmenopausal osteoporosis noting that most patients with PBC are females at a menopausal age. Various data indicate that hormone replacement therapy is effective and safe, contrary to previous beliefs<sup>[150-154]</sup>. Etidronate was suggested to be effective<sup>[155,156]</sup>, but not all studies reported positive results<sup>[157]</sup>, while alendronate was shown to be superior<sup>[158,159]</sup>. Calcitonin failed to improve bone mineral density in female patients with PBC<sup>[149]</sup>. The negligible improvement observed in one study<sup>[160]</sup>, is perhaps attributable to concomitant vitamin D and calcium supplementation. Several indications for the clinical management of metabolic bone disease associated with PBC are reported in Table 5. Finally it should be highlighted that UDCA, the specific treatment for PBC was shown to have no effects on the occurrence of bone loss<sup>[161]</sup>.

### Hyperlipidemia

It is still questionable if hypercholesterolaemia associated with PBC should be treated, and which patients need pharmacological treatment. Since increased cholesterol concentrations associated with cholestasis do not increase the atherosclerotic risk, it seems reasonable to treat hypercholesterolaemia only when hyperlipidemia of familial and nutritional origin probably coexists<sup>[162]</sup>. The extent of cholesterol reduction by UDCA administration<sup>[93]</sup> may be insufficient to protect this group of patients from cardiovascular risk. These patients probably would benefit from dietary modifications, weight loss, and the administration of specific lipid-lowering drugs. Cholestyramine may be indicated for its cholesterol lowering capacity in hypercholesterolaemic patients, especially if there is associated pruritus, while

**Table 5** Clinical management of metabolic bone disease associated with primary biliary cirrhosis

Clinical management	Efficacy	
	Moderate efficacy	Mild efficacy, insufficient data
Prevention		
1 Parenteral vitamin D3 supplementation	Indicated for all patients to prevent osteomalacic lesions	
2 Calcium carbonate supplementation		
Treatment		
1 Estrogen		Few data but effective and safe
2 Etidronate		Conflicting data Indicated in case of concomitant corticosteroid administration
3 Alendronate		Few data but effective and safe
4 Calcitonin		Probably ineffective

HMGC<sub>o</sub>A-reductase inhibitors should be limited to hypercholesterolaemic patients in whom serum levels of HDL are below the protective range, or if additional risk factors for cardiovascular disease are present<sup>[162]</sup>. In pilot studies, both simvastatin and atorvastatin proved to be safe and effective in reducing serum cholesterol levels in patients with PBC<sup>[163-165]</sup>.

### Malnutrition

During severe cholestasis, which occurs only at very advanced stages of PBC when liver transplantation is precluded, lipid malabsorption occurs with steatorrhea and weight loss. In such cases a reduction to 40 mg of the daily dietary fat intake is indicated and the same amount should be administered as medium chain triglycerides, which are digested and absorbed in the intestine even in the presence of low bile acid concentrations. In several cases administration of cholestyramine has to be discontinued.

Since malabsorption of lipophilic vitamins occurs even in the absence of clinically evident steatorrhea, preventive supplementation with vitamin D may be advisable in case of significant alterations of biochemical markers of cholestasis. Parenteral vitamin K supplementation should be given if prothrombin time is increased.

## SPECIFIC TREATMENT FOR PBC

Many therapeutic agents have been tested for PBC but difficulties have been encountered in establishing statistically significant long-term benefits for a disease with such a variable natural history. In addition, PBC surrogate markers of prognosis have several limitations: impairment of indices of liver synthetic function occurs only at very advanced phases of the disease, and the likelihood of sampling errors limits the value of liver histology. The only index which may be useful to assess prognosis is serum bilirubin, and this only in late phases of the disease. Randomized, controlled trials, recently

**Table 6** Efficacy and toxicity of the principal drugs investigated for the medical treatment of primary biliary cirrhosis

	Efficacy	Toxicity
D-penicillamine	-	+
Chlorambucil	+/-	+
Cyclosporine	+/-	+
Azathioprine	+/-	+
Methotrexate	+/-	+
Colchicine	+/-	-
Glucocorticoids	+/-	+/-
UDCA	+	-

re-evaluated by a meta-analysis<sup>[166]</sup>, have endorsed the failure of penicillamine. The only accepted treatment for PBC is UDCA that may delay but not halt the progression of the disease<sup>[167]</sup>. For several other agents, mainly immunosuppressive components, some interesting possibilities have been revealed but mainly in terms of combination treatment with UDCA. Data are summarised in Table 6. Regarding corticosteroid drugs, data are scanty mainly because bone demineralization represents a big concern in a population of female patients at postmenopausal age<sup>[168,169]</sup>. Corticosteroid monotherapy does not seem to offer a sufficient benefit *versus* side effects ratio for most PBC patients and its use should be limited to patients with other concomitant autoimmune diseases or with a PBC-autoimmune hepatitis overlap syndrome<sup>[170]</sup>. In such cases, co-administration of etidronate may prevent bone loss<sup>[156]</sup>.

Azathioprine administration should not be recommended on the ground of a limited efficacy and the substantial risk of side effects<sup>[121,171,172]</sup>. For chlorambucil, the frequency and potential severity of side effects outweighs potential benefits of this immunosuppressive drug, thus contraindicating its use in PBC<sup>[173]</sup>. After preliminary encouraging data coming from a pilot study<sup>[174]</sup>, Kaplan and colleagues have repeatedly reported biochemical and histological improvement after the administration of low dose of methotrexate (15 mg/wk), but no data on survival have been presented<sup>[175,176]</sup>. Aside from potentially serious complications<sup>[177]</sup>, the beneficial effects of methotrexate in the treatment of PBC, alone or in combination with UDCA, could not be confirmed by randomized, controlled trials performed by other groups<sup>[178-180]</sup>. There is no indication for the clinical use of cyclosporine in PBC, given the limited efficacy and known side effects<sup>[181]</sup>.

Available information indicates that colchicine with its anti-inflammatory and antifibrotic properties may exert limited beneficial effects on the natural history of PBC but without relevant side effects<sup>[182-185]</sup>. This is the reason why it has been largely tested in association with UDCA but showing no additional benefit in terms of clinically relevant end-points in comparison with UDCA monotherapy<sup>[186,187]</sup>.

### UDCA for the therapy of PBC

The rationale for the use of UDCA in the treatment of PBC depends on its ability in displacing and/or

diluting detergent and hepatotoxic bile acids from the bile acid pool. It is well known that in cholestatic conditions, endogenous bile acids are retained within hepatocytes, thus leading to the progressive deterioration of liver function. The beneficial effects of UDCA on indices of liver dysfunction have been attributed to its physicochemical properties, since UDCA is very hydrophilic and therefore non-toxic to biological membranes<sup>[188,189]</sup>. However, experimental data failed to support this hypothesis since a substantial shift towards hydrophilicity of the bile acid pool was not observed during UDCA administration<sup>[47]</sup>. It has been suggested that UDCA has a direct cytoprotective effect, and different molecular mechanisms may be responsible, such as regulation of cellular signalling systems and protection against apoptosis<sup>[190]</sup>. Immunomodulatory effects of UDCA have been also described<sup>[190]</sup>, although it is not conventionally used as an immunosuppressive drug in non-hepatic diseases.

A number of randomized controlled studies have been conducted to evaluate UDCA efficacy<sup>[43]</sup>. In all studies UDCA was well tolerated since no relevant side effects were reported. In all studies a significant improvement of serum liver enzymes markers of cholestasis and cytolysis occurred. Serum concentrations of bilirubin, the most important prognostic marker of the disease, were reduced by UDCA administration. A consistent reduction of IgM, which is an immunological marker of PBC was also reported.

Results of randomized placebo-controlled trials with a duration long enough to evaluate the effects on histology and on survival are summarized in Table 7<sup>[191-197]</sup>. Among the six studies that evaluated the effects of UDCA on pruritus<sup>[191-196]</sup>, an improvement was described in only three<sup>[191,194,196]</sup>, but these studies were not specifically designed to assess pruritus. In four studies a significant improvement of several histological indices was reported<sup>[191,192,194,196]</sup>. The Mayo Clinic group did not report any improvement of liver histology, but have suggested in a separate paper that UDCA delays the occurrence of esophageal varices<sup>[118]</sup>, thus indicating a positive effect on the progression of the disease.

To evaluate the effectiveness of a specific therapy for a severe life-threatening disease, the effects on survival should be explored. However, since PBC is a relatively uncommon disease with a long and variable natural history, a very large sample size and a very long follow-up are needed to obtain reliable data. No effect on survival was observed in any of the single studies reported in Table 7, and only after an extension of follow up was a positive effect on survival without OLT reported by the French and the Mayo Clinic studies<sup>[198,199]</sup>. During the 2-year extension of the French study all patients administered placebo were switched to UDCA, while in the Mayo Clinic study, UDCA was offered to all patients but, for the analysis, follow-up was censored at the end of the randomized phase for patients initially assigned to the placebo group, thus avoiding the limits of a switch-over design.

A combined analysis of three studies<sup>[167]</sup> and two meta-

**Table 7** Randomized, double-blind, placebo-controlled trials on ursodeoxycholic acid administration to patients with primary biliary cirrhosis

First author	No. of patients	Study design and duration of follow up	UDCA effects on		
			Pruritus	Histology	Survival
Poupon <sup>[191]</sup>	146	2 yr	Improved	Improved	No effect
Heathcote <sup>[192]</sup>	222	2 yr	No effect	Improved	No effect
Lindor <sup>[193]</sup>	180	Mean follow up: 2 yr	No effect	No effect	No effect
Combes <sup>[194]</sup>	151	2 yr	Improved	Improved (early stages)	No effect
Eriksson <sup>[195]</sup>	116	2 yr + 2 yr as open trial (UDCA)	No effect	No effect	No effect
Pares <sup>[196]</sup>	192	Mean follow up: 3.4 yr	Improved	Improved	No effect
Papatheodoritis <sup>[197]</sup>	86	Mean follow up 7.3 yr for UDCA 8.1 yr for controls	Not evaluated	No effect	No effect

analyses<sup>[200,201]</sup> have been performed, since the majority of the published studies had insufficient statistical power to explore the effects of UDCA on survival. The combined analysis was obtained by pooling of results from three trials with similar designs but dissimilar results. The analysis included 548 patients and a significant improvement of survival free from OLT was reported with the relative risk of death being 0.53 (0.36-0.77; 95% CI). A significant improvement of survival could be recorded only in patients with serum bilirubin higher than 1.4 mg/dL at baseline. The lack of an effect on survival in patients with less severe disease may well indicate that the time of observation was not sufficient to detect effects of UDCA in a population with a low probability of developing clinically relevant events. On the other hand, results of the two meta-analyses indicate no effects of UDCA on the natural history of the disease. Formal meta-analysis includes consideration of all relevant trials, justifies eventual exclusion of trials from the analysis, and explores heterogeneity between trials and the reason for variation in results. The main limit of a meta-analysis is that trials evaluated may be too different in their designs to be truly comparable. The reason for the opposite results reported by the combined analysis<sup>[167]</sup> and by the two meta-analyses<sup>[200,201]</sup> remains unclear. The main criticisms directed against the combined analysis were the limits of the switching over design, but the "intention to treat" basis of the analysis is protective against type I error, thus reducing the probability of demonstrating benefits of UDCA in the absence of a true beneficial effect. Conversely, the inclusion in the meta-analyses of studies using low doses of UDCA, and with a follow-up too short for assessment of effects on clinically relevant end-points, has been strongly criticized. The effects on surrogate markers of clinical outcome, such as serum bilirubin concentration, do indicate that UDCA may positively affect survival in PBC. In addition, the UDCA safety and its relatively low cost permit a wide scale use of this therapeutic bile acid.

So, in conclusion, our opinion is that UDCA does exert a favourable effect on the natural history of PBC, but since many studies had been characterized by an insufficient number of patients, insufficiently long follow-up periods, heterogeneity of evaluated indices, and inadequate study designs, an absolutely clear-cut demonstration of benefit was precluded. Indirect data on the beneficial effects of UDCA also in patients at the initial

stages of the disease are now available<sup>[117,202]</sup>. An excellent long-term survival, comparable to that observed in a control population, has been recently reported in patients with PBC showing biochemical response to UDCA<sup>[202]</sup>. These data were obtained by studying a cohort of 192 patients, mainly with stage 1 and 2 of the disease, who had been treated for a mean period of more than 6 years. In addition, in a recent study of 262 patients with PBC who received UDCA for a mean of 8 years, the survival rate of patients with stage 1 or 2 disease was similar to that of a healthy control population<sup>[117]</sup>. However, not all patients have a response to treatment, since in the same study, the probability of death or undergoing OLT in patients with stage 3 or 4 of PBC was significantly increased compared with a healthy population, despite UDCA treatment. Therefore strategies aimed at improving therapeutic agents for PBC are still needed, mainly by the use of associated treatments.

Several drugs have been tested in association with UDCA. The results obtained with colchicine, and budesonide are the more promising but none of the drugs studied was shown to provide any additional benefit, in terms of clinically relevant events, compared to UDCA monotherapy<sup>[186,187,203-205]</sup>.

### OLT for the therapy of PBC

Finally, OLT has greatly improved survival in patients with PBC since this is the only effective treatment in patients with very advanced disease. "The survival rates are 92% and 85% at 1 year and 5 years, respectively<sup>[206]</sup>. While the recurrence rate is 30% at 10 years<sup>[207]</sup>. Note that OLT is considered in detail in another article in this series.

## CONCLUSION

Data coming from the more recent epidemiological studies indicate that PBC is not a rare disease and its prevalence and incidence are apparently increasing. In addition, the clinical presentation of PBC has progressively changed from a highly symptomatic disorder with a bad prognosis to a slowly evolving disease. The changing methods used for the diagnosis, with an increasingly wide assessment of laboratory indices related to both cholestasis and immunology, together with improved case finding strategies, may explain these observations.

As a result, the recognition of earlier more indolent

cases led to the presence of a substantial proportion of asymptomatic patients within PBC cohorts. Therefore development of early prognostic indices may be useful to predict which patients are destined to develop a progressive disease thus requiring a more intensive follow-up.

UDCA does not act on the aetiology of the disease but reverses the detrimental effects of the retention of endogenous bile acids within the liver. Although several flaws of the available studies prevented a clear-cut demonstration of its efficacy, many indirect observations suggest that a beneficial effect occurs and we cannot exclude that the wide use of UDCA may have significantly changed the clinical course of the disease. However, UDCA is able to slow but not to halt the progression of the disease and, in advanced stages, when the large majority of bile ducts have been destroyed, OLT remains the only therapeutic option.

In the future, reliable epidemiological data to be obtained by screening the entire population at risk, will provide both a correct measurement of the real prevalence and incidence of PBC and a greater insight into aetiology and pathogenesis, thus leading to the possibility of a specifically targeted therapy.
