## Abstract

Irritable bowel syndrome (IBS) and inflammatory bowel disease (IBD) are two of the leading causes of chronic intestinal conditions in the world. This issue of *World Journal of Gastroenterology (WJG)* presents a series of papers from world experts who discuss the current knowledge and opinions on these important conditions. Although great strides have been made in the diagnosis, treatment and pathology of IBS and IBD; much has yet to be explained. The etiologies and risk factors of these multifactorial conditions remain elusive. Specific diagnostic biomarkers need to be developed and safer treatments developed. The burden of IBS and IBD on the healthcare system is felt with repeated medical care visits and high costs. IBS and IBD patients can account for 30%-50% of office visits at gastroenterology services/clinics. Over one million people have IBD in the United States, with 30000 new cases being diagnosed every year. One-quarter million people in the UK are afflicted with IBD. The cost of medical care in the United States for IBD is estimated to be \$1.8 billion/year.

## IRRITABLE BOWEL SYNDROME (IBS)

### Incidence of IBS

IBS is a global problem and is more common in women than men. In developed countries, the prevalence of IBS ranges from 3%-25% of adults<sup>[1-4]</sup> and in the United States, IBS affects 15 million adults<sup>[5]</sup>. In the United Kingdom, IBS affects 10%-15% of the adult population<sup>[6]</sup>. The cost of direct and indirect medical care for IBS reached over \$200 billion dollars in the United States<sup>[5,7]</sup>.

### Diagnosis of IBS

As there are no biologic markers for IBS, the diagnosis is usually based on symptoms and exclusion of other known causes of intestinal distress<sup>[6]</sup>. Unlike IBD, IBS does not cause severe inflammation, ulcers or other structural damage that aids the diagnosis of IBD. IBS is a functional disorder characterized by abdominal bloating, flatulence, abdominal pain and bowel dysfunction. The varying nature of symptoms and lack of structural abnormalities presents a diagnostic challenge. There are three main types of disease phenotypes: diarrhea-predominant (IBS-D), constipation-predominant (IBS-C) or alternating diarrhea-constipation (IBS-A). The diarrhea-predominant type is more common (48%) in males, whereas constipation-predominant (39%) or alternating types (48%) are more common in women<sup>[1]</sup>. Several tools (for example, Rome III, Manning criteria) have been developed to standardize the diagnosis of IBS. Most of the historic research has been focused on the pathophysiology of diarrhea, but constipation has not been as well described. The review by McCrea and colleagues in this issue summarizes our current knowledge about the physiology and pathology of constipation<sup>[8]</sup>. The prevalence of constipation ranges from 15%-25% in the general population and is more common in women than men and in ages over 70 years old<sup>[9]</sup>. The typical definition of constipation (less than three stools/week) may not be a sensitive measure for this condition, as individuals vary widely in their own bowel habits. An interesting finding in this review is that physicians and patients define constipation differently. Neurotransmitters are important in the pathophysiology of IBS and this paper reviews how neurotransmitters are involved in the normal and abnormal

function, and anatomy of the gastrointestinal tract. Age-related anatomical changes seem to have minimal impact on normal colonic function, which might help to explain why increasing age is not a significant risk factor for IBS. McCrea *et al* then describe the association of dysmotility on the pathology of IBS-C. This review of constipation highlights the need to conduct further research into the etiologies and functional causes of constipation, especially as it relates to disease conditions such as IBS.

### Consequences of IBS

Patients with IBS report a significant reduction in quality of life and sexual function and have increased suicide ideation, absenteeism, have higher rates of depression and are heavy users of medical care<sup>[6,10]</sup>.

### Pathogenesis

IBS is a multifactorial condition and the pathophysiology may involve a triad of factors: altered intestinal motility, psychosocial factors and heightened sensory function. Risk factors include genetic factors, food allergies and microbial dysbiosis<sup>[11]</sup>. The low grade mucosal inflammation, altered motility and altered bowel microflora give rise to the characteristic clinical symptoms of IBS.

### Treatment for IBS

Current treatments for IBS target the patient's predominant symptoms at the time of the acute episode and the efficacy of these treatments vary widely<sup>[4]</sup>. Hammerle and Surawicz review the challenges of treating patients with IBS<sup>[12]</sup>. The effectiveness of conventional therapy for IBS varies due to the need to treat different types of symptoms (IBS-D, IBS-C or IBS-A) and the need to limit underlying etiologic triggers, which are commonly unknown. The authors point out the need for individualized treatment regimes, as symptoms and treatment responses vary widely. The chronic nature of IBS necessitates life-long treatments that may need adjustments reflective of shifting clinical presentations. Hammerle and Surawicz also review the role that serotonin has on the function of the intestinal tract and how decreased levels of neurotransmitters are involved in the pathology of IBS. Pharmacotherapy directed at modulating neural transmitters offer a promising class of treatments for IBS. 5-HT<sub>4</sub> antagonists may be an effective choice for IBS-D as they slow intestinal transit, increase stool firmness and reduce intestinal secretion. In contrast, 5-HT agonists (such as tegaserod) are more effective for IBS-C. Octreotide has been tested in human volunteers and slows diarrheal symptoms, but is only available intravenously, limiting its usefulness. Other types of antagonists are reviewed, but clearly more randomized clinical trials are needed. Other types of treatments (including antidepressants, antispasmodics, antibiotics, fiber, probiotics and dietary changes) are reviewed and may be effective in some patients, but more research is needed for these types of treatments as well.

As patients with IBS have been shown to have disrupted intestinal microflora and some episodes of IBS are triggered by gastroenteritis, a treatment strategy that involves microbial replacement is attractive<sup>[13]</sup>. Probiotics are beneficial microbes that are given to restore normal microflora and have

been shown to be effective for other types of diarrhea (antibiotic-associated diarrhea, *Clostridium difficile* disease, traveler's diarrhea and pediatric diarrhea)<sup>[14,15]</sup>. The meta-analysis by McFarland and Dublin explores the efficacy of various probiotics for the treatment of IBS<sup>[16]</sup>. The results from 20 randomized clinical trials with 23 different probiotic treatment arms were compared to controls. Generally, probiotics were found to significantly reduce IBS symptoms globally [pooled odds ratio (OR), 0.78; 95% confidence interval (95% CI), 0.62-0.94]. However, no one type of probiotic had sufficient numbers of confirmatory trials to conclude one type of probiotic was more effective than another probiotic. Probiotic trials in the past have been directed by other types of diarrheal disease, but probiotic treatment for IBD and IBS is receiving renewed attention. This review is a call to arms for researchers interested in this area. Larger clinical trials are needed in the future in order to have sufficient power to detect significant differences between the treatment groups, multiple confirmatory trials using the same strain of probiotic are needed and a consensus on a common outcome measure is needed. Many of the trials of IBS used different outcome measures, some measuring a global response (no relapses of disease), some measuring a reduction in symptom scores and some creating their own individual outcome measures. Obviously, this makes comparing different study results challenging. Despite these limitations, probiotics may offer a safe and effective strategy for patients with IBS. More clinical trials are needed.

## IBD

### Incidence

Several intestinal conditions are under the umbrella of "Inflammatory Bowel Disease (IBD)", including Crohn's disease, ulcerative colitis and pouchitis. IBD, once considered a disease of industrialized countries, is now reported globally. The highest incidences (8-66/100 000 population) of Crohn's are found in Wales, New Zealand, Canada, Scotland, France, the Netherlands and Scandinavia<sup>[17]</sup>. Other industrial countries such as in the United Kingdom, the United States and in Europe have intermediate rates ranging from 4-7/100 000<sup>[17,18]</sup>. Historically, IBD was infrequently reported in developing countries, but currently low incidence rates are reported (0.2-3/100 000) in such countries like Brazil, China, Korea, Greece, Japan, Malta and Slovakia<sup>[19]</sup>. The incidence in these countries has increased in recent years, whether it is due to an actual increase in the number of cases or better diagnostic and detection methods is not known<sup>[18]</sup>. Interestingly, there is a north-south gradient in Europe, with more severe disease in northern European countries<sup>[17]</sup>. Recent studies have found that Crohn's disease is more common in young patients. Most (74%) of in one study were under 30 years old and the typical age of onset is usually 15-30 years of age<sup>[18]</sup>. Gender differences are not consistent across the country. More men than women are diagnosed with Crohn's disease in China, in contrast to the United States, where more women than men have Crohn's<sup>[18]</sup>.

### Diagnosis

As there are no standard biomarkers for IBD, the diag-

nosis of Crohn's disease and UC are typically made based on clinical symptoms, endoscopic and histologic findings. Variances in symptom types and frequency and a lack of structural abnormalities observed upon endoscopic examination typically may delay the diagnosis of IBD for 6 mo to 1 year<sup>[18]</sup>. The clinical presentation of Crohn's disease is abdominal pain, diarrhea and weight loss, while patients with UC most often complain of abdominal pain, bloody diarrhea and stool mucus<sup>[18,20]</sup>. Crohn's disease results in inflammation, deep fistulas or abscesses anywhere along the gastrointestinal tract, but most commonly along the ileocolon. Colonoscopic examination of patients with ulcerative colitis shows pathology is limited to the large colon with surface inflammation and left-sided colitis, proctitis and proctosigmoiditis being most common<sup>[20]</sup>. Recent innovations in diagnostic techniques including noninvasive imaging techniques and more sensitive endoscopic equipment may improve the diagnosis of IBD.

### Consequences of IBD

Complications for Crohn's disease are frequent (40%) and include lower gastrointestinal bleeding, intestinal obstruction, perforation and the need for surgery<sup>[18]</sup>. Mortality in IBD patients is generally low (about 6%) with some studies finding IBD significantly increases the risk of mortality (OR, 1.4; 95% CI, 1.2-1.6) compared to non-IBD patients. The risk of mortality is higher for patients with Crohn's are compared with patients with UC<sup>[21]</sup>. In studies that have followed large numbers of UC patients for at least ten years, 70%-100% suffered at least one relapse of UC<sup>[22]</sup>. In patients enrolled in clinical trials and randomized to placebo, relapse rates for Crohn's disease ranged from 10%-60% and 11%-90% of UC patients relapsed<sup>[23]</sup>.

Another important consequence of UC may be a higher risk of colorectal cancer. Whether precancerous lesions are an etiologic factor for IBD or whether chronic intestinal inflammation increases the risk of colon cancer has been debated. Zisman and Rubin review the epidemiology of cancer and dysplasia in IBD patients<sup>[24]</sup>. Using historical data, the cumulative incidence of colorectal cancer increased by the duration of UC, with highest rates present after 30-40 years of UC. However, this increase may be an example of a period-cohort bias, as increased colonoscopy in the younger patients (with shorter durations) may have reduced cancer rates. The authors explore the possible risk factors for colorectal cancer in UC patients. The degree of inflammation seems to correlate with increased risk of colorectal cancer. Further research may be needed to prospectively document inflammatory biomarkers and then follow patients for the development of cancer. Other risk factors are discussed, including family history of colon cancer, primary sclerosing cholangitis and strictures, but the weight of evidence is weak for these factors. The link between colorectal cancer and Crohn's disease is less clear, as many have no colonic involvement. Despite this, the incidence and risk factors for Crohn's disease patients and colon cancer are remarkably similar to UC. The importance of colonoscopy surveillance is highlighted. Dysplasia, thought to be an intermediate step between chronic inflammation and carcinoma, is also reviewed by these authors. The unpredictable course of not

only dysplasia, but IBD itself, complicates the determination of the role of molecular markers and mutations. It becomes more paramount that methods for prevention are pressed into clinical use. Evidence that prophylactic chemotherapy is effective in reducing colorectal cancer is not conclusive. Colonoscopy remains the most recommended preventive method for preventing colorectal cancer and its use should be encouraged. Innovations in novel imaging technology may increase the detection of early stages of cancer in IBD patients. Despite the scarcity of research in some areas in this field, it seems likely that the chronic inflammation insult to the colon present in IBD patients may increase the risk of colorectal cancer.

### Pathogenesis

While research has uncovered some of the risk factors for Crohn's and UC, much about the etiology of these two conditions remains unknown. The pathogenesis of IBD may involve four major areas: it appears to be immunologically mediated, microbial dysbiosis is usually present, environmental factors trigger symptoms and genetic predispositions may play an important role<sup>[25]</sup>. Proinflammatory cytokines are produced during IBD episodes and altered immune response is common in both Crohn's disease and UC. Microbial dysbiosis has been documented in patients with IBD<sup>[26]</sup>. The 'hygiene hypothesis' postulates that decreased exposure to environmental microbes due to increased disinfectant use in some industrialized cultures may alter the development of the immune system early in life<sup>[27]</sup>. However, there is only indirect evidence for this correlation and this hypothesis remains unproven. Several bacterial candidates, including *Mycobacterium avium paratuberculosis* (MAP), have been investigated as potential etiologies for IBD, but the research has been inconclusive<sup>[28]</sup>. It is thought that inappropriate or exaggerated mucosal immune response to enteric infections may be involved in the initial etiology of some cases of IBD. In infants less than one year old who developed IBD, 50% had a prior bacterial infection requiring antibiotic therapy<sup>[29]</sup>. Although as intriguing as this finding is, more research is needed to determine if enteric infections cause IBD.

Environmental triggers for IBD may include smoking, diet, stress, gallstones, surgery and exposure to microbes. In one study, the risk of Crohn's disease was significantly elevated (OR, 35;  $P < 0.05$ ) if the patient smoked, had a sibling with Crohn's and carried at least two CARD15 genes<sup>[30]</sup>. In contrast, the average age of patients developing ulcerative colitis was older (mean  $44 \pm 15$  years) and there are no large differences by gender<sup>[20]</sup>. Other risk factors for UC include prior smoking history (but not current smoking), family history of UC and high body weight (elevated BMI)<sup>[25]</sup>.

The carriage of susceptibility genes such as CARD15/NOD2, IBD5, DLG5, IL23R and ATG16LI are associated with increased rates of Crohn's disease in developed countries, but interestingly are not associated with an increase in Crohn's in Asian countries<sup>[17,30,31]</sup>.

### Treatment for IBD

Without an exact reason for the etiologies of Crohn's disease and UC, finding effective treatments are challenging. As a hyper-immune response plays an important part in

IBD, immunomodulators and immune-suppressives have been used as a standard treatment for IBD. Corticosteroids and 5-aminosalicylates have been the traditional treatments for IBD, although many patients do not respond to these treatments or develop serious adverse effects during prolonged use, including increases in serious infections, reactivation of tuberculosis, development of lymphoma or demyelinating disease<sup>[20]</sup>. Currently, there are two main strategies for the treatment of Crohn's disease: the top-down or the step-up approach. Shergill and Terdiman review the controversies and suggest another approach to the treatment of Crohn's disease<sup>[32]</sup>. The top-down approach starts patients with newly diagnosed disease with the newer immunomodulators and biologic agents. The step-up approach begins with more conventional treatments (5-aminosalicylates, mesalamine) and then steps up to steroids if those fail. Immunomodulators are started only after the other treatments have failed. Symptom abatement with the least toxic drug is the guiding principal of the step-up approach. Shergill and Terdiman reassess this paradigm and conclude using a more aggressive therapy earlier in the disease may limit irreversible damage to the bowel, preventing future hospitalizations, surgeries and disabilities. Challenges inherent in determining the most effective treatment strategy include the varying nature of the symptoms, the subjective nature of many of the outcome measures and the lack of correlation between mucosal healing and the Crohn's disease activity index (CDAI), commonly used to determine treatment response. The authors point out treatments that heal the mucosa are often only started after irreversible damage has been done. Steroids are effective in rapidly suppressing flares, but have no benefit on the underlying damage to the mucosa. In contrast, immunomodulators take longer to reduce symptoms, but are able to induce mucosal healing and are able to maintain remissions for a longer time. Both steroids and immunomodulators have side effects which complicates treatment. These authors propose a new hybrid approach described as an "accelerated step-up" approach. Patients presenting with mild symptoms should be treated with mesalamine, antibiotics or budesonide to quickly reduce symptoms. If symptoms do not resolve or if the patient relapses, immunomodulators are then started. Since these agents take 2-4 mo to heal the mucosa, short-term steroids are added in the early months of therapy (unless contra-indicated by fistula or perforations). Once remission is achieved, immunomodulators could be tapered off. If none of these are effective, biologics such as anti-TNF drugs can be tried. The bottom line is that treatment of Crohn's disease is not easy and must be tailored to the individual patient and be constantly adjusted if recurrences happen. The review by Shergill and Terdiman provides a thoughtful assessment of different therapeutic choices and a balanced discussion of the benefits and risks of each treatment choice.

The development of antibiotic resistance presents an additional challenge in the treatment of patients with IBD. Beckler and co-authors describe a new PCR method to detect rifabutin and rifampicin resistance in *Mycobacterium avium paratuberculosis* (MAP) strains<sup>[33]</sup>. As mentioned earlier, MAP is thought to be one of the etiologic agents of Crohn's disease. Proponents of this hypothesis cite

the lack of antibiotic response when patients are treated. However, the poor response may be due to antibiotic-resistance rather than the lack of an association between MAP and Crohn's disease. Beckler *et al* found mutations associated with increased antibiotic resistance were located on the *rpoB* gene of MAP. They developed a PCR tool to detect this antibiotic resistance and this tool provides a rapid method to detect MAP infection in IBD patients. Classic microbiologic methods of culturing MAP are slow and insensitive. The addition of this innovative tool may help to gather sufficient evidence to finally determine if MAP is associated with Crohn's disease or not.

If IBD persists and standard treatments fail or if the patient develops serious complications, surgery is often the only available option for the patient. The lifetime risk for colectomy surgery is 70%-80% for Crohn's disease patients and 20%-30% of UC patients<sup>[2]</sup>. In UC patients with colectomy, as many as 50% will develop at least one episode of pouchitis post-operatively<sup>[34]</sup>. The rationale, types of procedures, benefits and risks of surgery are reviewed by Hwang and Varma<sup>[35]</sup>. The paper presents an extensive description of the available types of surgeries depending upon the site and type of disease. Colectomy is typically restorative, but has a high post-operative complication rate (23%-48%) of sepsis or pouchitis. Revision surgery is often required (19%-24%) and 21%-50% of patients suffer remissions even after surgery. Small bowel surgery for patients with Crohn's disease is usually needed due to repeated flares of disease or the development of extra-intestinal manifestations despite medical treatment. Indications for surgery of the colon include treatment failures, dysplasia or colorectal cancer and toxic colitis. Regardless of the site of surgery, recurrences are common (40%-70%). Surgery is unfortunately usually not curative and associated with significant morbidity. This highlights the need to focus research on effective treatments to manage IBD and IBS.

Other alternative therapies being tested include hypnotherapy, herbal medicines and probiotics<sup>[36]</sup>. As prior enteric infections have been associated with the development of IBD, therapies that target or ameliorate the intestinal disruption brought on by antibiotic therapy seem a logical choice. In a survey of 86 children with IBD in Scotland, 44% reported that they used probiotics to control their IBD symptoms<sup>[37]</sup>. The effectiveness of probiotics for IBD has shown mixed results, depending upon the type of probiotic and the condition treated. Evidence from clinical trials found *Saccharomyces cerevisiae boulardii* was effective for Crohn's disease, while *E. coli* Nissle, VSL#3 (a mixture of 8 bacterial strains) and *Lactobacillus rhamnosus* GG were not effective<sup>[23,38]</sup>. Effective probiotics for UC include a mix of *Bifidobacterium* and *Lactobacillus acidophilus*, while other studied strains were not effective. More promising results were reported in five clinical trials when VSL#3 was tested to prevent pouchitis after colectomy surgery<sup>[23]</sup>.

This series of articles presents the challenges that face healthcare providers and patients with IBS and IBD. These chronic conditions place a heavy burden on healthcare institutions and contribute to significant morbidity. Newer treatment strategies may help patients remain in remission longer, but our efforts should be focused on unraveling the etiologies of these diseases so that preventive measures

can be developed that will stop irreversible damage from occurring in the first place, lofty goals, but well worth our efforts.

## TOPIC HIGHLIGHT

Lynne V McFarland, PhD, Series Editor

# Editorial statement

Lynne V McFarland

In the following eight articles we have provided an overview of the current research and epidemiology of two leading chronic gastrointestinal conditions that affect populations across the globe. The challenges of accurately diagnosing irritable bowel syndrome (IBS) are covered and the pathophysiology of constipation is thoroughly explored. Both standard and innovation strategies for the treatment of IBS are discussed, including 5-HT<sub>4</sub> antagonists, surgery and the use of probiotics. Inflammatory bowel disease (IBD) encompasses several multifactorial conditions including Crohn's disease, ulcerative colitis and pouchitis. An alarming link between IBD and colorectal cancer has been made, which heightens the importance of preventive colonoscopic screening. Treatment for IBD may involve immunomodulators, biologic agents and surgery. Technologic advances that increase the detection of etiologic agents for IBD are being developed and may help in the development of better therapeutic strategies for these complex conditions. I hope these articles will inspire clinicians and researchers to focus their efforts on preventing the development of these conditions before irreversible damage occurs and the difficult job of treating these patients is required.

### Abstract

This review provides information on the definition of constipation, normal continence and defecation and a description of the pathophysiologic mechanisms of constipation. In addition, changes in the anatomy and physiology of the lower gastrointestinal tract associated with aging that may contribute to constipation are described. MEDLINE (1966-2007) and CINAHL (1980-2007) were searched. The following MeSH terms were used: constipation/etiology OR constipation/physiology OR constipation/physiopathology) AND (age factors OR aged OR older OR 80 and over OR middle age). Constipation is not well defined in the literature. While self-reported constipation increases with age, findings from a limited number of clinical studies that utilized objective measures do not support this association. Dysmotility and pelvic floor dysfunction are important mechanisms associated with constipation. Changes in GI function associated with aging appear to be relatively subtle based on a limited amount of conflicting data. Additional research is warranted on the effects of aging on GI function, as well as on the timing of these changes.

### INTRODUCTION

Constipation is a problem that affects all ages. However, it is a common problem in older adults and is often a concern to elders and clinicians. In older people, acute bouts of constipation can occur with acute illness or dietary alterations. In contrast, chronic constipation usually has an insidious onset of many years, often dating to childhood. The symptom experience can range from a mild, acute event that is remedied with a shift in fluid and dietary intake to a chronic condition that requires daily interventions with mixed results. Elders may falsely believe that constipation is a "natural" part of aging<sup>[1-4]</sup>.

The purposes of this review are to: define constipation; provide an overview of normal continence and defecation; and describe the pathophysiologic mechanisms of constipation. In addition, the changes in the anatomy and physiology of the lower GI tract associated with aging that may contribute to constipation are described.

### METHODS

To identify the relevant studies on the pathophysiology of constipation in the older adult, a number of strategies were employed. A literature search was conducted that included the following databases and time periods: MEDLINE (1966-2007) and CINAHL (1980-2007). The following MeSH terms were used: (constipation/etiology OR constipation/physiology OR constipation/physiopathology) AND (age factors OR aged OR older OR 80 and over OR middle age).

### DEFINITION OF CONSTIPATION

Constipation is not a disease entity, but a general term that is used to describe the difficulties that patients experience with moving their bowels. Clinical and research

literature documents that patients and clinicians use different definitions of constipation. Clinicians consider the frequency of defecation episodes, stool weight, colonic transit time, and anorectal manometry as proxy measures for constipation<sup>[5,6]</sup>. A commonly held belief amongst clinicians is that the problem of constipation is more imagined than real, as “the great majority of those complaining of constipation have a bowel motion (movement) more frequently than three times a week”<sup>[7]</sup>. The actual problem lies in the definition of constipation. The term itself holds different meanings depending on the individual. Individual perception of bowel function, whether or not the symptoms associated with constipation are endured, is quite distinct from how the medical dictionary defines the problem. Because of the subjective nature of the condition, no consensus exists on the definition of constipation.

Measurement of the frequency of stools has been used to define constipation. “Normal” frequency of stool evacuation comprises a broad or narrow range of time that has large intra- and inter-individual variability. The “usual” range is anywhere from one to three times per day to three times per week<sup>[8]</sup>. Less than three times per week may be considered normal if this does not represent a change from the usual frequency of baseline defecation events and is not associated with discomfort<sup>[9]</sup>. This self-report criterion does not describe the entire symptom experience of constipation.

Patients define constipation quite differently from clinicians. A study of 531 general practice patients found that 50% of them gave a different definition of constipation than their physicians<sup>[10]</sup>. Most patients define it by one or more of the following symptoms: hard stools, infrequent stools, the need for excessive straining, a sense of incomplete evacuation, and/or an excessive amount of time spent on the toilet or in unsuccessful evacuation<sup>[11]</sup>. Patients may perceive any or all of the following as constipation: straining to expel hard, dry stools; difficulty with initiating a bowel movement or an inability to defecate when desired; feelings of incomplete evacuation; and/or abdominal cramping and bloating. Subjective reports among middle aged and older individuals have identified the most common definition of constipation as being difficulty with defecation<sup>[12]</sup>.

Most patients with a complaint of constipation have a functional disorder that affects the colon and/or anorectum. “Functional” is used to describe symptoms or problems that have no underlying anatomic abnormalities. However, the normal function of an organ has changed. Functional bowel disorders are functional gastrointestinal disorders with symptoms that arise in the middle or lower gastrointestinal tract<sup>[4]</sup>. Functional constipation is defined as the reduced frequency of bowel movements and/or an altered act of evacuation<sup>[13]</sup>.

Functional bowel disorders, including functional constipation, are diagnosed primarily through patients’ reports of symptoms. As a result, a symptom based classification is needed for clinical diagnosis, evidence based management, and research. Since 1989, an international panel of experts has met four times and issued recommendations

**Table 1 Rome III criteria for defining functional constipation**

Loose stools rarely present with laxative use and insufficient criteria for IBS and
Two or more of the following (fulfilled for the last 3 mo with symptom onset at least 6 mo prior to diagnosis):
Fewer than three bowel movements per week
Straining <sup>1</sup>
Lumpy or hard stools <sup>1</sup>
Sensation of incomplete evacuation <sup>1</sup>
Sensation of anorectal obstruction or blockade <sup>1</sup>
Manual maneuvers (e.g., digital evacuation, support of the pelvic floor) To facilitate a bowel movement <sup>1</sup>

<sup>1</sup> ≥ 25% of defecations. Longstreth GF, Thompson WG, Chey WD, Houghton LA, Mearin F, Spiller RC. Functional bowel disorders and functional abdominal pain. *Gastroenterology* 2006; 130: 1486.

on the diagnosis and management of Irritable Bowel Syndrome (IBS), as well as diagnostic criteria for other functional bowel disorders. Known as the Rome I, Rome II, and Rome III (Table 1) criteria, these recommendations have evolved to include functional anorectal disorders. All disorders are defined by specific symptoms. However, functional disorders of defecation include the results of diagnostic tests as part of the definition<sup>[14]</sup>.

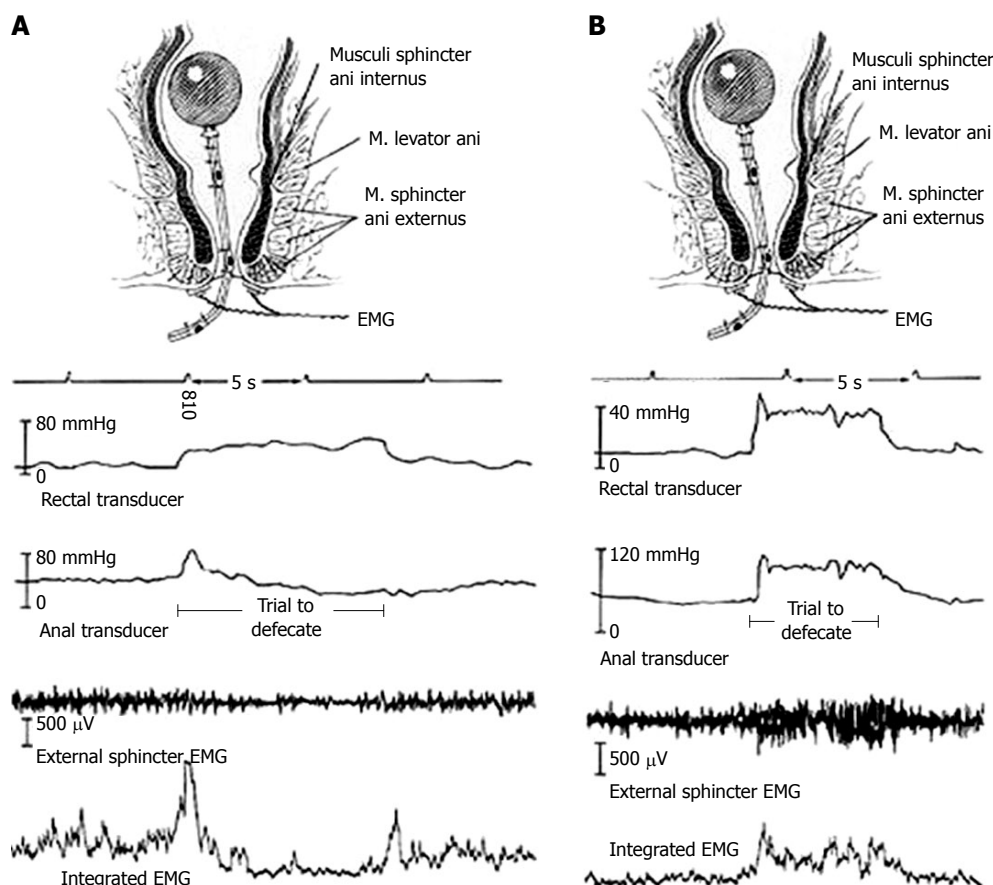

Rome III as a functional bowel disorder that presents as persistently difficult, infrequent, or seemingly incomplete defecation, which does not meet IBS criteria, defines functional constipation. Patients are diagnosed with functional constipation if they are devoid of organic alterations and present with at least two or more of the symptoms listed in Table 1, fulfilled for at least three months with symptom onset at least six months prior to diagnosis, and insufficient criteria for IBS<sup>[4]</sup>.

Several changes occurred in the development of the diagnostic criteria between Rome I and Rome III, in particular between Rome II and III. Studies using the Rome II criteria yielded lower prevalence rates for constipation than those using Rome I criteria. A factor that contributed to this decrease was a change in the Rome II criteria that did not allow for laxative-induced loose stools<sup>[15]</sup>. Rome III includes this criterion. In addition, the frequency of occurrence of the various criteria was modified from > 25% to ≥ 25%. This approach was taken to be consistent with the criteria for other functional bowel disorders<sup>[4]</sup>. Since Rome II, more consistent criteria for the diagnosis and management of constipation have appeared in the literature.

With this definition of constipation as background information, the next section of this paper reviews normal continence and defecation prior to a discussion of the pathophysiology of constipation and constipation in the older adult.

## NORMAL CONTINENCE AND DEFECATION

Normal anatomy and physiology of the gastrointestinal tract are well documented in the literature. Normal continence and defecation are complex processes that are altered in someone with constipation. Continence

**Figure 1** Manometric and electromyographic recordings seen with normal (A) and abnormal (B) defecation. EMG: Electromyography; Footnote: Wald A. Manometry. In: Schuster MM, Crowel MD, Koch KL, eds. *Atlas of Gastrointestinal Motility in Health and Disease* 2nd ed, Hamilton, and Ontario: BC Decker; 2002: 289-303.

is the ability to retain feces until an acceptable time for defecation. Defecation is the evacuation of fecal material from the colon. Both functions involve complex physiologic processes that are not completely understood. Voluntary regulation through the central nervous system (CNS) and involuntary intrinsic reflex mechanisms are involved in both of these functions. Fecal continence is maintained by anatomic factors, anorectal sensation, and rectal compliance<sup>[16]</sup>. Problems with continence and defecation can arise from an extrinsic disorder involving the central or peripheral nervous systems; from an intrinsic disorder of the colon, rectum, or anal sphincters; or from a combination of these mechanisms.

Normal stool output is about 200 mg daily. Activity in the proximal colon determines the consistency and volume of delivery of contents to the rectum. The rectum is a reservoir. As rectal filling gradually proceeds, anorectal sampling permits subconscious perception of the consistency of the content. An intact internal anal sphincter (IAS) ensures continence.

Autonomic neurons relay the anorectal sensation of the rectal contents. Activation of these afferents results in both conscious perception and activation of local reflexes, such as the rectoanal inhibitory reflex to begin the relaxation of the IAS. Reflex voluntary contraction of the external anal sphincter (EAS) maintains continence until voluntary defecation is possible. A similar reflex contraction occurs to maintain continence when a rise in abdominal pressure occurs, such as during a cough or with positional changes. Partial external contraction is

also observed during the passage of flatus, and coupled with an intact anorectal sensation this is the mechanism through which fecal continence is maintained during the passage of gas. Preservation of continence depends on the normal functioning of anorectal sensation, the appropriate perception of that sensory information, the integrity of lower and higher reflex arcs, and the action of the internal and external anal sphincters.

Defecation (Figure 1A) begins with rectal sensory awareness of a critical level of filling, which is relayed to the cerebral cortex as the perception of the need to evacuate the rectum. The actual volume that triggers the perception is dependent on the condition of the rectum (e.g. mucosal inflammation, rectal wall compliance) and the character of the contents (e.g. consistency, volume). When appropriate, the individual adopts a sitting or squatting position. This position results in a straightening of the anorectal angle that allows more effective propulsion of the rectal contents. The EAS and puborectalis muscles relax. The rectal contents provoke reflex relaxation of the IAS and the individual can then bear down. Abdominal pressure rises, abdominal wall muscles tense and relaxation of the pelvic floor allows some stool to enter the lower rectum. This movement of stool initiates a spontaneous rectosigmoid contraction, which pushes the stool through the relaxed anal canal<sup>[16]</sup>.

Large propulsive contractions of the rectum occur until the rectum is empty. Sensory input from the anus maintains the propulsive activity until the rectum is fully voided. This reflex appears to be mediated at the level of the spinal cord,

as even spinally injured patients can evacuate a complete stool from the rectum, once initiated<sup>[17]</sup>. Such patients tend to use digital rectal stimulation to initiate the propulsive contractions of the recto-sigmoid colon. As stool passes through the anal canal, it stretches the EAS and creates a traction force on it. After the last bolus of stool has passed, the closing reflex of the EAS is stimulated by the release of traction. Therefore, anal continence is maintained following defecation.

## CHANGES IN THE LOWER GASTROINTESTINAL TRACT ASSOCIATED WITH AGING

Age-related anatomic changes within the lower gastrointestinal tract may contribute to delayed transit time and decreased stool water content<sup>[18]</sup>. These changes can include intestinal wall atrophy, reduced blood supply, and intrinsic neuronal changes. However, no significant functional changes are readily apparent in the aging gastrointestinal tract. Secretion and absorption remain relatively constant. This constancy is thought to be due to the redundancy in each segment of the intestinal tract.

Gut transit time and colonic motility are similar in healthy older adults compared to younger participants<sup>[19]</sup>. In contrast, elderly people with chronic illness who report constipation have a prolonged total gut transit time of 4 to 9 d (normal < 3 d), with evacuation delayed through the lowest part of the large bowel and rectum. Nursing home residents have even more prolonged transit times of up to three weeks in those least mobile which makes them highly susceptible to slow transit constipation (STC) and overflow fecal incontinence<sup>[20]</sup>. Colonic function appears to be more influenced by factors associated with aging (e.g. chronic disease, immobility, and medications) than aging itself.

Age-related neurodegenerative changes in the enteric nervous system (ENS) may be key to functional changes observed with advanced age. In colons of people older than age 65, a 37% loss of enteric neurons was found when compared with younger people<sup>[21]</sup>. The number of nerve cells present in the myenteric plexus of the human large intestine was examined using laminar preparations of the muscularis externa in two groups of participants aged 20 to 35 and over 65 years. In addition, the collagen and elastic system related fibers in the myenteric ganglia were qualitatively evaluated. The total number of neurons was decreased in older individuals. Both collagen and elastic system fibers were more numerous in the ganglia from the older participants. The authors concluded that the decrease in neuron density with age is accompanied by an apparent increase in the fibrous components of the myenteric ganglia. These findings suggest that neurodegenerative changes may contribute to the disturbed colonic motility seen in the aging population.

Older people have age-related reductions in IAS pressure and pelvic muscle strength<sup>[22,23]</sup>, as well as changes in rectal sensitivity<sup>[24]</sup> and anal function. Women in particular, experience a larger decrease in squeeze pressures with aging especially after menopause, and due to injuries sustained during vaginal delivery<sup>[25,26]</sup>. These changes increase both the risk and the potential for constipation.

The interrelationship between aging and parity in the anorectal squeeze pressure in women is difficult to determine from currently available data. However, the authors suggested that menopausal effects might be relevant<sup>[3]</sup>. These age-related changes are not in and of them pathologic, but may contribute to the development of constipation in the elderly.

## PATHOPHYSIOLOGIC MECHANISMS OF CONSTIPATION

Two mechanisms explain the pathophysiology of constipation<sup>[27,28]</sup>. Colonic motility dysfunction, or dysmotility, is failure of coordinated motor activity to move stool through the colon. It is sometimes associated with: dietary factors, medications that can alter motility; or systemic disease (e.g. neurologic, metabolic, or endocrine disorders). Others exhibit abnormalities of the enteric nerves, such as decreased volume of interstitial cells of Cajal (ICC) and other neural elements<sup>[29]</sup>. The second mechanism involves pelvic floor dysfunction, or disorders of the anorectum and pelvic floor, which result in outlet dysfunction and an inability to adequately evacuate rectal contents. Functional constipation may occur as a result of disordered movement through the sigmoid colon and/or anorectum. Both mechanisms coexist in some patients<sup>[28]</sup>, making it difficult to determine the exact underlying mechanisms for constipation.

### Physiology of dysmotility

Dysmotility results in colonic delay (i.e. abnormally prolonged colonic transit time). Three types of colonic delay have been identified: right colonic (colonic inertia), left colonic, and rectosigmoid. Additionally, delay can occur in patients with no colonic dysmotility<sup>[30]</sup>. Mechanisms of delay include: dysfunction of the autonomic nervous system, disruption in the ENS<sup>[31]</sup>, disruptions in the neuroendocrine system<sup>[32,33]</sup>, and/or colonic myopathy<sup>[34,35]</sup>.

Impaired colonic propulsive activity may represent a major mechanism for colonic dysmotility. In patients with constipation ( $n = 45$ ), there were fewer mass movements segmental contractions<sup>[36]</sup>. No differences in post awakening values were found in patients with chronic constipation, which suggests that the brain-gut control of fundamental mechanisms governing colonic motility is preserved<sup>[37]</sup>.

A disorder of the ICC may have a role in the development of diminished or absent colonic motor activity<sup>[38]</sup>. In patients with STC, the number of ICC was significantly decreased in all layers of the colonic wall<sup>[29]</sup>, including the external muscle layer<sup>[39]</sup>. Thus, constipation in patients with colonic inertia is attributable to weak or absent electric activity.

When compared with healthy controls, patients with STC exhibit reduced daytime colonic pressure waves and a higher frequency of periodic rectal motor activity (PRMA) that were unrelated to proximal colonic activity. Their findings suggest that excessive and uncoordinated phasic rectal activity may further impede stool transport and contribute to STC<sup>[40]</sup>.

The gastrocolic response to ingestion of a meal in individuals with constipation is characterized by a shorter contractile activity in all three-colon segments and significantly fewer high amplitude propagated contractions (HAPCs)<sup>[41,42]</sup>. Changes in rectal wall contractility in response to feeding, as well as with the administration of a cholinergic agonist, and a smooth muscle relaxant, are decreased in constipated patients. This finding suggests an abnormality in rectal muscular wall contractility<sup>[43]</sup>.

The gastrocolic response after ingestion of a standardized liquid meal and the response to a local chemical stimulus were investigated in 10 healthy controls and 10 patients with STC. Increases in motility after a meal and bisacodyl were seen in healthy participants, but not in patients with STC. Timing of the high amplitude propagating contractions was prolonged and decreased in number in the patients with STC. In addition, symptom reports of a cramp felt at the time of a HAPC were significantly lower than in controls ( $P < 0.05$ )<sup>[44]</sup>.

The nerve fibers in the colonic circular muscle may be abnormal in patients with STC. A reduction in the density of excitatory nerve fibers with tachykinin and enkephalin immunoreactivity was found in the colonic circular muscle of patients with STC, whereas innervation of all the other layers was normal<sup>[45]</sup>. Small sensory fiber dysfunction has also been suggested in patients with STC<sup>[46]</sup>.

Abnormalities in neurotransmitters may contribute to dysmotility and the subsequent development of constipation. Changes in excitatory and inhibitory neurotransmitters have been evaluated with conflicting results. Levels of vasoactive intestinal peptide (VIP) were found to be unchanged<sup>[47]</sup> or increased<sup>[33]</sup> in patients with STC. The release of acetylcholine was found to be depressed in colonic tissue specimens from constipated patients<sup>[48]</sup>. Excessive nitric oxide was found in ICC preparations from the distal colon of patients with STC<sup>[49]</sup>. A decrease in serotonin immunoreactivity in the muscular mucosa and circular muscle was identified in patients who underwent subtotal colectomy for colonic inertia<sup>[50]</sup>. How changes in the release of various neurotransmitters contribute to the pathogenesis of STC has not been described in detail.

A number of gut hormones (i.e. cholecystokinin, peptide YY, somatostatin, enteroglucagon, pancreatic peptides) are thought to have potent effects on gastrointestinal motility. Plasma cholecystokinin and peptide YY have not been found to be altered in patients with STC<sup>[51]</sup>. However, specific abnormalities in circulating gut hormones have been identified in patients with STC including: higher levels of circulating somatostatin, lower levels of somatostatin integrated with an incremental meal response, and decreased levels of enteroglucagon 30-60 min after a meal<sup>[52]</sup>. Significantly fewer enteroglucagon and serotonin immunoreactive cells were found in patients with STC<sup>[33]</sup>. However, how changes in these hormones contribute to the pathogenesis of STC has not been described.

### **Changes in physiology associated with disease states**

Disease states that alter slowly wave patterns or spike responses will alter contraction and motility<sup>[53]</sup>. Abnormalities in colonic motility seen in diabetic patients

with constipation are due in part to altered autonomic neural control manifested as an abnormal gastrocolonic response. Slow wave patterns appear unaltered in healthy participants compared to patients with constipation and diabetes. Minimal spike potential activity is seen in both healthy and diabetic patients during fasting. Following a meal, spike potential activity quickly increases during the first 10 min and is sustained for 30 min in healthy participants. This activity is inhibited by the pre-administration of an anticholinergic drug, which suggests that the postprandial response is mediated through the cholinergic nervous system. In diabetic patients without constipation, the response to a meal is the same as in controls. In chronic insulin dependent diabetic patients with constipation, the normal postprandial increase in spike potential is not present. The lack of spike potential leads to abnormal postprandial motor activity in the colon, which results in constipation<sup>[54,55]</sup>.

### **Pelvic floor dysfunction**

The second major mechanism for constipation is pelvic floor dysfunction, which results in disordered defecation. It is most commonly due to dysfunction of the pelvic floor muscles or anal sphincters<sup>[15]</sup>. Different terms that are used to describe these disorders include anismus, pelvic-floor dyssynergia, paradoxical pelvic floor contraction, obstructed defecation, functional rectosigmoid obstruction, and functional fecal retention in childhood<sup>[56]</sup>. The pathophysiology of these disorders is not completely understood.

### **Physiology of pelvic floor dysfunction**

When constipation is accompanied by an immobile perineum, patients have impaired balloon expulsion, impaired and delayed artificial stool expulsion, decreased straightening of the anorectal angle, decreased descent of the pelvic floor with defecation, and prolonged rectosigmoid transit times. All are thought to be signs of pelvic floor dysfunction rather than delayed transit time<sup>[57]</sup>.

When compared to healthy controls, patients with obstructed defecation demonstrate lower intrarectal pressure and defecation indices and higher anal residual pressures on anorectal manometry recordings during straining (Figure 1B). Impaired rectal contraction, paradoxical anal contraction, or inadequate anal relaxation seen in patients with obstructed defecation suggests that rectoanal coordination is impaired<sup>[58]</sup>.

The overall frequency of propagating sequences in the colon does not differ between patients with obstructed defecation and healthy controls. In fact, patients with obstructed defecation were found to have a significant increase in the frequency of retrograde and antegrade propagating sequences ( $P < 0.05$ ) in the left colon and a significant reduction in the amplitude of propagating pressure waves throughout the entire colon ( $P < 0.03$ ). In the 15 min before defecation, controls showed a highly significant increase in frequency ( $P = 0.001$ ) and amplitude ( $P = 0.01$ ) of propagating sequences. In contrast, patients did not demonstrate this or the typical spatiotemporal organization of propagating sequences normally observed before expulsion of stool<sup>[59]</sup>.

### Neural influences on pelvic floor dysfunction

Parasympathetic afferent nerves are stimulated by both slow or cumulative and fast or intermittent distention of the rectum, whereas sympathetic afferent nerves are only stimulated by fast distention. In a study that examined the role of sympathetic afferent nerves in the mediation of rectal filling sensations, women with obstructed defecation were found to have either blunted or absent rectal sensory perception<sup>[60]</sup>. Participants experienced a nonspecific sensation in the pelvis or lower abdomen with fast distention, which suggested that sympathetic efferents were deficient. In spite of this, rectal wall compliance was normal in the patients with obstructed defecation<sup>[61]</sup>.

The gastrocolic reflex has been evaluated in patients with obstructed defecation. It was found to be absent or prolonged in patients with obstructive defecation in whom transit time is prolonged. The gastrocolic reflex was found to be intact if slow transit was absent<sup>[62]</sup>.

Patients with STC can also have anorectal motility disturbances. The minimum relaxation volume, the rectal defecatory threshold, the rectal maximal tolerable volume, and the rectal compliance are significantly higher in patients with STC than in healthy controls ( $P < 0.01$  or  $P < 0.05$ )<sup>[63]</sup>. The anorectal reflex is active in puborectalis paradoxical syndrome, but the rectoanal reflex is not, indicating a possible myogenic defect in the puborectalis muscle<sup>[64]</sup>.

How people develop defecation disorders is unclear. In two-thirds of patients, dyssynergic or obstructed defecation appears to be an acquired behavioral disorder of defecation and in the rest the process of defecation may not have been learned since childhood<sup>[65]</sup>.

## PATHOPHYSIOLOGY OF CONSTIPATION IN THE OLDER ADULT

Constipation is often considered a natural part of aging but it is a disorder that is not caused by aging itself. Although changes in the gastrointestinal tract associated with aging may predispose one to develop constipation, the disorder usually has a multifactorial etiology and may be a lifetime disorder.

As shown in Table 2, numerous factors may contribute to the development of constipation<sup>[6-9,66,67]</sup>. Though bowel transit time and frequency of bowel movements do not change with aging, a number of comorbid conditions may contribute to the development of constipation<sup>[66]</sup>. Some data suggest that older adults perceive constipation as straining during defecation rather than decreased bowel frequency<sup>[68,69]</sup>. Another study of elderly individuals who reported constipation demonstrated that straining and hard bowel movements were the most frequent complaints<sup>[69]</sup>. A determination of the most likely etiology for constipation requires identification of the primary complaint<sup>[66]</sup>.

Aging is associated with changes in the structure and function of the colon and defecatory mechanisms. Regional differences in colonic properties and in neurotransmitter functions have implications for normal function and dysfunction<sup>[70]</sup>.

Rectal sensation plays a critical role in normal defecation and may change with aging. In one study elderly patients

Table 2 Etiology of constipation in the older adult

Endocrine and metabolic disease
Diabetes mellitus
Hypothyroidism
Neurologic disease
Autonomic neuropathy
Cerebrovascular disease
Multiple sclerosis
Parkinson's disease
Spinal cord injury
Psychological conditions
Anxiety
Depression
Structural abnormalities
Anorectal conditions: fissures, hemorrhoids, rectal prolapse or rectocele
Obstructive colonic lesions
Lifestyle
Dehydration
Low calorie diet
Low fiber diet
Immobility
Iatrogenic
Medications

with constipation and a history of fecal impaction had impaired rectal and perineal sensation and required significantly larger volumes of rectal distention to stimulate the normal urge to defecate<sup>[24]</sup>. A second report described impaired rectal perception of stool in elderly patients with constipation<sup>[71]</sup>, while sensation appeared to remain intact in those patients without constipation.

Disordered defecation can occur as a result of injury to the pudendal nerve. The incidence of increased pudendal nerve terminal motor latency, an indicator of pudendal nerve dysfunction, is increased in elderly females<sup>[3]</sup>. Injury to the pudendal nerves can lead to abnormal perineal descent, which can impact rectal emptying by causing partial prolapse of the anal canal by the anterior rectal mucosa<sup>[72]</sup>.

Several types of anorectal abnormalities occur in older people with constipation including dyschezia and pelvic dyssynergia. Dyschezia is characterized by reduced tone, increased compliance, and impaired sensation such that a greater degree of rectal distention is required to induce the defecatory mechanism<sup>[24]</sup>. Seen most commonly in frail elders, these individuals have recurrent rectal impactions, a frequent consequence of which is fecal soiling. Fecal soiling affects 28% of older people. However, it is a problem that is not assessed by doctors or nurses<sup>[73]</sup>. Pelvic dyssynergia, also termed anismus, involves a failure to relax the pelvic floor and external anal sphincter muscles during defecation.

## IMPLICATIONS FOR FUTURE RESEARCH

Constipation is not a straightforward problem. However, recent research on the mechanisms and effects of constipation on the elderly is extremely sparse. Until the mechanisms of constipation are completely understood, it is likely that treatment will be at best, minimally successful. Dysmotility and pelvic floor dysfunction

are clearly important mechanisms associated with constipation, but further work is needed to understand the anatomic, physiologic, and lifestyle factors that affect these mechanisms. In addition, longitudinal data on gastrointestinal motility are needed to determine the effects of aging on normal lower GI and pelvic floor anatomy and function. Studies are needed that evaluate changes in the physiology of the pelvic floor in women over the menopause transition and whether these changes contribute to functional outcomes seen at that time and on into old age.

Changes in GI function associated with aging appear to be relatively subtle based on a limited amount of conflicting data. Additional research is warranted on the effects of aging on GI function, as well as on the timing of these changes. A deeper understanding of the basic mechanisms of dysfunction, changes in the colonic wall, and pelvic floor dysfunction in the older adult could provide new directions for the assessment and management of constipation in this vulnerable group.

While significant progress has occurred in the development of consensus criteria for the assessment of constipation the definition is not standardized. The Rome criteria constitute a self-reported, complaint-based diagnostic system with a significant overlap between the criteria for dysmotility and pelvic dysfunction disorders. Studies are needed to clarify the discrete differences between colonic motor dysfunction and functional defecation disorders.

### Abstract

Irritable bowel syndrome (IBS) is a highly prevalent gastrointestinal disorder characterized by abdominal pain and discomfort in association with altered bowel habits. It is estimated to affect 10%-15% of the Western population, and has a large impact on quality of life and (in)direct healthcare costs. IBS is a multifactorial disorder involving dysregulation within the brain-gut axis, and it is frequently associated with gastrointestinal motor and sensory dysfunction, enteric and central nervous system irregularities, neuroimmune dysregulation, and post-infectious inflammation. As with other functional medical disorders, the treatment for IBS can be challenging. Conventional therapy for those with moderate to severe symptoms is largely unsatisfactory, and the development of new and effective drugs is made difficult by the complex pathogenesis, variety of symptoms, and lack of objective clinical findings that are the hallmark of this disorder. Fortunately, research advances over the past several decades have provided insight into potential mechanisms responsible for the pathogenesis of IBS, and have led to the development of several promising pharmaceutical agents. In recent years there has been much publicity over several of these new IBS medications (alosetron and tegaserod) because of their reported association with ischemic colitis and cardiovascular disease. While these agents remain available for use under restricted prescribing programs, this highlights the need for continued development of safe and effective medication for IBS. This article provides a physiologically-based overview of recently developed and frequently employed pharmaceutical agents used to treat IBS, and discusses some non-pharmaceutical options that may be beneficial in this disorder.

### INTRODUCTION

Irritable bowel syndrome (IBS) is one of the most common functional gastrointestinal disorders affecting Western countries, with rates estimated as high as 10%-15% in the general population<sup>[1-3]</sup>. IBS is a heterogeneous condition broadly characterized by recurrent abdominal pain and discomfort with altered bowel habits and no detectable structural abnormalities<sup>[1]</sup>. In addition to constipation and/or diarrhea, frequently reported symptoms include abdominal pain and cramps, flatulence, fecal urgency, straining, a sense of incomplete evacuation and relief of pain or discomfort upon defecation.

IBS can be classified according to the predominant bowel symptoms: IBS with constipation predominant features (IBS-C), IBS with diarrhea predominant features (IBS-D), and IBS with alternating symptoms of diarrhea and constipation (IBS-A). While the exact pathophysiology of IBS is unclear, dysregulation within the brain-gut axis and interactions between genetics<sup>[4,5]</sup>, psychosocial factors<sup>[6,7]</sup>, post-inflammatory changes<sup>[8-10]</sup>, and motor<sup>[11]</sup> and sensory dysfunction<sup>[12]</sup> all likely play a role.

While only a fraction of IBS patients seek medical care<sup>[13]</sup>, this condition accounts for up to 20% of all referrals to gastroenterologists<sup>[14]</sup>. IBS has widespread economic ramifications in terms of both healthcare utilization and indirect costs incurred as a result of absenteeism from work<sup>[15,16]</sup>. Moreover, IBS is a cause of substantial morbidity and is associated with a lower health care-related quality of life<sup>[17]</sup>. It is clear that effective drugs for IBS are greatly needed.

### GENERAL TREATMENT APPROACH

IBS is a chronic, recurring condition with a wide range of symptoms. Therefore, the general goal of treatment

is to alleviate the symptoms of abdominal pain, altered bowel transit (diarrhea or constipation) and any associated symptoms such as bloating and fecal incontinence. The treatment approach should be individualized, and will depend on the intensity of symptoms and the degree of other comorbid conditions<sup>[18]</sup>. As with other functional medical disorders, the cornerstone of successful management revolves around establishing an effective patient-physician relationship<sup>[18,19]</sup>. The physician should be non-judgmental, listen actively to determine the patient's needs and concerns, and encourage the patient to participate in their medical care<sup>[20]</sup>. Well-established physician relationships and positive interactions with health care providers have been shown to be associated with fewer IBS-related follow-up visits and a lower utilization of health care resources<sup>[21]</sup>.

The majority of IBS patients are successfully managed in the primary care setting. These patients typically have mild symptoms and respond well to dietary and lifestyle modifications, education, and reassurance about their disease. Gut-directed medical therapy (anticholinergics, antispasmodics and newer IBS-specific agents) is used more frequently in patients with moderate to severe symptoms and is occasionally accompanied by the use of low dose tricyclic antidepressants (TCAs) and/or other psychiatric medications. The most severe, and smallest percentage of IBS cases, are often refractory to standard treatment and are likely to be seen at tertiary specialty centers. These patients will often require mental health providers, psychotropic medications, and may need frequent appointments with primary care providers to offer ongoing support throughout treatment<sup>[19,22]</sup>.

In all cases of IBS, it is important to establish realistic and consistent treatment goals<sup>[18]</sup>. Patients should be aware that a single drug is not likely to eradicate all symptoms, and that time, patience, and "trial and error" use of medications will be required. Additionally, physicians should educate patients about their diagnosis and provide reassurance that though this condition is a real medical disorder, it is a benign process that portends a normal life expectancy. In a long-term prognostic study of IBS, Owens and colleagues found that less than 10% of IBS patients developed an organic gastrointestinal disease, and that patients with IBS had survival rates not different from expected<sup>[21]</sup>. Misconceptions about the causes, diagnosis and treatment of IBS are common among patients. In a recent questionnaire-based study of 636 IBS patients, 80% believed their condition developed as a result of anxiety, nearly two-thirds believed diet was responsible for IBS, and one in seven patients believed that IBS leads to cancer<sup>[23]</sup>. Education about the possible mechanisms of IBS may dispel some of these misconceptions and it will help lay a foundation for the use of pharmacologic interventions if needed.

Physicians should be aware of other comorbidities that may worsen symptoms, and as with all chronic conditions, a detailed history about environmental stressors, social or emotional disturbances, impaired daily functioning, and underlying psychiatric conditions should be collected. This may help determine why the patient is seeking medical care and it could help uncover any potential hidden agendas.

## PHARMACEUTICAL THERAPIES

### Serotonin axis

Serotonin (5-hydroxytryptophan) is the most important neurotransmitter (NT) in the pathogenesis of IBS. It is a paracrine signaling molecule found extensively throughout the gastrointestinal tract (approximately 90% of all body stores) that modulates key functions such as motility, sensation, blood flow, and secretion<sup>[24-27]</sup>. Serotonin is stored primarily in enterochromaffin cells (90%) and in neurons of the enteric motor system (10%). Its release is triggered by luminal distension and chemical signals, and it binds to receptors located on enteric motor neurons, peripheral afferents, and within central nervous system domains that control appetite, mood and sexual function. The majority of serotonin receptors are G protein-coupled, with the exception of the 5-HT<sub>3</sub> receptor, which is a ligand-gated ion channel. 5-HT<sub>3</sub> and 5-HT<sub>4</sub> appear to be the most important NTs in IBS<sup>[28]</sup>. 5-HT<sub>3</sub> receptors modulate visceral pain, aid in peristalsis, and its receptors within the CNS appear to influence the emotional component of visceral stimulation<sup>[28-31]</sup>. 5-HT<sub>4</sub> is important in gastric emptying, colonic secretions, facilitating the peristaltic reflex, and it contracts or relaxes smooth muscle depending upon its location within the alimentary tract<sup>[26,32,33]</sup>. Serotonin levels and its activity on receptors are in part regulated by the serotonin reuptake transporter (SERT). Coates *et al* recently demonstrated that patients with IBS have decreased levels of SERT mRNA and protein expression in intestinal epithelial cells when compared to healthy volunteers<sup>[34]</sup>. Furthermore, polymorphisms within the SERT promoter region have been shown to be associated with the IBS-D phenotype<sup>[35]</sup>, and findings from a recent study suggest that their existence may influence the response to a 5-HT<sub>3</sub> antagonist in female IBS-D patients<sup>[36]</sup>. While the exact role of serotonin signaling in the pathophysiology of IBS remains to be fully elucidated, pharmacotherapy directed at modulating its activity has proven to be an effective way of treating many IBS symptoms.

### 5-HT<sub>3</sub> antagonists

Antagonism of the 5-HT<sub>3</sub> receptor results in slower small bowel and colonic transit times, a reduction in intestinal secretion, increased stool firmness, and an increase in colonic compliance<sup>[29,37]</sup>. There is also data suggesting that antagonism of this receptor in the amygdala, dorsal pons and ventral striatum may be responsible for perceived improvement in visceral pain, though the exact mechanism is unclear<sup>[38,39]</sup>.

Alosetron is a selective 5-HT<sub>3</sub> receptor antagonist initially approved by the Food and Drug Administration (FDA) in 2000 for use in female patients with IBS-D who fail in conservative treatment. Approval of this medication was based on several large randomized controlled-trials that found alosetron (1 mg *po* twice daily) was more effective than placebo in controlling abdominal pain and discomfort in IBS-D<sup>[40-43]</sup>. Alosetron was associated with a statistically significant decrease in the percentage of days with urgency, and it led to firmer stools and a decrease in stool frequency. Clinical improvement was noted throughout the treatment

period and usually occurred within 1-4 wk of therapy; symptoms returned to baseline following discontinuation of the medication. The most frequently reported adverse event was mild to moderate constipation which was self-limited and responded well to cessation of therapy. A meta-analysis by Cremonini in 2003 examined six randomized controlled-trials of alosetron and calculated a combined odds ratio of 1.8 for the adequate relief of pain [95% confidence interval (95% CI), 1.57-2.10] and the NNT of 7 patients in order to compare its relieving effect with placebo (95% CI, 5.74-9.43)<sup>[44]</sup>.

In late 2000, alosetron was withdrawn from the U.S. market over concerns regarding side-effects of severe constipation (approximately 70 cases), ischemic colitis (approximately 50 cases), and bowel perforation<sup>[45,46]</sup>. Following substantial public pressure, it was re-introduced into the U.S. market in 2002 under a restricted prescribing program and further post-marketing studies are currently underway. In a recent placebo-controlled study, Krause and colleagues examined the safety and efficacy of alosetron at varying doses, and found that one of 250 patients developed self-limited ischemic colitis (0.5 mg daily)<sup>[47]</sup>. In a systematic review of post-marketing surveillance data, Chang and colleagues estimated the rate of ischemic colitis to be 1.1 per 1000 patients. All cases of documented ischemic colitis were reversible and no long-term sequelae were noted<sup>[45]</sup>. These data suggest that the rate of adverse events is relatively low and that alosetron is a well-tolerated, effective medication that should be considered in the treatment of IBS-D. There are ongoing studies of alosetron in men.

Cilansetron is another 5-HT<sub>3</sub> antagonist that has been used for treatment for men and women with IBS-D. Its mechanism of action is similar to alosetron and it has comparable bioavailability and metabolism. Two large phase III trials have shown that cilansetron is similar in efficacy to alosetron, but concerns over ischemic colitis and severe constipation led to the FDA denying approval in 2005<sup>[48-51]</sup>.

Ramosetron is a potent 5-HT<sub>3</sub> receptor antagonist that is effective in relieving chemotherapy-induced nausea and vomiting, and is currently being developed for IBS-D<sup>[52,53]</sup>. Preliminary pharmacokinetic data suggest that it has a greater affinity, slower dissociation, and stronger antagonism at the 5-HT<sub>3</sub> receptor than either alosetron or cilansetron<sup>[54]</sup>. It also appears to be superior to both of these medications in inhibiting stress-induced defecation and stress-induced changes in colonic transit rates in rats<sup>[54,55]</sup>. Data in human use are not available but can be anticipated in the near future.

### 5-HT<sub>4</sub> antagonists

5-HT<sub>4</sub> receptors mediate the release of the excitatory NTs acetylcholine, substance P and calcitonin gene-related peptide which modulate peristalsis<sup>[32,33]</sup>. Selective antagonism at this receptor has been postulated to provide symptomatic relief in patients suffering from IBS-D. In a study of 52 healthy subjects, Piboserod (SB207266), a selective 5-HT<sub>4</sub> antagonist, was shown to block the effects of cisapride (5-HT<sub>4</sub> agonist) and it tended to delay colonic transit times

( $P = 0.06$ )<sup>[56]</sup>. In a placebo-controlled study of 15 patients with IBS-D, Houghton and colleagues reported that 20 mg of SB207266 significantly improved orocecal transit times and demonstrated a non-statistical trend toward improved rectal sensitivity<sup>[57]</sup>. Further studies with this class of medication are needed to confirm these results.

### 5-HT<sub>4</sub> agonists

Activation of 5-HT<sub>4</sub> receptors results in the release of excitatory neurotransmitters from enteric cholinergic neurons that function to modulate smooth muscle tone, electrolyte secretion and the peristaltic reflex<sup>[26,32,33]</sup>. Tegaserod is a 5-HT<sub>4</sub> agonist that was initially approved by the FDA for use in female patients with IBS-C, and in men and women under the age of 65 with chronic idiopathic constipation. It stimulates intestinal secretion of water and chloride and decreases the nociceptive response to rectal distension<sup>[58]</sup>. Several large, randomized-trials have shown that tegaserod has a significant impact on a patient's overall assessment of global relief, and that it statistically improves abdominal pain and bloating<sup>[59-62]</sup>. A 2004 Cochrane meta-analysis supported these results by concluding that tegaserod was associated with improvement in global relief of GI symptoms [relative risk (RR), 1.17; 95% CI, 1.08-1.27] and that it improved bowel consistency and frequency<sup>[63]</sup>. The primary side-effect of tegaserod is diarrhea (NNH of 20 patients), but it is usually transient and resolves with ongoing treatment<sup>[63,64]</sup>. Long-term use of tegaserod appears to be efficacious and re-treatment response rates appear to be similar to initial treatment<sup>[65,66]</sup>. Recent data regarding the effect of tegaserod in men have shown that it accelerates colonic transit time, but improvement in bowel symptoms failed to reach statistical significance<sup>[67]</sup>. In March 2007, Novartis voluntarily removed tegaserod from the U.S. and Canadian market as an FDA safety analysis of pooled data from 12 clinical trials demonstrated a statistical increase in the incidence of myocardial infarction, stroke and unstable angina. In July 2007, tegaserod was re-introduced to the U.S. market, but under a restricted investigational new drug (IND) protocol which limits its use to treatment of IBS-C and chronic idiopathic constipation in women under 55 years of age who meet specific guidelines. It continues to remain off market for general use.

Prucalopride is a new agent in a class of medications known as benzofurans. It is an agonist at the 5-HT<sub>4</sub> receptor, and data have suggested that it enhances GI transit in patients with functional constipation compared to placebo<sup>[68]</sup>. However, the clinical development of this drug remains unclear at this time based on the reported cases of intestinal carcinogenicity in animals<sup>[69]</sup>.

### Mixed 5-HT<sub>4</sub> agonist/5-HT<sub>3</sub> antagonist

Renzapride is a mixed agent that has shown promise for patients with IBS-C and with IBS-A. It is a full agonist of the 5-HT<sub>4</sub> receptor and an antagonist of the 5-HT<sub>3</sub> receptor. In a dose-ranging efficacy trial by Camilleri and colleagues, a statistically significant linear dose response to renzapride was observed for colonic transit and ascending colonic emptying time, but not for gastric emptying or small bowel transit time<sup>[70]</sup>. No clinical or laboratory adverse

events occurred during this study. In a dose-escalating pilot study of 17 patients, renzapride (2 mg twice daily) reduced overall gastrointestinal transit time and abdominal pain, increased the number of pain-free days and improved stool consistency<sup>[71]</sup>. Adverse events were similar in drug and placebo groups. Further studies are underway.

Mosapride is a benzamide compound with prokinetic properties that possesses both 5-HT<sub>4</sub> receptor agonist and 5-HT<sub>3</sub> receptor antagonist properties. In a study of Parkinson's patients, mosapride (15 mg/d) decreased colonic transit times and was associated with subjective improvements in bowel frequency<sup>[72]</sup>. Additional data in animals and humans have shown that mosapride accelerates gastric emptying and decreases overall colonic transit<sup>[73,74]</sup>, but does not appear to affect small bowel transit times<sup>[75]</sup>. The primary side effect is mild diarrhea, but unlike cisapride, it does not seem to cause the electrophysiological abnormalities that could lead to Torsades de Pointes<sup>[76]</sup>.

### ATI-7505

Another drug for the treatment of IBS-C is ATI-7505, a potent agonist of the 5HT<sub>4</sub> receptor that is similar in chemical structure to the prokinetic agent, cisapride. It has been engineered to reduce the cardiovascular toxicity of cisapride and does not have P450 dependent clearance at therapeutic levels<sup>[77]</sup>. Preliminary data from Camilleri and colleagues show that ATI-7505 accelerates overall colonic transit (10 mg three times daily), accelerates gastric emptying (20 mg three times daily), and loosens stool consistency. No safety issues were identified in this study<sup>[77]</sup>.

### Adrenergic modulators

Clonidine, an  $\alpha_2$  agonist initially developed as an antihypertensive agent, has been found to increase colonic compliance, delay small bowel transit, and reduce colonic tone and sensitivity in response to distension<sup>[78-81]</sup>. In a small study of 44 IBS-D patients, clonidine was associated with a significant reduction in bowel dysfunction and an improvement in IBS symptoms (67% *vs* 46% of placebo), but it did not alter gastrointestinal transit times or gastric volumes<sup>[82]</sup>. Relief was sustained throughout the 4-wk treatment protocol, and drowsiness, dizziness and dry mouth were the most frequently reported adverse events. Side-effects typically occurred when doses exceeded greater than 0.1 mg twice daily. This initial study suggests that  $\alpha_2$  agonists may play a beneficial role in IBS-D, though unwanted hypotension may be a side-effect that precludes its chronic use. Further studies are warranted.

### Somatostatin

Octreotide, a somatostatin analogue, works by activating somatostatin type-2 receptors and has been shown to reduce visceral sensitivity in response to rectal distension<sup>[83,84]</sup>. In healthy volunteers and in small numbers of IBS-D patients, octreotide administered in a 50 mg bolus was shown to prolong orocecal transit times and inhibit small bowel transit times<sup>[85,86]</sup>. While these results suggest that octreotide may have benefits in patients with IBS-D, its intravenous preparation precludes daily use, and to date, no studies with oral somatostatin analogues exist for the treatment of IBS.

### Opioid agents

Opioid receptors are found throughout the enteric nervous system and on nociceptive pathways that conduct pain to the central nervous system<sup>[87]</sup>. Altered bowel transit and visceral hypersensitivity are important components in IBS pathophysiology and peripherally-acting opioid receptors may be effective drug targets. Alvimopan is a peripherally acting  $\mu$ -opioid antagonist that is effective in treatment of post-operative ileus<sup>[88]</sup>. In a study of 74 healthy volunteers, it normalized colonic transit delays induced by the administration of codeine, and alone was shown to accelerate colonic transit<sup>[89]</sup>.

The  $\kappa$ -opioid agonist, asimadoline, exerts nociceptive properties on the GI tract at least in part by blocking Na receptor channels. It has been shown to decrease colonic tone during fasting and decrease colonic pain at low levels of distension<sup>[90]</sup>. In a study of 20 IBS-C patients, asimadoline was shown to be effective in decreasing pain perception from colonic distension without affecting colonic compliance or tone<sup>[91]</sup>.

More recently, a randomized, placebo-controlled trial by Szarka and colleagues showed that asimadoline (up to 1 mg four times daily) did not statistically improve abdominal pain when taken on an "as needed basis" compared to placebo<sup>[92]</sup>. Further studies are needed to determine the efficacy of this medication.

### CRH receptor antagonists

Corticotropin-releasing hormone (CRH) is a key mediator that regulates changes in colonic motility, visceral hypersensitivity, and autonomic function in response to stress<sup>[93,94]</sup>. Stress is processed within the CNS and increases both ACTH and CRH secretion, the latter stimulates colonic motility and inhibits gastric emptying<sup>[93,95]</sup>. Distension of the colon also activates CRH pathways in the brain, providing a plausible rationale for why visceral stimulation is perceived as anxiety or stress in some patients with IBS<sup>[93,96]</sup>. Fukudo and colleagues demonstrated that administration of intravenous CRH was associated with exaggeration of colonic motility and increased ACTH secretion in IBS patients compared to healthy controls<sup>[94]</sup>. More recently,  $\alpha$ -Helical CRH (a non-selective CRH receptor antagonist) has been shown to significantly reduce abdominal pain and anxiety ratings induced by electrical stimulation of the rectum of IBS patients, but not of controls<sup>[97]</sup>. Two CRH receptors appear important in the pathogenesis of IBS. Stimulation of the CRH-1 receptor is anxiogenic and associated with pro-inflammatory states, while CRH-2 receptors are involved in the inhibition of gastric emptying<sup>[96]</sup>. CRH-1 antagonists are currently under development for clinical use in IBS.

### Chloride channel activators

Lubiprostone is a member of a new class of bicyclic fatty-acid derivatives known as prostones, and was approved by the FDA in 2006 for the treatment of chronic constipation. It acts on type-2 chloride channels located on the apical side of gastrointestinal epithelial cells, and increases secretion of electrolyte-rich fluid into the small intestine, promoting increased motility<sup>[98,99]</sup>. Several studies have shown that in

patients with chronic constipation, lubiprostone is effective in improving the spontaneous bowel movement and is associated with less bloating, straining and abdominal discomfort<sup>[99,100]</sup>. The role of lubiprostone in IBS-C has recently been evaluated in a randomized, double-blinded placebo-controlled trial of approximately 200 patients<sup>[101]</sup>. The results of this study showed an overall improvement in abdominal symptoms and bowel movement when compared to placebo and the most frequently reported side-effect was mild to moderate nausea. To date, no serious adverse events have been noted in clinical trials<sup>[100,102]</sup>. Sucampo Pharmaceuticals submitted a supplemental New Drug Application to the FDA in September 2007 requesting approval for the use of lubiprostone in IBS-C. A decision is expected sometime in early 2008.

### **CCK antagonists**

Cholecystokinin (CCK) is a neuropeptide released by duodenal and jejunal enterochromaffin cells that stimulates secretion of pancreatic enzymes and decreases gastric emptying in response to dietary fat. CCK1 receptors are distributed within enteric neurons and vagal afferents, and antagonism at this receptor has been postulated to stimulate gut motility in patients with IBS-C. A recent double-blinded study found that the CCK antagonist, dexloxiglumide (200 mg three times daily) had no significant effect on satisfactory relief of IBS, and that it did not alter transit times in IBS-C<sup>[103]</sup>. Furthermore, two large phase III clinical studies of 1400 women with IBS-C found no statistical improvement in the symptoms of abdominal pain, discomfort or altered bowel habits when compared to placebo<sup>[103]</sup>. As a result, Forest Laboratories have discontinued development of this drug, though Rotta Research is pursuing additional placebo-controlled studies in Europe.

### **Neurokinin antagonists**

Substance P and neurokinin A are excitatory co-transmitters of cholinergic enteric neurons that have been well-linked to the pathophysiology of several neurologic and psychiatric disorders. Their receptors, neurokinin 1 (NK1) and NK2, play important roles in nociception and smooth muscle contraction, and the regulation of visceral sensitivity and mucosal inflammatory processes<sup>[104-107]</sup>. Clinical data is currently deficient. However, in one study of healthy volunteers using the selective NK2 antagonist nepadutant (MEN11420), IBS-like symptoms triggered by the infusion of neurokinin A were reduced<sup>[108]</sup>. Saredutant (SR48968), another NK2 antagonist, is also being developed for the treatment of IBS, but clinical results are not yet available.

### **Antidepressants**

Antidepressants are frequently prescribed by gastroenterologists for the treatment of IBS<sup>[109]</sup>. Their mechanism in IBS is not completely understood, but has been postulated to relate to an ability to modulate central and peripheral pain perception<sup>[110,111]</sup>, improve underlying psychiatric conditions, and possibly improve gut motility through modification of neurotransmitter activity<sup>[112,113]</sup>. Unfortunately, randomized-controlled trials to date

have largely been hindered by poor study design and methodological flaws, making it difficult to judge the therapeutic value of these agents<sup>[114-116]</sup>. Most studies provide little evidence that antidepressants are superior to placebo in improving specific IBS-related symptoms, but some do suggest that overall global well-being may be improved. In a recent meta-analysis evaluating 12 randomized-controlled trials, Jackson and colleagues concluded that tricyclic antidepressants are effective in improving global IBS symptoms (OR, 4.2; 95% CI, 2.3-7.9), and calculated an NNT of only 3 in order to see an effect<sup>[117]</sup>. Fewer studies have been conducted with SSRIs. In one randomized-controlled trial comparing paroxetine (10-40 mg/d) to placebo, patients treated with the SSRI reported a significant improvement in overall well-being, but did not experience improvement in abdominal pain<sup>[118]</sup>. Other studies with paroxetine have shown an improvement in abdominal pain and discomfort, and suggest that further studies with this class of medication are needed<sup>[119,120]</sup>. While certain subgroups of IBS patients (particularly those with psychiatric comorbidities such as depression or anxiety) will likely benefit from the use of antidepressants, their use in other patients (particularly the elderly) should be met with caution as side-effects are common. Furthermore, the anticholinergic nature of some of these medications limits their use in patients with IBS-C. Antidepressants should not be used to relieve the target symptoms of IBS, and their use will not likely alter GI motility or physiology. Instead, antidepressants should be used as an adjunct in patients with moderate to severe IBS to help improve overall quality of life, well-being, and patient satisfaction with treatment.

### **Antispasmodics**

Antispasmodic agents are believed to work in IBS based on their ability to decrease intestinal smooth muscle activity. There are two broad categories of antispasmodic agents: anticholinergics/antimuscarinic agents (e.g. hyoscyamine, dicyclomine, cimetropium) and direct smooth muscle relaxing agents (e.g. mebeverine, pinaverine, octylonium bromide). Most studies of smooth muscle relaxants have been hindered by poor study design, high drop-out rates, and low patient enrollment which have made assessment of their therapeutic value in IBS difficult<sup>[121-123]</sup>. In a recent meta-analysis, only octylonium bromide was found to have some benefit after excluding poor quality studies<sup>[122]</sup>.

In a review of anticholinergic drugs, Schoenfeld and colleagues found similar problems with study design, and based on the poor quality of trials and marginal data, concluded that any benefit observed with these agents was likely due to placebo effect<sup>[123]</sup>. Additionally, their substantial side-effect profile makes these agents a suboptimal choice for IBS therapy.

### **Antidiarrheals**

Loperamide is one of the most frequently used drugs for IBS-D. It is a synthetic opioid that decreases intestinal transit, and increases intestinal water and ion absorption. Several RCTs have provided a good evidence that loperamide decreases stool frequency and improves stool

consistency in IBS-D<sup>[124-126]</sup>. Loperamide does not appear to improve abdominal pain and should only be considered in cases of painless diarrhea.

### Benzodiazepines

Dextroisopam is a 2, 3 benzodiazepine that has been used outside of the U.S. for treatment of anxiety and autonomic and stress-related disorders. Unlike typical benzodiazepines which bind GABA receptors, dextroisopam binds 2, 3 benzodiazepine receptors. Results from a 12-wk placebo-controlled phase IIb trial showed that dextroisopam (200 mg twice daily) was associated with longer periods of overall relief from IBS symptoms than placebo during the treatment period (57% *vs* 43%). Stool frequency and consistency were also improved<sup>[127]</sup>. Further trials are underway.

### Antibiotics

Small intestinal bacterial overgrowth (SIBO) has been proposed to be common in patients with IBS. Using lactulose breath tests (LBT), Pimental and colleagues showed that 78% of IBS patients had SIBO<sup>[128]</sup> and that eradication with a seven-day course of neomycin was associated with a significant reduction in symptoms<sup>[129]</sup>. However, these results are somewhat controversial, as both the accuracy of the LBT and its ability to gauge treatment response has been questioned<sup>[130-133]</sup>. More recently, Posserud and colleagues conducted a study of 162 IBS patients using cultures of jejunal aspirates to detect SIBO<sup>[134]</sup>. They found that higher bacterial counts were present in IBS patients compared to placebo (43% *vs* 12%), but this finding was not related to small intestinal motility. Furthermore, using a standard definition of SIBO ( $> 10^5$  bacteria/mL), there was no difference between IBS patients and healthy controls. Further research is needed in this area, including a better evaluation of the long-term effects of SIBO eradication.

## NON-PHARMACEUTICAL THERAPY

### Bulking agents

The use of fiber and bulking agents remains a mainstay of therapy for patients with IBS-C, though their efficacy is controversial. The proposed mechanism for fiber is a decrease in intra-colonic pressures and an acceleration of oroanal transit<sup>[135,136]</sup> though results from studies on transit times are conflicting<sup>[137,138]</sup>. There have been a number of trials evaluating the effectiveness of fiber, but many have methodological limitations including small sample sizes, short follow-up periods, selection bias, and lack of well-defined endpoints<sup>[123,139]</sup>. In a recent systematic review of 17 randomized controlled trials examining the role of fiber in the treatment of IBS, Bijkerk *et al* found only a minimal improvement in overall relief of IBS global symptoms (RR 1.33; 95% CI, 1.19-1.50), and found no evidence that fiber reduces abdominal pain<sup>[140]</sup>. Furthermore, the effectiveness on individual symptoms was variable and insoluble fiber (corn, wheat bran) was found to actually worsen symptoms in some patients<sup>[140]</sup>. In another meta-analysis of 13 placebo-controlled studies, fiber was found to improve global symptoms of IBS. But after exclusion of low-quality

studies, the result did not reach statistical significance<sup>[122]</sup>. Abnormal bacterial fermentation and disturbed gas handling may also cause bloating and abdominal pain and may worsen clinical outcome<sup>[141]</sup>. The American College of Gastroenterology Functional Gastrointestinal Disorders Task Force currently recommends the use of fiber in patients with constipation, but does not recommend its use in IBS<sup>[142]</sup>.

### Probiotics

The presence of low-grade inflammation and immune activation in some patients with IBS suggests that alterations in indigenous gut flora may play an important role in this disorder. Probiotics may work by helping restore both qualitative (i.e. depleted bifidobacteria species) and quantitative (i.e. small intestinal bacterial overgrowth) alterations in intestinal flora<sup>[143,144]</sup>. Lactobacilli and bifidobacteria are two of the most frequently studied probiotics, and several trials have shown that their use is associated with improvement in IBS symptoms<sup>[145-148]</sup>. Niedzielin and colleagues demonstrated a complete resolution of abdominal pain in patients who took *L. plantarum* compared to approximately 50% of placebo controls<sup>[146]</sup>. Other studies have shown that *L. plantarum* is associated with a decrease in bloating and may reduce global IBS symptom index scores<sup>[145,147]</sup>. Post-infectious IBS may lead to abnormal immune activation and a persistent inflammatory state<sup>[149]</sup>. The bifidobacterial species may be beneficial in this subset of IBS as it appears to possess immune-modulating activity through an ability to alter levels of IL-10 and IL-12<sup>[150]</sup>.

To date, most studies assessing the efficacy of probiotics have been small, and it has been difficult to compare results across studies largely because of non-standardized formulations of probiotics. Nonetheless, data suggests that probiotics may be beneficial, and a good safety profile makes them a reasonable choice for IBS.

### Diet

Two-thirds of IBS patients believe that their disorder is related to diet<sup>[23]</sup>. They often complain of postprandial worsening of symptoms, and are intolerant to certain foods. Visceral hypersensitivity, motility disorders, gas-handling disturbances, and abnormal carbohydrate absorption are abnormalities that may explain some of these findings. However, presence of underlying psychological issues also affects the diet-related symptoms<sup>[151]</sup>. In a recent pilot study of 20 IBS patients, Drisko and colleagues found that elimination and rotation diets based on the results of IgG and IgE food and mold panels led to a substantial improvement in stool frequency, abdominal pain, and quality-of-life scores<sup>[152]</sup>. These results were sustained at the one year follow-up. Previous studies on elimination diets have produced more conflicting results, showing an effectiveness rate ranging from 15% to 71%<sup>[153]</sup>. Nonetheless, dietary modification may be an option for patients who fail in the standard therapy.

## CONCLUSION

The complex nature of IBS continues to pose a significant

treatment challenge for patients and practitioners. Traditional medications such as antispasmodics, bulking agents, and antidepressants are frequently prescribed for IBS. But, they are seldom efficacious in patients with advanced symptoms. Fortunately, the recent efforts of basic scientists and clinician investigators have elucidated many of the neurotransmitters, effectors and neuroenteric interactions involved in the pathophysiology of IBS, and have led to the development of several new and promising therapeutic agents. Over the past years, the serotonergic medications, tegaserod and alosetron, have been proven to significantly improve patients' overall quality of life and effectively manage many of the motor and sensory abnormalities in IBS. With more progress made in our understanding of IBS and more data obtained from phase III trials, we can expect to see several other classes of medications, such as CCK antagonists, NK antagonists, CRH antagonists, opioid-receptor agents and chloride channel activators, in the near future.

estimation of a pooled RR. While our analyses suggest that probiotic use may be associated with improvement in IBS symptoms compared to placebo, these results should be interpreted with caution, given the methodological limitations of contributing studies. Probiotics warrant further study as a potential therapy for IBS.

## Abstract

Irritable bowel syndrome (IBS) is a chronic condition affecting 3%-25% of the general population. As no curative treatment is available, therapy is aimed at reducing symptoms, often with little success. Because alteration of the normal intestinal microflora has been observed in IBS, probiotics (beneficial microbes taken to improve health) may be useful in reducing symptoms. This paper systematically reviews randomized, controlled, blinded trials of probiotics for the treatment of IBS and synthesizes data on efficacy across trials of adequate quality. PubMed, Medline, Google Scholar, NIH registry of clinical trials, metaRegister, and the Cochrane Central Register of Controlled Trials were searched from 1982-2007. We also conducted secondary searches of reference lists, reviews, commentaries, relevant articles on associated diseases, books and meeting abstracts. Twenty trials with 23 probiotic treatment arms and a total of 1404 subjects met inclusion criteria. Probiotic use was associated with improvement in global IBS symptoms compared to placebo [pooled relative risk (RR<sub>pooled</sub>) 0.77, 95% confidence interval (95% CI) 0.62-0.94]. Probiotics were also associated with less abdominal pain compared to placebo [RR<sub>pooled</sub> = 0.78 (0.69-0.88)]. Too few studies reported data on other IBS symptoms or on specific probiotic strains to allow

## INTRODUCTION

Irritable bowel syndrome (IBS) is a chronic condition that severely impacts the quality of life of affected individuals<sup>[1,2]</sup>. The prevalence of IBS in the general population ranges from 3%-25%<sup>[3]</sup>. IBS is characterized by intermittent abdominal pain, altered bowel habits (diarrhea and/or constipation) and other gastrointestinal symptoms such as bloating and flatulence in the absence of structural abnormalities in the intestine. The pathophysiology of IBS is multifactorial and may include motor and sensory dysfunction, immune responses, food sensitivities and genetic predisposition<sup>[3,4]</sup>. Risk factors include female gender (2-3 times more common), acute gastrointestinal infections (e.g. *Campylobacter* or *Salmonella*) and psychological factors<sup>[3,5,6]</sup>. As no curative treatments are available, therapy for IBS is palliative and supportive, targeting specific symptoms, but is notoriously unsatisfactory<sup>[7,8]</sup>. Although 30% of patients report resolution of symptoms within one year, nearly 70% report that symptoms recur within five years<sup>[3]</sup>.

Studies have observed altered intestinal microflora in IBS patients and an increase in symptoms after enteric infections<sup>[9-12]</sup>, suggesting that restoration of the intestinal

microflora may be a useful therapeutic goal. One strategy to restore normal flora is the use of probiotics<sup>[13,14]</sup>. Probiotics are “beneficial bacteria or yeasts that are ingested to improve health”<sup>[15]</sup>. Probiotics are also known to modulate the immune response and reduce cytokine production<sup>[9,16-18]</sup>. Strong evidence for the beneficial role of probiotics exists for the prevention of antibiotic-associated diarrhea, traveler’s diarrhea and pediatric diarrhea<sup>[19-22]</sup>. There is emerging evidence that probiotics may be useful in preventing or treating *Clostridium difficile* diarrhea and pouchitis<sup>[20,23,24]</sup>. Studies of probiotics for IBS have yielded contradictory results, which may be due to a variety of factors: small sample size; variability in trial design; heterogeneity of probiotic strain, dose and treatment duration; and patient characteristics. The wide availability of probiotics as non-prescription products and the lack of a synthesis of data regarding efficacy have prompted us to conduct this meta-analysis.

We conducted a systematic review of randomized, controlled trials published as full articles or meeting abstracts to: (1) assess the characteristics and quality of randomized clinical trials in this area and (2) synthesize data across studies regarding the efficacy of probiotics for IBS.

## SEARCH STRATEGY

PubMed, Medline and Google Scholar were searched from 1982-2007 for articles unrestricted by language. Three on-line clinical trial registers were searched: Cochrane Central Register of Controlled Trials ([www.cochrane.org](http://www.cochrane.org)), metaRegister of Controlled Trials ([www.controlled-trials.com/mrct](http://www.controlled-trials.com/mrct)) and National Institutes of Health ([www.clinicaltrials.gov](http://www.clinicaltrials.gov)). Secondary and hand searches of reference lists, other studies cross-indexed by authors, reviews, commentaries, books and meeting abstracts also were performed. Search terms included: irritable bowel syndrome, diarrhea, probiotics, risk factors, Rome criteria, Manning criteria, randomized controlled trials, placebo-controlled, bloating and associated author names. Search strategies were broad-based initially, then narrowed to the disease of interest to increase the search network<sup>[25]</sup>. The procedure for this meta-analysis was designed as suggested by Egger *et al* with clearly delineated parameters, *a priori* inclusion and exclusion criteria and standardized data extraction<sup>[26,27]</sup>. Abstracts of all citations and retrieved studies were reviewed and rated for inclusion. Full articles were retrieved if specific treatments were given for IBS. In some cases, only published abstracts from meetings were available. Published abstracts from meetings were included to lessen the potential for publication bias due to failure to publish negative findings.

## INCLUSION AND EXCLUSION CRITERIA

The primary objective of this meta-analysis was to determine the overall efficacy of probiotics for IBS by comparing a common outcome in treated patients with a control group. Inclusion criteria included: randomized, controlled, blinded efficacy trials in humans published as full articles or meeting abstracts in peer-reviewed journals.

Exclusion criteria included: pre-clinical studies, safety studies, case reports or case series, phase 1 studies in volunteers, reviews, duplicate reports, trials of unspecified treatments, uncontrolled studies, prebiotic treatments only (no living organisms) or insufficient data in article.

## ASSESSMENT OF METHODOLOGICAL QUALITY

Studies that met the inclusion criteria were graded for quality using the Linde Internal Validity Scale (LIVS), which includes the following six items: method of allocation to groups, concealment of allocation, baseline comparability of intervention and placebo groups, blinding of patients, blinding of evaluators, and intention to treat/handling of withdrawals and drop-outs<sup>[28-29]</sup>. If no information was provided for an item or it was unclear, authors were contacted for more information. If available information was still inadequate, then zero points were given for that item. Total possible scores range from 0 to 6. All trials included in the meta-analysis had a total quality score of 3 or more and those with a score less than 3 were excluded. Two independent reviewers independently assessed inclusion criteria and quality of the trials. Inconsistencies were resolved by discussion.

## INTENT-TO-TREAT (ITT) ANALYSIS

Studies were considered to have adhered to intention-to-treat principles if all subjects who were randomized were analyzed with the group to which they were originally assigned and if exclusions were primarily due to patient withdrawal or loss to follow-up. If the investigators excluded patients after randomization due to use of non-study medications or antibiotics, noncompliance with assigned treatment, or non-response to therapy, the analysis was not considered to be ITT.

## DATA EXTRACTION

Information on study design, methods, interventions, outcomes, adverse effects and treatments was extracted from each article using a standardized extraction table. When necessary, authors were contacted for data not reported in the original article.

## OUTCOMES AND DEFINITIONS

We documented the types of outcomes for trials involving IBS and probiotic in the literature. Outcomes were reported by different studies as either the proportion of subjects reporting improvement or the change in symptom scores from baseline. We did not attempt to synthesize results from studies reporting changes in symptom scores because of numerous challenges including heterogeneity in scales and scoring systems across studies and inconsistent or incomplete reporting of numeric symptom scores. Thus, we selected the proportion of subjects with improvement in global IBS symptoms as the primary outcome for this meta-analysis. Secondary outcomes

included the proportion of subjects with improvement in one of three common IBS symptoms: abdominal pain, bloating or flatulence. Documentation of the outcome was based on subject self-report and/or clinician assessment.

## META-ANALYSIS METHODS

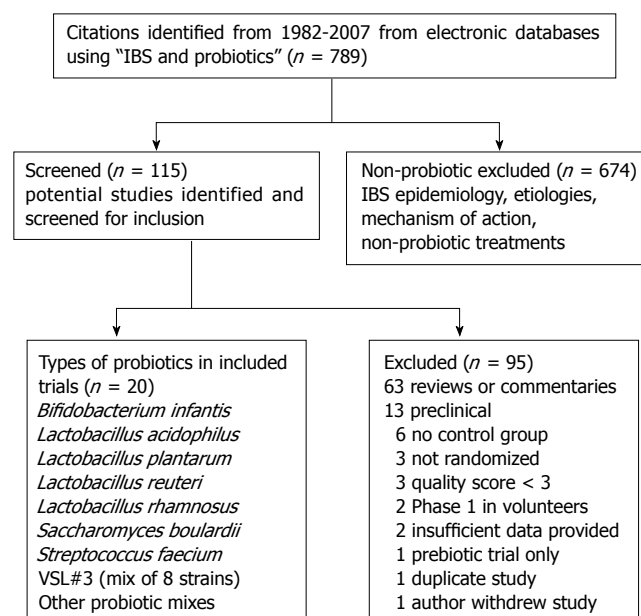

To estimate pooled relative risks across studies, we first evaluated heterogeneity between and within trials using the  $\chi^2$  test<sup>[30]</sup>. The relative risks of responding to probiotic therapy were pooled using a random-effects model if significant heterogeneity was found or a fixed-effects model if the studies were homogenous<sup>[31]</sup>. The number needed to treat (NNT) was calculated using the reciprocal of the pooled absolute risk reduction. *P* values less than 0.05 were considered significant. Analyses were performed using Stata software version 9.2 (Stata Corporation, College Station, Texas).

## PUBLICATION BIAS

We used a funnel scatterplot to assess the potential for publication bias<sup>[32]</sup>. Risk ratios were plotted against the standard error of the risk ratio (a surrogate for study size) of each study to detect asymmetry in the distribution of trials. Larger studies usually provide a more precise estimate of the true effect of the treatment and form the narrow spout of the funnel plot. Smaller trials provide less precise estimates, and the increased variability results in a wider cone of the funnel plot. A gap in the funnel plot (commonly, the absence of small studies with negative findings) suggests potential publication bias or methodological problems in smaller studies. Begg's test was also used to assess potential publication bias<sup>[33,34]</sup>.

## STUDY CHARACTERISTICS PREDICTIVE OF POSITIVE FINDINGS

Because there was heterogeneity across studies, we examined study design characteristics that we hypothesized could be associated with results favoring probiotics over placebo. These analyses examined results for the primary outcome variable, reduction in global IBS symptoms. We classified studies as favoring probiotics if the unpooled RR was 0.67 or less. The study by Whorwell *et al* included 3 different probiotic dose arms but was considered as a single study for the purposes of this analysis<sup>[35]</sup>. Since one of the 3 arms showed results favoring probiotic, we classified this study as favoring probiotics. Characteristics examined as possible predictors included sample size, LIVS quality score, proportion of female subjects, probiotic dose, treatment duration, attrition > 20%, ITT analysis and use of a proprietary (commercial) *vs* nonproprietary product. To explore possible predictive variables, we first examined descriptive statistics (median and interquartile range for continuous variables, proportions for categorical variables). To test for statistical significance, we used the Wilcoxon rank-sum test for continuous data and Fisher's exact test for categorical data.

**Figure 1** QUOROM flow diagram of included and excluded studies of probiotics for the treatment of Irritable Bowel Syndrome.

## LITERATURE SCREENING

The literature search yielded 3552 citations on probiotics, of which 789 addressed probiotics and IBS. Based on review of abstracts, 115 were selected for detailed screening.

## STUDY SELECTION

The study selection process is shown in a QUOROM (Quality of Reporting of Meta-analysis) flow diagram (Figure 1)<sup>[27]</sup>. Overall, 95 studies that were screened failed to meet 1 or more of the inclusion criteria: 63 (66%) were reviews, 13 (14%) were pre-clinical studies, 6 (6%) had no control group<sup>[36-41]</sup>, 3 (3%) were not randomized<sup>[42-44]</sup>, and 10 (10%) were excluded for a variety of reasons. A total of 20 articles met inclusion criteria and provided data on 23 probiotic treatment arms for 1404 patients with IBS (Table 1)<sup>[17,35,45-62]</sup>. An additional seven trials were excluded after article retrieval and screening for issues related to quality and/or study design (Table 2)<sup>[63-68]</sup>.

## STUDY QUALITY

The study quality of 23 treatments was assessed, and 20 trials with LIVS quality scores > 3.0 were included (Table 3). The median quality score was 4 (range 3 to 6). Nine studies did not describe the method of randomization, 8 did not provide baseline comparison of groups, 14 did not specifically state that evaluators were blinded and 20 did not perform intention-to-treat analysis and/or did not fully describe withdrawals. For six studies, the published article or abstract did not contain sufficient information to allow quality scoring, requiring communication with the authors. Only three studies (15%) clearly documented their adherence to intention-to-treat principles<sup>[45,50,60]</sup>.

There were a variety of ways in which studies failed to

Table 1 Description of 20 randomized, controlled trials of probiotics for IBS included in systematic review

Reference	Probiotic	Type of control	Number of subjects randomized	Number analyzed	Dose (cfu/d)	Duration of treatment (wk)	% attrition

Moon <sup>[68]</sup>	<i>Bacillus subtilis</i> + <i>St. faecium</i>	34	34	750 mL/d, cfu/d not given	4 wk	Outcome data not provided for each group in abstract

cfu/mL: Colony forming units per milliliter; IBS: Irritable bowel syndrome; *L.*: *Lactobacillus*; *Bifido.*: *Bifidobacterium*.

adhere to ITT principles. Seven studies excluded participants who used prohibited/non-study medications, including antibiotics, during the treatment phase<sup>[17,46,48,49,51,55,59]</sup>, while five studies excluded subjects who demonstrated poor compliance with study medications<sup>[47,52,54,56,61]</sup>. Three studies reported that subjects either dropped out or were excluded due to inadequate response to treatment<sup>[49,58,62]</sup>, while in 4 studies, subjects were excluded for worsening abdominal pain<sup>[51,52,54,56]</sup>. Often, it was unclear whether subjects with inadequate response or worsening symptoms were excluded

at the investigators' discretion or withdrew from the study of their own accord.

## DESCRIPTION OF INCLUDED STUDIES

A standardized data extraction table (Table 1) was used to characterize each clinical trial. Twenty randomized controlled trials provided adequate data regarding efficacy in a total of 1404 patients with IBS. In 20 trials, 23 probiotic treatment arms were compared to placebo control arms.

<sup>1</sup>Linde Internal Validity Scale score is based on columns 3-8; range, 0 (poor) to 6 (excellent). (Linde 1996)<sup>[29]</sup>; <sup>2</sup>Indicates whether additional contact with authors was required to obtain information needed for quality scoring; <sup>3</sup>Data from published meeting abstract only.

**Figure 2** Number of randomized patients in 20 randomized, controlled clinical trials of probiotics for the treatment of Irritable Bowel Syndrome.

Eighteen studies compared a single probiotic treatment arm to placebo, one study compared two probiotic treatments to placebo<sup>[17]</sup>, and one study compared three doses of one probiotic against placebo<sup>[35]</sup>. The number of patients in each of these studies was generally small, with a median of 54 randomized subjects (range, 25-363; Figure 2). The daily dose of probiotic treatment ranged from 450 to  $1 \times 10^{12}$  colony-forming units (cfu)/day (median =  $9 \times 10^9$ ). For the most part, the length of treatment in these studies was brief (median = 4 wk), with 90% of studies having a treatment phase of 8 wk or less.

## PROBIOTIC STRAIN

Only two probiotics were tested in multiple trials: *Lactobacillus rhamnosus* GG in three trials<sup>[49,52,60]</sup> and *Bifidobacterium infantis* in two trials<sup>[17,35]</sup>. None of the *L. rhamnosus* GG trials provided evaluable data on either the primary or secondary outcomes, which prevented analysis by strain type.

## ASSESSMENT AND REPORTING OF OUTCOMES

The outcomes assessed and reported varied widely across the 20 studies. The effect on global IBS symptoms (measured as either proportion with symptom improvement or a reduction in severity scores) was reported in 15/20 (75%) of studies (Table 4) and was the primary outcome for 7 (35%) of studies. Effects on abdominal pain were reported by all studies. But, only 4 (20%) used this as a primary outcome measure<sup>[35,50,52,60]</sup>.

Other symptoms were less consistently assessed (e.g. flatulence, 13/20 studies; mucus in stool, 3/20 studies; bloating, 15/20 studies). Only five studies collected some measure of quality of life<sup>[17,54,56,61,62]</sup>. Seven studies reported data for 3 or more symptoms or outcomes without specifying a primary outcome<sup>[17,46,48,49,53,54,56]</sup>.

Some studies reported the number and proportion of subjects with improvement, while others reported change in numeric symptom scores since baseline. The scales used to measure the severity of IBS symptoms varied widely between studies, making it challenging to compare results across studies. Visual analogue scales were most often used, but still only used by 6 studies<sup>[17,46,48,51,55,57]</sup>. Likert scales were used by 3 studies<sup>[17,49,52]</sup>, and specific validated scales were used by several studies: Gastrointestinal Symptom Rating Scale (GSRS)<sup>[52,58]</sup> and IBS Severity Scoring System (IBS-SSS)<sup>[56,58,62]</sup>. Several studies used their own study-specific scale or scoring system<sup>[17,35,45,47,50,53,54,59-61]</sup>. Often it was unclear whether this scale had been validated.

While many studies assessed a wide range of IBS symptoms, few reported detailed results across the spectrum of symptoms (Table 4), making it more difficult to combine data across studies. For instance, only 8 of 13 studies reporting that they had collected data on flatulence

Table 4 Outcome assessment and reporting for 20 included clinical trials of probiotics for IBS

<sup>1</sup>Unless otherwise stated, all primary outcomes are defined based on patient report. <sup>2</sup>VSL#3 is a mixture of 8 probiotic strains (*Lactobacillus casei*, *L. plantarum*, *L. acidophilus*, *L. bulgaricus*, *Bifidobacterium longum*, *Bifidobacterium breve*, *Bifidobacterium infantis* and *Streptococcus thermophilus*).

provided this data in their paper and only 5 of 15 reporting they had collected data on stool frequency reported any such data in their paper.

## GLOBAL RESPONDERS

The primary outcome selected for this analysis was the proportion of patients in each group with global IBS symptoms by the end of treatment, with 'responders'

being a dichotomous variable defined by study investigators (Table 5). Of the 23 treatment arms, 14 (61%) had evaluable data for this outcome. Eight treatment arms either did not collect data on global symptom relief<sup>[49,52,55,60]</sup> or reported change in symptom scores rather than proportion with improvement<sup>[17,53,56,57]</sup>.

When the meta-analysis model was fitted, the  $\chi^2$  test for heterogeneity was 41.0 ( $P < 0.001$ ), indicating a high degree of heterogeneity; so a random-effects model was used to

**Figure 3** Forest Plot of randomized controlled trials of 14 treatment arms from 12 studies measuring relative risk of IBS symptoms after probiotic treatment compared to placebo. X-axis is relative risk, with black dot indicating the relative risk, line indicating 95% confidence interval and the size of the grey box proportional to sample size.

**Figure 4** Funnel plots of randomized controlled trials for examining presence of IBS symptoms with probiotic or placebo treatments. RR: Relative risk of global IBS symptoms; s.e. of RR: Standard error of relative risk, an indicator of sample size.

pool these results. The forest plot, weighted on sample size, is shown in Figure 3. Compared to placebo, probiotics were significantly protective (less global IBS symptoms compared to placebo at the end of the study) [pooled relative risk ( $RR_{pooled}$ ) = 0.77; 95% confidence interval (95% CI), 0.62-0.94]. The number needed to treat was 7.3. The funnel plot (Figure 4) is generally symmetrical, showing little evidence of publication bias. Begg's test did not show statistically significant publication bias ( $z = 0.93$ ,  $P = 0.35$ ).

## SENSITIVITY ANALYSES

We repeated the meta-analysis weighting by study quality score rather than sample size, with similar results ( $RR_{pooled} = 0.65$ ; 95% CI, 0.52-0.82). As it appeared that the pooled risk estimate was heavily influenced by one large study<sup>[59]</sup>, we re-ran the analysis excluding the study, but similar results were found ( $RR_{pooled} = 0.82$ ; 95% CI, 0.67-0.99).

## SECONDARY OUTCOMES

*A priori* secondary outcomes for this study included

the proportion of subjects who reported one of three IBS symptoms: abdominal pain, bloating/distension, or flatulence (gas). Of 23 treatment arms, 12 (52%) had evaluable data on at least one of these secondary outcomes. Fourteen treatment arms either did not collect data on these secondary outcomes<sup>[45,47,51,58,61,62]</sup> or reported symptom scores rather than proportion with symptoms<sup>[17,53,56,57]</sup>. As only five treatment arms reported proportion of subjects with reduced bloating<sup>[46,49,52,54,55]</sup> and four reported proportion with improved flatulence<sup>[46,48,50,54]</sup>, further statistical analyses were not performed for these outcomes.

Eight trials (11 probiotic treatment arms) had evaluable data for the proportion of patients reporting abdominal pain at the end of follow-up (Table 6)<sup>[35,46,48-50,52,54,59,60]</sup>. There was a high degree of heterogeneity ( $\chi^2 = 36.6$ ,  $P < 0.001$ ), and so a random-effects model was used. The forest plot, weighted on sample size, is shown in Figure 5. Compared to placebo, probiotics were associated with less risk of abdominal pain ( $RR_{pooled} = 0.78$ ; 95% CI, 0.69-0.88). The number needed to treat was 8.9. The funnel plot was generally symmetrical, showing little evidence of publication bias, and Begg's test did not show statistically significant publication bias ( $z = -0.70$ ,  $P = 0.48$ ). The pooled relative risk for abdominal pain was similar when weighted by study quality ( $RR_{pooled} = 0.61$ ; 95% CI, 0.45-0.81) and after exclusion of the two trials conducted in children ( $RR_{pooled} = 0.77$ ; 95% CI, 0.68-0.88)<sup>[52,60]</sup>.

## STUDY CHARACTERISTICS PREDICTING POSITIVE RESULTS

We compared the characteristics of six studies that favored probiotics over placebo (study  $RR < 0.67$  for improvement in global IBS symptoms)<sup>[35,46,48,50,54,59]</sup> with six studies showing a weak effect or no benefit<sup>[45,47,51,58,61,62]</sup>. Studies with a stronger probiotic effect were larger than those showing weak or no effect (median 80.5 subjects *vs* 50 subjects,  $P = 0.20$ ) and had shorter duration of treatment (median 4 wk *vs* 6 wk,  $P = 0.60$ ). but, these

Table 6 Relief of abdominal pain in 11 probiotic/placebo treatment arms

Gawronska <sup>[60]</sup>	<i>Lacto rhamnosus</i> GG	6/18 (33)	1/19 (5)	Absence of pain

<sup>1</sup>All secondary outcomes are defined based on patient report.

**Figure 5** Forest plot of randomized controlled trials of 12 treatment arms from 10 studies measuring relative risk of abdominal pain after treatment with a probiotic compared to placebo. The X-axis depicts relative risk, with black dot indicating the relative risk, line indicating 95% CI and the size of the grey box proportional to sample size.

differences were not statistically significant. Two-thirds of studies showing strong protective effects used proprietary (commercial) products, compared to 100% of those showing weak or no effect ( $P = 0.46$ ). In bivariate analyses, no characteristics differed significantly between the two types of studies.

## ADVERSE EVENTS

Most studies (17/20, 85%) provided only minimal information about adverse events. Fourteen studies (70%) stated that no serious adverse reactions were noted, but failed to provide any information on how adverse events were ascertained or what types of reactions were considered. Three (15%) of the trials did provide limited data on adverse reactions, including reactions such as “increased intestinal symptoms”, “epistaxis”, “aftertaste”, “anxiety” and “angina”, but did not report rates of adverse reactions by treatment group<sup>[17,49,54]</sup>. Three trials (15%) did not report any safety data<sup>[47,58,59]</sup>.

We identified 20 clinical trials that met inclusion criteria

and provided relevant information about the efficacy of probiotics for IBS symptoms. These trials included 23 probiotic treatment arms and 1404 subjects. Trials were generally small and of short duration and had moderate quality. But, the majority did not follow intention-to-treat principles. Overall, probiotic use was associated with less likelihood of global IBS symptoms compared to placebo (RR = 0.77; 95% CI, 0.62-0.94) and with abdominal pain by the end of follow-up (RR = 0.78; 95% CI, 0.69-0.88). There was not sufficient data to examine other individual IBS symptoms or the efficacy of individual probiotic strains.

## STRENGTHS AND LIMITATIONS

We performed a comprehensive review of the literature and made an effort to minimize publication bias by including recent studies as well as those published only as meeting abstracts. Validated quality scoring and data extraction were performed by two reviewers independently, using standardized templates, and differences were resolved by

discussion. We excluded studies of poor quality, limiting the impact of serious study design flaws. We selected a primary outcome (global improvement in IBS symptoms) that is clinically relevant and of great concern to IBS patients, as is also true for our secondary outcome (relief of abdominal pain). Communication with study authors was a productive tool for obtaining data not reported in detail in some studies.

Our findings should be interpreted with caution due to important limitations of the existing literature. Two important limitations in the existing trials included the lack of ITT analysis and the presence of heterogeneity in both outcome assessment and study design. A crucial issue is the quality of included studies, with only 3 of 20 studies performing true intention-to-treat analyses. In many studies, participants were excluded from final analyses for reasons such as noncompliance, failure to respond to treatment, or use of prohibited medications. It is difficult to predict how these exclusions may have affected results. But, it is certainly possible that substantial bias could have been introduced, which could account for the apparent beneficial effects observed when data were pooled across studies. Missing values may cause both systematic and unpredictable bias in controlled trial results<sup>[69-71]</sup>. A recent meta-analysis of chondroitin for osteoarthritis found that small trials and those not analyzed according to ITT principles were more likely to report benefits from chondroitin, while larger studies with greater methodological rigor did not find an effect<sup>[72]</sup>. Larger studies utilizing ITT have not been performed to examine probiotics as potential therapy for IBS.

Heterogeneity was another important limitation of the published literature, including heterogeneity in the strain and dose of probiotic (which prevented analysis of effects of specific strains); sample size (smaller studies resulted in low power to detect effects in individual studies); duration of treatment and follow-up (short trials do not allow adequate follow-up given the chronic relapsing nature of IBS); and in the assessment and reporting of outcomes. All these sources of heterogeneity made it difficult to combine data from all twenty studies. Another important problem is the lack of systematic data collection and reporting about adverse effects. As a result, it is difficult to be sure that the probiotics studied have been adequately evaluated for safety.

## COMPARISON WITH OTHER SYSTEMATIC REVIEWS

To date, no other meta-analysis of probiotics for IBS has been published. Recent published reviews of probiotics for IBS included fewer studies (range, 4 to 12) and focused primarily on evaluating the rationale and potential mechanisms for probiotics as treatment for IBS<sup>[9,13,73]</sup>. No prior reviews have attempted to calculate a pooled estimate of efficacy, and few reviews provided a detailed summary of individual studies' outcome data or unpooled risk estimates.

## IMPLICATIONS FOR FUTURE RESEARCH

This review highlights important considerations for the design of future studies of probiotics as a potential

**Table 7 Recommendations for future research studies examining probiotics as a treatment for irritable bowel syndrome**

### Recommendations

- More trials testing the same probiotic strain
- Larger sample size
- Longer duration of treatment and follow-up
- Intention to treat analysis:
  - All participants analyzed with the group to which they were originally assigned, regardless of compliance with treatment, response to treatment, or use of prohibited (non-study) medications.
- Greater efforts to minimize loss to follow-up
- Standardized assessment of IBS outcomes
  - Provide some assessment of global relief of IBS symptoms
  - Detailed collection and reporting of data on potential adverse reactions

treatment for IBS (Table 7). There is a need for standardized outcome assessments and larger studies, preferably with longer duration of treatment and follow-up. Future studies should make every effort to minimize loss-to-follow-up and to adhere to ITT principles, analyzing all subjects with the group to which they were originally assigned, notwithstanding potential noncompliance with treatment or the use of other (non-study) medications. Following these methodological principles will provide greater assurance that results are not due to bias. Future studies would benefit from better standardization of outcomes to be studied, including the use of uniform symptom scales. We recommend that future studies examine overall relief of IBS symptoms as an outcome. Although many prior studies primarily reported symptom scores, a statistically significant reduction in symptom score may not be meaningful to an individual patient suffering from IBS. Bijkerk *et al* examined the validity of 10 methods to assess IBS response and found a single question asking about 'adequate relief of IBS-related symptoms' was as valid as more detailed questionnaires on outcome<sup>[74]</sup>. In order to determine if one probiotic strain is more effective for IBS than others, confirmatory trials with the same probiotic strains are required.

Finally, it is important that future studies systematically assess potential adverse effects and provide detailed results, including rates of adverse effects in the treatment and placebo groups.

## IMPLICATIONS FOR CLINICAL PRACTICE

While our findings provide preliminary evidence that probiotics may be useful in treating IBS, it is too soon to recommend their use in clinical practice. The pooled relative risks reported here are based on studies with significant methodological limitations, and bias cannot be ruled out as the explanation for these positive findings. Since we did not find any evidence of significant adverse effects from these treatments, and given the lack of available conventional treatments, clinicians should strongly consider discussing the evidence of benefits and risks of probiotics with their patients with IBS. Although the costs of probiotics vary widely, the cost may be similar to other over-the-counter remedies for IBS (such as loperamide).

An important consideration is the lack of regulation of the commercial probiotic products that are currently available. No universal quality assurance programs exist to ensure that commercial products contain the probiotic strain and concentration that are claimed, or to ensure the absence of contamination that could pose risks to consumers. Some resources are available to provide further information about product testing; for example, ConsumerLab is an independent company in the U.S. that tests commercially available health and nutrition products and publishes data about the contents of various commercial products, including the presence of contaminants (<http://www.consumerlab.com>). They also offer a voluntary certification program. In the summer of 2007, the Food and Drug Administration issued new rules regarding good manufacturing practices for supplement manufacturers, aimed at ensuring more uniform quality of supplements. It remains to be seen whether these new rules will substantially improve the quality and safety of nutritional supplements.

## CONCLUSION

In summary, the present meta-analysis suggests that probiotics offer promise for the treatment of IBS. Results should be interpreted cautiously given the methodological limitations of published studies. Future studies are needed, in particular larger studies of longer duration with greater methodological rigor. In addition, more data are needed regarding which specific strains and doses are most likely to be effective. The use of probiotics for IBS warrants further study, particularly given the chronic nature of this condition, its major impact on patients' quality of life, and the dearth of other effective treatments.

## Abstract

Both ulcerative colitis and Crohn's disease carry an increased risk of developing colorectal cancer. Established risk factors for cancer among patients with inflammatory bowel disease (IBD) include the younger age at diagnosis, greater extent and duration of disease, increased severity of inflammation, family history of colorectal cancer and coexisting primary sclerosing cholangitis. Recent evidence suggests that current medical therapies and surgical techniques for inflammatory bowel disease may be reducing the incidence of this complication. Nonetheless heightened vigilance and a careful, comprehensive approach to prevent or minimize the complications of invasive cancer are warranted in this unique cohort of patients. Current guidelines for the prevention and early detection of cancer in this high risk population are grounded in the concept of an inflammation-dysplasia-carcinoma sequence. A thorough understanding of the definition and natural history of dysplasia in IBD, as well as the challenges associated with detection and interpretation of dysplasia are fundamental to developing an effective strategy for surveillance and prevention, and understanding the limitations of the current approach to prevention. This article reviews the current consensus guidelines for screening and surveillance of cancer in IBD, as well as presenting the evidence and rationale for chemoprevention of cancer and a discussion of emerging technologies for the detection of dysplasia.

## INTRODUCTION

Patients with inflammatory bowel disease (IBD) have an increased risk of developing intestinal cancer. The magnitude of that increased risk as well as how best to mitigate it remain a topic of ongoing investigation in the field. Although only 1% of all cases of colorectal cancer (CRC) occur in patients with ulcerative colitis (UC) or Crohn's disease<sup>[1]</sup>, patients with IBD represent one of the highest risk groups for developing this dreaded complication. Strategies to reduce or prevent the complications associated with invasive cancer are essential in this high-risk population. Current guidelines advocate routine surveillance colonoscopy as the cornerstone of prevention. For patients in whom precancerous dysplastic lesions or early cancer are detected, surgical removal of the colon can be a potentially curative procedure for both the cancer and the colitis. This secondary prevention strategy has several drawbacks, however. Colonoscopy is less sensitive for detecting precancerous dysplasia in IBD patients than in the general population. Unlike in sporadic CRC in which dysplastic adenomas begin as raised polypoid lesions, dysplasia in IBD can arise in mucosa that is indistinct from surrounding mucosa, making it "invisible" to the endoscopist. Consequently many lesions may be missed. Additionally, the molecular biology of cancer in IBD is unique in that the accumulation of molecular and genetic alterations may occur more rapidly or in an unconventional sequence when compared to sporadic CRC. Given the limitations of the current surveillance approach, primary cancer prevention via chemoprevention has been proposed as an alternative or additive strategy. Although such a prospect would be ideal, the effectiveness of medications to mitigate cancer risk in IBD has not been firmly established. Further research is directed toward improving detection of dysplasia during colonoscopy through the use of novel endoscopic imaging techniques.

These exciting and promising developments are hoped to impact the approach to cancer prevention in patients with IBD. This article reviews the epidemiology of cancer and dysplasia in IBD, as well as the evidence and rationale behind consensus guidelines for screening and surveillance.

## EPIDEMIOLOGY OF CANCER IN ULCERATIVE COLITIS

The increased risk of colorectal cancer in UC has been recognized for decades, although estimates of the magnitude of that risk vary considerably in the literature. Some authors have described a cumulative probability as high as 60% for developing cancer after 40 years of disease<sup>[2]</sup>, while others have demonstrated a risk level on par with that of the general population<sup>[3]</sup>. Several reasons have been proposed to explain these discrepant results, including a lack of uniformity in study design and case definitions, geographic differences in incidence based on environmental factors, and referral center bias. In an effort to bring clarity to this issue, Eaden and colleagues performed a meta-analysis in 2001 in which they reviewed 116 studies (41 of which were included in the analysis), encompassing 54478 patients with UC and 1698 cases of CRC, to yield an overall prevalence of CRC in UC of 3.7%<sup>[4]</sup>. By pooling the results of the studies that reported data on duration of disease by decade the authors were able to calculate a cumulative probability of CRC in UC of 2% after 10 years, 8% after 20 years, and 18% after 30 years of disease. Since this landmark publication, however, several more recent population-based and referral-based studies suggest that this risk may be declining over time or may simply be lower than previously accepted. Bernstein *et al* conducted a large population-based study in Manitoba, Canada, including 19655 person years of follow-up in which they described an increased incidence rate ratio for developing CRC of 2.75 [95% confidence interval (95% CI), 1.91-3.97] compared to the general population<sup>[5]</sup>. This estimate of risk is approximately half that reported in the Eaden meta-analysis. These results were replicated in a population-based study in Hungary where the cumulative incidence of CRC was found to be 0.6% after 10 years, 5.4% after 20 years, and 7.5% after 30 years of chronic UC<sup>[6]</sup>. A small population study from Olmsted County in the United States followed 378 patients diagnosed with UC between 1940 and 2001<sup>[7]</sup>. Only 6 cases of CRC were discovered in 5567 person-years of follow-up, yielding a 30-year cumulative probability of CRC in this cohort of only 2%, not significantly different from the non-IBD patients in this population cohort. Interestingly, no cases of CRC were discovered in patients whose UC was diagnosed after 1980. Although the number of patients in this study was relatively small, these results were reinforced by a much larger study in Denmark involving 22290 person-years of follow-up that demonstrated no increase in CRC risk among UC patients<sup>[3]</sup>. The 30-year cumulative probability of CRC was only 2.1% among UC patients in this population. This declining trend in CRC incidence among UC patients holds true at referral centers as well. In 2006, Rutter and colleagues from St. Mark's Hospital in the

United Kingdom reported on their 30 year experience with the longest prospectively collected database on surveillance for dysplasia and cancer in UC<sup>[8]</sup>. The cumulative incidence of CRC in this referral population was 2.5% at 20 years, 7.6% at 30 years and 10.8% after 40 years of disease. The reasons for this observed change in incidence may be the more widespread use of surveillance colonoscopy, a chemoprotective effect attributable to the more widespread use of maintenance therapies, more aggressive surgical intervention or dietary or environmental factors. Despite the encouraging finding that CRC in UC appears to be less common than previously believed, one should take caution in interpreting the results of these more recent studies as evidence to relax the practice of routine screening and surveillance. Rather these results may indicate that a comprehensive approach to screening, surveillance and control of disease inflammation is highly effective and that physicians should maintain an appropriate level of vigilance in this high-risk patient population<sup>[9]</sup>.

## RISK FACTORS FOR CRC IN ULCERATIVE COLITIS

Several factors have been identified that increase the risk of CRC in patients with UC. The observation that cumulative cancer risk increases over time<sup>[4,10]</sup> establishes that increasing duration of disease is an important risk factor. Consistent with an intuitive understanding of CRC risk as being associated with the cumulative effect of chronic inflammation, the extent of colon involvement in UC is an independent predictor of cancer risk<sup>[10]</sup>. A Swedish study reported that the relative risk of CRC was 1.7 for ulcerative proctitis, whereas the risk in left-sided colitis was 2.8 and this risk rose to 14.8 in patients with extensive colitis<sup>[10]</sup>.

Until relatively recently there was no hard evidence to support the intuitive notion that the degree of inflammation correlates with cancer risk. This may in part be due to the difficulty of demonstrating an independent effect of inflammatory activity while controlling for duration and extent of disease, two factors that are surrogate measures of cumulative inflammation. Three recent studies have confirmed this association, however. In a retrospective analysis from the St. Mark's Hospital in the UK, Rutter and colleagues demonstrated that severity of inflammation on biopsy independently predicted risk of CRC<sup>[11]</sup>. This finding was reinforced by studies from the University of Chicago and Mt. Sinai Medical Center in New York in which inflammatory activity was shown to be independently associated with CRC risk<sup>[12,13]</sup>. In several studies, a younger age at diagnosis is also associated with an elevated risk of CRC, independent of disease duration<sup>[10]</sup>. Although the reason for this association is not known, it may in part be related to the finding that patients with an early age of diagnosis tend to have more severe inflammation<sup>[11]</sup>. Several studies have demonstrated that a family history of CRC, independent of a family history of IBD is associated with higher risk of developing cancer<sup>[14-17]</sup>. Additionally, coexistent primary sclerosing cholangitis (PSC) confers an elevated risk of CRC in UC

patients, with a meta-analysis by Soetikno *et al* describing an odds ratio of 4.09 (95% CI, 2.89-5.76) when compared to UC patients without PSC<sup>[18]</sup>. This finding has led to the recommendation of closer surveillance in this unique high-risk subset of UC patients. The reason for elevated CRC risk in PSC may be that PSC is a marker for longstanding subclinical disease<sup>[19]</sup>. However, the finding that treatment with ursodeoxycholic acid (UDCA) can lessen CRC risk suggests that the altered bile acid milieu of PSC may play a role in carcinogenesis<sup>[20,21]</sup>. Additionally, one study has demonstrated that backwash ileitis may be an independent predictor of increased CRC risk<sup>[22]</sup>. The finding of a stricture or dysplasia during colonoscopy also carries a heightened risk of malignancy<sup>[23,24]</sup>.

Thus, cancer risk in UC appears to result from the combined effects of chronic inflammation (as estimated by the extent and duration of disease and the degree of histologic inflammation) and an individual's underlying genetic predisposition (as suggested by family history, coexistent PSC and early age of diagnosis). Unfortunately, severity of inflammation appears to be the only modifiable risk factor, underscoring the importance of medical management in mitigating cancer risk, and highlighting the need for a preventive approach to cancer and pre-cancer detection.

## CANCER IN CROHN'S DISEASE

While the relationship between UC and CRC has been appreciated for many years, the association between Crohn's disease and CRC has gained increasing recognition recently. Measuring the risk of CRC in Crohn's disease poses several methodological challenges, relating to the heterogeneous nature of the disease, with many patients having no colonic involvement. Even among patients with Crohn's colitis it is difficult to control for the extent of colonic inflammation, given that the disease can involve any area of the colon in a patchy distribution, and many Crohn's patients have undergone partial surgical resection of the colon, removing some of the at-risk tissue. Consequently, there is substantial variation among the articles that attempt to quantify the risk of CRC in Crohn's, in terms of both study design and results.

Several publications offer estimates of CRC risk in colonic Crohn's disease. Gyde and colleagues reported the relative risk of CRC in Crohn's colitis to be 23.8, whereas the risk was 4.3 in the general Crohn's population<sup>[25]</sup>. Greenstein and colleagues calculated a relative risk of 6.9 for developing CRC in isolated colonic Crohn's<sup>[26]</sup>. A landmark study from Sweden demonstrated a relative risk of CRC of 5.6 for those with exclusively colonic involvement, as compared to a relative risk of 3.2 for patients with ileocolitis and 1.0 for patients with ileal involvement only<sup>[27]</sup>. This not only established that Crohn's carries a higher risk of CRC, but also that this risk correlates with the extent of colonic involvement. Additionally, a subset analysis revealed that patients whose IBD was diagnosed prior to age 30 had a higher relative risk than patients diagnosed at an older age, similar to patients with ulcerative colitis.

A meta-analysis of twelve hospital-based and population-

based studies of CRC risk in Crohn's disease revealed an overall relative risk of CRC in all Crohn's patients of 2.5 (95% CI, 1.3-4.7)<sup>[28]</sup>. In the subset of patients with colonic disease this risk rose to 4.5 (95% CI, 1.3-14.9), while for patients with ileal disease only the risk was not significantly different from the general population. The cumulative risk of CRC for all patients with Crohn's disease, regardless of disease distribution, was 2.9% after 10 years, 5.6% after 20 years and 8.3% after 30 years of disease. In contrast to the Canavan meta-analysis that included population and referral-based studies, Jess *et al* performed a meta-analysis restricted to population studies of intestinal cancer risk in Crohn's<sup>[29]</sup>. Six papers met the inclusion criteria and reported varying estimates of relative risk of CRC ranging from 0.9 to 2.2, with a pooled estimate of 1.9 (95% CI, 1.4-2.5).

The risk of CRC risk in Crohn's is equivalent to that in UC when comparison is controlled for similar extent of disease. In a study by Gillen and colleagues from the UK, patients with extensive Crohn's colitis were compared to patients with extensive ulcerative colitis with regard to CRC risk<sup>[30]</sup>. The results were astonishingly similar with a relative risk of developing CRC of 18 for Crohn's colitis and 19 for UC. The cumulative risk of CRC was 8% at 22 years for patients with Crohn's versus 7% at 22 years for patients with UC. A large population-based study in Canada demonstrated increased incidence rate ratio of CRC in Crohn's patients of 2.64 (95% CI, 1.69-4.12) compared to the general population<sup>[5]</sup>. This was remarkably similar to the risk of CRC in UC patients in the same study, reinforcing the finding that Crohn's and UC share a similar risk of CRC. In addition to a similar magnitude of risk, Crohn's patients share many of the same risk factors for CRC as UC patients, including younger age at diagnosis, greater extent of colonic involvement and longer duration of disease. In addition it appears that bypassed segments of bowel<sup>[31]</sup> and perianal fistulae<sup>[32]</sup> in Crohn's disease may also be sites at increased risk for neoplastic transformation and warrant heightened vigilance. Furthermore, bowel strictures in Crohn's disease may harbor dysplasia or cancer<sup>[33]</sup> and should be carefully biopsied and resected if a pediatric or upper endoscope cannot traverse them. Different from UC, however, is that benign strictures are considered a possible manifestation of the disease so may not need resection otherwise.

While it is technically difficult to determine the exact risk of CRC in Crohn's disease, it is generally accepted that patients with Crohn's disease of the colon are at increased risk for dysplasia and CRC, and that this risk is related to cumulative effect of colonic inflammation, akin to UC. With the exception of strictures as described above, screening and surveillance of CRC in patients with Crohn's should be handled identically to patients with UC, matched for extent of colonic involvement.

## DYSPLASIA IN INFLAMMATORY BOWEL DISEASE

The current approach to surveillance is grounded in the concept of an inflammation-dysplasia-carcinoma sequence, with dysplasia representing a premalignant

phase during which intervention can prevent or minimize the complications associated with invasive cancer. An understanding of the definition, diagnostic challenges and natural history of dysplasia in IBD is, therefore, essential when contemplating complex clinical management decisions.

Dysplasia is defined as unequivocal neoplasia of the epithelium confined to the basement membrane, without invasion into the lamina propria<sup>[34]</sup>. Dysplasia can be classified as raised or flat based on its endoscopic appearance. Flat dysplasia is classically thought to be endoscopically invisible and is detected only on random biopsy specimens. At least 2 authors, however, have demonstrated that many of these lesions are in fact visible through standard white light endoscopy using newer generation colonoscopes with higher optical resolution<sup>[35,36]</sup>. Elevated lesions that are endoscopically visible, but not amenable to endoscopic resection are often referred to as DALMs (dysplasia associated lesion or mass) a term with ominous connotation attributable to the high rate of synchronous malignancy associated with these lesions<sup>[24,37]</sup>. A newer term ALM (adenoma-like lesion or mass) has been introduced to describe the finding of a polypoid lesion resembling a sporadic adenoma that is found in an area of the colon not involved by chronic colitis. Irrespective of the endoscopic appearance of a lesion as raised or flat, pathologists use the same set of criteria to describe the histologic appearance of dysplasia in IBD. A standardized classification system introduced by Riddell and colleagues in 1983 divides dysplasia into categories, including indefinite dysplasia, low grade dysplasia (LGD), high grade dysplasia (HGD) and cancer<sup>[34]</sup>. Although this system remains widely employed, it has several acknowledged limitations, including poor inter-observer agreement and intra-observer reliability, even among expert gastrointestinal pathologists<sup>[34,38]</sup>. This lack of concordance of biopsy interpretations has led to the routine practice of requiring confirmation of a dysplasia diagnosis by a second expert pathologist prior to making critical treatment decisions.

Management of dysplasia, once diagnosed, relies on an understanding of the natural history. In 1994, two groups published data revealing that approximately one in 8 patients with UC will have dysplasia or cancer found on their initial screening colonoscopy, but that those with a negative initial exam have a low incidence (about 3%) of developing high grade dysplasia or cancer on subsequent surveillance colonoscopies<sup>[24,39]</sup>. Among patients with LGD who undergo immediate colectomy 19% will already harbor concurrent CRC or HGD<sup>[24]</sup> and an additional 29%-54% will subsequently develop advanced neoplasia over the next 5 years<sup>[24,39,40]</sup>. HGD carries a 43% risk of synchronous malignancy and is therefore considered to be an indication for immediate colectomy<sup>[24]</sup>. DALMs associated with a similarly high rate of CRC are likewise an indication for total proctocolectomy<sup>[24,37]</sup>. In contrast to DALMs, however, adenoma-like lesions can be safely managed by polypectomy with biopsies of the surrounding flat mucosa<sup>[41]</sup>. If the lesion is successfully removed in its entirety and the surrounding mucosa is free of dysplasia, a regimen of more frequent surveillance colonoscopy is

recommended. The finding of adjacent dysplasia in the flat mucosa prompts immediate colectomy by most experts, given the likelihood of concurrent cancer or progression to cancer.

## MOLECULAR BIOLOGY OF CANCER IN IBD

Several of the molecular alterations that contribute to sporadic CRC are also found in colitis-associated CRC, including loss of APC and p53 tumor suppressor gene function. However, the timing and sequence in which these genetic mutations occur differs from sporadic CRC. Whereas APC loss is considered an early development in the adenoma-carcinoma sequence of sporadic CRC, and p53 represents the final mutation that transforms adenoma into carcinoma, the opposite is often true in IBD-associated CRC. While the description of an inflammation-dysplasia-carcinoma sequence facilitates our understanding of the molecular alterations involved in IBD-associated CRC, it is important to recognize that this process does not necessarily occur in a systematic and sequential progression from inflammation to indefinite dysplasia to LGD to HGD and ultimately to carcinoma. Cancer can develop without any apparent preceding dysplasia, and the natural history of low grade dysplasia has been described to regress or to progress to cancer without evolving first into HGD<sup>[42]</sup>. This unpredictable course of dysplasia in IBD complicates efforts to develop molecular or histologic markers of neoplastic progression or future cancer risk. Currently our limited understanding of the molecular biology of IBD-associated cancer is not sufficient to use these markers for clinical management decisions. However, as our knowledge advances, it is possible that such markers will one day complement or supplant histologic evidence of dysplasia in assigning cancer risk in patients with IBD.

## CHEMOPREVENTION OF DYSPLASIA AND CANCER

Chemoprevention refers to the use of chemical compounds to prevent, halt, or reverse the development of cancer. One advantage of chemoprevention over the current secondary prevention strategy of routine colonoscopy is the potential to intervene early enough in the carcinogenic sequence to avoid not only cancer, but also the need for colectomy. The goal of chemoprevention should be to reduce CRC risk, allowing for less frequent surveillance exams and a reduction in the number of invasive cancers. The bulk of evidence for chemoprevention in IBD relates to the use of 5-aminosalicylates (5-ASA). Unfortunately, no prospective data exist, and retrospective studies have yielded mixed results with regard to the protective effect of 5-ASA medications. A meta-analysis by Velayos *et al* including 9 case control and cohort studies revealed a pooled odds ratio of 0.51 (95% CI, 0.38-0.69) for the development of dysplasia or cancer in patients with regular use of 5-ASA medications<sup>[43]</sup>. Given the substantial heterogeneity of individual study results, this pooled estimate signifies the most accurate estimate of the protective effect of 5-ASA.

The most compelling evidence for chemoprevention

in IBD comes from a prospective randomized placebo-controlled trial of UDCA in the high-risk subset of UC patients with coexisting PSC<sup>[20]</sup>. Compared to the placebo group, patients who received UDCA had a relative risk of 0.26 (95% CI, 0.06-0.92) for developing CRC or dysplasia. A retrospective study at the University of Washington of patients with PSC and UC corroborated these results by demonstrating a strong negative association between UDCA use and dysplasia, with an odds ratio of 0.18 ( $P = 0.005$ )<sup>[21]</sup>.

While other medications have been explored as potential chemopreventive agents, none have yielded satisfactory results. The adverse effects of corticosteroids and non-steroidal anti-inflammatory drugs preclude their long-term use for chemoprevention in IBD patients, despite some evidence to suggest a protective effect in both IBD and non-IBD patients. The use of folate for chemoprevention has sound rationale and an excellent safety profile, but inadequate evidence of a protective benefit. Likewise despite the rationale of medically controlling inflammation as a potential mechanism of cancer prevention, there are insufficient data to recommend azathioprine or 6-mercaptopurine for chemoprevention.

## SURVEILLANCE FOR DYSPLASIA AND CANCER

Periodic surveillance colonoscopy is the foundation of our current approach to cancer prevention in IBD. This strategy relies on the ability to detect CRC at a preclinical phase of dysplasia during which intervention can avert the adverse consequences of invasive cancer. Detection of dysplasia depends on the frequency and technique of surveillance colonoscopy, as well as the quality of pathologic review. Itzkowitz and Harpaz report that a typical biopsy samples less than 0.05% of the colon<sup>[44]</sup>, highlighting the potential for sampling error associated with nontargeted biopsies to look for flat dysplasia. Rubin *et al* retrospectively determined that 33 biopsies are required to detect dysplasia with 90% sensitivity, and 64 biopsies are needed to achieve 95% sensitivity<sup>[45]</sup>. Although consensus guidelines incorporate this finding and recommend 30-40 biopsies, this can be quite cumbersome to perform. Additionally, many gastroenterologists are either not fully aware of these recommendations or intentionally do not adhere to them<sup>[46,47]</sup>. Newer imaging technologies such as chromoendoscopy, magnification endoscopy and confocal laser microscopy offer the potential to enhance detection of dysplasia during surveillance colonoscopy, allowing endoscopists to take fewer high-yield biopsies of targeted abnormal mucosa.

The recommendation to perform surveillance in IBD patients comes from consensus expert opinion, supported by solid rationale and an ethical imperative to attempt prevention in an at risk population<sup>[48]</sup>. However, hard evidence of efficacy is lacking. A Cochrane review concluded that although there is no clear evidence that surveillance colonoscopy prolongs survival in IBD patients; there are data to suggest that cancers tend to be detected at an earlier stage with a correspondingly more

favorable prognosis<sup>[49]</sup>. The authors include the caveat that lead time bias may contribute substantially to these results. Additionally they conclude that indirect evidence supports surveillance as a cost-effective endeavor<sup>[49]</sup>.

A number of guidelines published over the past decade offer direction to gastroenterologists in their approach to surveillance of dysplasia and cancer in IBD<sup>[23,50-53]</sup>. An international panel of experts convened by the Crohn's and Colitis Foundation of America published consensus guidelines in 2005 suggesting that an initial screening colonoscopy be performed in all UC patients 8-10 years after onset of symptoms attributable to UC<sup>[23]</sup>. The dual purpose of this initial screening exam is to identify dysplasia or cancer, if present, as well as to evaluate for possible reclassification of disease extent. The extent of disease in a given UC patient should be considered the greatest extent of involvement documented on either gross or histologic exam at the time of diagnosis of UC or at initial screening colonoscopy. Patients with Crohn's disease should be managed in an identical manner to UC patients of comparable extent of colonic involvement. Crohn's patients with at least one third of their colon involved are considered to have extensive colitis. Those patients with left-sided or extensive colitis (UC or Crohn's) who have a negative screening examination should continue periodic surveillance at an interval of every 1 year to 2 years. In light of the increased risk imposed by coexistent PSC, annual surveillance is warranted beginning at the time of PSC diagnosis. The technique of colonoscopy should involve 4 quadrant random biopsies at 10 cm increments throughout the colon in addition to targeted biopsies of suspiciously abnormal mucosa. All abnormal biopsies results should be confirmed through independent review by a second pathologist. A finding of indefinite dysplasia should prompt accelerated surveillance with a repeat exam in 3 to 6 mo. Management of low grade dysplasia is a subject of debate among experts with no clear consensus on optimal management. In the setting of LGD, physicians should initiate an informed discussion with their patients regarding the risks and benefits of immediate surgery versus heightened colonoscopic surveillance. Prophylactic colectomy should be offered due to the about 20% prevalence of concurrent malignancy<sup>[8]</sup>, with counseling about possible surgical complications including incontinence, adhesions, pouchitis and decreased fertility in female patients. Patients who elect nonoperative management should be informed regarding the drawbacks of surveillance, including limitations with endoscopic detection and sampling and challenges with histologic interpretation. An accelerated program of surveillance colonoscopy every 6 mo should be pursued with adherence to an extensive biopsy protocol.

The finding of high grade dysplasia should prompt referral for immediate total proctocolectomy attributable to the high rate of concurrent or subsequent malignancy<sup>[24]</sup>. Raised lesions found within an area of colitis should be removed, and the surrounding mucosa biopsied. If the lesion is amenable to complete endoscopic resection and the adjacent mucosa is free of dysplasia, a regimen of more frequent surveillance colonoscopy is recommended. The

finding of adjacent dysplasia in the flat mucosa warrants referral for colectomy. Raised lesions resembling adenomas that are encountered in areas free of inflammation can be handled in accordance with standard guidelines for management of sporadic adenomas<sup>[23]</sup>.

Strictures represent a unique circumstance that merits a higher degree of vigilance. Colonic strictures in UC often harbor malignancy and are considered a strong indication for surgery, even if biopsies and brushing of that area are unrevealing<sup>[23]</sup>. In Crohn's disease, colonic strictures may be followed with annual surveillance and biopsy if the lesion can be traversed with a standard pediatric colonoscope. In the setting of longstanding Crohn's disease, consideration should be given to surgical resection of a stricture due to the heightened risk of CRC<sup>[23]</sup>.

## NOVEL IMAGING TECHNIQUES

Despite improvements in optical resolution of modern endoscopes, surveillance colonoscopy has suboptimal sensitivity for detecting flat dysplasia. Consequently, a protocol of nontargeted biopsies is still advocated to detect these "invisible" lesions. This approach is time-consuming and cumbersome, however, and adherence to this regimen by physicians is poor<sup>[47]</sup>. Endoscopic techniques to improve macroscopic and microscopic visibility of dysplastic lesions are crucial to enhancing the diagnostic yield of surveillance colonoscopy and reducing the number of missed lesions. Chromoendoscopy, magnification endoscopy, narrow band imaging and confocal laser endomicroscopy are evolving technologies that hold promise in this regard.

Chromoendoscopy involves the application of dye during colonoscopy to highlight subtle mucosal changes that cannot be appreciated by standard white light imaging techniques. Indigo carmine is a contrast dye that augments subtle mucosal alterations, whereas methylene blue is an absorptive dye that is avidly taken up by normal mucosa, but does not stain areas of inflammation or dysplasia, thereby creating a contrast gradient that enhances visualization. At least 3 prospective studies have demonstrated that chromoendoscopy improves the sensitivity of detecting neoplasia in UC patients<sup>[54-56]</sup>. In addition to this improved sensitivity, chromoendoscopy offers the potential to improve specificity as well, by facilitating enhanced endoscopic characterization of lesions, thereby allowing the endoscopist to perform fewer biopsies that are more targeted. The combination of chromoendoscopy with magnification permits a detailed analysis of the mucosal architecture, and can assist gastroenterologists in differentiating benign from neoplastic lesions during colonoscopy, improving the yield of targeted biopsies<sup>[57]</sup>.

Narrow band imaging uses specialized light filters to enhance visualization of the tissue microvasculature, facilitating distinction between normal mucosa and neoplasia. Although this novel and innovative technology remains to be thoroughly evaluated in the setting of surveillance in IBD, it holds the potential to offer the same benefits as chromoendoscopy with greater ease of application.

Confocal laser endomicroscopy (CLE) enables real-time histologic evaluation of the colonic mucosa during endoscopy and can be combined with chromoendoscopy. Suspicious lesions identified through application of dye can be subsequently examined with extreme detail at the subcellular level of resolution with CLE prior to targeted biopsy. In a randomized trial in UC patients of chromoendoscopy in conjunction with CLE compared to conventional colonoscopy, the presence of neoplasia could be predicted with 94.7% sensitivity, 98.3% specificity and 97.8% accuracy<sup>[58]</sup>. In this study of 153 patients, the mean examination time was 42 min using chromoendoscopy with CLE compared with 31 min in the standard colonoscopy group. This innovative imaging technique has major implications for the future of colonoscopic surveillance in IBD.

Despite the promise and emerging information about these new techniques, factors of cost and training remain far from answered, and chromoendoscopy is not yet considered a standard of care approach to surveillance in the United States.

## CONCLUSION

Patients with UC and Crohn's disease have an increased risk of developing CRC. This risk appears to be related to the cumulative effect of chronic inflammation and correlates directly with the extent and duration of disease as well as the severity of inflammatory activity. Additional factors that further increase CRC risk in IBD patients include a younger age at diagnosis, coexistent PSC and a family history of CRC. Despite varying estimates of the magnitude of cancer risk in IBD, it remains widely accepted that patients with IBD represent a high-risk group for developing CRC in whom current therapies and surgical techniques may be affecting the incidence of this complication, so a careful approach to prevention and surveillance is still warranted. The overall approach to cancer prevention in IBD should be a comprehensive strategy, including regular follow-up visits and intensive control of disease activity through medical therapy, in concert with routine surveillance colonoscopy involving extensive biopsies. Despite several acknowledged limitations, periodic surveillance colonoscopy continues to serve as the foundation of a prevention strategy, with colectomy reserved for patients in whom dysplasia or cancer are discovered. Cancer risk reduction through regular use of chemopreventive medications remains an attractive concept, and the most compelling data is in the setting of PSC and IBD, in which UDCA offers substantial benefit. The accumulated data appears to favor 5-ASA as a chemopreventive agent, but this remains inconclusive due to the retrospective nature of these studies. Novel endoscopic imaging technologies to enhance detection of neoplasia are under investigation and hold promise for improving the yield of surveillance colonoscopy.

## Abstract

The ideal treatment strategy for Crohn's disease (CD) remains uncertain, as does the optimal endpoint of therapy. Top-down versus step-up describes two different approaches: early use of immunomodulators and biological agents in the former versus initial treatment with steroids in the latter, with escalation to immunomodulators or biological drugs in patients proven to be steroid refractory or steroid dependent. Top-down therapy has been associated with higher rates of mucosal healing. If mucosal healing proves to be associated with better long-term outcomes, such as a decreased need for hospitalization and surgery, top-down therapy may be the better approach for many patients. The main concern with the top-down approach is the toxicity of the immunomodulators and biological agents, which have been linked with infectious complications as well as an increased risk of lymphoma. It is unlikely that one strategy will be best for all patients given the underlying heterogeneity of CD presentation and severity. Ultimately, we must weigh the safety and efficacy of the therapies with the risks of the disease itself. Unfortunately our ability to risk stratify patients at diagnosis remains rudimentary. The purpose of this paper is to review the data that supports or refutes the differing treatment paradigms in CD, and to provide a rationale for an approach, termed the "accelerated step-up" approach, which attempts to balance the risks and benefits of our currently available therapies with the risk of disease related complications as we understand them in 2008.

## INTRODUCTION

Crohn's disease (CD) is an idiopathic, chronic inflammatory disorder of the intestines with no known cure. Traditionally, the principal goal of treatment has been symptom control. Upon diagnosis, patients are usually started on medications based on the severity of the presenting symptoms. Patients with mild or moderate symptoms are often started on medications such as 5-aminosalicylates (5-ASA) or antibiotics. Though the efficacy of mesalamine is limited in CD<sup>[1]</sup>, therapy with mesalamine is initiated because of its minimal toxicity and excellent safety profile. For sicker patients, physicians often initiate therapy with corticosteroids, because of their superior ability to control symptoms<sup>[2]</sup>. In this setting, the short-term toxicities of steroids are tolerated with the hope that the patient will enter a durable symptomatic remission and stop steroid therapy before any long-term steroid-related complications develop. Therapy with the immunomodulators, azathioprine (AZA) or methotrexate, or biological agents, such as infliximab or adalimumab, is reserved for patients who either fail to respond to steroids or fail to enter a steroid free remission. Despite the recognized efficacy of the immunomodulators and biological agents to both induce and maintain remission in CD<sup>[3,4]</sup>, early use of these drugs is tempered by the fear

of their complications, such as life threatening infections or malignancy. Symptom abatement with the least toxic drug regimen is the guiding principle of this type of “step-up” approach to the management of CD. However, recent studies and emerging expert opinion have begun to question these traditional treatment goals and approaches<sup>[5,6]</sup>.

Not only can medical therapies lead to symptom control, but they may actually alter the natural history of CD by reducing the rates of surgery, hospitalizations and disability. In fact, using “aggressive” therapy earlier in the disease course, i.e. immunomodulators and/or biological agents, may be the best approach to prevent irreversible damage to the bowel. Currently, this relationship between medical therapy, mucosal healing and improved clinical outcomes is being investigated. Standard “step-up” therapies fail to induce mucosal healing in many patients, and the overall morbidity, and even mortality, of Crohn’s patients may be reduced by a more timely use of immunomodulators and biological agents<sup>[6-8]</sup>. This treatment paradigm in which immunomodulators and/or biological agents are used immediately in newly diagnosed Crohn’s patients to induce a rapid remission has been labeled the “top-down” approach. Once remission has been achieved, an attempt is made to reduce the maintenance therapy to the medications with the least presumed toxicity. The more potent medications are used again if the patient flares, on an on-demand basis. However, for many patients, tapering down these therapies may not be possible, or even prudent to try. Therefore, it is unclear if a top-down approach is practical; perhaps the optimal treatment approach is actually “top and STAY PUT”.

Ultimately, we must weigh the safety and efficacy of the therapies with the risks of the disease itself. The purpose of this paper is to review the data regarding the differing treatment approaches to CD and to synthesize these data into an optimal treatment approach circa 2008.

## NATURAL HISTORY OF CD

The natural history of CD remains poor for many, if not most, patients. Symptomatic flares, leading to reduced quality of life, are inevitable for almost all patients over a ten year period<sup>[9]</sup>. Steroid use is common, often incompletely effective, and is associated with many side-effects and complications<sup>[10]</sup>. For most patients there is an inexorable progression of bowel injury culminating in the need for intestinal resection in upwards of 80% of patients during their lifetime<sup>[11,12]</sup>. Hospitalization and surgery account for the majority of the direct cost of caring for patients with CD<sup>[13,14]</sup>. Unfortunately, surgery is not curative, with endoscopic recurrence in 75% of patients at 1 year after surgery, and symptomatic recurrence in 50% of patients at 5 years<sup>[15]</sup>.

## WHAT SHOULD BE THE GOALS OF THERAPY: SYMPTOM CONTROL OR MUCOSAL HEALING?

The traditional goal of therapy in CD in the clinical setting

has been relief of symptoms, such as abdominal pain and diarrhea, with restoration of a general sense of well-being. In research studies, the CD Activity Index (CDAI) has been used to define treatment responses and remission. However, many of the factors in the CDAI are considered subjective measures of patient symptoms, and more objective therapeutic endpoints, such as mucosal healing, are being evaluated.

The major morbidity from CD is a result of uncontrolled inflammation of the intestines and perianal area, leading to ulceration. Intestinal ulceration can lead to bleeding and anemia, perforation with abscess or fistula formation, or subsequent fibrosis with obstruction. Presumably, if the mucosa is healed, then these complications cannot occur. Interestingly, there appears to be a disconnect in CD between symptoms and mucosal healing. For example, in the endoscopic substudy of A Crohn's Disease Clinical Trial Evaluating Infliximab in a New Long-Term Treatment Regimen I (ACCENT I), mucosal healing did not correlate with CDAI. At 10 wk, only 36% of patients with mucosal healing were in remission as defined by the CDAI, and 40% of patients in clinical remission by CDAI did not have endoscopic remission<sup>[16]</sup>. So what is the optimal endpoint of therapy in CD? Ideally, patients should feel well, but should they also be treated to reduce intestinal injury in the hope of reducing the need for surgery?

Symptom control may not be enough, but unfortunately there is still no definite evidence that pushing therapy to achieve mucosal healing modifies the natural history of CD, though there are emerging data that this may be the case. In the postoperative setting, seminal work by Rutgeerts and colleagues has demonstrated that endoscopic recurrence precedes and predicts clinical recurrence<sup>[15]</sup>. Patients with no or very mild lesions (few aphthous ulcers) at follow-up endoscopy one year after resection had a low risk of endoscopic progression or clinical recurrence, with clinical recurrence rates remaining less than 10% over 5-10 years of follow-up. However, patients with advanced lesions (diffusely inflamed mucosa or worse) seen at follow-up endoscopy one year after resection had a poor prognosis with further endoscopic progression and clinical recurrence occurring in upwards of 90% over time<sup>[15]</sup>. In the ACCENT I study, patients on maintenance infliximab with mucosal healing required fewer hospitalizations and surgical interventions<sup>[17]</sup>. Nine patients had evidence of mucosal healing at both 10 wk and 54 wk endoscopic evaluations, and no CD related hospitalizations were required in this group. Patients with evidence of mucosal healing at 1 visit (either 10 wk or 54 wk) required fewer CD related hospitalizations as compared to patients with no healing at either visit (18.8% *vs* 28%)<sup>[16]</sup>. In a Norwegian population-based cohort, mucosal healing after one year of treatment was associated with decreased disease activity during the follow-up period and decreased need for active treatment over five years<sup>[18]</sup>.

Though the data to support mucosal healing as the optimal endpoint for CD therapies remains scant, one could argue that the reason we have not yet seen a change in the natural history of CD in the general population is because according to our standard treatment approaches,

we are only using drugs with a good potential to heal mucosa, such as the immunomodulators or biological agents, on the most refractory patients. Often, this is when the chronic inflammation of the bowel has already led to irreversible injury, manifest as high-grade strictures or bowel perforation with abscess or fistula formation. These complications may be beyond the capacity of any medicine to rectify.

## TO WHAT EXTENT DO THE CURRENT THERAPIES ACHIEVE THESE GOALS OF TREATMENTS?

First line therapies often include treatment with 5ASA or antibiotics as these are presumed to have low or limited toxicity. However, multiple studies have failed to demonstrate robust clinical efficacy for 5-ASA agents, particularly in patients with small bowel or ileocolic disease<sup>[1,2,19]</sup>. Limited data exist on the efficacy of antibiotics, as well. But, the use of antibiotics in CD has been poorly studied<sup>[20]</sup>. pH release formulations of budesonide (Entocort), a corticosteroid with limited systemic bioavailability, and therefore, less short term side-effects than prednisone, can be used to induce remission in right sided colonic and ileal disease, but at 1 year is unlikely to maintain remission<sup>[21,22]</sup>. For moderate to severe disease activity, systemic corticosteroids, such as prednisone, are often used, but are known to have significant short and long-term side effects. In addition, studies indicate that although steroids are effective at suppressing acute inflammation quickly, they have shown no benefit in maintaining a remission, preventing new flares or inducing mucosal healing<sup>[23]</sup>. Population based studies from Olmstead County have shown that 43% of CD patients required treatment with steroids; of these, the majority (85%) were able to achieve complete or partial response at one mo. However, at one year only one-third of patients had a sustained response: 28% patients were steroid dependent and 38% patients required surgical intervention<sup>[10]</sup>. In addition, less than one third of patients in a clinical remission on steroids had evidence of mucosal healing at 7 wk<sup>[24]</sup>. Steroids may also worsen disease, especially in patients with fistula, leading to higher rates of abscess formation and sepsis<sup>[25]</sup>.

Immunomodulators, such as azathioprine (AZA) or 6-mercaptopurine (6-MP), have a slow onset of action in CD, so their utility for the rapid induction of remission is limited<sup>[26]</sup>; however, they have been shown to maintain a remission in CD, and are able to induce mucosal healing<sup>[8]</sup>. Treatment with AZA/6MP results in an approximately 40% steroid-free remission rate at 1 year<sup>[27]</sup>. A study of 20 patients with Crohn's colitis or ileocolitis treated with azathioprine demonstrated that in the colon, 70% of patients had complete mucosal healing, while in the ileum, 54% had complete healing<sup>[28]</sup>. Even with their demonstrated ability to heal mucosa and be steroid sparing in CD, Cosnes *et al* did not find a decrease in rates of operations for Crohn's over the past two decades, despite an increased use of AZA/6-MP over this time period<sup>[29]</sup>. One major caveat to this finding is that the majority of

patients on immunosuppression were on therapy for less than 3 mo prior to their operation, which is often too short a treatment period to expect any real benefit from immunomodulators. Studies from the pediatric literature suggest that immunomodulators can have longstanding effects on CD that may alter the natural history. In one randomized controlled trial of children aged 13 (+/-2) years with moderate to severe CD on steroids and within 8 wk of CD diagnosis, immunomodulator use was able to induce a durable steroid-free remission, with a long term remission rate of 89% at 18 mo<sup>[30]</sup>.

The data is even more compelling for infliximab, an anti-tumor necrosis factor (anti-TNF) agent. In ACCENT I, regularly scheduled infusions of infliximab led to superior remission and response rates, superior mucosal healing, and decreased need for hospitalizations and surgery compared with placebo or episodic infusions of infliximab<sup>[17]</sup>. In the scheduled treatment group, 31% of patients had evidence of complete mucosal healing at 10 wk and 50% of patients had complete mucosal healing at wk 54<sup>[16]</sup>. Currently, these medications are often reserved for patients who are steroid refractory or steroid dependent, who are either not responding or too sick to wait for the effects of immunomodulators. The main reason for reserving anti-TNF therapy for sicker patients is the presumed risk-benefit profile.

## DOES TOP-DOWN THERAPY EXPOSE PATIENTS TO AN INCREASED RISK OF MEDICATION-RELATED COMPLICATIONS? THE RATIONALE FOR STEP-UP THERAPY

A small number of CD patient's will have a very mild course, requiring only treatment with 5-ASAs, antibiotics or a short course of budesonide, without further need for systemic steroids or immunomodulators. A top-down approach would unnecessarily expose these patients to the side effects of the immunomodulators and biologics. Immunomodulator use has been associated with an increased risk of infection, hepatitis, bone marrow suppression, pancreatitis and lymphoma<sup>[31]</sup>. Two to five percent of patients will experience bone marrow suppression secondary to azathioprine/6MP, and even in the absence of leukopenia, there is a risk of serious infection<sup>[4]</sup>. A recent meta-analysis suggests a four-fold increased risk of lymphoma in IBD patients treated with azathioprine/6-MP<sup>[32]</sup>. Side effects of the biologics can include infectious complications, malignancy, demyelinating disorders, autoimmunity and worsening of CHF<sup>[3]</sup>. Anti-TNF agents are associated with a 2.8%-4% increased risk of serious infections<sup>[3]</sup>. Analysis of the Crohn's Therapy, Resource, Evaluation and Assessment Tool (TREAT) registry demonstrated a relative risk of lymphoproliferative disorders of 1.3<sup>[14]</sup>. Recently, the risk of a rare form of lymphoma, hepatosplenic T-cell lymphoma, has been seen in association with infliximab and concomitant immunomodulator use. This type of lymphoma predominantly affects patients age 10-30 (the oldest reported patient is 31), and has not been seen in patients on infliximab alone<sup>[33]</sup>. This list of serious

and potentially life-threatening side effects has resulted in the limited use of biologic therapy to only the most severe cases of CD, which are resistant to conventional therapies. The recent American Gastroenterological Society (AGA) technical review on corticosteroids, immunomodulators and infliximab in IBD specifies that current indications for infliximab include severely active CD resistant to medical therapy or intolerant of medical therapy<sup>[4]</sup>.

Given these potential toxicities, a recent decision analysis evaluated the risks and benefits of infliximab as compared to standard therapy. This model suggested that despite an increased risk of lymphoma and death, infliximab results in increased quality of life years secondary to clinical response and remission rates and decreased surgical rates, and in properly selected patients, the benefits outweigh the risks<sup>[7]</sup>. The modeling likely underestimated the response and remission rates, and overestimated the mortality rates as data from the TREAT registry were excluded<sup>[34]</sup>. Interestingly, analysis of the TREAT registry revealed that infliximab, in multivariate, logistic regression analysis, was not an independent predictor of serious infections. Factors independently associated with serious infection included prednisone use, narcotic analgesic use, and moderate to severe disease activity. No increased risk of malignancy was associated with infliximab use, and the only factor associated with increased mortality was use of prednisone<sup>[14]</sup>. It is important to note that exposure to prednisone is likely greater over time with the step-up treatment approach.

### CAN THE TIMING AND ORDER OF MEDICINES CHANGE THE NATURAL HISTORY OF CD? THE RATIONALE FOR TOP-DOWN THERAPY

Studies in the pediatric population suggest that early treatment may alter the course of CD, and response to therapy may be related to disease duration. In a prospective, placebo controlled trial of newly diagnosed pediatric CD patients with moderate to severe disease on steroids, early (within 8 wk of initial diagnosis) treatment with 6-MP resulted in a 85% sustained steroid-free remission as compared to 54% of patients receiving placebo<sup>[30]</sup>. In a small study of 15 patients, Kugathesan *et al* treated 15 children with medically refractory CD in a prospective, open-label trial of a single, 5 mg/kg infliximab infusion. Fourteen of fifteen children responded. Of the 14 patients who responded, six had early CD (< 2 years from time of diagnosis) and eight had late CD (> 2 years from time of diagnosis). Three of six children with early disease maintained clinical response through the 12-mo trial period, compared to none of the eight children with late disease<sup>[35]</sup>. What is most remarkable about this study is that a single infusion of infliximab was able to induce such a profound and prolonged clinical response. This was a small study, but the positive findings suggest that there is something different about the newly presenting CD patient versus the relapsing/remitting CD patient. Based on this and other studies, there has been some speculation that earlier in the disease, medications such as infliximab may be able to

change the natural history of CD.

In the REACH (Response and Remission Related to Infliximab in Pediatric Patients with Moderate to Severe CD) trial, pediatric patients on concurrent immunomodulators, with mean disease duration of only 1.6 years, were given an infliximab induction regimen. Responders were randomized to infliximab 5 mg/kg every 8 wk or every 12 wk. At 10 wk there was an 88% clinical response and 59% clinical remission rate. At 54 wk, subjects receiving every 8 wk infliximab had a 64% response rate and 56% remission rate<sup>[36]</sup>. These response and remission rates are superior to those seen in ACCENT I study of infliximab in adults with a median disease duration of > 7 years, where the 10 wk remission rate was 40% and 54 wk remission rate was 30%<sup>[17]</sup>.

Retrospective analysis of data from Pegylated Antibody Fragment Evaluation in Crohn's Disease Safety and Efficacy 2 (PRECiSE 2) and Crohn's trial of the fully Human antibody Adalimumab for Remission Maintenance (CHARM) have demonstrated similar results. In PRECiSE 2, a higher percentage of patients were able to achieve a clinical response or remission with monthly certolizumab if they had < 1 year of disease activity versus those who had a longer duration of disease (> 2 years)<sup>[37]</sup>. A subanalysis of the CHARM study presented at DDW 2007 evaluated patients who responded to treatment with adalimumab at a 4 wk evaluation, and randomized these wk-4 responders to a maintenance regimen of placebo, adalimumab 40 mg subcutaneous weekly or adalimumab 40 mg subcutaneous every other week. In logistic regression analysis controlling for age, gender, CRP, concomitant therapies, presence of fistulas and active treatment with adalimumab, patients with disease duration of less than 2 years achieved the highest remission rates, confirming that disease duration had a significant effect on ability to achieve and maintain a remission<sup>[38]</sup>.

The potential for biologics to induce mucosal healing and potentially change the natural history of CD has been further illustrated by the Top Down/Step Up trial, which is currently awaiting publication, but has been presented in abstract form at DDW 2006<sup>[39,40]</sup>. This is an open-label, multicenter trial in 26 centers in the Netherlands and Belgium. Patients with active CD of less than 4 years duration were eligible for enrollment. Subjects were randomized to a top-down arm (infliximab induction 0, 2, 6 wk with AZA maintenance, with on-demand infliximab for flares; systemic steroids were added only if patients did not respond to the combination of infliximab and AZA) or a step-up arm (Prednisone 40 mg daily; permitted 2 steroid tapers before starting AZA; and then infliximab if failed treatment with immunomodulators). Co-primary endpoints were steroid-free remission and need for surgery at 6 and 12 mo. All patients underwent endoscopy at baseline with blinded scoring of ulcers. At 6 and 12 mo, significantly more top-down patients were in a steroid-free remission without resection as compared to the step-up arm (60% *vs* 36% at 6 mo, 62% *vs* 42% at 12 mo). At 24 mo, no statistically significant difference was found between the two groups. The most remarkable finding in this cohort was the results of the endoscopic substudy,

in which 44 patients were evaluated at 2 years after study initiation. 71% (17/24) of patients in the top-down arm achieved mucosal healing versus 30% (6/20) in the step-up arm. Some of the patients in the top-down arm had only received an induction dose of infliximab<sup>[39,40]</sup>.

Why might earlier use of immunomodulators or biological drugs lead to better long-term outcomes in CD? Later exposure to these potent therapies may be less effective because irreversible bowel injury may have occurred, with transformation of an inflammatory phenotype to a stricturing or penetrating phenotype, which is beyond the ability of medical therapy to repair. Alternatively, the immune dysregulation may be more difficult to reverse in long-standing disease, maybe more so in patients previously exposed to corticosteroids<sup>[41]</sup>.

### **ONCE YOU START BIOLOGICAL THERAPY, CAN YOU EVER STOP IT? IS THE NOTION OF TOP-DOWN THERAPY A MYTH?**

The idea of top-down therapy would be more palatable if many patients exposed to these more potent, but potentially toxic therapies can have these treatments tapered or discontinued over time. However, it is not clear if this is possible for many patients. ACCENT I data clearly support the use of scheduled infliximab therapy as compared to episodic therapy<sup>[17]</sup>, and this has become the standard of care when treating with infliximab. In the Top Down/Step Up trial, patients randomized to the Top-Down arm were given infliximab as induction therapy, and maintained with immunomodulators. Infliximab was given on-demand for symptom relapse<sup>[40]</sup>. Practically, it is rare for practitioners to use biologic agents as a bridge to other therapies or to use biologics episodically. Is a top-down approach realistic, or is it really a top and stay therapy?

Infliximab has been evaluated as a bridge to azathioprine therapy in steroid-dependent CD<sup>[42]</sup>. Patients received an induction regimen of infliximab or placebo, and all patients were given either Azathioprine or 6 MP; relapse was treated with steroids. At 52 wk, 40% of patients receiving infliximab induction followed by AZA/6MP were in a steroid-free remission as compared to 22% of patients who received placebo and then AZA/6MP. Although there is a statistically significant difference favoring induction with infliximab, a gradual loss of efficacy was seen when compared to the wk 12 steroid-free remission rates: 75% in the infliximab group and 38% in the placebo group<sup>[42]</sup>.

Data from the Step-Up/Top-Down trial also indicate that a substantial proportion of patients started on biologics have to remain on them. At one year, 41% of patients in the Top-Down group required at least one additional dose of infliximab, with a median interval of infusion of 16 wk<sup>[40]</sup>.

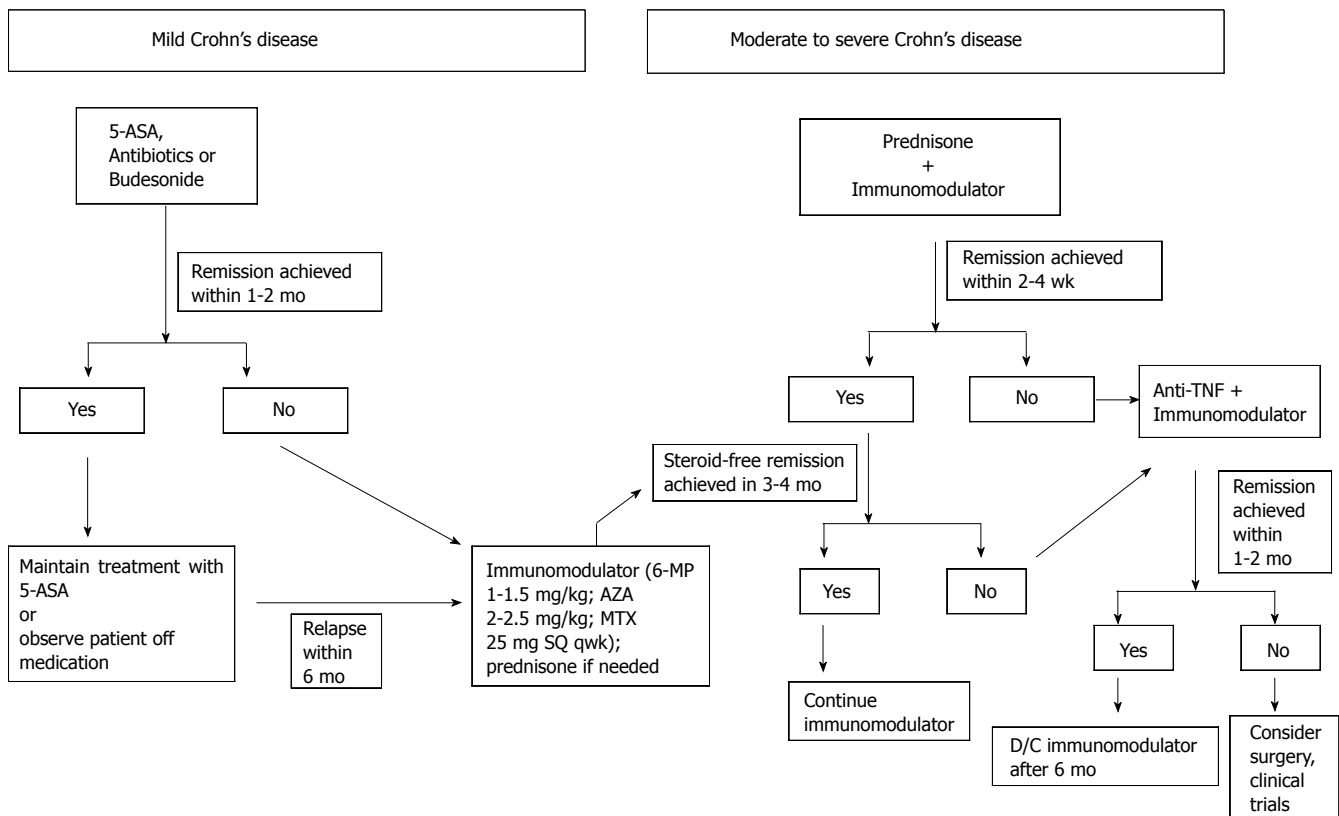

The association of combination infliximab and immunomodulator use (specifically AZA/6MP) with hepatosplenic T-cell lymphoma<sup>[33]</sup> has led many practitioners to move towards monotherapy, but most clinicians are choosing biologic monotherapy

over immunomodulator monotherapy. Initial results from the Infliximab Maintenance Immunosuppression Discontinuation (IMID) trial demonstrated no clinically significant benefit of combined therapy with infliximab and immunomodulator as compared to infliximab alone<sup>[43]</sup>. Patients in clinical remission on combination infliximab and immunomodulator (AZA/6MP) therapy were randomized to continue or discontinue immunomodulators after at least 6 mo of concomitant therapy. There was no difference in percent of patients requiring a change in infliximab dosing or discontinuation of infliximab therapy due to loss of response or intolerance between the two groups, and no difference in mucosal healing rates (61% in combination therapy group and 67% in infliximab monotherapy group). The only significant findings were that patients on combination therapy had higher median infliximab levels, higher trough serum infliximab levels, and lower incidence of antibodies to infliximab, although the clinical significance of these findings was unclear<sup>[43]</sup>. Additionally, data from ACCENT I and CHARM did not show any difference in remission rates with or without concomitant immunomodulator therapy at one year<sup>[44,45]</sup>.

### **IS ONE TREATMENT PARADIGM APPROPRIATE FOR ALL CROHN'S PATIENTS?**

A proportion of patients will have only very mild disease activity, and some may never have a flare requiring treatment with steroids. How do we differentiate patients who will never have a progressive, complicating disease course, in order to avoid the unnecessary exposure and the increased expense that would be associated with a top-down strategy? Ideally, we would apply a top-down approach to the subset of patients with the most aggressive disease, before the disease may become more resistant to treatment with biologics.

A retrospective study of 1123 CD patients at a tertiary referral center found a disabling disease course in 85% patients over 5 years of follow-up<sup>[46]</sup>. Disabling disease course was defined as greater than 2 steroid courses or steroid-dependence, hospitalizations, disabling chronic symptoms, need for immunosuppressive treatment, and intestinal resection or surgery for perianal disease. Clinical factors associated with a disabling disease course included: young age at onset of disease, presence of perianal lesions, early need for systemic steroids, and isolated small bowel involvement<sup>[46]</sup>. A second retrospective, cohort study of 83 patients undergoing surgery within the first three years of CD diagnosis found that smoking, isolated ileal involvement and oral corticosteroid use within the first 6 mo of diagnosis were associated with an increased risk of surgery<sup>[47]</sup>. Additional prognostic information may be attained from evaluation of serum markers such as ASCA, anti-OmpC, Anti-CBir1 and anti-I2. In a prospective study of 196 pediatric patients, the frequency of internal penetrating and/or stricturing disease increased with the number of positive markers, and the odds of developing internal penetrating and/or stricturing disease was highest

**Figure 1** "Accelerated" step-up treatment algorithm.

in patients with all four immune markers<sup>[48]</sup>. Genetic markers show promise; CARD15 mutations are thought to be responsible for approximately 20% of the genetic predisposition to CD<sup>[49]</sup>.

Ultimately, our ability to risk stratify patients remains crude. There is an urgent need for the ability to assess prognosis at the time of diagnosis, in order to personalize treatment options by targeting the patients who are at greatest risk of progressing to complicated disease with earlier, more potent anti-inflammatory therapy.

## MAKING PRACTICAL SENSE OF THE TREATMENT PARADIGMS: HOW MIGHT THEY BE IMPLEMENTED?

For now it seems that both the step-up and top-down treatment approaches, as they are conventionally defined, are lacking for many patients. It does not make sense to attempt to treat patients with severe symptoms at presentation with mesalamine, nor does it make sense to allow two attempts at a steroid taper before escalating therapy to an immunomodulator, as was done in Hommes' Step I Up/Top-Down study. At the same time, it makes little sense to expose all newly diagnosed patients to treatment with a biological drug, and it is increasingly unclear if patients treated with a biological drug should be treated concurrently with an immunomodulator. Based on the current data, we believe that a hybrid treatment approach, one that still "steps-up" therapy, but does so aggressively, is best. This approach can be described as an

"accelerated" step-up strategy (Figure 1).

The accelerated step-up treatment approach preserves the tactic of matching disease severity with treatment potency, but keeps in mind that earlier use of these potent therapies may have better outcomes. For patients with mild presenting symptoms, we still seek to achieve remission with mesalamine, antibiotics or budesonide. If remission is achieved within 1-2 mo, then options are to attempt to maintain remission with mesalamine, or observe the patient off medications. If the initial remission is not achieved within this short period of time, or for patients who relapse within 6 mo, therapy is started with an immunomodulator (6-MP with target dose of 1-1.5 mg/kg per day, AZA with target dose of 2-2.5 mg/kg per day or MTX with dose of 25 mg sq per week). Therapy with prednisone is initiated for patients with moderate or severe symptoms that do not permit one to wait the 2-4 mo required for the immunomodulators to take effect, though steroid use is avoided in patients with known perforating/fistulizing disease. Patients started on an immunomodulator are expected to be in a steroid free remission within 3-4 mo. For those that do not achieve this goal within that time frame, therapy with one of the anti-TNF drugs is initiated. At the present time, therapy with the immunomodulator is continued at the outset of therapy with a biological agent, but once the patient enters remission, concomitant therapy with the immunomodulator is stopped in most cases. For patients receiving infliximab infusions, intravenous hydrocortisone 200 mg is given as a premedication.

Biologics, i.e. anti-TNF drugs, are started even earlier if steroids are not able to induce a remission within 2-4 wk,

if a patient is intolerant of steroids or if a patient is intolerant of an immunomodulator. In addition, steroids are not used at all in patients with fistulizing or perforating disease, even at the outset. These patients are treated immediately with antibiotics, and in all but the mildest cases, one of the immunomodulators. If the patient is too ill to wait for the immunomodulators to take effect, then therapy is initiated immediately with a biological drug. In all cases therapy with immunomodulators and/or biological agents is not initiated until it is clear there is no infection that requires therapy and there is no indication for immediate operative intervention. With all of these therapies, the treatment endpoint remains symptom resolution. Though the authors concede the potential importance of mucosal healing in addition to symptom relief as a treatment goal, the authors do not yet document mucosal healing in all patients, nor do they push therapy in asymptomatic or minimally symptomatic patients if persistent inflammation is seen on endoscopy or imaging studies.

## CONCLUSIONS AND FUTURE DIRECTIONS

The ideal treatment approach in CD remains uncertain, as does the optimal endpoint of therapy. Since CD is heterogeneous with respect to phenotype and severity, it is unlikely that one approach will be best for all patients. Nevertheless, it is the authors' opinion that many physicians are not aggressive enough with therapy, delaying the use of potentially disease-modifying agents, such as the immunomodulators and/or biological agents, in patients with moderated to severe CD. In addition, there is a growing body of evidence that suggests that mucosal healing, which is most rapidly achieved with biologic therapy, is an appropriate treatment endpoint in CD patients. It does appear that earlier therapy with biologic drugs results in an increased response to therapy. Although no clear prospective study has been able to show that either mucosal healing or early biologic therapy are associated with a long-term change in the natural history of CD, there is a documented association with decreased hospitalizations and decreased need for surgery over one year of therapy. The greatest burden of CD comes from hospitalizations and surgeries, and thus early, aggressive therapy may have improved outcomes at an individual as well as a societal level. For now the authors recommend the "accelerated step-up" approach to therapy as outline above as the best way to induce and maintain CD remission while minimizing the risk of unnecessary medication toxicities. What is urgently needed are studies to improve the ability of clinicians to risk stratify patients upon diagnosis, and to predict response to therapies, so that treatment approaches can be individualized and optimized. Additional studies also are needed to demonstrate conclusively that mucosal healing, in addition to symptom control, should be a primary goal of therapy in CD.

## Abstract

Despite the new and ever expanding array of medications for the treatment of inflammatory bowel disease (IBD), there are still clear indications for operative management of IBD and its complications. We present an overview of indications, procedures, considerations, and controversies in the surgical therapy of IBD.

## ULCERATIVE COLITIS

Approximately 25%-35% of ulcerative colitis patients will ultimately require surgery for either a complication of the disease or inadequate control of symptoms<sup>[1,2]</sup>. While most of these surgeries can be done in the setting of an elective operation, a minority will require emergent or urgent treatment. A number of options are available in the

surgical management of ulcerative colitis, many of which may require more than one operation. Each procedure is associated with its own benefits and drawbacks, so a thorough understanding of each procedure, and its indications, is important.

## EMERGENT OR URGENT OPERATION FOR ULCERATIVE COLITIS

### Indications

Worsening signs and symptoms of colitis, including numerous bloody stools per day, fever, elevated heart rate, anemia, elevated sedimentation rate, radiographic evidence of colonic distension, and abdominal distension with tenderness on exam<sup>[3]</sup>, can predict the need for surgery. In most cases, acute flares of severe colitis respond to medical therapy. Up to 80% of patients with severe colitis will avoid an operation<sup>[4,5]</sup>. Failure to improve within a few days following an initial stabilization period, or worsening colitis should trigger consideration for operative intervention. Most studies define 48-96 h as an adequate trial of medical therapy in which significant improvement should occur<sup>[6,7]</sup>. One study of 49 patients with severe colitis cites an 85% colectomy rate if patients are still having 8 bowel movements per day, or 3-8 bowel movements per day with a C-reactive protein of > 45 mg/mL, despite 3 d of medical therapy<sup>[7]</sup>. Further, patients with an incomplete response within 7 d of medical management (as defined by four or more bowel movements per day or visible blood in the stools) had a 60% chance of continuing colitis symptoms and a 40% chance of colectomy within 1 year<sup>[7]</sup>.

The diagnosis of toxic megacolon, defined by a transverse colon diameter exceeding 6 centimeters, in ulcerative colitis has been reported in 7%-17% of patients requiring hospitalization and is thought to have a lifetime incidence of 0.5%-2.5%<sup>[8]</sup>. A European study looking at 796 patients showed that the mortality rate from toxic megacolon was only 0.2% in ulcerative colitis patients over a 4-year follow-up<sup>[9]</sup>. However, this accounted for 50% of all ulcerative colitis patient deaths over the same period. As such, most surgeons consider the development of toxic megacolon in ulcerative colitis, particularly in the context of perforation, progressive colonic dilatation, massive hemorrhage or hemodynamic instability, to be an indication for emergent colectomy<sup>[8,9]</sup>. However, severely ill patients can have toxic symptoms without dilatation that still warrants urgent surgical intervention. Greenstein has published a series of 7 ulcerative colitis patients diagnosed

with colonic perforation in the absence of colonic dilatation<sup>[10]</sup>. Six of them did not display classic signs of perforation including peritonitis and rebound tenderness. Impending perforation is extremely difficult to predict. The authors speculated that this lack of symptoms may have been due to the use of high-dose steroids. Patients with signs of actual or impending perforation should receive emergent surgery. The associated mortality rate of perforation in ulcerative colitis patients is between 27% and 57%<sup>[10]</sup>.

As might be predicted, the development of hemodynamic instability or multi-organ failure is also predictive of a poor outcome and warrants resuscitation and emergent operation. Caprilli cited a 72.7% mortality rate in ulcerative colitis patients developing multi-organ dysfunction<sup>[11]</sup>. They suggest that early signs of multi-organ dysfunction, including disproportionate tachycardia, tachypnea, oliguria, jaundice, hypoxemia and mental confusion, should prompt an aggressive therapeutic approach including ICU admission and early colectomy.

### **Surgical options**

Surgical management of ulcerative colitis in the emergent setting is aimed toward removing the inflamed bowel while minimizing morbidity, and a total abdominal colectomy and end ileostomy is the procedure of choice<sup>[12]</sup>. This procedure removes the majority of diseased bowel while avoiding the complications associated with both pelvic dissection and an enteric anastomosis.

A number of studies have shown that total abdominal colectomy with end ileostomy is a safe procedure in the emergent setting with a post-operative complication rate of 23%-33% and low mortality in the absence of a perforation (0%-4%)<sup>[13,14]</sup>. Some debate has centered on the management of the rectal stump. One study suggested that exteriorization of the stump, either by bringing it up into the subcutaneous tissues or by creating a formal mucous fistula, may decrease the incidence of pelvic septic complications and facilitate future pelvic dissection<sup>[15]</sup>. They found a 12% rate of pelvic abscess with an intraperitoneal rectal stump compared to a 4%-7% abscess rate when the stump was exteriorized. However, Karch and colleagues published a pelvic sepsis rate of only 2.6% (3 of 114 patients) in patients with an intraperitoneal stump<sup>[16]</sup>. One of these three patients responded well to transanal drainage prompting the authors to suggest that routine transanal drainage of the rectal stump may be warranted. Forty-one consecutive patients in this series underwent routine transanal drainage with no incidence of pelvic sepsis peri-operatively<sup>[16]</sup>.

Another advantage of this procedure is that after the abdominal colon is resected, the specimen undergoes histopathological assessment to confirm the diagnosis of ulcerative colitis. Surprisingly, the number of patients found to have Crohn's disease instead of ulcerative colitis after this procedure is appreciable. In a recent review of patients undergoing emergent total abdominal colectomy, of the 52 patients with ulcerative colitis, 13% had their diagnosis altered post-operatively (5 diagnosed with Crohn's disease and 1 with indeterminate colitis)<sup>[14]</sup>. Thus, in a

patient with indeterminate colitis, this may be the preferred surgical option to further define the diagnosis.

More extensive and definitive procedures for ulcerative colitis are often technically feasible at the time of an emergent operation. However, proctectomy is rarely required for symptomatic relief at the time of an emergent surgery and residual rectal inflammation can be treated medically<sup>[17]</sup>. Furthermore, these patients are often nutritionally deplete, anemic, and on high-dose steroids which increases the risk for an anastomotic complication. As such, we believe the safest approach is to salvage the patient and avoid proctectomy in the emergent setting. Interestingly, a significant proportion of patients, particularly in the elderly, may elect not to reverse their ileostomy. In Hyman's series of 52 ulcerative colitis patients undergoing emergent surgery, 20 patients elected not to reverse the ileostomy, choosing either completion proctectomy or no further surgery<sup>[14]</sup>.

## **ELECTIVE OPERATION FOR ULCERATIVE COLITIS**

### **Indications**

Failure of medical management remains the most frequent indication for elective surgery in ulcerative colitis<sup>[12]</sup>. Intractability may be defined by inadequate control of symptoms despite optimal medical management, chronic disability due to disease, or control of symptoms with therapy associated with high probability of long-term morbidity such as steroids. Growth failure in the pediatric population may be considered a consequence of intractable disease and is an indication for surgery<sup>[18]</sup>.

Risk of malignancy is also an indication for elective operation. A meta-analysis by Eaden cites an overall cancer incidence of 3.7% in ulcerative colitis patients, increasing to 5.4% in patients with pancolitis. This incidence rises with a longer duration of disease symptoms. Cancer risk in ulcerative colitis patients is 2% at 10 years, 8% at 20 years and 18% at 30 years<sup>[19]</sup>. As such, surveillance colonoscopy has been suggested in ulcerative colitis patients despite a paucity of clear evidence that this process increases survival. At present, practice guidelines of the American Society of Colon and Rectal Surgeons<sup>[12]</sup> suggest that patients with pancolitis undergo surveillance endoscopy after 8 years of disease symptoms and those with left-sided disease undergo surveillance endoscopy after 15 years of symptoms. The consensus of experts is that 4 quadrant biopsies should be taken every 10 cm<sup>[20]</sup>.

While an established carcinoma is an absolute indication for surgery, the management of dysplasia is somewhat more controversial. High grade dysplasia and dysplasia-associated lesions or masses (DALM) have a high incidence of synchronous cancer and are generally considered indications for surgery. A systemic review by Bernstein reported that 42% of patients with high-grade dysplasia and 43% of patients with DALM had synchronous cancers at the time of immediate colectomy<sup>[21]</sup>. However, a high rate of inter-observer variability in the pre-operative diagnosis of dysplastic lesions in ulcerative colitis patients has cast some doubt on this data. Variability in the diagnosis of low

or high-grade dysplasia may be as high as 60% even among experts<sup>[22]</sup>. It has been noted that pathologists may alter their diagnosis over time with experience or with new knowledge in the field<sup>[21]</sup>.

Several studies have suggested that adenoma-like DALMs may not be associated with as aggressive a natural history as previously believed and can be treated with endoscopic resection. Odze and colleagues published a series of 34 ulcerative colitis patients found to have either adenoma-like DALM or sporadic adenoma who were compared to 49 non-ulcerative colitis patients with sporadic adenoma. Their findings suggested that the rates of recurrent adenoma after endoscopic resection were similar in both groups and that ongoing surveillance endoscopy was adequate<sup>[23]</sup>.

The treatment of low-grade dysplasia in the absence of a DALM is even more ambiguous as the natural history of these lesions is not well understood. Several studies have suggested a high incidence of synchronous cancers in the presence of low-grade dysplasia as well as a significant rate of progression to high-grade dysplasia<sup>[21]</sup>. As such, many colorectal surgeons advocate for colectomy with a diagnosis of low-grade dysplasia. However, Befrits has shown over an average endoscopic follow-up of 10 years that progression of low-grade dysplastic lesions to high grade dysplasia or cancer in the absence of a DALM did not occur in 60 patients<sup>[24]</sup>. Lim and colleagues have also published a series of 160 chronic ulcerative colitis patients of whom 40 were diagnosed with low-grade dysplasia on colonoscopy. Over a 10-year follow-up, 10% of low-grade dysplasia progressed to high-grade dysplasia or cancer. However this rate of high-grade dysplasia or cancer in previously diagnosed low-grade dysplasia patients was not found to be significantly different from ulcerative colitis patients without dysplasia. The authors suggested that surveillance endoscopy for low-grade dysplasia was a reasonable option. As stated above, part of the discrepancy in reported rates of progression to high-grade dysplasia or cancer may be due to the lack of standardized pathological definitions for low grade dysplasia in ulcerative colitis<sup>[22]</sup>.

The management of a stricture in the context of low-grade dysplasia is more clear cut as up to 20%-24% of strictures are malignant<sup>[25]</sup>. Biopsies of strictures are inadequate to rule out malignancy and, as such, strictures in general should be considered an indication for surgery<sup>[12]</sup>. Strictures in the setting of ulcerative colitis may also be indicative of Crohn's disease and thus, operative treatment should be adjusted accordingly.

Elective surgery should also be considered for treatment of severe extra-intestinal manifestations of ulcerative colitis. Monoarticular arthritis, uveitis, and iritis are often ameliorated by colectomy while primary sclerosing cholangitis, ankylosing spondylitis and sacroiliitis are not improved<sup>[26]</sup>. The utility of colectomy for control of cutaneous manifestations such as erythema nodosum and pyoderma gangrenosum is uncertain as the response to surgery is variable<sup>[26]</sup>.

### **Surgical options**

A number of surgical procedures may be considered for

the treatment of ulcerative colitis, each with its own set of benefits and drawbacks. When selecting a procedure, the surgeon must consider a number of factors including pre-existing bowel dysfunction, patient stability, the presence of cancer and other medical comorbidities. Primary goals include removal of all diseased colon and rectum, elimination of cancer risk and restoration of normal bowel function. However, accomplishment of these goals may result in increased morbidity and decreased quality of life. As such, selection of an appropriate procedure is largely dependent on patient expectations and requires an ongoing dialogue between the patient, gastroenterologist, and surgeon.

Total proctocolectomy with end ileostomy remains the operative standard against which all other resections for ulcerative colitis are compared<sup>[12]</sup>. This operation removes all disease and eliminates the risk of colorectal cancer. It also eliminates issues of bowel function such as defecatory frequency, urgency and night waking and is generally associated with few dietary restrictions. It is still the procedure of choice for those with impaired anal sphincter function, or a distal rectal cancer. Other candidates include those patients who do not wish to undergo a restorative procedure and hope to have a single operation<sup>[27]</sup>.

While total proctocolectomy with end ileostomy is generally a safe procedure, it is still associated with significant morbidity. The most common complications include stoma-related issues such as parastomal herniation, skin excoriation and stomal stenosis<sup>[28,29]</sup>. A prospective analysis of 104 ulcerative colitis patients with total proctocolectomy and end ileostomy cited a 24% rate of stoma revision over 8 years<sup>[29]</sup>. The majority of these revisions were for stenosis or regression of the stoma. Small bowel obstructions are also a frequent complication but can often be treated conservatively<sup>[28]</sup>. Other morbidities associated with this operation that are intrinsic to pelvic dissection include sexual dysfunction, infertility, altered bladder function, and delayed perineal wound healing<sup>[30]</sup>. Interestingly, despite the fact that these patients live with a permanent stoma, they have a remarkably similar quality of life to age- and sex-matched patients with restorative procedures<sup>[31]</sup>.

As a result of patient's dissatisfaction with having a permanent end ileostomy and need to wear an appliance, Kock advocated the continent ileostomy in the 1960s and 1970s<sup>[32]</sup>. The terminal ileum is intussuscepted within a proximal ileal pouch forming a continent nipple valve. This procedure is performed with decreasing frequency due to significant rates of failure of the continence mechanism as well as the success of restorative proctocolectomy. A study of 96 Kock pouches showed an overall failure rate (that is, conversion to conventional ileostomy or ileal pouch-anal anastomosis) of 29% at 29 years. Fifty-nine percent of patients required a revision of their Kock pouch with 19% requiring more than 1 revision. However, it was noted that the 71% long-term success rate of Kock pouch was similar to that of restorative proctocolectomy<sup>[33]</sup>.

Although it is considered an option for the elective treatment of ulcerative colitis in a certain selection of patients, total abdominal colectomy with ileorectal anastomosis is not a common procedure. It may be

appropriate in the context of minimal rectal involvement or indeterminant colitis. A Swedish study of 51 ulcerative colitis patients treated by total colectomy with ileorectal anastomosis demonstrated that 29 patients (57%) ultimately failed this procedure and required completion proctectomy or restorative proctocolectomy<sup>[34]</sup>. Most (23 of 29 patients) failed due to ongoing rectal inflammation and diarrhea, but dysplasia was detected in 3 patients necessitating proctectomy.

Currently, the most frequent elective procedure performed for ulcerative colitis is the restorative proctocolectomy with ileal pouch-anal anastomosis (IPAA). Its greatest benefits are removal of disease up to the anal transition zone, maintenance of a normal pathway for defecation, and avoidance of a perineal wound and permanent stoma. Disadvantages of IPAA include the need for a second operation to close the diverting loop ileostomy, the need for continued surveillance of the residual anal transition zone<sup>[27]</sup>, and ongoing management of bowel function.

IPAA is an appropriate procedure for most patients with ulcerative colitis. Two large, retrospective cohort studies from the Cleveland Clinic and Mayo Clinic have shown that it is a relatively safe and durable procedure with a low perioperative mortality rate of 0.2%-1.0%<sup>[35,36]</sup>. However, the morbidity of this procedure is still considerable. In the peri-operative period, the incidence of anastomotic separation has been cited between 5% and 10%<sup>[35-37]</sup>. The need for aggressive therapy is often unnecessary in the immediate post-operative period as routine pelvic drainage and diverting ileostomy obviate the need for surgical or radiologic management. In this setting, reversal of the ileostomy should be delayed until there is both clinical and radiographic evidence of complete resolution of the anastomotic separation.

A relatively common complication often associated with anastomotic dehiscence is ileal pouch-vaginal fistulas which occur in 3%-16% of IPAA performed in women<sup>[38]</sup>. The spectrum of disease may range from relatively asymptomatic leakage of gas, to debilitating soilage and pelvic sepsis. Pelvic sepsis secondary to anastomotic dehiscence is thought to be the major contributor to the development of these fistulas. However, other causative factors may include anal cryptoglandular disease and vaginal injury during rectal dissection. Treatment is associated with a high failure rate. A recent study of 22 patients with pouch-vaginal fistula repairs cited a 50% recurrence rate after surgery. Combined abdominoperineal approaches were associated with a significantly higher success rate than local perineal repairs (52.9% *vs* 7.9%). Overall, 21% of patients required pouch excision for non-functional pouches and recurrent fistulas<sup>[39]</sup>.

The most frequent long-term complication of IPAA is pouchitis, a non-specific inflammation of the ileal pouch that occurs in 24%-48% of IPAA patients depending on the length of follow-up<sup>[35,36]</sup>. Presenting symptoms include cramping, fever, chills, perineal pain and an increase in stool frequency. The mainstay of treatment is antibiotics such as ciprofloxacin or metronidazole. Patients can develop antibiotic-dependent or antibiotic-resistant

pouchitis that requires escalation of treatment and a small fraction may need to be treated with pouch excision<sup>[40]</sup>.

Recent studies have suggested that fertility following IPAA is significantly decreased<sup>[41,42]</sup>. A Canadian study comparing 153 females with ulcerative colitis who had IPAA with 60 females who were medically managed showed an infertility rate of 38.6% which is 3 to 4 times higher than that in the normal population<sup>[41]</sup>. A history of post-operative small bowel obstruction, pelvic sepsis, or greater number of abdominal operations was not found to increase infertility. This is somewhat surprising as the etiology of decreased fertility following IPAA is suspected to be related to the presence of post-operative adhesions in the pelvis which may cause obstruction of the fallopian tube<sup>[42]</sup>.

The most common long-term complications of the pouch are related to altered bowel function<sup>[43,44]</sup>. A number of studies have suggested that IPAA patients have, on average 6 stools during the day with 1-2 stools overnight. Occasional daytime fecal incontinence may occur in 31%-45% of patients and this rate increases to 40%-59% at night. Up to 55% of patients use an undergarment pad to absorb seepage and 45% of patients will require bulking agents or anti-diarrheal medications to help regulate their bowels. A recent meta-analysis by Hueting and colleagues evaluated 43 observational studies encompassing 9317 patients. Severe and urge incontinence rates were reported at 3.7% and 7.3% respectively<sup>[45]</sup>. They found a pouch failure rate of 6.8% at a median follow-up of 36.7 mo increasing to 8.5% with follow-up over 60 mo.

Despite these morbidities, IPAA is an exceptionally durable and well tolerated procedure which results in markedly improved quality of life. A study of 1895 patients suggested that quality of life and quality of health following IPAA was similar that of the general population<sup>[44]</sup>. In patients under 65, social, work and sexual restrictions were experienced in only 11%-17% of those who had an IPAA. Interestingly, 98% stated that they would have the surgery again or recommend it to someone else with ulcerative colitis<sup>[44]</sup>. In addition, health-related quality of life has been found to be closely linked to pouch function<sup>[46,47]</sup>. Carmon and colleagues also found that elderly patients tended to have worse quality of life as well as pouch function<sup>[47]</sup>.

---

## CONTROVERSIES IN THE SURGICAL MANAGEMENT OF ULCERATIVE COLITIS

---

### Age

A debatable issue is whether IPAA should be offered to elderly patients, mainly due to increased incidence of anal sphincter dysfunction and comorbidities in this cohort. Several groups have shown that IPAA is feasible in the elderly<sup>[44,48]</sup>. The Cleveland Clinic published their series of 17 IPAA patients over the age of 70 and found similar functional outcomes to younger patients<sup>[49]</sup>. However, while continence in the first 10 years of IPAA remains relatively stable, it is uncertain whether this deteriorates with time, particularly in the elderly. Delaney and colleagues have shown that incontinence and night

seepage in patients over 65 approach rates of 67% and 60%, respectively<sup>[44]</sup>. However, the authors are quick to note that these decreased levels of perfect continence do not seem to translate into a decreased quality of life or satisfaction with the surgical outcome. While it seems that chronologic age alone should not be a contraindication to IPAA, older patients must be appropriately motivated and well-informed regarding the potential problems of IPAA.

### **Hand sewn vs stapled anastomosis**

Another debate centers on the need to perform a mucosectomy to remove the last 1-2 cm of rectal mucosa and, thus, require a hand sewn ileal pouch anal anastomosis. This approach was the only technique available until the advent of the circular staplers in the early 1990s. Most surgeons quickly switched to using a double-stapled anastomosis for ileal pouches due to the ease of this technique. This involves leaving the distal 1-2 cm of rectal mucosa intact, transecting the rectum above the anorectal junction with a stapler, and performing the anastomosis with the circular stapler. Because this method avoids a mucosectomy, the abundant nerve supply to the anal transition zone is preserved and sphincter injury is minimized. Additionally, double-stapled techniques are associated with less tension on the anastomosis<sup>[12]</sup>. With increasing experience, it was felt that "mucosectomy" led to unnecessary anal sphincter and nerve damage with minimal benefit in terms of disease control. A meta-analysis of 4183 patients (2699 hand sewn with mucosectomy and 1484 with stapled IPAA) showed no significant difference in the rate of post-operative complications<sup>[50]</sup>. While the frequency of bowel movements and use of anti-diarrheal medications did not differ in the two groups, the incidence of nocturnal seepage and usage of pads favored stapled IPAA. Further, manometric measures suggested that resting and squeeze pressures were significantly reduced in the hand sewn population<sup>[50]</sup>.

Detractors of double-stapled approaches will cite the potential for ongoing rectal cuff inflammation and the consequent risk of malignancy. However, a recent review of the literature cites a total of only 17 reported cases of cancer in the pouch or anastomosis<sup>[51]</sup>. In 12 cases, dysplasia or cancer was present in the original resection specimen. All 17 patients had a diagnosis of ulcerative colitis for at least 10 years at the time of the IPAA cancer diagnosis. The authors recommended surveillance starting at 10 years after disease onset. In post-IPAA patients, they recommended more intensive surveillance with biopsies in patients with cancer or dysplasia in the original specimen<sup>[51]</sup>.

### **Routine proximal diversion**

Routine diversion of the fecal stream by loop ileostomy following IPAA is also a debated issue. Ileostomies are thought to minimize both postoperative septic complications and morbidity associated with anastomotic leak<sup>[52]</sup>. However, many surgeons believe that routine diverting loops ileostomy is counterproductive. First, loop ileostomies are associated with some morbidity including poor body image, leakage, and skin breakdown. A second

procedure to reverse the ileostomy, with its' associated cost and morbidity, is also required. It has been suggested that routine diversion is not needed in carefully selected patients depending on patient, disease, and operative factors<sup>[53]</sup>. A relatively healthy, well-nourished patient, who is not anemic, or on high dose steroids would be a candidate<sup>[53]</sup>. Intraoperative factors, such as healthy-appearing, well-vascularized small bowel, low blood loss, hemodynamic stability, and a tensionless anastomosis, may allow for omission of a diverting loop ileostomy<sup>[53]</sup>.

Using these criteria for omission of a diverting loop ileostomy, Remzi retrospectively studied 2002 IPAA patients (1725 diverted by ileostomy and 277 undiverted)<sup>[53]</sup>. While a single stage procedure was associated with a higher incidence of post-operative ileus, he found no significant differences in septic complications, quality of life or functional outcomes in the two groups. This contrasts an earlier report from the same institution that rates of septic complications are increased, particularly in patients taking high doses of steroids<sup>[52]</sup>. Another report has suggested that the routine omission of a diverting loops ileostomy is associated with an increased risk to life<sup>[54]</sup>. As such, Remzi and others have suggested that only carefully selected patients are suitable for one-stage restorative proctocolectomy.

## **LAPAROSCOPIC PROCEDURES FOR ULCERATIVE COLITIS**

All operations for ulcerative colitis can be performed laparoscopically, including subtotal colectomy, total proctocolectomy and restorative proctocolectomy. Earlier reports in the mid-1990's demonstrated significantly longer operative times without a benefit in post-operative ileus or length of stay (traditional rationales for minimally invasive procedures)<sup>[55]</sup>. Further, it was shown that postoperative morbidity and transfusion requirements were higher in laparoscopic procedures<sup>[56]</sup>.

With better experience and technique, the increased morbidity of laparoscopic procedures for ulcerative colitis has decreased<sup>[57]</sup>. Marcello and colleagues have published a series using only experienced surgeons who have performed more than 700 laparoscopic colorectal procedures of which at least 100 were total abdominal colectomies<sup>[58]</sup>. The study compared 20 consecutive laparoscopic restorative proctocolectomies with 20 conventional procedures. While a significant increase in operative time was noted in the laparoscopic group (100 min), many of the previously cited morbidities associated with laparoscopic procedures, including blood loss and post-operative infection, were not significantly different from the open group. The length of stay in hospital was also shorter (7 d *vs* 8 d). A few subsequent studies have confirmed Marcello's findings<sup>[59,60]</sup>. Further, recent analysis of functional outcomes including number of bowel movements, stool consistency, incontinence, need for anti-diarrheal medications, and dietary restrictions has not revealed a significant difference between laparoscopic and conventional IPAA<sup>[60]</sup>.

A randomized, prospective study by Milsom has shown that laparoscopic resection in ileocolic Crohn's disease is associated with less blood loss, fewer respiratory

complications, faster return of bowel function and shorter hospital stay<sup>[61]</sup>; no similar study has been performed for laparoscopic procedures in the treatment of ulcerative colitis. Part of the problem is the lack of agreement on the optimal technique for laparoscopic IPAA which makes a comparative study with the open procedure difficult<sup>[57]</sup>. As discussed, there is also a steep learning curve associated with laparoscopic IPAA; most recent published results involve very experienced surgeons. It may be difficult to attain this experience outside of dedicated colorectal centers with a high volume of laparoscopic inflammatory bowel disease cases. While the current data suggest that laparoscopic IPAA may be a safe and effective treatment in the hands of an experienced surgeon, there are insufficient studies to recommend its general use. Further, despite improvements in technology, increased operative times may pose a barrier in institutions where operating room time is at a premium<sup>[57]</sup>.

## CROHN'S DISEASE

While advances in the medical management of Crohn's disease have decreased the need for surgery, it is estimated that between 70% and 90% of Crohn's patients will need a surgical intervention at some point during their disease<sup>[62]</sup>. The panenteric nature of Crohn's disease results in a variety of presentations depending on both the location of the disease as well as the disease behavior. Nonetheless, as Crohn's disease cannot be cured, the indications for surgery remain relatively straight-forward: failure of medical management and complications of the disease process. The specific surgical managements available are often multiple and selection of the most appropriate modality is dependent on several patient and disease factors.

## CROHN'S DISEASE: SMALL BOWEL

### Indications

Failure of medical management remains the most common indication for surgery in most series of patients with small bowel Crohn's disease<sup>[63,64]</sup>. Failure is defined by (1) symptoms that cannot be controlled or progress with maximum medical therapy, (2) problems with treatment side effects, and (3) inability of patient to maintain compliance with a medical regimen. Extra-intestinal manifestations (EIM) of disease are another indication for surgery and may occur in as many as 25% of Crohn's patients<sup>[65]</sup>. Disorders of the skin, mouth, eye and joints are common in colonic disease and tend to parallel disease activity. As such, surgical resection of diseased bowel tends to ameliorate these EIMs. Hepatic, vascular, hematologic, pulmonary, cardiac and neurologic system EIMs tend to act independently of intestinal disease. Other disorders such as nephrolithiasis and cholelithiasis are actually complications of disease secondary to altered intestinal absorption. As such, surgical resection may improve these conditions.

Intestinal obstruction represents a frequent complication of small bowel Crohn's disease<sup>[63,64]</sup>. Acute obstruction can occur due to a primary stricture or series of strictures.

Healthy, non-diseased, bowel may be mechanically obstructed as part of an inflammatory mass or fistula. Acute obstructions are more likely to be the result of active inflammation and will often resolve with medical management<sup>[66]</sup>. Conversely, chronic obstruction, which is usually the result of a fixed fibrostenotic lesion, tends to require surgical management<sup>[66]</sup>. Surgery usually involves a resection of the diseased segment, but other options include intestinal bypass, creation of ileostomy, or stricturoplasty (discussed below).

Fistulas with associated abscess or stricture are another common complications of small bowel Crohn's that requires surgery<sup>[63,64]</sup>. In a study of 1379 patients, Michelassi found fistulas in 35% of surgically managed patients. However, fistula was the primary surgical indication in only 6.3% of patients<sup>[67]</sup>. Enterointestinal fistulas are the most common type of fistula and may be relatively asymptomatic unless a large segment of intestine is bypassed or complications of obstruction arise. Broe and colleagues published that 40% of patients with fistula initially managed non-operatively eventually required surgery within 1 year, usually secondary to medical intractability<sup>[68]</sup>. The surgical management of enterointestinal fistulas generally involves resection of the primary site that has active disease and simple debridement and primary closure of the secondary site that is usually normal. Enteral fistulas to the vagina and urinary bladder often require surgery and treatment adheres to similar principles of primary site resection with repair of the secondary site. Ileal-sigmoid fistulas may represent an exception to this rule. Fazio and colleagues have shown that primary repair of a sigmoid defect is vulnerable to breakdown, particularly when the sigmoid is involved in a phlegmon<sup>[69]</sup>. They suggest that a minimal sigmoid resection can be performed with minimal morbidity<sup>[69]</sup>.

Enterocutaneous fistulas deserve special mention as these fistulas will occasionally respond to medical therapy. The most promising trials to date have evaluated the use of infliximab. The ACCENT-1 trial suggested a rapid response to 3 infusions of infliximab in 46% of patients, but the duration of effect was short-lived (only 3-4 mo)<sup>[70]</sup>. The follow-up ACCENT-2 trial showed that the duration of effect could be sustained in 46% of patients with maintenance doses of infliximab every 8 wk<sup>[71]</sup>. Surgical principles for the management of enterocutaneous fistulas parallel that for other types of fistulas. Those patients with short fistula tracts, exposed bowel mucosa, and high outputs will generally require operative intervention, but this should be delayed until the patient's health and nutritional status have been optimized.

The life-time risk for developing an abscess in Crohn's patients is estimated to be around 25%<sup>[72]</sup>. Using radiographic techniques, abscesses can often be drained percutaneously. However, some controversy exists as to whether abscesses must eventually be followed up with surgical resection of the associated diseased bowel. One study has shown that abscesses recur more frequently when they are percutaneously drained compared to surgically drained abscesses (56% *vs* 12% respectively)<sup>[73]</sup>. However, Gutierrez and colleagues have shown in a study of 66 patients only one third of patients who were

percutaneously drained required surgery at 1 year follow-up<sup>[74]</sup>. Certainly, if an abscess contains enteric contents, it is less likely to resolve without surgical resection<sup>[62]</sup>.

Other less common indications for surgery in small bowel include perforation, bleeding and cancer. Free perforation is associated with a high mortality if not treated and surgical management should involve resection rather than repair<sup>[75]</sup>. Massive hemorrhage due to Crohn's is a rare indication for surgery<sup>[76]</sup>. Other more common sources of bleeding such as peptic ulcer disease or diverticulitis must be actively ruled out. Adenocarcinoma of the small intestine, while rare, is increased 12-fold to 60-fold compared to the general population<sup>[77]</sup>. Prognosis is generally poor due to the often advanced stage of disease at the time of diagnosis. Mortality rates at 1 year or 2 years have been reported to be 30%-60%<sup>[77]</sup>.

### Surgical options

Resection is the most commonly performed surgical procedure for small bowel Crohn's disease. In general, the panenteric nature of Crohn's disease has resulted in a surgical philosophy of conservatism. Recurrence rates tend to increase with the passage of time<sup>[78]</sup> and Crohn's disease patients may eventually require multiple resections, each increasing the risk of short-bowel syndrome and its associated metabolic morbidities. Of note, Glehen and colleagues have reported that Crohn's disease patients start out with shorter bowel than the normal population<sup>[79]</sup>.

A number of studies have investigated whether certain technical factors, including resection margin and configuration of anastomosis, influence the rate of recurrence. Two retrospective Swedish studies suggested that "radical" resection resulted in a much lower rate of resection and better quality of life in Crohn's patients. Krause and colleagues studied 186 patients with margins of uninvolved bowel of less than 10 cm or greater than 10 cm (a radical resection). They reported a 31% recurrence rate and better quality of life with radical resection compared to an 83% recurrence rate in the other group<sup>[80]</sup>. Softley and colleagues used a 4 cm histologic margin and found that impingement on this margin resulted in a ten-fold increase in recurrence<sup>[81]</sup>.

However, the best evidence available that large resection margins do not decrease the rate of recurrence is based on a study performed by Fazio<sup>[82]</sup> where 131 patients were randomized to resection with margins of either 2 cm of uninvolved bowel (75 patients) or 12 cm (56 patients). Although the rate of recurrence was lower in the group with more extensive resection (25% *vs* 18%), this difference did not achieve statistical significance. In Fazio's study, grossly normal resection margins were used. Hamilton and colleagues studied the role of frozen section examination of bowel wall at the resection margins during surgery and found there was no difference in reoperation or recurrence rates in Crohn's patients with disease-free margins that were detected histologically or grossly<sup>[82]</sup>.

The type of anastomosis performed in small bowel resections has also been speculated to affect recurrence rates. Since fibrostenotic disease is a described clinical phenotype of Crohn's disease by the Vienna Classification<sup>[83]</sup>, it was

thought that the larger lumen of a side-to-side anastomosis would be less likely to obstruct and require re-operation. Stapled anastomoses have been reported to have lower morbidity and recurrence rates<sup>[84,85]</sup>. Resegotti also reported lower anastomotic leak rates in stapled versus hand-sewn anastomosis<sup>[86]</sup>. However, it has been suggested that certain circumstances clearly favor hand-sewn anastomosis, particularly when joining thickened (but grossly disease-free) bowel which may exceed the specifications of a bowel stapler<sup>[62]</sup>.

Recurrence rates following resection remain high and although not all symptomatic recurrence requires surgery, it has been reported that surgical re-intervention occurs in 25%-35% of patients at 5 years and 40%-70% at 15 years<sup>[87]</sup>. However, several trials have been done to evaluate patient and disease factors as well as medication regimens which may decrease recurrence. Yamamoto has recently published a comprehensive systematic review of factors affecting Crohn's recurrence after surgery<sup>[88]</sup>. His review concludes that cessation of smoking seems to be the most consistent factor in reducing recurrence. While several other factors (including 5-ASA use, immunosuppressant drugs, wider anastomosis, and disease duration) may affect recurrence rates, further studies are still required<sup>[88]</sup>. Post-surgical recurrence in Crohn's disease is still largely unpredictable<sup>[89]</sup>.

When preservation of intestinal length is an issue, stricturoplasty represents an alternative to resection and can reduce the risk of short bowel syndrome. Indications for stricturoplasty include short fibrous strictures; diffuse involvement of the small bowel involving multiple strictures, a stricture in someone who has short bowel syndrome or a history of multiple prior small bowel resections, patients with a rapid recurrence of Crohn's disease manifested as obstruction, or patients with duodenal Crohn's disease. Stricturoplasties should not be done in patients with multiple strictures within a short segment, a long (< 20 cm) stricture, or stricture close to a site of resection<sup>[62]</sup>. Perforation, fistula and phlegmon at the site of stricture are also contraindications to stricturoplasty. The largest stricturoplasty experience published to date comes from the Cleveland Clinic in which 698 stricturoplasties were performed in 162 patients<sup>[90]</sup>. Their cited recurrence rate at 5 years was 28% which is similar to published rates of recurrence following resection. In addition to relieving obstruction, there have been reports of disease regression at sites of stricturoplasty<sup>[91]</sup>. Indeed, in the Cleveland Clinic series, documented recurrences only occurred at the previous stricturoplasty site in 5% of cases<sup>[90]</sup>. Fearnhead and colleagues have recently published a long-term follow-up of 479 stricturoplasties in 100 patients<sup>[92]</sup>. Over a mean follow-up of 85 mo, the overall morbidity rate was 22.6% with septic complications (leak, fistula or abscess) occurring in 11.3%. Obstruction occurred in 4.4% of patients while rate peri-operative mortality rate was 0.6%. Although bleeding from stricturoplasty sites has previously been cited as a potentially serious problem due to the presence of a suture line in diseased bowel, Fearnhead found a gastrointestinal hemorrhage incidence of only 3.8%<sup>[92]</sup>.

One disadvantage of performing a stricturoplasty is

that a malignancy of the bowel can be missed. Several case reports have been published of adenocarcinoma arising from Crohn's-related stricture sites. To avoid missing a cancer in a longstanding stricture, it has been suggested that full-thickness biopsies should be taken for frozen section to aid the surgeon in the decision to perform either stricturoplasty or resection<sup>[93]</sup>.

Other surgical options for the treatment of small bowel Crohn's disease include bypass operations or ileostomy formation. Bypass operations have largely been abandoned due to the risk of malignancy and continued disease activity<sup>[62]</sup>. A role for bypass may be for temporary relief of obstruction when a future resection is planned<sup>[62]</sup>. An ileostomy may be required in Crohn's patients when enteric anastomosis is unsafe (sepsis, unstable patient, severe malnutrition, chronic immunosuppression) or when small bowel resection is done in conjunction with colonic or rectal resection.

## CROHN'S DISEASE: COLON

### Indications

Crohn's colitis occurs in approximately one quarter of Crohn's patients although colonic disease is most frequently seen in conjunction with terminal ileal disease<sup>[62]</sup>. As with small bowel Crohn's disease, indications for surgery in colonic Crohn's disease can be grouped into complications of the disease and failure of medical therapy. Indications specific to colonic disease include the development of dysplasia or colorectal cancer and toxic colitis. The treatment of obstruction and fistula of the colon may differ from that in the small bowel.

Obstruction from colonic strictures may be present in as many as 17% of patients with Crohn's colitis<sup>[94]</sup>. There is some evidence to suggest that benign strictures may be adequately treated by endoscopic balloon dilatation<sup>[95,96]</sup>. A recent series of 16 patients by Nomura showed 75% had symptomatic relief after an initial dilation with one third of patients requiring further dilations within two years<sup>[96]</sup>. All colonic strictures should be endoscopically biopsied as 7%-10% may contain malignancy<sup>[94]</sup>.

Despite earlier studies suggesting that the risk of colorectal cancer was lower than that seen in ulcerative colitis, the current literature suggests that the risk is equivalent<sup>[97]</sup>. Maykel and colleagues have published a retrospective analysis of 222 patients who underwent resection for colonic Crohn's disease<sup>[98]</sup>. Five cases of dysplasia (2.3%) and 6 cases of adenocarcinoma (2.7%) were identified. Of note, in only 3 of the dysplasia cases and 1 of the adenocarcinoma cases was the abnormality identified preoperatively. Consistent with previous reports, Maykel further identified older age at diagnosis of Crohn's disease, duration of disease (greater than 8 years) and extent of disease (pancolitis) as risk factors for the development of dysplasia or cancer<sup>[98]</sup>.

As with ulcerative colitis, surgery is indicated for a proven malignancy, high-grade dysplasia, or DALM in colonic Crohn's disease and the diagnosis and management of low-grade dysplasia is still controversial<sup>[99]</sup>. A recent Cochrane review suggests that surveillance endoscopy does

not necessarily improve survival despite the earlier detection of cancers<sup>[100]</sup>. Nonetheless, current recommendations for surveillance in Crohn's colitis mirror those for ulcerative colitis<sup>[19]</sup>.

Fistulous disease can also occur with Crohn's colitis. However, it is important when assessing fistulas involving the colon to determine the primary site of the fistula. Endoscopic evaluation of the colonic mucosa should be performed. Enterocolonic fistulas in Crohn's patients are often a result of primary small bowel disease with the colon only secondarily involved. In these circumstances, it is generally preferable to debride the colonic side of the fistula and close the defect rather than perform a colonic resection<sup>[101]</sup>. Despite the introduction of new medical therapies, such as infliximab, 50%-75% of patients with colonic fistulas will require surgery<sup>[102]</sup>.

Toxic colitis in Crohn's disease has a similar presentation to that in ulcerative colitis. Operative indications include perforation, lack of improvement with medical management, fulminant colitis, massive hemorrhage and hemodynamic instability. As with ulcerative colitis, the most common procedure for toxic colitis in Crohn's disease patients is subtotal colectomy and end ileostomy<sup>[62]</sup>.

### Surgical options

The extent of resection in patients with only segmental colonic disease is a subject of some debate. A recent meta-analysis of six studies encompassing 488 patients suggests that there is no significant difference in overall recurrence rate, complications or need for permanent stoma between segmental colectomy and total abdominal colectomy with ileorectal anastomosis, but time to recurrence was longer in the total abdominal colectomy group by 4.4 years<sup>[103]</sup>. This is in contrast to previous studies which actually suggested the more extensive procedure (total abdominal colectomy) was associated with a higher recurrence. Bernell published a review of 833 patients and found the 10 year recurrence rate of total abdominal colectomy and ileorectal anastomosis to be 58% compared to 47% in the segmental colectomy group<sup>[87]</sup>. Another study found similar recurrence rates in both groups, but better functional outcomes in the segmental colectomy group<sup>[104]</sup>. In patients with diffuse colitis and proctitis, total proctocolectomy has been associated with less medication use 1 year after operation as well as increased time interval to first recurrence when compared to total abdominal colectomy or segmental colectomy<sup>[105]</sup>. Tekkis has suggested that more extensive resection such as total abdominal colectomy may be more appropriate when 2 or more segments of colon are diseased<sup>[103]</sup>.

Restorative proctocolectomy with ileal pouch-anal anastomosis (IPAA) for Crohn's disease has most often occurred in the setting of a changed diagnosis following IPAA for ulcerative colitis or indeterminate colitis<sup>[62]</sup>. A majority of studies suggest that IPAA in Crohn's disease is associated with a significantly higher rate of morbidity (including pouch failure, incontinence, and pouchitis) than in ulcerative colitis<sup>[106,107]</sup>. Although a few authors have suggested that IPAA may be appropriate in highly selected patients with Crohn's disease<sup>[108,109]</sup>, the current literature

certainly does not support its general use in the Crohn's population.

## ANORECTAL CROHN'S DISEASE

### *Indications for surgery*

About 10%-15% of Crohn's disease patients will have disease limited to the anorectal area but up to 90% of all patients have some manifestation of anorectal disease<sup>[110]</sup>. Perianal disease, including fissures, fistulas and abscesses, can have both typical and atypical presentations. Damage of even a small amount of sphincter muscle can lead to severe morbidity.

Anal skin tags and hemorrhoidal disease may present in up to 70% of patients with anorectal Crohn's<sup>[110]</sup>. These lesions are most often asymptomatic, but may present problems with hygiene, particularly in the context of a diarrheal illness. Patients being seen for potential surgical therapy of these problems should be counseled regarding the risk for non-healing wounds and loss of continence following surgery. Anal skin tags and hemorrhoidal disease are best treated conservatively<sup>[111]</sup>.

Anal fissures are a challenging problem in the Crohn's population. These fissures are often painless and do not necessarily present in the anterior or posterior midline. Often, there is concomitant disease or multiple fissures. While the initial therapy for fissures should be conservative (that is, fiber and fluid supplementation with local medications to aid in sphincter relaxation), some studies have shown that 50% of Crohn's patients will fail medical management<sup>[112]</sup>. Thus, if patients are suffering from significant symptoms of pain, these authors have advocated for a more aggressive approach including lateral sphincterotomy. Wolomir and colleagues published a series of 25 Crohn's patients who underwent sphincterotomy<sup>[113]</sup>. Twenty-two patients had completely healed their fissures within 2 mo and at an average follow-up of 7.5 years, there were no direct complications of sphincterotomy. However, given the risks of decreased continence with surgery, surgical management should be reserved for those with minimal active anorectal inflammation who have truly failed conservative management and have significant symptoms. Division of sphincter muscle should be minimal.

Anorectal abscesses and fistula-in-ano are common problems in the Crohn's population. Treatment of simple abscesses involves incision and drainage. It is important to place the incision as close to the anal verge as possible while still achieving adequate drainage as a fistula may form in the future. It is unclear whether fistulas from Crohn's disease are more common following abscesses or develop in the same way as those of a cryptoglandular origin. As such, Crohn's fistulas may erode deep into sphincter muscle or have complicated, blind tracts. Treatment of these fistulas is closely associated with the anatomy of the fistula, the amount of sphincter complex involved, as well as the status of the patient's fecal and gas continence. Furthermore, the surgeon must consider active disease elsewhere in the gastrointestinal tract and the potential for chronic diarrhea. Aggressive procedures which may

alter continence should be avoided. Treatment options include setons, fistula plugs and mucosal advancement flaps. While several authors have suggested that these procedures can be performed with similar success rates to identical procedures performed in non-Crohn's patients, these studies tend to lack appropriate follow-up<sup>[62]</sup>. There has been some suggestion that fecal diversion following a definitive procedure for fistula-in-ano may improve resolution rates<sup>[114]</sup>.

In rare cases, anorectal disease is insufficiently controlled by adequate drainage of infection and medical management. Assuming that Crohn's disease is still the primary diagnosis, these patients may be assessed for diversion with or without proctectomy<sup>[62]</sup>. While the vast majority of patients will respond to medical management or conservative surgical management such as seton placement, there is evidence that fecal diversion helps the resolution of peri-anal disease, at least temporarily<sup>[115]</sup>. As many as 80% of patients with peri-anal Crohn's manifestations will respond to diversion, but relapse may occur despite a stoma, and restoration of intestinal continuity occurs in a minority of patients<sup>[115]</sup>. A multivariate analysis performed by Galandiuk and colleagues suggest that colonic Crohn's disease and anal stenosis are risk factors for fecal diversion<sup>[116]</sup>.

## LAPAROSCOPIC PROCEDURES FOR CROHN'S DISEASE

The safety and feasibility of laparoscopic resections for treatment of Crohn's disease has been extensively studied<sup>[117]</sup>. Unlike ulcerative colitis, robust data is available for laparoscopic resection in Crohn's disease. Two randomized, controlled studies have been published suggesting that the laparoscopic ileocolic resection is associated with decreased morbidity and length of stay in the hospital<sup>[61,118]</sup>. Maartense further suggested that overall costs of laparoscopic resection were lower<sup>[118]</sup>. While operative times have decreased with increased experience, most studies still suggest significantly longer operative times when compared to open procedures.

## PREPARING THE IBD PATIENT FOR SURGERY

Preparation for surgery is a multidisciplinary approach. Surgery for inflammatory bowel disease differs from cancer surgery in several aspects. Surgery is generally elective and several treatment options are available. Medically intractability and unacceptable symptoms are subjective in nature. Pre-operatively, the patients may be severely malnourished or on high-dose immunosuppressants or steroids. Patients are generally younger and issues including future child-bearing, sexual function and body image have increased importance. Preparation for surgery requires close interaction between many health care team members (including surgeons, gastroenterologist, primary care physicians and enterostomal therapists) and the patient.

Counseling should include a discussion of the extent of disease, the specific indication for surgery,

and alternatives to surgery. A description of the surgical procedure should include risks and complications of the surgery, but also possible intra-operative findings and a discussion about how intra-operative decisions will be made. Particular attention should be made towards issues of bowel function and continence. It is important to assess the patient's expectations from surgery. As stated above, surgery is often elective, but still associated with significant morbidity. The specific surgical procedure or timing of the procedure should be modified, as possible, to reflect the needs of the patient.

Finally, we recommend that patients undergoing surgery for inflammatory bowel disease are referred to former patients who have had similar procedures. In our experience, previous patients are very willing to share their experiences, offer a different perspective and are usually helpful. If possible, we try to match patients according to sex, age and marital status.

## CONCLUSION

While the indications for surgery in IBD are relatively straight forward (intractability or complications), the precise timing and specific procedure(s) to be performed are often fraught with controversy. In ulcerative colitis, the correct diagnosis and management of low grade dysplasia is still a work in evolution. IPAA is the most common procedure performed, but may be contraindicated in certain populations such as the elderly. Other patient cohorts may be appropriate for single-stage IPAA. The performance of a mucosectomy (and its associated morbidity) may be indicated, particularly in those with rectal dysplasia or cancer. In Crohn's disease, the panenteric nature of the disease leads to significant recurrence rates. While surgical conservatism is the current general rule, several authors have advocated for a more aggressive approach in small bowel, colonic, and anorectal disease. In both ulcerative colitis and Crohn's disease, laparoscopic procedures seem to be associated with increased operative times, but could also result in decreased morbidity while providing similar functional results to open procedures.

## Abstract

Metastasis is the principal cause of cancer mortality, with the lymphatic system being the first route of tumor dissemination. The glycoproteins VEGF-C and VEGF-D are members of the vascular endothelial growth factor (VEGF) family, whose role has been recently recognized as lymphatic system regulators during embryogenesis and in pathological processes such as inflammation, lymphatic system disorders and malignant tumor metastasis. They are ligands for the VEGFR-3 receptor on the membrane of the lymphatic endothelial cell, resulting in dilatation of existing lymphatic vessels as well as in vegetation of new ones (lymphangiogenesis). Their determination is feasible in the circulating blood by immunoabsorption and in the tissue specimen by immunohistochemistry and reverse transcription polymerase chain reaction (RT-PCR). Experimental and clinicopathological studies have linked the VEGF-C, VEGF-D/VEGFR3 axis to lymphatic spread as well as to the clinical outcome in several human solid tumors. The majority of these data are derived from surgical specimens and malignant cell series, rendering their clinical application questionable, due to subjectivity factors and post-treatment quantification. In an effort to overcome these drawbacks, an alternative method of immunodetection of the circulating levels of these molecules has been used in studies on gastric, esophageal and colorectal cancer. Their results denote

## INTRODUCTION

Lymph node metastasis (LNM) is a major prognostic factor for most human solid epithelial tumors.

Although the phenomenon of lymphatic spread of tumors is well recognized for over a century, many aspects of cancer cells entrance, survival and proliferation in the lymphatic system remain unclear<sup>[1,2]</sup>. To date, the experimental findings regarding active lymphangiogenesis in human solid tumors are contradictory<sup>[3,4]</sup>.

The molecular and functional mechanisms of lymphatic system regulation and cancerous involvement have only recently been recognized, mainly due to the discovery of lymphatic endothelial cells (LEC) specific markers (LYVE-1, Prox-1, podoplanin, VEGFR3) in the past decade<sup>[5,6]</sup>.

## THE VEGF-C, D/VEGFR-3 SYSTEM

VEGFR-3 (fms-like tyrosine kinase 4, Flt4) is one of the first LECs surface molecules to be identified. It is a member of the VEGFR family, also including VEGFR-1 (Flt-1), VEGFR-2 (KDR), and which belongs to the platelet derived growth factor receptor sub-family of receptor tyrosine kinases<sup>[7]</sup>. VEGFR-3 is present on all endothelia during

development, but in the adult its expression is restricted to LECs and certain fenestrated blood vascular ECs<sup>[8,9]</sup>.

The importance of VEGFR-3 for the development of the lymphatic vasculature has been shown recently, where early onset primary lymphedema was linked to the VEGFR3 locus in distal chromosome 5q<sup>[10,11]</sup>. It also protects LECs from serum deprivation-induced apoptosis, induces their growth and migration, while one study on a corneal model showed that it could play a role in adaptive immunity<sup>[12,13]</sup>. Nevertheless, this LEC specificity seems to be lacking in cancer cell types, an observation which contributes to the difficulty of defining molecular regulation of LNM<sup>[14]</sup>.

The vascular endothelial growth factor (VEGF) family of glycoproteins comprises the most crucial group of neovascularization regulators in development and disease (Table 1). Currently, it consists of 5 cytokines in mammals, VEGF, PlGF (platelet induced growth factor), VEGF-B, VEGF-C and VEGF-D, and in addition, *parapoxvirus* genome-encoded VEGF (viral VEGF, also denoted as VEGF-E) and snake venom-derived VEGF (also referred as VEGF-F)<sup>[17-19]</sup>.

VEGF-C and VEGF-D subtypes have been identified as the ligands for the lymphatic endothelial receptor VEGFR3, as well as for the blood vessels endothelial receptor VEGFR2, while VEGF-C also binds the LEC surface molecule NRP-2<sup>[20-23]</sup>.

Among the other family members, they share a central VEGF homology domain, but they differ because of the distinct presence of long N- and C-terminal propeptides. VEGF-C and VEGF-D are secreted as precursor proteins, which are cleaved to their VEGFR-specific active forms through a two-step proteolytic procedure<sup>[24-27]</sup>. The extent of the proteolytic process defines its receptor affinity and presumably its biological activity, although this connection is only partially understood. Both VEGF-C and VEGF-D are able to induce proliferation and migration of lymphatic endothelial cells *in vitro*<sup>[23]</sup>.

The correlation of VEGF-C, D/VEGFR3 axis to the lymphatic spread of tumors is documented in several experimental models and clinicopathological studies in a variety of human malignancies.

The findings derived from malignant cell line models provide the most “direct” evidence for the implication of lymphangiogenic growth factors in tumor lymphatic spread<sup>[28-32]</sup>. However, the observed correlation does not explain the underlying mechanisms, nor does it clarify the role of active tumor induced lymphangiogenesis in cancer metastasis. Nevertheless, and more importantly, the inhibition of the ligand-receptor axis raised interest in anti-lymphangiogenic targeting research, a potentially promising novel field of cancer treatment<sup>[33-35]</sup>.

Taking into account the rationale of VEGF-C and VEGF-D involvement in lymphatic system regulation, researchers throughout the world studied the expression of these growth factors in human tumors and their possible connection to metastatic potential<sup>[36,37]</sup>. The methodology used for “quantitative” determination was either immunohistochemistry (IHC), or RT-PCR to detect mRNA and subsequently the level of gene expression. These studies include a wide range of solid tumors (gastrointestinal, breast, genitourinary, melanoma, thyroid, head and neck),

**Table 1** Mammalian vascular endothelial growth factor family of ligands

	Receptor	Chromosomal location	Angiogenesis	Lymphangiogenesis
VEGF	VEGFR1, VEGFR2, NRP1	6p23.1	+	Conflicting data <sup>1</sup>
VEGF-B	VEGFR1, NRP1	11q13	Conflicting data	-

VEGF-C	VEGFR2	4q34	Modest	+
VEGF-D	VEGFR2, VEGFR3	Xp22.31	Modest	+

<sup>1</sup>Indirect lymphangiogenic effect, by recruiting VEGF-C and VEGF-D producing macrophages<sup>[15]</sup>. Lymphangiogenesis *via* alternative, VEGFR3-independent pathway<sup>[16]</sup>.

in an attempt to relate VEGF-C and VEGF-D expression to clinicopathological parameters (lymph node involvement, lymphatic and vascular invasion, clinical outcome).

The majority of such studies confirmed a positive correlation between growth factor expression and adverse oncological features. Yet, the results are not always consistent<sup>[38-41]</sup>.

Conflicting results could be attributed to methodological considerations<sup>[42,43]</sup>: (1) Immunohistochemical quantification is a somehow subjective observer-dependant modality. Terms like “overexpression” are not always well defined, as they are based on variable scoring systems; (2) RT-PCR does not discriminate the location of mRNA expression among cancer cells, adjacent normal epithelium and stromal cells in a tissue specimen, nor does it necessarily reflect the actual protein level<sup>[44]</sup>.

Van der Auwera *et al*<sup>[45]</sup> proposed a composite method for lymphangiogenesis quantification in solid tumors, in order to establish standardization of immunohistochemical assessment.

## CIRCULATING VEGF-C AND VEGF-D IN HUMAN SOLID TUMORS

An alternative method of VEGF-C and VEGF-D quantification is indirect enzyme-linked immunoadsorption assay (ELISA), which measures the protein levels in peripheral circulation samples. This approach has been applied in selected studies during the last 5 years (Table 2).

The quantification of circulating cytokines has the advantage of being more objective approach, which lacks the drawback of interobserver variability. Moreover, as a preoperatively practicable modality, it exhibits a potential application as a readily available LNM marker and subsequently surgical decision making tool, particularly in cases such as: (1) Early malignant lesions, which bear a small, yet substantial risk of lymphatic dissemination and which, otherwise, could be treated with minimally invasive techniques; (2) Cancers which necessitate accurate preoperative staging, in order to employ stage-specific neoadjuvant therapy; (3) Cancers whose treatment approach relies on the presence or extent of lymph nodes metastasis.

**Table 2** Studies on circulating VEGF-C/D in human solid malignancies (clinicopathological association)

Tumor	Marker	Sample	Cases (n)	LNM	Prognostic impact	Ref.
Gastric cancer	VEGF-C	Serum	80	$P = 0.001$	$P = 0.001$	67

ND: Not determined; <sup>1</sup>Indirect result; <sup>2</sup>None statistically significant; <sup>3</sup>Post-treatment study; <sup>4</sup>Non small cell; <sup>5</sup>Head and Neck Squamous Cell Carcinoma.

Circulating lymphangiogenic growth factors have been investigated in malignant tumors whose lymph node status detection is crucial in terms of treatment planning, including cancers of the gastrointestinal tract.

### Gastric cancer

Gastric cancer remains a leading cause of cancer mortality worldwide, despite its declining incidence in the West in the last decades, and lymph node metastasis is the most powerful prognostic factor in R0 resected cases.

Clinicopathological studies mainly from Japan, where gastric cancer is the most common malignancy, have correlated mRNA and immunohistochemical expression of VEGF-C and VEGF-D in gastric tumour cells with lymphatic invasion and lymph node metastasis<sup>[56-60]</sup>. Their quantitative expression has been reported as a prognostic factor<sup>[56,59]</sup>, while the experimental blocking of the VEGFR-3 signalling pathway is under investigation<sup>[61]</sup>. Nikiteas *et al.*<sup>[62]</sup> showed that VEGF is also implicated in lymphatic spread of gastric cancers, a finding reproduced in a Japanese population<sup>[63]</sup>.

Studies on early gastric adenocarcinoma (EGC) have been carried out as well. Kabashima *et al.*<sup>[64]</sup> found using immunohistochemistry that the incidence of positive expression of VEGF-C in lymphatic invasion-positive EGC (36%) was significantly higher than that in lymphatic invasion-negative EGC (14%). The incidence of positive expression of VEGF-C in nodes (+) or venous invasion-positive EGC tended to be higher than that in nodes (-) or venous invasion-negative EGC. Ishikawa *et al.*<sup>[65]</sup> studied the expression of VEGF-C and VEGF-D in resection specimens related to tumors differentiation, concluding that in EGC of histologically undifferentiated type with negative expression of VEGF-C and -D, limited surgery might be safely applied because the possibility of nodal metastasis is very low. Onogawa *et al.*<sup>[66]</sup> investigated whether expres-

sion of VEGF-C and/or VEGF-D correlates with clinicopathological features of submucosally invasive gastric carcinoma. VEGF-C immunoreactivity was associated with histological type, lymphatic invasion, lymph node metastasis, and microvessel density, while no association was identified between VEGF-D immunoreactivity and clinicopathological variables. Those studies suggest that the detection of VEGF-C and VEGF-D could play a role as an additional element of EGC local excision criteria.

One study on circulating VEGF-C in gastric cancer has been reported so far. Wang *et al.*<sup>[67]</sup> investigated whether serum VEGF-C and immunohistochemically determined VEGF-C expression and lymphatic vessel density (LVD) in tumor tissues are related to lymph node metastasis and prognosis in gastric cancer. LVD was determined based on brown staining of endothelial cells with podoplanin under a 200-fold light microscopic field.

The sVEGF-C level was significantly ( $P = 0.000$ ) higher in patients with gastric cancer ( $595.9 \pm 201.0$  ng/L) than in healthy donors ( $360.0 \pm 97.4$  ng/L). With a cut-off value for sVEGF-C of 367.5 ng/L, the sensitivity and specificity for diagnosis of gastric cancer patients was 85% and 80%, respectively ( $P = 0.000$ ). VEGF-C positive expression was significantly ( $P = 0.001$ ) higher in gastric cancer tissue (50/80) than in normal gastric tissue (4/20). There was significantly ( $P = 0.000$ ) more LVD in the experimental group ( $10.7 \pm 3.1/200$  HP) than in control subjects ( $4.9 \pm 1.3/200$  HP). The sVEGF-C level was significantly ( $P = 0.000$ ) higher in VEGF-C positive patients ( $675.4 \pm 153.9$  ng/L) than in negative patients ( $463.5 \pm 200.4$  ng/L). There was a positive correlation between sVEGF-C and LVD ( $r = 0.728$ ,  $P = 0.000$ ). LVD in VEGF-C positive and negative groups was  $12.2 \pm 2.8/200$  HP and  $8.3 \pm 2.0/200$  HP, respectively ( $P = 0.000$ ).

With respect to clinicopathological correlations, sVEGF-C was significantly ( $P = 0.001$ ) higher in differentiation degree G3 group, LNM (+) group, M (+) group and pTNM III-IV group. With a 3 year follow up, the mean survival of patients with high ( $> 595.9$  ng/L) sVEGF-C and low ( $< 595.9$  ng/L) sVEGF-C was  $29.1 \pm 13.3$  mo and  $44.0 \pm 4.6$  mo, respectively ( $P = 0.001$ ).

**Clinical relevance:** It is well known that a notable discrepancy exists between Japan and USA-Europe regarding gastric cancer, with respect to staging, surgical management and outcome<sup>[68-70]</sup>. The extent of lymph node dissection (D1 vs D2) is considered a major factor of curative outcome according to the Japanese. The reluctance of the Western surgical community to uniformly adopt this approach is supported with evidence derived by two large prospective randomized controlled studies conducted in Europe in the 1990s<sup>[71,72]</sup>. Both trials concluded that D2 dissection is followed by significantly higher morbidity and mortality, without an overall proven survival benefit. However, the same investigators revised their long term results<sup>[73-75]</sup> and acknowledged that the complications should be largely attributed to modifiable technical aspects, such as splenectomy and distal pancreatectomy and to limited experience, and most importantly, there is evidence that D2 dissection could be beneficial for a subgroup of patients, basically

those with stage II and IIIa according to TNM. Similar conclusions are derived from non-randomized and retrospective studies from selected centers<sup>[76-80]</sup>.

Taking into account the suggestion of stage-specific benefit, the next challenge would be to identify the candidates for extended lymph nodes dissection. Several modalities for preoperative staging have been studied; but, the results on nodal detection are insufficient to dictate an individualized surgical approach.

Imaging techniques are the most widely used, relying on morphologic criteria<sup>[81-85]</sup>. Abdominal CT scan is the most popular method, with poor specificity on detecting N status, as the sole factor is nodal size, and without capability for accurate number detection. Endoscopic ultrasound is considered more valuable for evaluating primary tumors; yet it is not proven superior to CT regarding nodal involvement evaluation. Positron emission tomography scan is helpful in detecting occult distant metastasis; but, has no role in regional nodal staging. Besides, modern imaging techniques bear a considerable cost and entail operator-dependant variables.

Invasive staging methods, such as laparoscopy, peritoneal cytology and intraoperative ultrasonography are certainly not "preoperative" and studies on sentinel lymph node biopsy using radiographic mapping seem promising in gastric cancer staging; yet, the latter necessitates trained personnel and special equipment and is not widely applicable<sup>[86,87]</sup>. Maruyama and co-workers developed a computerized database program to calculate the probability of individual lymph node station involvement, a model with limited clinical impact<sup>[88,89]</sup>.

The connection of VEGF-C and VEGF-D to lymphatic spread, as previously shown in clinicopathological studies, provides the rationale that preoperative quantification of these cytokines could yield additional information regarding lymph nodes involvement in gastric cancer patients.

Wang *et al*<sup>[67]</sup> study converges as to that point. This study indicates that preoperative serum VEGF-C level might be a useful biomarker for the presence of LNM in patients with gastric cancer and a prognostic parameter to identify patients with poor outcome. Nonetheless, the researchers provide no evidence with respect to the extent of lymph node dissection they employed, and so no correlation can be made regarding prognostic significance of VEGF-C and extent of surgery.

### Esophageal cancer

Cancer of the esophagus is a human malignancy with unfavorable prognosis, regardless histological type and despite the induction of multimodality approach in the treatment of this formidable disease. The prevalence of adenocarcinoma of the distal esophagus in particular, is reported to increase in Western populations<sup>[90]</sup> and due to its location, bilateral lymph node metastasis to thoracic and abdominal cavity occurs with adverse prognostic aftermath.

Clinicopathological and experimental studies on VEGF-C/D expression in squamous cell (escc)<sup>[41,91-94]</sup> as well in adenocarcinoma (ac)<sup>[94-96]</sup> specimens have been published. Studies on escc resulted on a relatively consistent correlation of growth factors expression to tumor

progression and lymphatic spread, while evidence for their role in ac is contradictory. Interestingly, all studies on adenocarcinoma come from the West.

It is worth noting that there is evidence which correlate lymphangiogenic growth factors to malignant potential of early or precancerous lesions. Auvinen *et al*<sup>[97]</sup> showed immunohistochemically that VEGF-C expression increases in Barrett's epithelium as it progresses through dysplasia to adenocarcinoma and that VEGFR3 parallels this increase. Additionally, tumor-induced lymphatics were detected which could provide the route for systemic cancer dissemination. Ishikawa *et al*<sup>[98]</sup> examined the expression of VEGF-C and -D in 26 esophageal carcinoma cases and 11 dysplasia cases using IHC and found that active production of VEGF-C and -D was observed, not only in esophageal carcinomas, but also in some dysplastic lesions and in none of the normal mucosa specimens, raising the possibility that VEGF-C and -D might play positive roles in the early stage of esophageal carcinogenesis. Matsumoto *et al*<sup>[99]</sup> examined VEGF-C expression and tumor microvessel density of the primary tumors in escc and analyzed relationships between VEGF-C expression and clinicopathological findings, including lymph node micrometastasis (LMM), in 87 submucosal esccs. The findings indicate that in escc with submucosal invasion, VEGF-C overexpression of the primary tumor is a strong high risk factor for lymph node metastasis, including LMM.

Two studies on serum VEGF-C as biological marker in escc have been reported, both from the same department<sup>[101,102]</sup>. Krzystek-Korpacka *et al*<sup>[100]</sup> examined serum concentrations of VEGF-C in 70 patients with escc and 47 healthy individuals. However, only 23 patients were subjected to surgery, due to advanced disease of the remainder, which were staged using endoscopy, imaging modalities and laparoscopy. Median serum VEGF-C level (sVEGF-C) in escc patients was significantly elevated in comparison to controls (17.40 ng/mL *vs* 10.57 ng/mL,  $P < 0.001$ ). Serum VEGF-C was significantly elevated when metastatic lymph nodes were present, as median sVEGF-C was 21.78 ng/mL in N0 *vs* 15.77 ng/mL in N1 cases ( $P = 0.022$ ). The authors also examined the dependence of sVEGF-C and combined TN status of the examined cancers and found no stage-specific correlation, presumably due to a small sample of patients. The optimal cut-off value for application of sVEGF-C as a marker of the disease presence was calculated 14.57 ng/mL (mean  $\pm$  SD), whereas 16.24 ng/mL (mean  $\pm$  1.5 SD) for detection of metastatic lymph nodes. The accuracy of sVEGF-C determination as a disease marker was 83.7% while 64.4% as a lymph node involvement marker. Moreover, in an effort to address the issue of tumor induced secretion, the authors correlated WBC and PLT count to TNM stage and concluded that WBCs parallel sVEGF-C levels, rather than contribute to their elevation.

The same team enrolled the former group of patients and controls in a study on circulating levels of midkine (sMK), a cytokine whose secretion found to be an escc marker and prognostic factor in Japanese populations<sup>[102,103]</sup>. Statistically higher sMK levels were found in cancer patients than in controls (1373 pg/mL *vs* 130 pg/mL) and in cases with lymph nodes metastasis (775 pg/mL in N0 *vs*

1893 pg/mL in N1). The utility of sMK as a LNM marker was calculated to have a 91.2% sensitivity and a 77.8% specificity. The best cut-off values calculated were 563 pg/mL for determination of the presence of disease and 937 pg/mL for evaluation of LNM. Correlations of sMK and TNM stage have been implied as well. Serum midkine levels correlated significantly with serum VEGF-C levels in N1 ( $P = 0.008$ ) and combined N + M ( $P = 0.001$ ) cases.

**Clinical relevance:** Surgical resection offers the only realistic chance for cure in patients with esophageal cancer and accurate preoperative staging is of outmost importance when surgery with curative intent is contemplated.

Esophagectomy procedures are associated with high morbidity and mortality, especially when performed in low volume centers<sup>[104,105]</sup>, and even if successful, they negatively impact quality of life over a considerable period of time<sup>[106]</sup>, so it is imperative to identify resectable cases among the patients. Lymph nodes involvement is a major determinant of resectability, as LNM beyond regional lymph nodes as defined by the American Joint Commission in Cancer<sup>[107]</sup> precludes surgical treatment, with a debatable exception of celiac axis involvement<sup>[108]</sup>.

Despite the importance of R0 resection, prognosis of esophageal cancer remains bleak, and a multimodality strategy has been introduced currently, in an effort to improve curative outcome. This approach includes the combination of surgery, chemotherapy and radiotherapy. Nevertheless, much controversy exists regarding the appropriate combination of these modalities and the determination of patient categories which will mostly benefit from multimodality treatment<sup>[109-112]</sup>. Although hard evidence is lacking, the trend is to treat patients with locally advanced esophageal cancer (stage III, T3-4, N1) with neoadjuvant chemoradiotherapy followed by surgery, a strategy which necessitates accurate preoperative staging.

Imaging techniques are again the mainstay of staging, including CT, EUS, EUS-FNA, FDG-PET and CT-PET, with variable sensitivity, specificity, and feasibility<sup>[113-117]</sup>. Moreover, the value of case volume has been reported to influence preoperative staging accuracy<sup>[118]</sup>. The fact that only a subgroup of patients within the same pathological stage benefit from neoadjuvant therapy raised the need to identify the cases with biological favourable tumors, so as to avoid unnecessary toxicity without concomitant survival benefit<sup>[109,119]</sup>. Imaging modalities in this setting are not sufficient, as they fall short of discriminating viable tumor from necrotic or scar tissue and to date there is no universally accepted morphological means of monitoring the response to neoadjuvant chemoradiotherapy<sup>[120-122]</sup>.

The most innovative alternative is the identification of genetic and molecular markers of response to neoadjuvant therapy<sup>[123-125]</sup>, including gene expression, genomic polymorphism, growth factors receptors, angiogenic factors, cell cycle regulators and apoptotic factors. Experimental studies provide promising data to incorporate such markers in multimodality and targeted treatment.

Krzystek-Korpaczka *et al.*<sup>[100]</sup> reported up-regulation of serum VEGF-C in esophageal squamous cell carcinoma, a finding which parallels VEGF-C expression in tissue specimens. They also correlated serum levels with the presence

of lymph node metastasis and concluded that sVEGF-C up-regulation did not arise from platelets or white blood cells. Their results show that serum VEGF-C levels can be considered a biomarker of esophageal squamous cell cancer and a predictive molecular marker of lymph nodes metastasis in particular. This remark indicates a potential utility of serum lymphangiogenic growth factors in escc as a tool for early detection and LNM evaluation.

### Colorectal cancer

LNM is a significant prognostic factor in colorectal cancer and a determinant of combined therapy regarding adjuvant as well as neoadjuvant treatment strategies.

Several clinicopathological studies on VEGF-C and VEGF-D tumoral expression have been reported, providing evidence that they correlate to LNM and prognosis<sup>[126-130]</sup>, although findings are not always consistent<sup>[138,131]</sup>. Furodoi *et al.*<sup>[131]</sup> detected VEGF-C expression at the deepest invasive site in 71 of 152 lesions (46.7%) and correlated it to histological grade, depth of invasion, lymph node metastasis, venous invasion, liver metastasis and Duke's stage. At the central portion and superficial part, there were no significant differences between VEGF-C expression and clinicopathological findings.

With respect to early lesions, Maeda *et al.*<sup>[132]</sup> examined 221 endoscopically biopsied specimens from patients with T1 colorectal carcinoma prior to operation using IHC and found that VEGF-C expression was more frequently observed in tumors with nodal metastasis than in those without metastasis. Moreover, a multivariate analysis indicated that VEGF-C expression is an independent predictor of lymph node metastasis in T1 colorectal carcinoma. Kojima *et al.*<sup>[133]</sup> investigated VEGF-C and VEGF expression at the invasive end of 65 T1 resected carcinomas and significantly correlated VEGF-C with the presence of LNM. Kazama *et al.*<sup>[134]</sup> examined VEGF-C and VEGF-D expression in submucosal colorectal cancers and concluded that VEGF-C overexpression correlated with lymphatic involvement ( $P = 0.01$ ) and lymph node metastasis ( $P = 0.02$ ), but VEGF-D overexpression did not correlate significantly.

Limited studies on circulating VEGF-C, D in colorectal cancer (CRC) yielded conflicting results.

George *et al.*<sup>[38]</sup> studied a sample of normal mucosa, adenomatous polyps and CRCs regarding IHC expression and RT-PCR mRNA expression of VEGF-C and VEGF-D and also plasma levels of VEGF-D. Plasma levels of VEGF-D were similar in normal controls, polyp patients, and CRC patients [median 494 (303-744) pg/mL, 416 (351-938) pg/mL, and 463 (291-745) pg/mL, respectively]. An interesting finding was an inverse balance of VEGF-C/VEGF-D mRNA expression in CRC samples, indicating that VEGF-D could act as a competitive antagonist to other family members.

Duff *et al.*<sup>[135]</sup> measured plasma VEGF-C in 41 CRC patients and 31 normal controls. Median plasma levels of VEGF-C were 35.0 U/mL in colorectal cancer patients compared to 11.5 U/mL in controls ( $P < 0.001$ ). VEGF-C levels tended to be elevated in patients with advanced disease (Dukes C and D) compared to early disease, but this was not statistically significant owing to a relatively

small number of patients in each group. Plasma levels of VEGF-C in their study may represent both partially processed and fully mature forms of the cytokine.

Nevertheless, another study by Duff *et al*<sup>[136]</sup>, including 120 CRC patients, failed to show significant differences in plasma VEGF-C or VEGF-D levels between patients subgrouped by clinicopathological variables. In particular, there were no differences in median plasma VEGF-C or VEGF-D level in patients with and without lymph-node involvement (VEGF-C: 11.2 U/mL *vs* 9.9 U/mL; *P* = 0.90; VEGF-D: 335 pg/mL *vs* 316.5 pg/mL; *P* = 0.68).

Finally, in a study from China<sup>[137]</sup> 66 CRC patients and 30 controls were enrolled in quantification of serum levels of VEGF-C and VEGF. Serum VEGF-C and VEGF levels were reported higher in patients with colorectal carcinoma than in healthy controls as well as in patients with lymph node metastasis than those without lymph node metastasis. Serum VEGF-C levels reached a sensitivity of 81% and a specificity of 76% with a cut-off value of 1438.0 pg/mL.

**Clinical relevance:** Rectal cancer is the type of large intestinal malignancy whose management is the most challenging regarding surgical resection and preoperative staging. With the introduction of total mesorectal excision (TME), optimal surgical technique is considered the most pivotal factor influencing curative outcome<sup>[138-140]</sup>.

However, major rectal surgery is technically challenging, related to increased risks and can not eliminate local recurrence rates. Additionally, oncological resections may lead to debilitating functional results and substantially influence quality of life. Currently, treatment of rectal cancer should be individualized and evaluation of the extent of primary cancer is essential for planning the appropriate therapy regimen, spanning from simple local excision to complex multimodality treatments.

Transanal excision is considered an acceptable alternative to radical resection when treating intramural cancer without distant spread (T1N0M0). This approach is followed even with curative intent in some centers when confronting low-risk tumors with highly favourable features<sup>[141]</sup>. Major advantages are low morbidity and mortality rates and excellent functional outcome. On the other hand, T1 tumors are related to up to 12% risk of LNM<sup>[142,143]</sup> and to recurrence rates of 10%-25% following local excision, with a fatal result for half of these patents<sup>[144-146]</sup>. The key for these unsatisfactory results could lie in imperfect preoperative staging and unrecognizable biological behaviour.

Neoadjuvant chemoradiotherapy (CRT) has been shown to significantly reduce local recurrence rates of locally advanced rectal cancer (T3-4, N0-1) without concomitant proven benefit regarding overall survival while its effect on sphincter preservation is controversial<sup>[140,147]</sup>. Nevertheless, preoperative radiation is not without of toxicity, postoperative complications and considerable cost<sup>[148,149]</sup>. Moreover, studies evaluating treatment outcome after neoadjuvant CRT have demonstrated improved survival in responding patients compared to partial or non-responders<sup>[150,151]</sup>. These findings highlight the need for accurate preoperative staging so as not to overtreat unsuit-

able patients, but also for identification of biologically favorable cancers in order to predict an optimal response.

Pre-treatment clinical staging of rectal cancer is based on integration of information obtained from digital examination, endoscopy and imaging modalities. Endoluminal imaging is considered the most valuable in locoregional staging. Endorectal ultrasonography is reported to have the best accuracy in nodal staging with a mean rate of 75%, although its performance may be overestimated in the literature due to publication bias<sup>[152,153]</sup>. MRI techniques with endorectal coil is the best means for evaluating T stage and circumferential resection margin, yet LNM detection remains problematic because it relies on non specific morphological criteria<sup>[154,155]</sup>.

To date, there are no clinically useful molecular predictors of response to preoperative CRT which could assist to better patient selection<sup>[156]</sup>. The clinicopathological correlations of VEGF-C and VEGF-D in colorectal cancer, including early lesions, provide evidence that these cytokines play a role in colorectal LNM. Studies on circulating levels are contradictory, yet they do not discriminate between colon and rectal cancers and as a consequence their results can not be clarified.

## CONCLUSION

The role of lymphangiogenic growth factors VEGF-C and VEGF-D in malignant tumors metastasis is a novel field of cancer research. The results of current studies on their tumoral expression are strongly indicative of an active involvement of these cytokines to lymphatic spread, although the experimental and clinicopathological findings are not always consistent. Determination of circulating levels in preoperative blood samples might be a useful marker of advanced disease and a predictive factor of lymph node metastasis in gastric, esophageal and colorectal cancer, providing an additional tool in pre-treatment planning. Available studies are currently scant, with limited sample size and inadequate to conclude more than a presumption of a potential application of VEGF-C and VEGF-D in diagnostic and therapeutic regimens. However, modern research on understanding the mechanisms of lymphangiogenesis in human solid tumors is intensive and further studies on circulating growth factors are both desirable and justifiable in order to refine their role as nodal status biomarkers in gastrointestinal malignancies.

Maehata T, Taniguchi H, Yamamoto H, Nosho K, Adachi Y, Miyamoto N, Miyamoto C, Akutsu N, Yamaoka S, Itoh F. Transcriptional silencing of Dickkopf gene family by CpG island hypermethylation in human gastrointestinal cancer. *World J Gastroenterol* 2008; 14(17): 2702-2714 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2702.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2702>

## Abstract

**AIM:** To clarify alterations of Dickkopfs (Dkks) and Kremen2 (Krm2) in gastrointestinal cancer.

**METHODS:** We investigated the expression profiles and epigenetic alterations of Dkks and Krm2 genes in gastrointestinal cancer using RT-PCR, tissue microarray analysis, and methylation specific PCR (MSP). Cancer cells were treated with the demethylating agent and/or histone deacetylase inhibitor. WST-8 assays and *in vitro* invasion assays after treatment with specific siRNA for those genes were performed.

**RESULTS:** Dkks and Krm2 expression levels were reduced in a certain subset of the gastrointestinal cancer cell lines and cancer tissues. This was correlated with promoter hypermethylation. There were significant correlations between Dkks over-expression levels and beta-catenin over-expression in colorectal cancer. In colorectal cancers with beta-catenin over-expression, Dkk-1 expression levels were significantly lower in those with lymph node metastases than in those without. Down-regulation of Dkks expression by siRNA resulted in a significant increase in cancer cell growth and invasiveness *in vitro*.

## INTRODUCTION

Wnt proteins influence many aspects such as embryonic development and tumorigenesis, and their activities are regulated by several secreted antagonists<sup>[1,2]</sup>. Canonical Wnt signaling *via* the beta-catenin pathway is transduced by two receptor families. Frizzled proteins and lipoprotein-receptor-related proteins 5 and 6 (LRP5/6) bind Wnts and transmit their signals by stabilizing intracellular beta-catenin. Dickkopfs (Dkks) are secreted antagonists of Wnt signaling and are important for induction of head formation<sup>[3]</sup>. Dkks contain two distinct cysteine-rich domains in which the positions of 10 cysteine residues are highly conserved between family members. Secreted Dkk-2 and Dkk-4 undergo proteolytic processing that results in cleavage of the second cysteine-rich domain from the full-length protein<sup>[4]</sup>. Members of the human Dkk-related family differ not only in their structures and expression patterns, but also in their abilities to inhibit Wnt signaling.

The human Dkk-1 (chromosome 10q11.2) gene encodes a powerful inhibitor of the Wnt signaling pathway by binding to and antagonizing LRP5/6<sup>[5]</sup>. Dkk-1 is a transcriptional target of TCF and p53<sup>[4,5]</sup>. Many chemotherapeutic agents that induce DNA adducts significantly enhanced the expression of Dkk-1 in human tumor cell lines, irrespective of their p53 gene

status<sup>[6]</sup>. Dkk-1 expression level was decreased in human colon cancers, mesothelioma, and malignant melanoma, suggesting that Dkk-1 acts as a tumor suppressor gene in these neoplasms<sup>[5,7-9]</sup>. The Wnt/beta-catenin pathway was down-regulated by the induction of Dkk-1 expression, a mechanism that is lost in a subset of colon cancers<sup>[5]</sup>. The Dkk-1 gene was silenced by CpG island promoter hypermethylation in colon cancer cell lines and in 9 (17%) of 54 primary colorectal cancers, especially in advanced Dukes' C and D colorectal cancers<sup>[7]</sup>. Dkk-1 showed suppressive effects on tumor growth through beta-catenin-independent non-canonical pathways (i.e., Wnt/JNK pathways) in human mesothelioma<sup>[8]</sup>. Kremen2 (Krm2) forms a ternary complex with Dkk-1 and LRP6 and induces rapid endocytosis and removal of the Wnt receptor LRP6 from the plasma membrane<sup>[10]</sup>.

Dkk-2 (chromosome 4q25) activates rather than inhibits the Wnt/beta-catenin signaling pathway in *Xenopus* embryos. Co-transfection of Krm2 blocked the ability of Dkk-2 to activate LRP6 and enhanced inhibition of Wnt/Frizzled signaling in human 293 fibroblasts. Dkk-2 expression was down-regulated in malignant melanoma cell lines and in most tumor samples<sup>[9]</sup>. Krm2 also cooperates with Dkk-4, but not with Dkk-3, to inhibit Wnt signaling. Krm2 can function as a switch that changes Dkk-2 from an activator to an inhibitor of Wnt/LRP6 signaling<sup>[11]</sup>.

Dkk-3/REIC gene (chromosome 11p15.2) expression level was reported to be decreased in non-small cell lung cancer<sup>[12,13]</sup>, renal clear cell carcinoma, urinary bladder cancer, prostate cancer, pancreatic carcinoma, hepatoma, malignant melanoma, and acute lymphocytic leukemia (ALL)<sup>[9,14-16]</sup>. Dkk-3 methylation occurred at an early stage in ALL pathogenesis and also influenced the prognosis<sup>[15]</sup>. Transfection of Dkk-3 into HeLa and Hep3B cells significantly reduced invasion capacity, cell motility, and tumor growth rate in inoculated athymic nude mice<sup>[16]</sup>.

Dkk-4 (chromosome 8p11.2-p11.1) mRNA was expressed in human embryonic stem cells differentiated to an early endodermal cell type, in breast cancer, and in diffuse-type gastric cancer. Dkk-4 is thought to be involved in the negative feedback mechanism of the canonical WNT/beta-catenin signaling pathway<sup>[17]</sup>.

Therefore, altered expression of Dkks and Krm2 appear to play important roles in tumor development and progression. Activated Wnt signal pathway, characterized by the stabilization of beta-catenin, plays an important role in most gastrointestinal cancers. We investigated the expression profiles and epigenetic alterations of the Dkks and Krm2 genes in gastrointestinal cancer in which the Wnt signaling plays an important role.

## MATERIALS AND METHODS

### Cell lines and tissue samples

Human esophageal cancer cell lines (TE 1, 3, 5, 6, 8-11, 14 and 15) were provided by the Cell Resource Center for Biomedical Research Institute of Development, Aging and Cancer, Tohoku University. Other esophageal cancer (T.T and T.Tn), gastric adenocarcinoma cell lines (AZ521, NUGC3, NUGC4, MKN28, MKN45, MKN74, KATOIII,

SNU1, SNU638, HGC27, and GC1Y), colorectal adenocarcinoma cell lines (Colo320DM, DLD1, HCT8, HCT15, HCT116, LoVo, LS123, LS174T, LS180, SKCO1, SW48, SW480, SW620, SW1116, SW1417 and WiDr), hepatocellular carcinoma cell line (CHC4, CHC32, Hep3B, HLF, HuH7 and PLC/PRF), biliary tract adenocarcinoma cell lines (TGBC1TKB and TGBC2TKB), pancreatic adenocarcinoma cell lines (BxPC3, Kp4, MiaPaCa, Panc1 and SuSu86) were purchased from the Japanese Cancer Research Resources Bank (Tokyo, Japan), Riken Cell Bank (Tokyo), or the American Type Culture Collection (Manassas, VA). Cells were cultured in DMEM or RPMI1640 supplemented with 10% fetal bovine serum. Paired specimens of tumor and adjacent non-tumor tissues of the esophagus ( $n = 10$ ), stomach ( $n = 24$ ), colorectum ( $n = 30$ ) and pancreas ( $n = 7$ ) were purchased from Genomics Collaborative (Laurel, MD). For RT-PCR, tumor cellularity is important. Only specimens containing more than 80% tumor cells were used for analysis.

### Semi-quantitative RT-PCR

Semi-quantitative reverse transcriptase-PCR was done as described previously<sup>[18,19]</sup>. Primer sequences were 5'-TCCGAGGAGAAATTGAGGAA-3' and 5'-CTGAGGCACAGTCTGATGA-3' for the Dkk-1 gene, 5'-AGTACCCGCTGCAATAATGG-3' and 5'-GAAATGACGAGCACAGCAAA-3' for the Dkk-2 gene, 5'-CTGGGAGCTAGAGCCTGATG-3' and 5'-TCA-TACTCATCGGGGACCTC-3' for the Dkk-3 gene, 5'-AGCTCTGGTCCTGGA CTTC-3' and 5'-CAACCCACGACATGTAGCAC-3' for the Dkk-4 gene, and 5'-ACGC AGCAACACAGCTACAG-3' and 5'-ATGTGACAGGAGGGGATGTC-3' for the Krm2 gene. Glyceraldehyde-3-phosphate dehydrogenase (GAPDH) served as an internal control of the reaction. All reactions were done at least in duplicate. The levels of gene transcripts were quantified as the ratio of the intensity of the Dkk or Krm2 gene to the intensity of GAPDH. To perform semi-quantitative RT-PCR, the ranges of linear amplification for the Dkk or Krm2 gene and for the GAPDH gene were studied by using standard curves. Underexpression or overexpression was judged when target gene expression in the tumor sample was at least four times lower or higher than that in the corresponding normal sample.

### Methylation-specific PCR (MSP)

Bisulfite modification of genomic DNA and MSP analysis were performed as described previously<sup>[20]</sup> using primers corresponding to the Dkk promoter region sequences. Sequences of methylation-specific primers were 5'-CGTTCGTTGGTAGTTTATTTATTCGA-3' and 5'-GCGACTACCTTTATACCGCGAA-3' for the Dkk-1 gene, 5'-GAGTAGAGAGA GAGAAA GCGGGAGTTC-3' and 5'-GTTATCCCCTAACTCA CAAAAACAACG-3' for the Dkk-2 gene, 5'-CGG TTTTTCGTTTTCGGG-3' and 5'-CAAACC GCTACATCTCC GCT-3' for the Dkk-3 gene, 5'-AGAAAAGTAGTGATAAATAGACGACGT-3' and 5'-CAACACTATACGTCACCAAAACGAA-3' for the Dkk-4

gene, and 5'-CGAGGCGGGTAG GAGTTAGTTC-3' and 5'-CGAAAAAATCTAACCGAAAAACGTT-3' for the Krm2 gene. Sequences of unmethylation-specific primers were 5'-TGTTTGTTGGTAGTTTTTATTTTG A-3' and 5'-ACCACAACCTTTATACCACAAA-3' for the Dkk-1 gene, 5'-AGAGAG TAGAGAGAG AGAAAGTGGGAGTTT-3' and 5'-ATTATCCCC TAACTCACAAAAAAC AAAAA-3' for the Dkk-2 gene, 5'-TTTTGGTTTTTTTTTTGTTTTTTGGG-3' and 5'-CCAA ACCACTACATCTCCACT-3' for the Dkk-3 gene, 5'-AGAAAAAGTAGTGATAAATAGA TGATGT-3' and 5'-CAACACTATACATCA CCAAAACAAA-3' for the Dkk-4 gene, and 5'-GTG AGGTGGGTAGGAGTTAGTTTGT-3' and 5'-AAA AAAAATCTAACCAAAAAACATT-3' for the Krm2 gene.

### Treatment of cancer cells

Cancer cells were treated with 2  $\mu$ mol/L or 5  $\mu$ mol/L of 5-aza-2'-deoxycytidine (5-aza-dC) (Sigma-Aldrich, MO, USA) for 72 h or with 600 nmol/L of trichostatin A (TSA) (ICN Biomedicals) for 24 h. Cells were also treated with 2  $\mu$ mol/L of 5-aza-dC for 72 h followed by 600 nmol/L of TSA for an additional 24 h. The timing and sequencing of 5-aza-dC and/or TSA was based on similar preliminary studies as well as published studies<sup>[21]</sup>. Immediately after completion of treatments, cells were harvested for RNA purification. RT-PCR was performed after 5-aza-dC and/or TSA treatment.

### Immunohistochemistry on tissue microarray

A tissue microarray (SuperBioChips Laboratories, Seoul, Korea) was used for immunohistochemistry. Immunohistochemistry was performed as described previously<sup>[22,23]</sup>. The antibodies used were as follows: goat anti-human Dkk-1 and Dkk-3 (ABCAM, Cambridge, UK), rabbit anti-human Dkk-2 and Krm (ABGENT, San Diego, CA), rabbit anti-human Dkk-4 (Santa Cruz, CA, USA), mouse anti-human Rac (Sigma-Aldrich), rabbit anti-human phospho-Rac (Cell Signaling, MA), rabbit anti-human Ca<sup>2+</sup>/calmodulin-dependent protein kinaseII (CaMKII) (Santa Cruz), and rabbit anti-human phospho-CaMKII (EPITOMICS, CA, USA). Normal rabbit or mouse immunoglobulins were substituted for each primary antibody as negative controls. The results were analyzed based on the intensity of the expression in the tumors; negative (no staining at high magnification), weak (only visible at high magnification), moderate (readily visible at low magnification) and strong (strikingly positive at low magnification).

### Western blot analysis

Western blot analysis was performed as described previously<sup>[18]</sup>. The protein signals were visualized by an enhanced chemiluminescence using ECL Western blotting detection reagents (Amersham, IL, USA).

### siRNA preparation and in vitro transfection

siRNA preparation and *in vitro* transfection were performed as described previously<sup>[22]</sup>. Levels of mRNA and protein inhibition were analyzed by RT-PCR and

Western blot analysis. siRNA-transfected cells were used for WST-8 and cell invasion assays.

### WST-8 assay

Tumor cell growth was evaluated using the tetrazolium compound WST-8 (Cell Counting Kit-8 Dojindo Laboratories, Kumamoto, Japan) as described previously<sup>[22]</sup>. Cell viability was determined according to the manufacturer's instructions.

### In vitro invasion assay

Assays were performed by the modified Boyden Chamber method as described previously<sup>[24]</sup>. The results were presented as mean  $\pm$  SD for each sample.

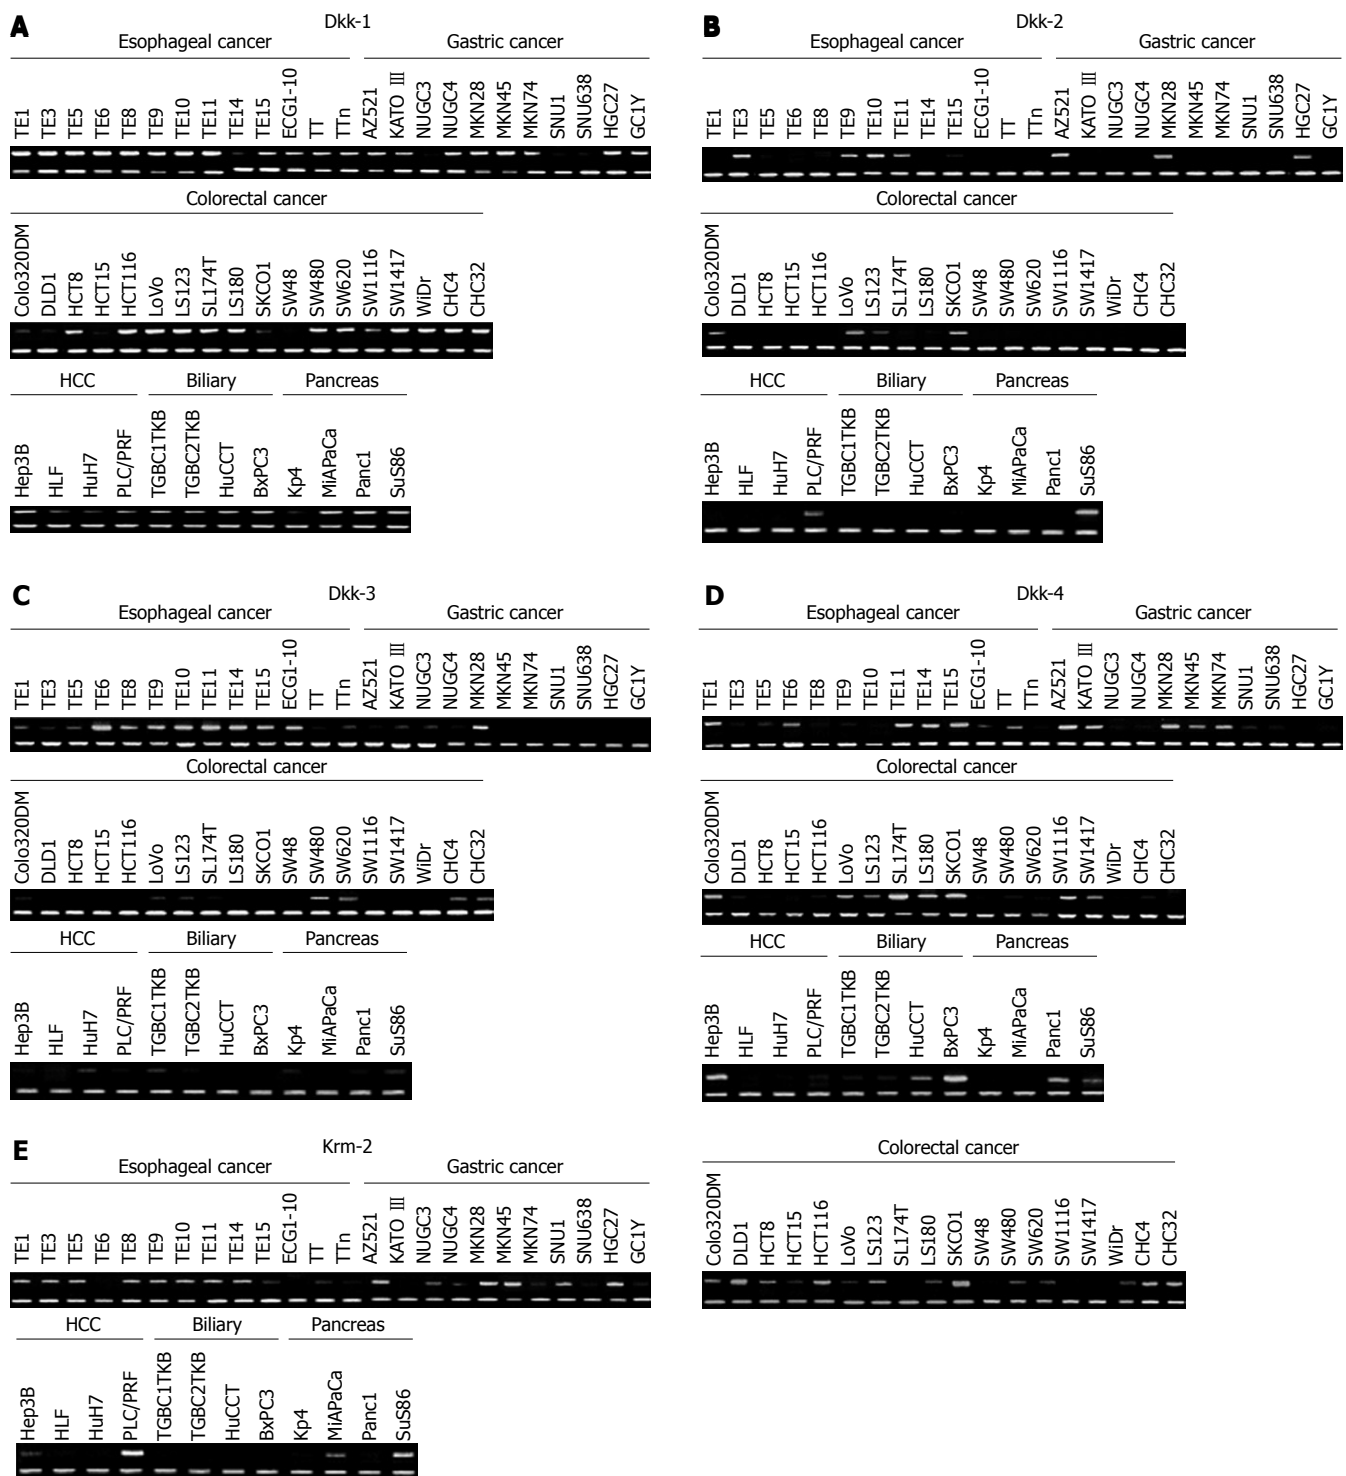

### Statistical analysis

Data were analyzed by using the computer software package SPSS for Windows 12.0. A *P* value less than 0.05 was considered statistically significant. The expression level of the Dkks and Krm2 genes was assessed for associations with clinicopathological characteristics using the following statistical tests: Student's *t*-test for age; the Mann-Whitney test for histological type, depth of invasion, pathological TNM stage; and the chi-square test or Fisher's exact test for the remaining parameters. For cell growth and invasion assay, all of the data were analyzed by one-way analysis of variance and the Bonferroni (Dunn) multiple-comparison method.

## RESULTS

### mRNA expression of the Dkk subfamily genes and Krm2 gene in gastrointestinal cancers

Expression levels of the Dkk genes and Krm2 gene in cancer cell lines and paired normal and cancer tissues were analyzed by using semi-quantitative RT-PCR and immunohistochemistry. The mRNA expression levels of Dkks were reduced in a certain subset of the esophageal, gastric, colorectal, hepatocellular, and pancreatic cancer cell lines (Figure 1). Reduction in the mRNA expression levels of Dkk-1, Dkk-2, Dkk-3, Dkk-4, and Krm2 was observed in 2/10 (20.0%), 3/10 (30.0%), 3/10 (30.0%), 3/10 (30.0%), and 4/10 (40.0%) of esophageal cancer tissues, in 5/24 (20.8%), 2/24 (8.3%), 6/24 (25.0%), 8/24 (33.3%), and 21/24 (87.5%) of gastric cancer tissues, in 6/30 (20.0%), 8/30 (26.7%), 12/30 (40.0%), 4/30 (13.3%), and 0/30 (0%) of colorectal cancer tissues, and in 1/7 (14.3%), 1/7 (14.3%), 2/7 (28.6%), 1/7 (14.3%) and 0/7 (0%; no expression) of pancreatic cancer tissues, respectively (Figure 2 and data not shown). On the other hand, over-expression of Dkks and Krm2 mRNA was also found in these cancer tissues. Dkk-1, Dkk-2, Dkk-3, Dkk-4 and Krm2 mRNA over-expression was observed in 5/10 (50.0%), 3/10 (30.0%), 2/10 (20.0%), 4/10 (40.0%) and 4/10 (40.0%) of esophageal cancer tissues, in 9/24 (37.5%), 16/24 (66.7%), 9/24 (37.5%), 11/24 (45.8%), and 3/24 (12.5%) of gastric cancer tissues, in 15/30 (50.0%), 14/30 (46.7%), 7/30 (23.3%), 16/30 (53.3%) and 4/30 (13.3%) of colorectal cancer tissues, and in 3/7 (42.9%), 3/7 (42.9%), 2/7 (28.6%), 3/7 (42.9%) and 0/7 (0%;

**Figure 1** RT-PCR analysis of the Dkks and Krm2 genes in gastrointestinal cancer cell lines. RT-PCR was performed using cDNA from 13 esophageal, 11 gastric, 16 colorectal, 6 hepatocellular, 3 biliary tract and 5 pancreas cancer cell lines.

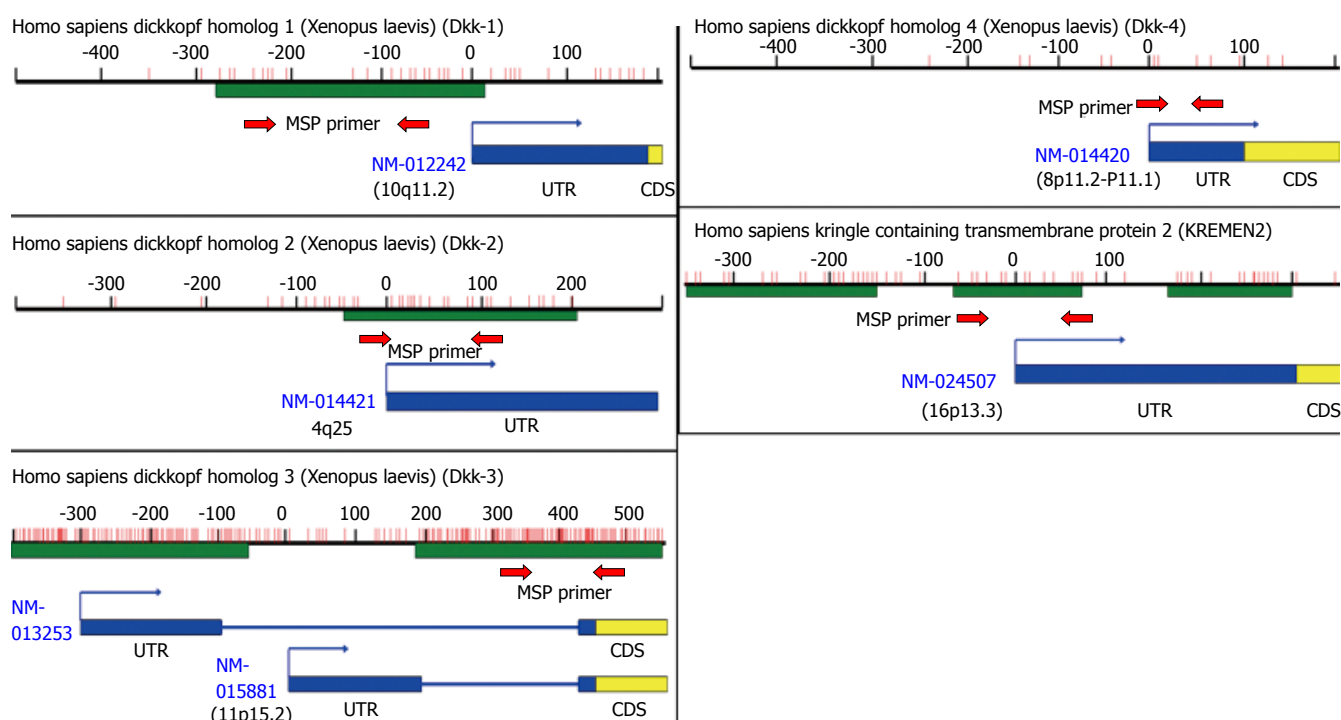

no expression) of pancreatic cancer tissues, respectively (Figure 2 and some data not shown).

### Protein expression of the Dkk subfamily genes and Krm2 gene in gastrointestinal cancers

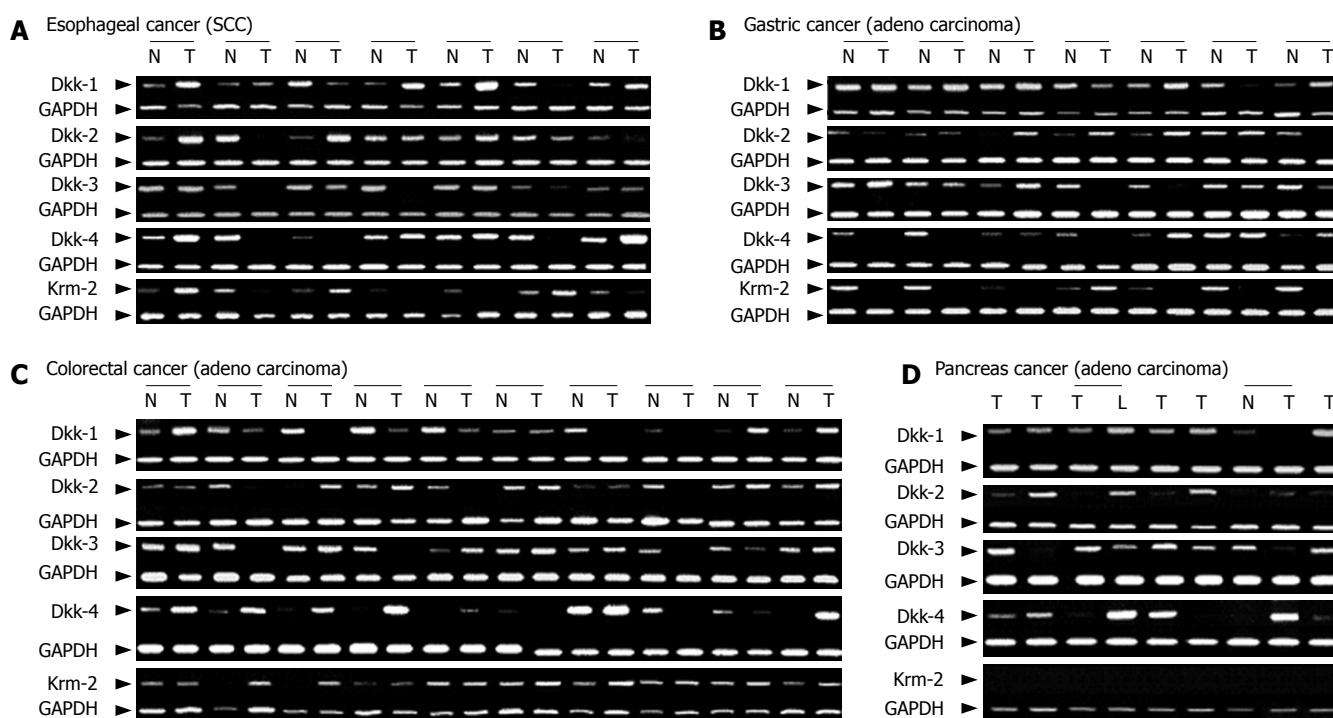

In normal tissues, the squamous epithelium in the esophagus expressed Dkks and Krm2 protein in the more keratinized cells of the epithelium (Figure 3A). Expression levels of Dkk-1, Dkk-2, Dkk-4, and Krm2 protein were strong in secreting cells of the gastric glands.

Expression level of Dkk-3 protein was weak in the gastric glands (Figure 3A). In the normal colorectal mucosa, Dkk-1, Dkk-3, Dkk-4, and Krm2 were localized in well-differentiated cells of crypts, whereas Dkk-2 was localized in secreting cells in proliferation layer in crypts (Figure 3A). These results may explain, at least in part, the variable levels of mRNA for these genes in normal tissues. There was no detectable immunoreactivity with the control normal rabbit or mouse immunoglobulins (data not shown).

The protein expression levels of Dkks and Krm2

**Figure 4** Scheme of the promoter regions of the Dkk genes and Krm2 gene. The 5' regions of the genes were identified by a BLAST search. We used a CpG island searcher that screens for CpG islands that meet the following criteria: CG percentage > 55% observed CpG/expected CpG > 0.65 length > 500 bp. CpG sites are represented by vertical bars. The arrows below CpG islands represent regions analyzed by MSP. The Dkk-1, Dkk-2, Dkk-3, and Krm2 genes contain CpG islands at their 5' ends and Dkk-4 has a few CpGs in the promoter region.

**Figure 2** RT-PCR analysis of the Dkks and Krm2 genes in gastrointestinal cancer tissues. Expression of GAPDH was examined to monitor cDNA integrity. N and T are matched samples from non-tumor and tumor tissue, respectively.

were reduced in a certain subset of the cancer tissues (Figure 3B-D). The protein expression levels of Dkk-1, Dkk-2, Dkk-3, Dkk-4, and Krm2 were negative or weak in 7/59 (11.9%), 33/59 (55.9%), 18/59 (30.5%), 7/59 (11.9%)

and 22/59 (37.3%) of esophageal cancer tissues, in 18/60 (30.0%), 19/60 (31.7%), 20/59 (33.9%), 6/59 (10.2%) and 21/60 (35.0%) of gastric cancer tissues, and in 21/60 (35.0%), 27/60 (45.0%), 27/60 (45.0%), 7/60 (11.7%) and

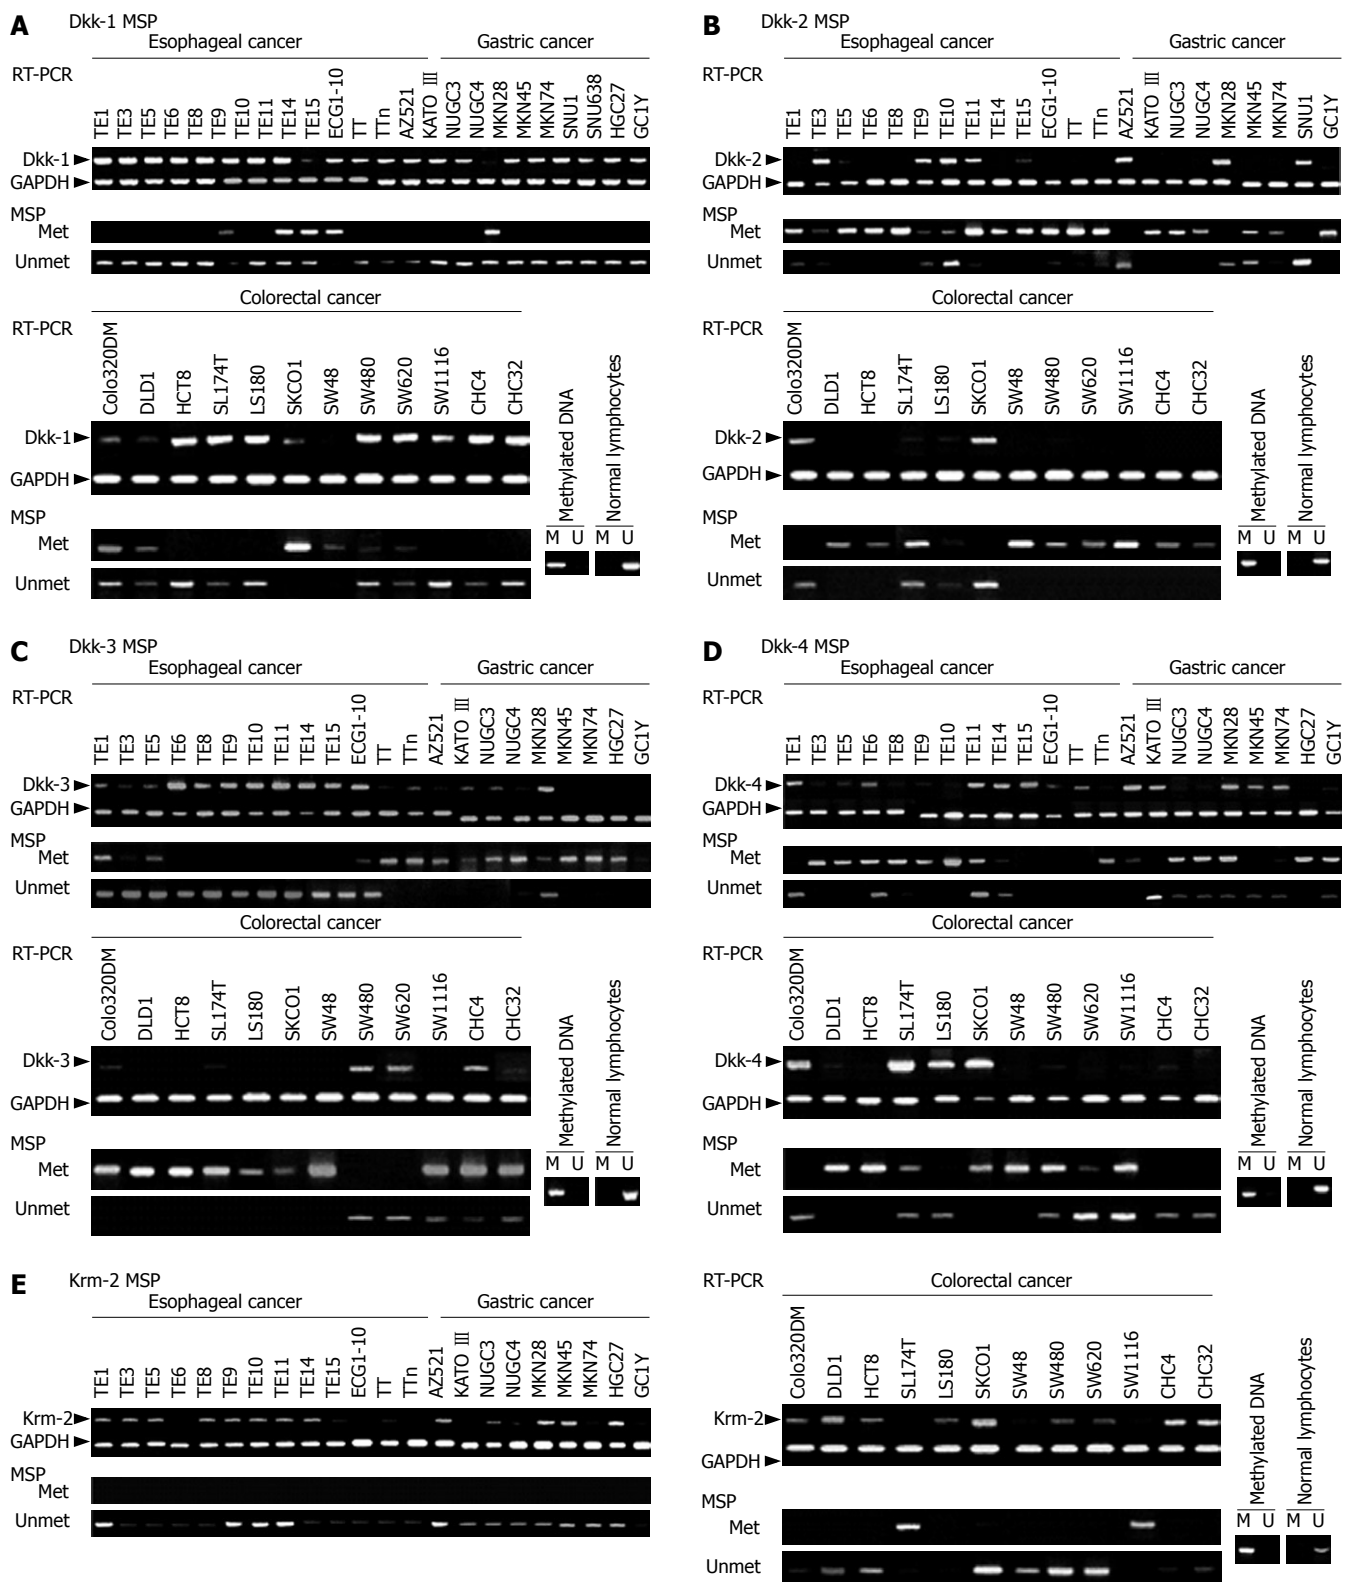

**Figure 3** Immunohistochemical expression of Dkks in gastrointestinal normal and cancer tissues. **A:** Normal tissues; **B:** Esophageal cancer tissues; **C:** Gastric cancer tissues; **D:** Colorectal cancer tissues ( $\times 200$ ).

6/60 (10.0%) of colorectal cancer tissues, respectively. On the other hand, strong staining of Dkk-1, Dkk-2, Dkk-3, Dkk-4, and Krm2 was found in 28/59 (47.5%), 9/59 (15.3%), 10/59 (16.9%), 28/59 (47.5%) and 11/59 (18.6%) of esophageal cancer tissues, in 15/60 (25.0%), 14/60

(23.3%), 22/59 (37.3%), 33/59 (55.9%) and 7/60 (11.7%) of gastric cancer tissues, and in 10/60 (16.7%), 12/60 (20.0%), 6/60 (10.0%), 35/60 (58.3%) and 28/60 (46.7%) of colorectal cancer tissues, respectively (Figure 3B-D and data not shown). Expression levels of Dkks and Krm2

**Figure 5** Correlation of methylation in the promoter region with silencing of the Dkk genes in gastrointestinal cancer cell lines. RT-PCR and MSP were carried out using cDNA and genomic DNA from the indicated cancer cell lines, respectively. *In vitro* methylated DNA (CpG Genome Universal Methylated DNA from Chemicon International, Temecula, CA) was used as a positive control for methylated alleles, while DNA from normal lymphocytes was used as negative controls.

were not correlated with any of the clinicopathological characteristics. However, in colorectal cancers with beta-catenin over-expression, Dkk-1 expression levels were significantly lower in those with lymph node metastasis than in those without lymph node metastasis ( $P = 0.003$ ).

### CpG island hypermethylation of the Dkk subfamily genes in gastrointestinal cancer

Using Blast and CpG island searcher, we found that Dkk-1, Dkk-2, Dkk-3, and Krm2 genes contain CpG islands at their 5'ends and that Dkk-4 has a few CpGs in the

**Figure 6** Reactivation of Dkks expression by 5-aza-dC treatment in gastrointestinal cancer cell lines. Cells were treated indicated.

promoter region (Figure 4). Therefore, we analyzed the methylation status of the CpG islands of these genes in cancer cell lines and tissue samples using MSP. Methylation status was significantly associated with silencing of Dkks mRNA expression in cancer cell lines (Figure 5 and data not shown). Methylation status was associated with silencing of Krm2 mRNA expression in only some cancer cell lines, such as LS174T and SW1116 cells (Figure 5E). In cancer tissues, Dkk-1, Dkk-2, Dkk-3, and Dkk-4 were hypermethylated in 4/11 (36.4%), 1/11 (9.1%), 1/11 (9.1%) and 3/11 (27.3%) of esophageal cancer tissues, in 2/8 (25.0%), 2/8 (25.0%), 2/8 (25.0%) and 3/8 (37.5%) of gastric cancer tissues, and in 7/20 (35.0%), 13/20 (65.0%), 7/20 (35.0%) and 4/20 (20.0%) of colorectal cancer tissues, respectively (data not shown).

To confirm the role of epigenetic change in silencing of the Dkk genes, cell lines that lacked the Dkk genes expression were treated with 5-aza-dC and/or TSA. Treatment with 5-aza-dC resulted in restoration of Dkk-1 in colo320DM, DLD-1, and SW48 cells, restoration of Dkk-2 expression in DLD-1, SW48, and TE1 cells, restoration of Dkk-3 expression in colo320DM and DLD-1 cells, and restoration of Dkk-4 expression in DLD-1, SW48, and SW480 cells (Figure 6). However, treatment with TSA had no effect.

### **Correlations between expression levels of Dkks and those of canonical and non-canonical Wnt pathway signal genes in gastrointestinal cancer**

There were some binding motifs of beta-catenin (5'-YCTTTGWW-3') in the promoter regions of Dkk-1 and Dkk-4. Dkk-2, Dkk-3 and Krm2 did not have TCF-binding motifs in their promoter regions. There were significant correlations between levels of Dkk-1, Dkk-3, Dkk-4 and Krm2 and those of beta-catenin expression in

colorectal cancer tissues in tissue microarray data obtained by immunohistochemistry. Dkk-1 ( $r = 0.500$ ,  $P < 0.0001$ ), Dkk-3 ( $r = 0.326$ ,  $P = 0.0130$ ), Dkk-4 ( $r = 0.480$ ,  $P = 0.0003$ ) and Krm2 ( $r = 0.454$ ,  $P = 0.0005$ ) expression levels showed significant correlations with beta-catenin over-expression. However, no correlation was found between expression levels of these molecules and beta-catenin over-expression in gastric or esophageal cancer tissues (data not shown). We then analyzed expression levels of beta-catenin and phosphorylated beta-catenin in Dkk1 or Dkk4-specific siRNA-treated colon cancer cells with APC mutation (SW480, WiDr, and colo320DM cells) and SW48 cells with beta-catenin mutation using Western blot analysis. SW480 and WiDr cells treated with Dkk1-specific siRNA showed higher levels of beta-catenin expression and lower levels of phosphorylated beta-catenin compared with those of the control siRNA-treated cells (Figure 7). On the other hand, Dkk1-negative SW48 cells treated with Dkk1-specific siRNA showed no difference compared with the control cells. Colo320DM cells treated with Dkk4-specific siRNA showed higher levels of beta-catenin expression and lower levels of phosphorylated beta-catenin compared with those of the control siRNA-treated cells (Figure 7). On the other hand, Dkk4-negative SW48 cells treated with Dkk4-specific siRNA showed no difference compared with the control cells.

Next, we examined expression of Rac and phosphorylated Rac/CDC42, which Wnt4/5A/11 activates through Dvl, and CaMKII and phosphorylated CaMKII to investigate the effects on Wnt-PCP and Wnt-Ca<sup>2+</sup> signal transduction. Expression of Rac, phospho-Rac, CaMKII, and phospho-CaMKII was not correlated with any of the clinicopathological features. Rac activation ratio ((phospho-Rac) level/(Rac) level)/(Rac) level) was negatively correlated with Dkk-1 in colorectal cancer ( $r = -0.366$ ,  $P = 0.0053$ )

**Figure 7** Western blot analysis in cancer cells treated with Dkk-specific siRNA.

and with Dkk-2 ( $r = -0.290$ ,  $P = 0.0299$ ) and Dkk-3 ( $r = -0.3880$ ,  $P = 0.0037$ ) in esophageal cancer, but not in gastric cancer. On the other hand, CaMKII activation ratio was positively correlated with Dkk-2 ( $r = 0.285$ ,  $P = 0.0314$ ) and Krm2 ( $r = 0.3640$ ,  $P = 0.0075$ ) in esophageal cancer, but not in colorectal cancer or gastric cancer. We analyzed Rac expression level and the phosphorylation status of Rac in cells treated with Dkk1-specific siRNA using Western blot analysis. SW480 and WiDr cells treated with Dkk1-specific siRNA showed similar expression levels of Rac and higher levels of phosphorylated Rac compared with those of cells treated with the control siRNA (Figure 7). On the other hand, Dkk-1-negative SW48 cells treated with Dkk1-specific siRNA showed no difference compared with the control cells.

#### Enhancement of cancer cell growth and invasiveness by Dkk-1, Dkk-2, Dkk-3, or Dkk-4 siRNA treatment

WST-8 assays and *in vitro* invasion assays after treatment with specific siRNA for the Dkk genes were performed to assess the role of the expression of Dkks in cancer cell growth and invasiveness. Transfection with siRNA resulted in over 80% inhibition of mRNA and protein expression (data not shown). Transfection with Dkk1-specific siRNA enhanced the growth of SW480 and WiDr cells compared with control siRNA-transfected counterparts (Figure 8A;  $P < 0.01$ ). Transfection with Dkk2-, Dkk3- and Dkk4-specific siRNA enhanced the growth of TE9, SW480 and colo320DM cells compared with control siRNA-transfected counterparts, respectively (Figure 8A;  $P < 0.05$ ,  $P < 0.001$  and  $P < 0.001$ ). Transfection with Dkk-1, Dkk-3, or Dkk-4-specific siRNA enhanced the invasiveness of TE-1 cells compared with control siRNA-transfected counterparts (Figure 8B and C  $P < 0.01$ ). Transfection with Dkk-1 or Dkk-3-specific siRNA enhanced the invasiveness of TE-8 cells compared with control siRNA-transfected counterparts (Figure 8B and C,  $P < 0.01$ ). Transfection with Dkk-1-specific siRNA enhanced the invasiveness of SW480 cells compared with control siRNA-transfected counterparts (Figure 8B and C,  $P < 0.01$ ).

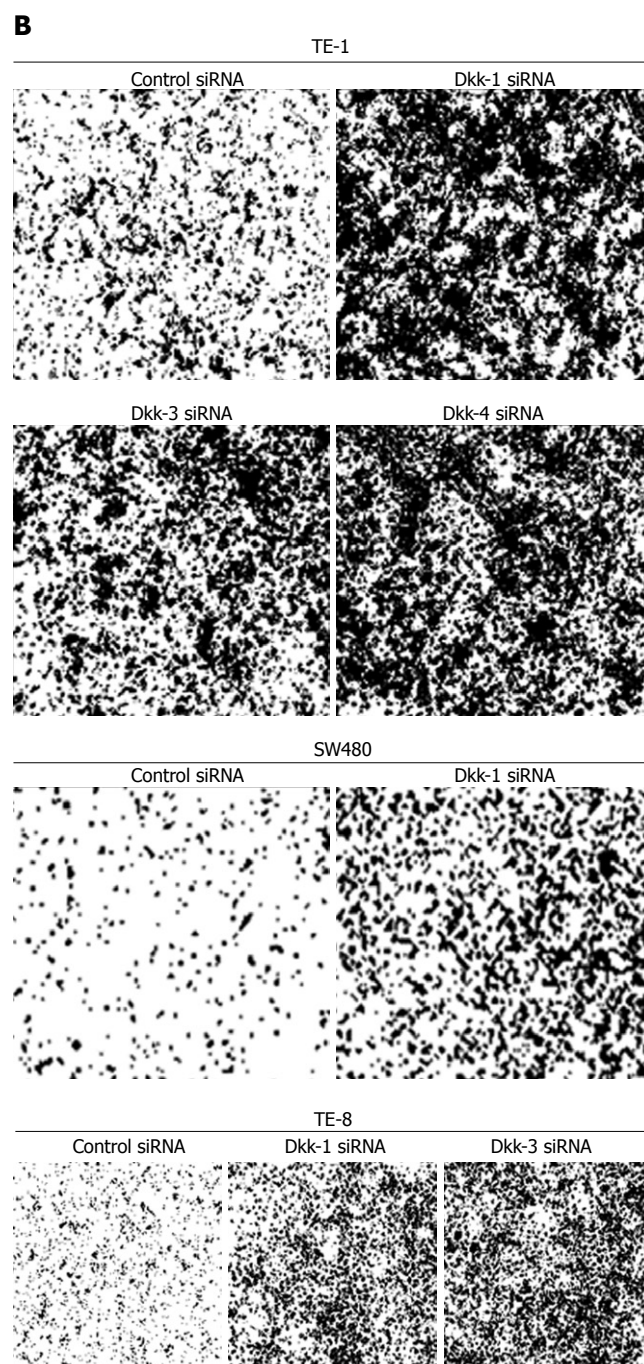

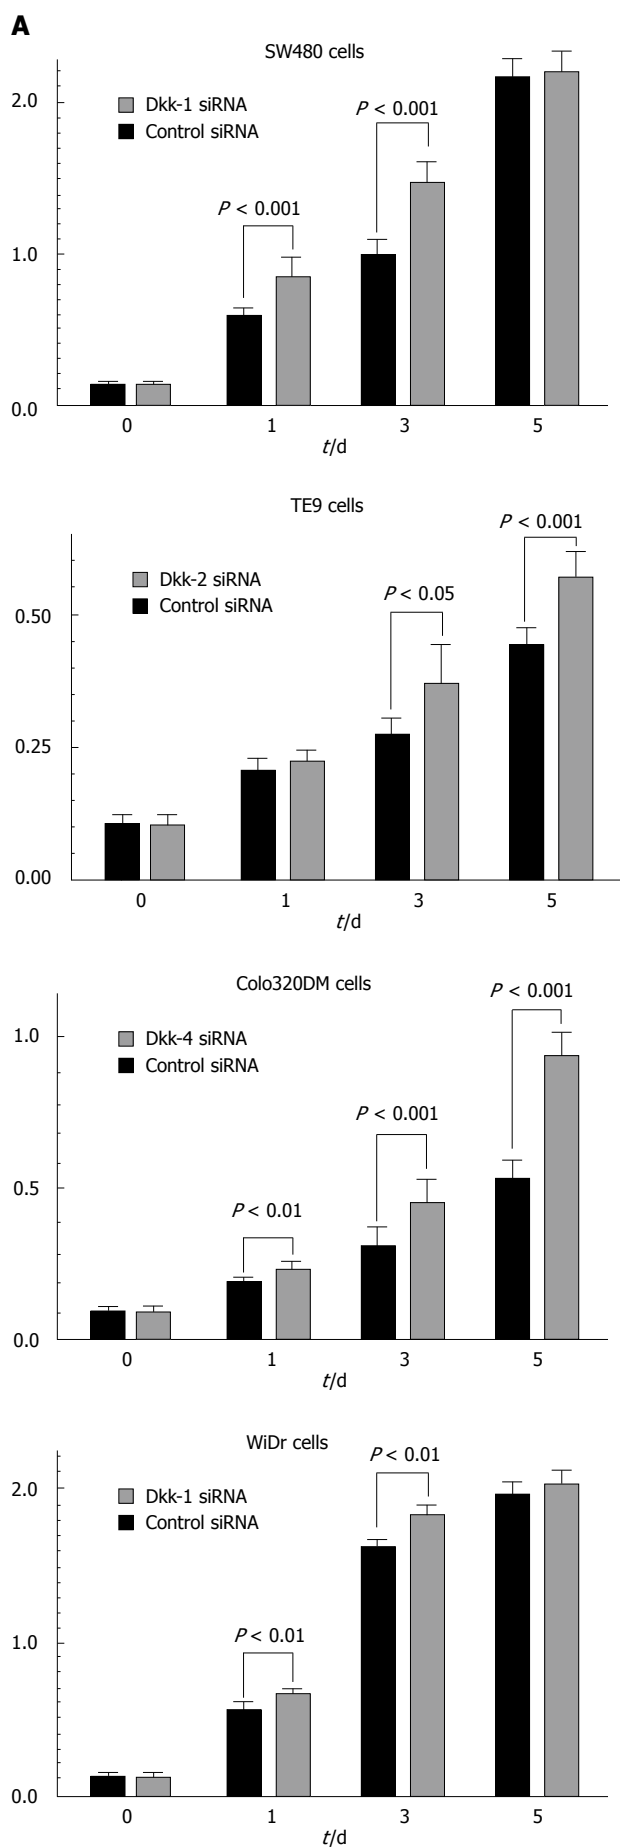

## DISCUSSION

In the present study, we investigated the expression profiles

and epigenetic alterations of the Dkks and Krm2 genes in gastrointestinal cancer. Dkks and Krm2 expression levels were reduced in a certain subset of gastrointestinal cancer cell lines and cancer tissues. Methylation of Dkk-1, Dkk-2, Dkk-3 and Dkk-4 was significantly correlated with down-regulation of expression in gastrointestinal cancer cell lines and cancer tissues. Moreover, Dkk-1, Dkk-2, Dkk-3 and Dkk-4 mRNA expression was restored by treatment with the DNA-demethylating agent. These results suggest that promoter hypermethylation is an important mechanism of silencing of Dkk family in gastrointestinal cancer. Although there were only a few CpGs in the Dkk-4 promoter region, these CpG sites in cancer tissues were more methylated than in normal tissues. Similarly, the expression of rat placental lactogen-1 (rPL-I) has been reported to be controlled by DNA methylation although the gene has only 17 CpG sites in the 5'-flanking region<sup>[25]</sup>.

Over-expression of Dkk-1, Dkk-2, Dkk-3 and Dkk-4 was also found in a subset of gastrointestinal cancer tissues. This is not a surprising result, because of the following reasons. There are binding motifs of beta-catenin in the promoter regions of Dkk-1 and Dkk-4. Multiple beta-catenin/TCF4 sites in the Dkk-1 gene promoter have been reported to contribute to Dkk-1 activation, thus initiating a negative feedback loop<sup>[5]</sup>. In fact, Dkk-1 mRNA levels have been increased in a subset of colorectal cancer tissues compared to normal tissues<sup>[5]</sup>. In our study, Dkk-1, Dkk-3, Dkk-4 and Krm2 expression was correlated with beta-catenin over-expression in colorectal cancer tissues. Moreover, knockdown of Dkk-1 or Dkk-4 up-regulated levels of beta-catenin expression and down-regulated levels of phosphorylated beta-catenin. Therefore, Dkks and Krm2 could be directly and/or indirectly induced by Wnt signals, at least in part, as components of negative feedback loops; but, this mechanism may be lost or abolished in a certain subset of colorectal cancers by promoter hypermethylation. On the other hand, no correlation was found between expression levels of Dkks and Krm2 and beta-catenin over-expression in gastric or esophageal cancer tissues. Further analysis is required to clarify the mechanism of over-expression of Dkks and Krm2 in a subset of gastric and esophageal cancers.

**Figure 8** Enhancement of cancer cell growth and invasiveness by Dkk siRNA treatment. **A:** WST-8 assays after treatment with specific siRNA for the Dkk genes were performed to assess the role of the expression of Dkks in cancer cell proliferation; **B and C:** *In vitro* invasion assays after treatment with specific siRNA for the Dkk genes were performed to assess the role of the expression of Dkks in cancer cell invasiveness.

Next, we examined correlations of altered expression of Dkks and Krm2 with expression of the Wnt non-canonical pathway genes. It has been reported that the Wnt canonical pathway activation stabilizes beta-catenin and that the non-canonical pathway activates Rho, Rac, JNK, and PKC or activates CaMK II<sup>[26]</sup>. The TAK1-NLK MAPK cascade is activated by the non-canonical Wnt-5A/Ca<sup>2+</sup> pathway and antagonizes canonical Wnt/beta-catenin signaling<sup>[27,28]</sup>. In the present study, Rac activation was negatively correlated with Dkk-1 expression in colorectal cancer and with Dkk-2 and Dkk-3 in esophageal cancer. These results suggest that Dkk-1 down-regulation in colorectal cancer and Dkk-2 or Dkk-3 down-regulation in esophageal cancer play a role in Rac activation. Moreover, knockdown of Dkk-1 using Dkk-1-specific siRNA induced Rac phosphorylation. On the other hand, CaMKII activation showed a weak positive correlation with Dkk-2 and Krm2 in esophageal cancer. Although further investigation is required, these results suggest additional effects of Dkks and Krm2 on the Wnt non-canonical pathway.

In colorectal cancers with beta-catenin over-expression, Dkk-1 expression levels were significantly lower in those with lymph node metastasis than in those without lymph node metastasis. Dkk-1 promoter has been reported to be hypermethylated in advanced Dukes' C and Dukes' D colorectal cancers<sup>[7]</sup>. Transfection of Dkk-3 has been reported to reduce invasion of osteosarcoma and malignant melanoma<sup>[9]</sup>. We further revealed that down-regulation of Dkks expression by siRNA resulted in a significant increase in esophageal and colon cancer cell growth and invasion *in vitro*. Thus, down-regulation of Dkks may contribute to the more aggressive phenotype of esophageal and colorectal cancer cells.

Our results indicate that promoter hypermethylation is an important mechanism of silencing of Dkk family in gastrointestinal cancer. Suzuki *et al.*<sup>[29,30]</sup> reported epigenetic inactivation of secreted frizzled-related proteins (sFRPs) in colorectal and gastric cancer. We reported silencing of the Wnt inhibitory factor-1 gene due to promoter hypermethylation in gastrointestinal tumors<sup>[18]</sup>. Thus, CpG island promoter hypermethylation is a common mechanism of the inactivation of extracellular Wnt

antagonists in gastrointestinal cancer. Activated Wnt signal pathway, characterized by the stabilization of beta-catenin, plays an important role in most gastrointestinal cancers. Modulation of the Wnt pathway, through reversal of extracellular Wnt antagonists silencing by demethylating agents, may be a potential target for treatment and/or prevention of gastrointestinal cancer.

## COMMENTS

### Background

Dickkopfs (Dkks) are secreted antagonists of Wnt signaling pathway. Activated Wnt signal pathway, characterized by the stabilization of beta-catenin, plays an important role in most gastrointestinal cancers. Extracellular Wnt antagonists such as secreted frizzled-related proteins (SFRPs) and WIF-1 is frequently inactivated in gastrointestinal cancer. Thus, Dkks may be also inactivated in gastrointestinal cancer.

### Research frontiers

Epigenetic transcriptional silencing of tumor suppressor genes plays a key role in gastrointestinal cancer and becomes one of the most important research areas. CpG island promoter hypermethylation is a common mechanism for the inactivation of extracellular Wnt antagonists such as SFRPs and WIF-1 in gastrointestinal cancer.

### Innovations and breakthroughs

The expression profiles and epigenetic alterations of Dkks (Dkk1, Dkk2, Dkk3 and Dkk4) and Kremen2 (Krm2) genes were systematically analyzed in many gastrointestinal cancer cell lines and tissues by using RT-PCR, tissue microarray analysis, and methylation specific PCR (MSP).

### Applications

Our study demonstrated that down-regulation of the Dkk gene family and Krm2 gene associated to promoter hypermethylation is frequently involved in gastrointestinal tumorigenesis. Hypermethylated Dkks could be a marker for screening gastrointestinal cancer. Modulation of the Wnt pathway, through reversal of Dkks and/or Krm2 gene silencing by demethylating agents, may be a potential target for treatment and/or prevention of gastrointestinal cancer.

### Peer review

This paper studied alterations of Dkks and Krm2 in gastrointestinal cancer. The authors showed that down-regulation of the Dkks and Krm2 associated to promoter hypermethylation is frequently involved in gastrointestinal tumorigenesis. Hypermethylated Dkks could be a marker for screening gastrointestinal cancer and reactivation of Dkks and/or Krm2 gene could be a promising strategy for treatment and/or prevention of gastrointestinal cancer.

## Abstract

**AIM:** To assess the economics of various chemotherapeutic regimens for advanced gastric cancer (AGC), and to select the best cost-effective regimen for the common Chinese patients.

**METHODS:** Data source used in this study was the Chinese Biomedical Disk Database. Patients were diagnosed as AGC and any regimen was eligible. Outcome measures included median survival time (MST) and percentage of complete and partial response (CR+PR). Economic statistics was per capita direct medical cost (DMC) of a single cycle. TreeAge Pro Healthcare 2007 software was used to carry out cost-effectiveness and incremental cost-effectiveness analysis. Sensitivity analyses were applied by altering willingness-to-pay and annual discount rate, and also re-analyzed by excluding the studies with apparent heterogeneity.

**RESULTS:** Seven retrospective economics studies on 760 patients were included. 5-fluorouracil-based regimens were universal, and also some new agents were involved, such as docetaxel, paclitaxel, and

oxaliplatin. By processing analysis, we could recommend etoposide, leucovorin and 5-fluorouracil (ELF) regimen as preference, with a DMC/MST ratio of 2543 RMB/11.7 mo and a DMC/CR+PR ratio of 2543 RMB/53.3%. Uracil-tegafur, etoposide and cisplatin (FEP) or 5-fluorouracil, adrimycin/epirubin and mitomycin (FAM) regimens could be regarded as optional first-line chemotherapy for AGC in common Chinese patients. With no regard for willingness-to-pay, the docetaxel, cisplatin and 5-fluorouracil (DCF) regimen could be chosen as either a first- or a second-line chemotherapy, with a DMC/CR+PR ratio of 9979 RMB/56.3%.

**CONCLUSION:** 5-fluorouracil regimens are still considered the mainstream for AGC, while new agents such as taxanes are optional. More randomized clinical trials are required before any mandatory recommendation of certain regimens for patients with AGC in China is made.

## INTRODUCTION

Gastric cancer is the fourth most common malignancy worldwide, and China is one of the countries with a high incidence of the disease<sup>[1]</sup>. It is one of the most common causes for cancer mortality and leads to approximately 160 000 deaths annually in China<sup>[2]</sup>. Surgery remains the only established curative treatment for this disease in resectable stages<sup>[3]</sup>. However, about 84% of patients with gastric cancer will have advanced disease, and their median survival time (MST) is only 3-4 mo if they are not treated with chemotherapy<sup>[4]</sup>. Chemotherapy for advanced gastric

cancer (AGC) can improve either time-to-progression or MST, and are well tolerated<sup>[4]</sup>. However, recommended regimens are still controversial since their survival benefit appears marginal in some studies<sup>[3]</sup>. Additionally, in China, a developing country with a huge population, oncologists need to know which regimen is the best cost-effective for the common Chinese patients. The present study was to review the Chinese literature and to make an economic assessment of various regimens for AGC.

## MATERIALS AND METHODS

### Search strategy

We searched the Chinese Biomedical Disk Database (CBMdisc) as the data source. The search strategy was ("gastric cancer" OR "gastric carcinoma" OR "gastric adenocarcinoma") AND ("economics" OR "cost-effectiveness" OR "CEA"). There was no limitation to publication year. Two reviewers (Chen XZ and Jiang K) carried out selection and assessment independently.

### Inclusion criteria

Either prospective or retrospective controlled studies were eligible; but, case serial reports were excluded. Patients were diagnosed having gastric cancer by gastric endoscopy and biopsy or postoperative pathological test. The staging system used was either UICC or Japanese TNM classification. Patients with early gastric cancer (stage I) were excluded. Any regimen of chemotherapy was acceptable for the present analysis. All patients should receive at least two cycles of chemotherapy. Surgery was either resection or explorative laparotomy. Any other therapies were ineligible, such as radiotherapy and biotherapy. The MST (month) was used as the primary outcome measure, or/and percentage of complete and partial response (CR+PR, %) as the secondary outcome measure. The economic parameter and direct medical cost (DMC, RMB) of a single cycle should be available from literature. The criteria for CR/PR were the standard World Health Organization (WHO) tumor response criteria. DMC contained the expenditure of drugs, tests, treatment, nursing and hospitalization.

### Data extraction and synthesis

Basic information about studies was extracted by two reviewers (Chen XZ and Jiang K) independently, including publication year, city of the hospital, sample and demography, and details of regimens. The effectiveness data contained percentage of CR+PR and length of MST. The percentage of CR+PR was numerical data, and was accumulated as  $100 \times (\sum n_i) / (\sum N_i)$ . The length of MST was parameter data, and was synthesized as  $[\sum (x_i N_i)] / (\sum N_i)$ . The abbreviations were respectively shown as ( $n$ ) = number of patients reaching CR or PR criteria in any regimen of individual study, ( $N$ ) = number of patients undertaking any regimen of individual study, ( $x$ ) = months of MST in any regimen of individual study, and ( $i$ ) = number of included studies for any regimen. The economic data were DMC, and synthesized as  $[\sum (y_i N_i)] / (\sum N_i)$ . The abbreviations were shown as ( $y$ ) = per capita DMC (¥, RMB) in a single cycle of any regimen of individual study, all of which were

converted to the 2007 price by discount rate. The annual discount rate was assumed as 1% initially, and ( $n$ ), ( $N$ ) and ( $i$ ) were the same as in the above formulas.

### Statistical analysis

TreeAge Pro Healthcare 2007 software was used in modeling and analyses. Both cost-effectiveness analysis and incremental cost-effectiveness analysis were considered, with C/E ratio and incremental C/E ( $\Delta C / \Delta E$ ) ratio calculated, respectively. The regimen of the lowest cost was selected as the common baseline for other regimens to refer to. For the thresholds, we enacted the expected MST as  $\geq 9$  mo, CR+PR percentage as  $\geq 50\%$ , and willingness-to-pay (WTP) for a single cycle as  $\leq 3000$  RMB (DMC/MST ratio  $\leq 333.3$  RMB, and DMC/CR+PR ratio  $\leq 60$  RMB). Once uncertainty was met in decision making, sensitivity analysis was carried out by alternating the willing-to-pay (WTP) from 1000 RMB to 10000 RMB, or the discount rate from 1% to 10%, or even excluding the studies with a potential heterogeneity.

## RESULTS

### Literature number

Seven studies on 760 patients were included in the present analysis<sup>[5-11]</sup>. All the included studies were retrospective case-control cost-effectiveness analyses. The detailed information is listed in Table 1. Eleven regimens were involved, eight of which were 5-fluorouracil-based and two were uracil-tegafur-based. One study included stages II and III mainly<sup>[5]</sup>. The components of reported DMC were different to some extent. One study, on capecitabine and cisplatin regimen versus oxaplatin and 5-fluorouracil regimen, was excluded for only overall cost of all cycles retrieved, but per capita DMC of a single cycle<sup>[12]</sup>.

### Data retrieval and synthesis

The primary data about the clinical and economic outcomes were retrieved (Table 2), and the data were synthesized according to the method specified before (Table 3). The data about the overall survival were not enough to be analyzed. The MST of each regimen ranged from 6.1 to 11.7 mo, and CR+PR percentage from 21.0% to 56.3%. However, the MST data about the TCF, DCF and FOLFOX regimens with new chemotherapeutic agents were not reported. The per capita DMC of a single cycle ranged from 1756.95 RMB to 9979.00 RMB.

### Cost-effectiveness analysis

The C/E ratios of DMC/MST and DMC/CR+PR were calculated, respectively (Table 4). The ELF regimen had the longest MST (11.7 mo), and the DCF regimen had the highest percentage of CR+PR (56.3%). The FAM regimen was of the lowest DMC/MST ratio (183.17 RMB for per 1-mo survival), and the FEP regimen was of the lowest DMC/CR+PR ratio (42.46 RMB for per 0.01 probability of CR+PR). The FAMTX regimen with the lowest per capita DMC in a single cycle was selected as the common baseline for other regimens to refer to. Incremental cost-effectiveness analysis showed that FAM and ELF regimens

CR: Complete response; PR: Partial response; DMC: Per capita direct medical cost of single cycle; 5FU: 5-fluorouracil; ADM: Adriamycin; EPI: Epirubicin; MMC: Mitomycin; DDP: Cisplatin; VP-16: Etoposide; CF: Calcium Leucovorin; UFT: Uracil-tegafur; MTX: Methotrexate; PTX: Paclitaxel; DXL: Docetaxel; L-OHP: Oxaliplatin; UR: Unretrieved data; FAM: 5FU+ADM/EPI+MMC; EAP: DDP+VP-16+ADM/EPI; ELF: 5FU+VP-16+CF; UFTM: UFT+MMC; LFP/M: 5FU+CF+DDP+MMC; FAMTX: 5FU+CF+ADM+MTX; ECF: 5FU+EPI+DDP; TCF: 5FU+DDP+PTX; FOLFOX: 5FU+CF+L-OHP; DCF: 5FU+CF+DXL+DDP.

were not dominated in the DMC/MST analysis. The FEP, ELF and DCF regimens were not dominated in the DMC/CR+PR analysis (Table 4 and Figure 1). According to our previous enacted thresholds, the considerable regimens included ELF, FAM, FEP, LFP/M, EAP, TCF and DCF, but only ELF regimen was conformed to all the thresholds.

### Sensitivity analysis

When altering the willingness-to-pay (WTP), if we want to get the longest survival time, the ELF regimen was

selected without doubt, while if we want to get the best tumor response probability, the ELF regimen was selected on WTP below 2579.00 RMB, while the DCF regimen was selected beyond 2579.00 RMB (Figure 2). Additionally, the FAM, FEP and EAP regimens were conformed to the previous enacted thresholds, but inferior to the ELF and DCF regimens.

When altering the annual discount rate from 1% to 10%, the targeted EAP, FAM, ELF and FEP regimens were rejected once the annual discount rate was more than 1%, 3%, 4% and 8%, respectively, according to

CR: Complete response; PR: Partial response; MST: Median survival time; DMC: Per capita direct medical cost of single cycle; 5FU: 5-fluorouracil; ADM: Adriamycin; EPI: Epirubicin; MMC: Mitomycin; DDP: Cisplatin; VP-16: Etoposide; CF: Calcium Leucovorin; UFT: Uracil-tegafur; MTX: Methotrexate; PTX: Paclitaxel; DXL: Docetaxel; L-OHP: Oxaliplatin; UR: Unretrieved data.

the previous enacted thresholds (Figure 3). The ECF and TCF regimens were not rejected based on these sensitivity analyses. If considering the discount rate as an annual increase in Chinese consumption price index, i.e. 1.0%-3.9% from 1999 to 2005<sup>[13]</sup>, we assumed that the discount rate increased from 1.0% to 4.0%. Thus, only ELF, FEP, ECF and TCF regimens were not rejected in this aspect.

Additionally, further sensitivity analyses were carried out by excluding those studies with a potential heterogeneity (Table 5). After excluding the two studies contaminated with stage II disease<sup>[5,7]</sup> on the FAM, EAP and ELF regimens, re-analysis was carried out, showing that the FAM and ELF regimens were not dominated.

Considering the economic gap between northern and southern areas, or western and eastern areas of China, we excluded the two studies on FAM, EAP, ELF, FAMTX and ECF regimens conducted in relatively poor developing areas<sup>[5,9]</sup>, and the cost-effectiveness was re-analyzed, showing that only ELF regimen was not dominated.

If only the recent studies published within 5 years (2003-2007)<sup>[9-11]</sup> were included, the re-analysis of FAMTX, ECF, TCF, DCF and FOLFOX regimens showed that ECF, TCF and DCF regimens were not dominated.

Table 3 Accumulated and synthesized data

Regimens	Accumulated n	Synthesized MST (mo)	Accumulated CR + PR (%)	Synthesized DMC <sup>1</sup> (¥, RMB)
5FU+ADM/EPI+MMC (FAM)	84	10.8	38.1	1978.23
5FU+VP-16+CF (ELF)	45	11.7	53.3	2543.12
5FU+CF+DDP+MMC (LFP/M)	91	9.0	44.0	3056.08
5FU+CF+ADM+MTX (FAMTX)	UR	6.1	21.0	1756.95
5FU+EPI+DDP (ECF)	UR	8.7	44.4 <sup>2</sup>	2276.43 <sup>2</sup>
5FU+DDP+PTX (TCF)	22	UR	50.0	2667.01
5FU+CF+DXL+DDP (DCF)	32	UR	56.3	9979.00
5FU+CF+L-OHP (FOLFOX)	60	UR	50.0	3244.31
UFT+MMC (UFTM)	49	8.5	32.7	2441.29
UFT+DDP+VP-16 (FEP)	51	10.0	47.1	1999.97
DDP+VP-16+ADM/EPI (EAP)	40	8.5	52.5	2790.23

<sup>1</sup>All the cost data were converted to 2007 price by preset discount rate (1%);

<sup>2</sup>The data were synthesized by giving the weights equal to those of the studies (Table 1). CR: Complete response; PR: Partial response; MST: Median survival time; DMC: Per capita direct medical cost of single cycle; 5FU: 5-fluorouracil; ADM: Adriamycin; EPI: Epirubicin; MMC: Mitomycin; DDP: Cisplatin; VP-16: Etoposide; CF: Calcium Leucovorin; UFT: Uracil-tegafur; MTX: Methotrexate; PTX: Paclitaxel; DXL: Docetaxel; L-OHP: Oxaliplatin; UR: Unretrieved data.

However, the incremental cost-effectiveness analysis found that paclitaxel regimen was paid more than 69.75 RMB per cycle to gain a higher 0.01 probability of CR+PR more than ECF regimen, and docetaxel regimen was paid 1160.63 RMB more than TCF regimen. However, the outcome data about MST were insufficient in recent studies.

If the studies weighted more than 25% of the overall included participants influencing the results most were excluded<sup>[8,9]</sup>, the FAM, ELF and DCF regimens were not dominated. The docetaxel regimen was more expensive to gain a higher CR+PR rate than FAM and ELF regimens.

Finally, if our previous enacted thresholds were used to assess each regimen in excluding sensitivity analysis (Table 5), the results in CR+PR aspect indicated that only TCF regimen conformed to the threshold limitation, and with no regard for publication date, EAP or ELF regimen was acceptable. Besides, in MST aspect, regimens with new agents were lack of outcome data. With no regard for publication date, either FAM or ELF regimen was better in improving the median survival according to the threshold limitation.

In conclusion, although FAM or FEP regimen was the best cost-effective choice, ELF regimen trended to be paid more attention to gaining a better response and survival outcome. The taxanes regimen was also attractive in the case of a high level of willingness-to-pay.

## DISCUSSION

The present cost-effectiveness analysis was based on 7 Chinese retrospective economic case-control studies with a limited sample, which might contain apparent observation bias. The level of evidence source was low (level 3b according to Oxford standard)<sup>[14]</sup>, and there was a potential heterogeneity in some aspects. One study<sup>[5]</sup> half patients had stage II disease, and another study<sup>[7]</sup> was also contaminated with patients of the disease at stage II (Table 1). Moreover, although all the studies reported the information about DMC, the detailed items, such as fee counted in some studies, were slightly different, but not in the others (Table 1). The homogeneity in

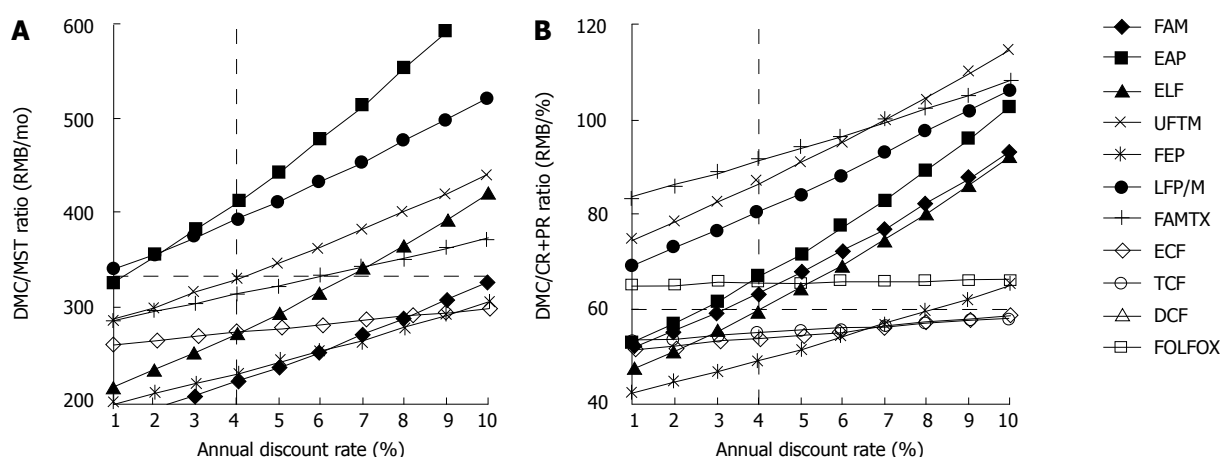

participants should also be questioned, because some studies included patients with recurrence/metastases after curative operation for the disease, while others were newly diagnosed as AGC. Therefore, these factors might remarkably influence the validity of the present analysis.

To our knowledge, there is no standard chemotherapy protocol for AGC worldwide. However, 5-fluorouracil-based regimens have been recommended as a standard modality of chemotherapy for gastric cancer<sup>[1,3]</sup>. Cisplatin plus 5Fu (FP) or etoposide (EP) in the treatment of several types of cancer, including AGC, has been widely used in the treatment of cancer due to their synergistic activity *in vitro*<sup>[15]</sup>. Based on the current available evidence, 5FU-based regimens are universally used in the treatment

**Figure 2** Sensitivity analyses by altering the willingness-to-pay from 1000 RMB to 10000 RMB for DMC, DMC/MST data (the MST data of TCF, DCF and FOLFOX regimens were not reported) (A), and DMC/CR+PR (the curves for FAM, UFTM, LFP/M, FAMTX and ECF regimens are below the bottom of the chart) (B).

**Figure 3** Sensitivity analysis by altering the annual discount rate from 1% to 10% for DMC, DMC/MST data (the MST data of TCF, DCF and FOLFOX regimens were not reported) (A), and DMC/CR+PR (the curve for DCF regimen is beyond the top of the chart) (B).

of Chinese patients, and uracil-tegafur-based regimens are also optional. In the present study, the ELF and FAM regimens had a longer MST of over 10 mo. The ECF regimen was recommended for AGC in NCCN guideline, which appears to improve MST and quality of life<sup>[1]</sup>. However, the results of studies in China are compromising and less cost-effective. Thus, we cannot simply transplant the Western experience to the common Chinese patients, and the ECF regimen requires more prospective randomized controlled trials to confirm its efficacy for the common Chinese patients.

Moreover, some new agents have been applied to the treatment of AGC, such as paclitaxel, docetaxel, oxaliplatin and capecitabine, usually used as second-line regimens. The present literature review found that regimens with the new agents would get a relatively higher CR+PR percentage, but increased the DMC. A retrospective study showed that capecitabine (Xeloda) plus cisplatin regimen could reach a CR+PR percentage of 64.3%<sup>[12]</sup>. Capecitabine is considered a promising agent for the treatment of gastric cancer. Phase III trials of capecitabine-based regimens, comparing its efficacy and safety with those of parenteral

5FU-based regimens in the first-line metastatic setting, are important<sup>[16]</sup>. It was reported that oxaliplatin regimens also have a good efficacy and acceptable safety profile in AGC<sup>[17]</sup>. It has been shown that oxaliplatin, folinic acid, 5-fluorouracil and irinotecan (COFFI) regimen could reach a 67% CR+PR rate in AGC<sup>[17]</sup>, while FOLFOX-4 regimen as a first-line therapy for elderly patients could reach 31%<sup>[18]</sup>, suggesting that irinotecan might play a positive role in the treatment of AGC, and other studies reported that irinotecan, 5-fluorouracil and folinic acid (FOLFIRI) regimen is a very promising and useful treatment of AGC<sup>[19,20]</sup>.

Based on the available data, we could recommend ELF regimen as the preference, and FAM or FEP regimen as a first- or a second-line therapy for AGC in common Chinese patients. With no regard for willingness-to-pay, the DCF regimen can be chosen as either the first-line chemotherapy or the second-line chemotherapy. A recent study showed that combined docetaxel, cisplatin and fluorouracil (DCF) regimen not only significantly improves clinical benefit, quality of life, disease progression and overall survival compared with CF regimen<sup>[21]</sup>. Besides,

Table 5 Sensitivity analyses by excluding the studies with a potential heterogeneity

<sup>1</sup>The regimen with the lowest direct medical cost in a single cycle was selected as the common baseline for other regimens to refer to. Eff: Effectiveness; ICER: Incremental cost/effectiveness ratio; CR: Complete response; PR: Partial response; MST: Median survival time; DMC: Per capita direct medical cost of single cycle; DT: Dominated by just the less costly one; 5FU: 5-fluorouracil; ADM: Adriamycin; EPI: Epirubicin; MMC: Mitomycin; DDP: Cisplatin; VP-16: Etoposide; CF: Calcium Leucovorin; UFT: Uracil-tegafur; MTX: Methotrexate; PTX: Paclitaxel; DXL: Docetaxel; L-OHP: Oxaliplatin.

paclitaxel regimen is also considered an active and well tolerated therapy for AGC<sup>[22]</sup>. Generally, the TCF regimen is recommended as a second- or a third-line therapy for AGC, with a tolerable and acceptable toxicity profile<sup>[23,24]</sup>. It was reported that PTX plus 5FU as a first-line chemotherapy can prolong the MST and 1-year survival rate<sup>[25]</sup>. However, another study reported that only 27% of patients with measurable disease have achieved a MST of 26 wk<sup>[26]</sup>. Thus, chemotherapy with docetaxel appears to be promising in the treatment of AGC, while chemotherapy with paclitaxel needs further confirmation<sup>[27]</sup>. Based on the availability of agents, physician/patient expectations and the “standard” regimens will disappear in the future oncology fields of individualized therapy<sup>[28]</sup>.

In conclusion, 5-fluorouracil regimens, especially ELF regimens, are still recommended as the mainstream for AGC in China, while some new agents are optional, such as taxanes. More randomized clinical trials are required before mandatory recommendation for certain regimens for patients with AGC in China is made.

## COMMENTS

### Background

Gastric cancer is the forth common malignancy worldwide, and China is one of the countries with a high incidence of the disease. About 84% of patients with Gastric cancer will progress to its advanced stage in about 84% of patients. If they do not receive chemotherapy, their median survival time (MST) is only 3-4 mo. Studies

have found that chemotherapy for Advanced gastric cancer (AGC) might improve the MST and can be well tolerated. However, recommendation for regimens is still controversial, since the survival appears marginal in some studies.

### Research frontiers

In China, a developing country with a huge population, oncologists need to know which regimen is the best cost-effective for the common Chinese patients. The present paper reviews the Chinese literatures and makes an economics assessment of various regimens for AGC.

### Innovations and breakthroughs

Some new agents have been applied to the treatment of AGC, such as paclitaxel, docetaxel, oxaliplatin and capecitabine, usually used as the second-line regimen drugs. The present literature review found that regimens with new agents could get a relatively higher CR+PR percentage while increasing the direct medical cost (DMC).

### Applications

In any case, regimens with 5-fluorouracil are still considered the mainstream for the treatment of AGC, while new agents are optional, such as taxane. More randomized clinical trials are required before mandatory regimen recommendations are made for patients with AGC in China.

### Terminology

AGC is an adenocarcinoma of the stomach at a more advanced stage than T1 stage, i.e. the primary lesion penetrates into tissues beyond the mucosal layer, which can be divided as a locally advanced or metastatic disease. 5-fluorouracil (5FU), a chemotherapeutic agent used to treat several types of cancer, including digestive, head and neck cancers, can prevent cells from making DNA and RNA to disrupt the growth of cancer cells. Taxanes are a group of chemotherapeutic agents including paclitaxel (PTX) and docetaxel (DXL), which are also able to prevent the growth of cancer cells.

## Peer review

This paper reports a health economics assessment of various chemotherapeutic regimens for AGC, and the authors selected the best cost-effective regimen for common Chinese patients. Although they concluded that more randomized clinical trials are required before any mandatory recommendation of certain regimens is made for patients with AGC in China, this paper offers a lot of important information.

### Abstract

**AIM:** To investigate overlapping regions of the *rpoB* gene previously involved with rifamycin resistance in *M. tuberculosis* and seek correlation between *rpoB* mutations in clinical MAP strains with susceptibility to RIF and RFB.

**METHODS:** We designed a molecular-based PCR method for the evaluation of rifabutin (RFB) and rifampicin (RIF) resistance based on probable determinant regions within the *rpoB* gene of MAP, including the 81 bp variable site located between nucleotides 1363 and 1443. The minimum inhibitory concentration (MIC) for RIF was also determined against 11 MAP isolates in attempt to seek correlation with *rpoB* sequences.

**RESULTS:** We determined that MAP strain 18 had an MIC of  $> 30$  mg/L and  $\leq 5$  mg/L for RIF and RFB respectively, and a significant and novel *rpoB* mutation C1367T, compared to an MIC of  $\leq 1.0$  mg/L for both drugs in the wild type MAP. The 30-fold increase in the MIC was a direct result of the *rpoB* mutation C1367T, which caused an amino acid change Thr456 to Ile456 in the drug's binding site. In addition, MAP strain 185 contained five silent *rpoB* mutations and exhibited an MIC comparable to the wild-type. Moreover, our *in vitro*

selected mutation in MAP strain UCF5 resulted in the generation of a new resistant strain (UCF5-RIF16r) that possessed T1442C *rpoB* mutation and an MIC  $> 30$  mg/L and  $> 10$  mg/L for RIF and RFB respectively. Sequencing of the entire *rpoB* gene in MAP strains UCF4, 18, and UCF5-RIF16r revealed an *rpoB* mutation A2284C further downstream of the 81 bp variable region in UCF4, accounting for observed slight increase in MIC. In addition, no other significant mutations were found in strains 18 and UCF-RIF16r.

**CONCLUSION:** The data clearly illustrates that clinical and *in vitro*-selected MAP mutants with *rpoB* mutations result in resistance to RIF and RFB, and that a single amino acid change in the beta subunit may have a significant impact on RIF resistance. Unconventional drug susceptibility testing such as our molecular approach will be beneficial for evaluation of antibiotic effectiveness. This molecular approach may also serve as a model for other drugs used for treatment of MAP infections.

### INTRODUCTION

Crohn's disease (CD) is an inflammatory bowel disease that detrimentally affects the epithelial lining of the digestive tract and presents with symptoms such as diarrhea, weight loss, abdominal pain, and constipation<sup>[1]</sup>. Despite the gross similarity of histological and pathological characteristics between CD and the inflammatory intestinal disease found

in cattle with Johne's disease (JD), both diseases remain distinct<sup>[1,2]</sup>. There is a strong debate currently between CD's potential autoimmune cause and its relation to bacteria, and either concept has yet to be proven. *Mycobacterium avium* subspecies *paratuberculosis* (MAP) is known to be the causative agent of JD and has previously been implicated in etiological studies of CD<sup>[2-8]</sup>. Available information regarding MAP's role in CD pathogenesis has promoted the ongoing studies to continue investigating the relationship between the MAP bacterium and the human bowel disease<sup>[3]</sup>. A most recent report has shown that antibiotics including rifabutin (RFB) is beneficial to CD patients despite the fact that the clinical trial study met with a few shortcomings regarding drug dosage, duration, and lack of MAP testing for the participating subjects<sup>[9]</sup>. The latter is best detected using PCR-based assays that amplify regions of the insertion sequence IS900 as shown by many investigators<sup>[10-12]</sup>.

RFB and rifampicin (RIF) are antibiotics that belong to the rifamycin drug family and are very similar in chemical structure. The function of these antibiotics are to inhibit the growth of bacteria, specifically by binding to the beta subunit of RNA polymerase through direct and indirect amino acid interactions, and preventing the production of nascent RNA transcripts<sup>[13]</sup>. The *rpoB* gene in prokaryotes encodes the beta subunit, and mutations within this gene result in a higher level of resistance to the rifamycin antibiotics in several bacteria<sup>[14-19]</sup>. Moreover, mutations within an 81 base pair region in *rpoB* spanning nucleotides 1276-1356 in *M. tuberculosis* have been shown to contain the majority of alterations relating to rifamycin resistance<sup>[20]</sup>. In addition, mutations at the beginning of *rpoB* are associated with rifamycin resistance in some strains of *M. tuberculosis*. However, these occurrences are not as prevalent as the former<sup>[15,21]</sup>.

Previous reports have shown that RFB may potentially serve as a therapeutic agent for the treatment of CD<sup>[22-27]</sup>, and as an effective drug against MAP<sup>[28]</sup>. In addition, other treatments such as anti-inflammatory agents have been proved to relieve symptoms of CD<sup>[29]</sup>; however these treatments are not as beneficial as antibiotic therapy<sup>[22]</sup>. As a result, more attention has been focused on the possible use of antibiotics as an alternative remedy. However, a screening method for RIF and RFB resistant strains of MAP has yet to be established. Therefore, as CD therapy becomes more focused on antibiotics, it is essential to develop a method for susceptibility testing in order to detect and monitor MAP strains for RIF and RFB resistance.

Unlike other prokaryotes, MAP is very fastidious and requires unusual *in vitro* growth conditions, including the addition of *Mycobacterin J*. Additionally, MAP cultured from CD samples has shown to lack a cell wall, and this characteristic is a major contributing factor to the complexity of the bacteria's primary isolation process<sup>[11,30,31]</sup>. Consequently, conventional drug susceptibility tests involving MAP are not reliable and may result in inaccurate results. Therefore, the challenges faced when working with this bacterium must be counteracted *via* alternate approaches that could potentially result in the exposition of significant data in order to effectively treat MAP infections. In this study, we adopted a molecular approach based on PCR amplification, followed by nucleotide sequencing of regions within

the *rpoB* gene of MAP. We attempted to investigate the overlapping regions of the *rpoB* gene previously involved with rifamycin resistance in *M. tuberculosis*. The ultimate goal is to seek the correlation between *rpoB* mutations in clinical MAP strains with susceptibility to RIF and RFB.

## MATERIALS AND METHODS

### Bacterial strains and growth conditions

All clinical strains including UCF3, UCF4, UCF5, UCF7, UCF8, MAP18, MAP185, and 61a were isolated in our laboratory from clinical samples obtained from CD patients<sup>[32]</sup>. Each MAP isolate was taken from different patients; however the anatomical sources for each overlap. For instance, each MAP isolate was isolated from their corresponding anatomical sources of individual CD patients: UCF3, UCF4, UCF8, 18, and 61a from the ileal; UCF5 and UCF7 from ileocolonic tissue; and 185 from the mesenteric lymph node. These MAP strains originated from surgical tissue samples obtained from CD patients<sup>[32-34]</sup>. Cow2013 and Cow5 MAP strains were recently isolated from ground beef samples from two cattles with JD. Briefly, tissue samples were ground, homogenized, decontaminated and then inoculated into MGIT culture media with supplements including OADC, *Mycobacterin J* and PANTA as described previously<sup>[32]</sup>.

All American type culture collection (ATCC) strains were verified in our laboratory by biochemical and molecular testing, including MAP strain 43544, *M. avium* subspecies *avium* 25291, *M. tuberculosis* strain 25177, and *M. smegmatis* strain 607. All cultures were subcultured in 7H10 agar supplemented with oleic acid-albumin-dextrose-catalase (OADC) and *Mycobacterin J*. Plates were incubated at 37°C until visible colonies were observed. Colonies from pure culture verified by Ziehl-Neelsen acid fast stain and IS900-based PCR for MAP were used to inoculate BACTEC 7H9 broth culture supplemented with 500 µL OADC and 2.4 µmol/L *Mycobacterin J*. Growth index (GI) was read weekly until optimum growth index was observed. The fresh culture was then used for drug susceptibility testing and for molecular studies.

### Minimum inhibitory concentration (MIC) measurement

MIC for RIF and RFB were determined against all micro-organisms used for this study. Starting cultures with a GI range of 500-600 were found optimal for inoculation. The inoculum size for each Bactec bottle used in the drug susceptibility study was approximately  $1.0 \times 10^5$  CFUs. Serial dilutions of RIF concentration ranging from 0 to 4 mg/L were evaluated against all micro-organisms. MAP strains resistant to RIF > 1.0 mg/L were further tested against RIF concentrations of 10, 20 and 30 mg/L for MIC measurement. These MAP strains were also evaluated against RFB at concentrations ranging from 0.0 to 10 mg/L, excluding UCF4. MAP wild type was included as a control in each batch of analysis. Experiments were repeated for confirmations. Micro-organisms other than MAP were also evaluated for RIF concentrations ranging from 0.0 to 10.0 mg/L. The percentage of RIF or RFB inhibition was used to determine the level of susceptibility for each

concentration of antibiotics as follows: % Inhibition = 1 minus (GI of Bactec culture without drug minus GI of Bactec culture with drug)/GI of Bactec culture without drug). The MIC was also determined for each bacterial sample, and was defined as the minimum concentration of antibiotics that induced inhibition of growth by 90%.

### Microbial genomic DNA extraction, nested PCR and nucleotide sequencing

Extraction of genomic DNA from mycobacterial isolates was performed for verification of the presence of the IS900 gene and for analysis of rpoB gene sequence. The DNA extraction, purification and quantification were performed as described previously<sup>[11]</sup>. Nested PCR for IS900 amplification was performed using the primers p90/91 and AV1/AV2 as listed in Table 1<sup>[11]</sup>. The size of amplified product was determined on 2% agarose gel. Appropriate negative controls for PCR consisting of sterile TE buffer or sterile water in place of the DNA template were used in parallel with each round of PCR preparation. Positive MAP DNA from strain ATCC 43015 was prepared independently and added to PCR tubes at a different facility using separate supplies.

Unlike the nested IS900-based PCR assay, only one round of PCR assays was developed for amplification of two different regions of the rpoB gene. Therefore, one PCR reaction contained the UCF1/UCF2 primers for amplification of 448 bp whereas the second PCR reaction contained the Knight1/Knight2 primers for amplification of 587 bp. The ingredients and protocol conditions of the rpoB-based PCR assays were as described previously<sup>[11]</sup>. Table 2 lists the nucleotide sequence for all primers used in this study. Each PCR product was purified from agarose using the Purelink Quick Gel Extraction Kit following the procedure described by the manufacturer (Invitrogen). Purified DNA was then quantitated and subjected to

nucleotide sequencing. The latter was performed using the GenomeLab DTCS-Quick Start Kit following the manufacturer's instructions (Beckman Coulter). Both DNA strands were sequenced for each PCR product using appropriate nucleotide primers at the Biomolecular Science Center DNA Sequencing Core Facility at the University of Central Florida. BLAST analysis was performed using the Pubmed.gov database, and the rpoB sequence from MAP strain K-10<sup>[35]</sup> was used as our reference wildtype control sequence for comparison purposes.

### In vitro selected RIF-MAP mutant

An RIF resistant MAP mutant (UCF5-RIF16r) was selected through the generation of rpoB mutation *via* adaptive resistance in the presence of antibiotics. This was performed by exposing our wild-type MAP strain UCF5 to increase the concentrations of RIF ranging from 1 to 16 mg/L. Initially, MAP strain UCF5 was inoculated into a BACTEC bottle containing 1 mg/L RIF. Following incubation, the surviving MAP cells were sub-cultured into a new BACTEC bottle with double RIF concentrations. The process was repeated several times until a new MAP strain (UCF5-RIF16r) was selected that was able to survive in the presence of 16 mg/L of RIF. This new resistant strain was then tested for MIC against RIF and RFB and investigated for possible rpoB mutations as described earlier.

## RESULTS

### Identification of MAP

Genomic DNA from all bacterial isolates was subjected to IS900-based PCR in order to confirm the identity of all MAP strains. This procedure involved two rounds of PCR, using p90/91 primers in the first round to amplify a 400 bp sequence. The use of AV1/AV2 in the second round of PCR amplified a 308 bp sequence and provided exceptional sensitivity and enhanced specificity for the confirmation of MAP. As expected, all 11 MAP isolates were confirmed for the presence of IS900. In addition, *M. avium* subspecies *avium*, *M. smegmatis* and *M. tuberculosis* displayed negative results for the presence of the IS900.

### rpoB amplification and sequence analysis

Following the IS900 PCR analysis, genomic DNA from each identified MAP strain was used as template for PCR employing rpoB primers (Table 1). Amplification of rpoB sequences enabled the possibility for amplicon purification, sequencing, and subsequently BLAST analysis. The use of primers UCF1/UCF2 and Knight1/Knight2 enabled the amplification of two regions of the rpoB gene of MAP. These regions overlapped similar sequences in the rpoB gene of *M. tuberculosis* previously associated with rifamycin resistance. Moreover, PCR with Knight1/Knight2 primers amplified a sequence that harbored the 81 bp variable site 1363-1443, a highly probable determinant region for rifamycin resistance in closely related bacteria. Amplicons from both regions of the rpoB gene were obtained by successful PCR.

Nucleotide sequencing of both rpoB regions for all MAP strains was performed for both forward and reverse primer reactions to exclude any possible errors in the data.

Table 2 rpoB and susceptibility data for all micro-organization

<sup>1</sup>Limited investigation involving MAP18, MAP185, and UCF5-RIF16r; <sup>2</sup>Values are expressed as mean ± SD; <sup>3</sup>Wild type (WT) indicates identical investigated rpoB sequence compared to MAP K-10 strain, and differentially expressed rpoB mutations are indicated; <sup>4</sup>Amino acid positions correspond to MAP strain K-10 numbering system from Li *et al* 2005, and the alteration is indicated with single letter amino acid codes and the corresponding codon number. NC corresponds to no change in beta subunit sequence based on investigated rpoB regions; <sup>5</sup>rpoB sequence was not investigated.

Furthermore, sequence data was reported as completely accurate upon the confirmation of error-free reactions. In addition, rpoB sequences for all MAP strains were compared through BLAST analysis using MAP strain K-10 as a reference strain, and amino acid positions were numbered based on MAP strain K-10. The numbering system for *E. coli* provided by Ramaswamy *et al* in 1998 was also used in order to avoid discrimination of our observed results, and to enable a more general comparison of previously published data relevant to other mycobacterial species.

Sequence analysis found identical, or wild-type (WT), and non-identical sequences. MAP strains consisting of the latter were further characterized for silent mutations with no effect on amino acid expression, or mutations that differentially expressed the amino acid sequence of the beta subunit. Of the 11 MAP clinical isolates, 9 consisted of no rpoB mutation in the two regions initially investigated (Table 2). However, two MAP strains possessed rpoB mutations, and these consisted of MAP strain 18 and 185. The rpoB mutations for MAP strain 18 included C1367T and T1375C. The C1367T mutation had significant amino acid changes from Thr456 to Ile456 in the beta subunit of RNA polymerase, which corresponded to a Ser508 to Ile508 change according to the *E. coli* numbering system. To our knowledge, this amino acid change was considered novel as well as indicative of RIF and RFB resistance. The T1375C mutation had no effect on the beta subunit, and was, therefore, characterized as being silent (Table 2). Alternatively, MAP strain 185, which was also isolated in our laboratory from the surgical mesenteric lymph node tissues of a CD patient, showed a total of five rpoB mutations including T534C, T795C, C1335A, T1375C, and C1578T (Table 2). None of the five mutations altered the amino acid sequence in the beta subunit, and consequently were also termed silent. The effects of all rpoB mutations on RIF and RFB susceptibility were investigated following sequence analysis.

### Effect of rpoB mutations on MIC

Correlation between rpoB sequence analysis and inhibitory

growth rates of RIF was assessed for all MAP strains. Initially, we tested all MAP strains in the presence of 1 mg/L RIF for comparison purposes (Table 2). This concentration was found to be the MIC of our wild-type control. Hence, our initial susceptibility test was to screen for suspicious growth characteristics against this concentration of RIF. Of the bacterial isolates studied, 8 MAP strains including ATCC43544 (control), UCF3, UCF5, UCF7-8, 61a, Cow2013, Cow5, and two non-MAP controls including *M. tuberculosis* and *M. avium* subspecies *avium* had an MIC ≤ 1.0 mg/L RIF (Table 2). In addition, there were no observed rpoB mutations in these 8 RIF susceptible MAP strains. The MIC for RIF of the remaining MAP strains 18, 185, UCF4, and *M. smegmatis* was determined as ≥ 30, ≤ 4.0, ≤ 2.5 and ≥ 9.0 mg/L, respectively (Table 2). Furthermore, MAP strains 18 and 185 had rpoB mutations in the 81 bp variable region as discussed earlier, and MAP strain UCF4 had no rpoB mutations within the two regions. Despite the lack of rpoB mutations, *M. smegmatis* had MIC of ≥ 9 mg/L RIF. RIF-resistance MAP strains were also evaluated for susceptibility against RFB, a more potent rifamycin antibiotic. Interestingly, the MIC for RFB against MAP strain 18 and 185 was ≤ 5.0 mg/L and ≤ 1.0 mg/L, respectively (Table 2). The MIC values for the drugs against all microorganisms are listed in Table 2.

### Correlation between selected rpoB resistant mutation and MIC in UCF5-RIF16r

An RIF resistant MAP strain, termed UCF5-RIF16r, was selected via culturing wild-type parent strain UCF5 in increasing concentrations of RIF over an extended time period. Specifically, this was accomplished by exposing parent strain UCF5 to a five-fold increase in RIF concentrations over approximately 2 mo. UCF5-RIF16r was then maintained in cultures with > 16.0 mg/L RIF. Genomic DNA was then extracted and followed by IS900-nested PCR and rpoB-based PCR analysis. Consequently, the newly selected resistant strain was confirmed for the

**Figure 1** Sequence alignment of 81 bp region in rpoB gene of MAP. The region overlaps the 81 bp rifamycin resistant determinant region within *M. tuberculosis*. For MAP, this sequence is harbored in the region amplified by primers Knight1/Knight2. Differentially expressed rpoB mutations are indicated for MAP strains 18 and UCF5-RIF16r. Base pairs and amino acids range from 1363-1443 and 456-481. Numbering of amino acids correspond to MAP strain K-10 beta subunit. Dots correspond to homologous bases and specific nucleotides are underlined in the control sequence. MAP strain 185 is excluded from diagram.

presence of IS900, and both regions of the rpoB gene were analyzed. We detected a single nucleotide rpoB mutation T1442C, which caused a differentially expressed amino acid from Leu481 to Pro481 in the beta subunit of RNA polymerase, which corresponded to a Leu533 to Pro533 change according to the *E. coli* numbering system (Table 2). Furthermore, the rpoB mutation was located within the 81 bp variable region, and the effect of the selected mutation on susceptibility to RIF was then investigated. The MIC for UCF5-RIF16r against RIF and RFB was  $\geq 30$  mg/L and  $\geq 10$  mg/L, respectively.

### Sequencing rpoB genes in MAP strains 18, UCF4 and UCF5-RIF16r

We attempted to sequence the entire 3.6 kb rpoB gene in order to determine the source of the variable increase in MIC for RIF against MAP strain UCF4, and to detect any other possible rpoB mutations leading to amino acid alterations in strains 18 and UCF5-RIF16r. We designed additional primers for PCR amplification of sequences outside that amplified by primers UCF1/UCF2 and Knight1/Knight2 (Table 1). After successful PCR amplification of these regions, nucleotide sequencing was performed. Through BLAST analysis, we found a significant rpoB mutation further downstream of the 81 bp variable region in MAP strain UCF4. Specifically, an A2284C mutation occurred within the region amplified by primers Ex1a/Ex2a. This mutation resulted in an Asn762 to His762 amino acid change, leading to a possible explanation for the higher MIC for RIF compared to our wild-type control strain 43544. No other rpoB mutations leading to amino acid changes were observed in MAP strains 18, UCF5-RIF16r, and UCF4. After obtaining collective sequence information for all MAP isolates, we aligned the 81 bp variable region to display the location of each mutation amino acid change that correlated with a high level of RIF resistance (Figure 1).

### Detection of rpoB in PBMNC infected with MAP

To show the potential for sequence analysis in the rpoB gene of MAP clinical isolates in correspondence with RIF and RFB resistance, we contaminated human PBMNC with  $1.0 \times 10^3$  CFU of MAP strain 18. Prokaryotic

genomic DNA was then extracted from the blood mixture, followed by IS900-PCR and rpoB-based PCR analysis. As expected, our protocol detected MAP in the blood sample and successfully amplified both regions of the rpoB gene of MAP (data not shown). The nucleotide sequence was then analyzed for the possible prediction of susceptibility to RIF or RFB.

## DISCUSSION

The main purpose of our study was (1) to characterize MAP's potential for developing RFB and RIF resistance, (2) associate RFB and RIF resistance with mutations in the rpoB gene of MAP, and (3) provide an effective protocol for detecting resistant mutations in MAP strains linked to CD. Despite the fact that *M. smegmatis* is known to be naturally resistant to rifamycins without rpoB mutations<sup>[36]</sup>, microorganisms such as *M. avium* spp. *avium*, *E. coli*, *H. pylori*, *S. aureus* and *M. kansasii* have laid the foundation for this association<sup>[14,16,18,19,21,37]</sup>. Moreover, various strains of closely related *M. tuberculosis* have set a fine trend for rifamycin resistance, as seen through rpoB mutations<sup>[6,17,21,38-46]</sup>. Our goal was to discover this trend in MAP, and develop an effective method for analyzing RFB and RIF resistance in the bacterium through rpoB-based PCR analysis.

Unlike *M. tuberculosis* and members of the *M. avium* complex (MAC), MAP is a fastidious micro-organism and requires prolonged incubation time. Consequently, conventional drug susceptibility testing against MAP strains is ineffective, thus leading us to develop an alternative method for determining drug resistance in MAP.

The UCF1/UCF2 and Knight1/Knight2 rpoB primers enabled the successful amplification and sequencing of two probable RFB and RIF resistant determinant regions (Table 1). These regions overlap similar sequences in the rpoB gene of *M. tuberculosis* that have displayed mutations upon rifamycin resistance, including the 81 bp region 1276-1356 within cluster I, and a region further located in the upstream of the beginning of rpoB<sup>[6,15,20]</sup>. Consequently, our determinant regions of interest in the rpoB gene of MAP were concluded based on the available information for closely related bacteria.

All MAP isolates were identified through an IS900 nested PCR reaction and each was investigated for rpoB

sequences and susceptibility tests against RIF. Those isolates suspected to be RIF resistant based on high MIC results were subjected to susceptibility tests against RFB. Consequently, the control, MAP strain 18 and UCF5-RIF16r were included in a RFB inhibition test. MAP strain 185 was also included in the RFB test due to the strain's suspicious susceptibility against RIF. Unlike RIF, RFB is not commercially available for laboratory use. Hence, information based on antibiotic resistance in our study was subjective mainly for RIF.

Our significant findings included the discovery of *rpoB* mutations within MAP strains 18, UCF5-RIF16r, and UCF4. Both strains 18 and UCF5-RIF16r showed a significant increase in the level of resistance due to amino acid alterations within the binding site of RIF. Moreover, upon our additional sequencing of the entire 3.6 kb *rpoB* gene for all three MAP strains along with a control, a significant *rpoB* mutation A2284C was uncovered leading to an Asn762 to His762 amino acid change in the beta subunit. These results justified the minor increase in MIC against RIF for strain UCF4. In addition, the complete sequencing of the *rpoB* in MAP strains 18 and UCF5-RIF16r proved that no additional *rpoB* mutations leading to an amino acid change were present, confirming the correlation between detected mutations and increased MIC in these micro-organisms. The finding illustrates that a single amino acid change in the *rpoB* gene of MAP may result in an increased level of resistance to RIF, which may have a significant clinical impact, specifically when the amino acid alterations occur within the drug's binding site.

Overall, our results display a novel *rpoB* mutation, C1367T, in MAP strain 18 not previously reported in the literature including *rpoB* studies in *E. coli* and *M. tuberculosis*. In addition, the A2284C *rpoB* mutation discovered in MAP strain UCF4 was also novel to our knowledge; however this mutation did not influence RIF resistance significantly compared to MAP strains 18 and UCF5-RIF16r. A possible explanation for this observation is that the mutation in strain UCF4 was located distant from the drug binding site. The selected *rpoB* mutation in strain UCF5-RIF16r has previously been reported to occur in *M. tuberculosis* as well as in *E. coli*<sup>[13]</sup>. More significantly, Leu481 in the beta subunit of MAP overlaps that of Leu413 in *Thermus aquaticus*, and this amino acid has been reported to make direct contacts with RIF in its bound state through Vanderwaals interactions<sup>[13]</sup>. Hence, the selected change from Leu481 to Pro481 in MAP strain UCF5-RIF16r may have affected the direct interaction between the beta subunit and the drug.

The rationale in selecting the RIF resistant mutant UCF5-RIF16r was to determine the potential for MAP to evolve adaptive resistance to RIF, and the location of the *rpoB* mutation that accounted for the resistance. This data, combined with our analysis of MAP strain 18, showed the potential for MAP to evolve resistance to RFB and RIF *in vivo* and *in vitro* through mutations in the 81 bp variable region. Collectively, after analyzing the resistance characteristics for MAP strain 18 and UCF5-RIF16r, we considered the *rpoB* 81 bp variable regions to be the most significant for determining resistant mutations for RFB and RIF.

MAP strain 185 consisting of five silent mutations within *rpoB* was not considered significant because they did not alter the beta subunit sequence. Moreover, we encountered unusual PCR results and difficulties in extracting genomic DNA from strain 185; therefore, we were unable to sequence its entire *rpoB* gene and account for the slight resistance to RIF. Hence, the mechanism of the partial resistance against RIF for this strain remained undetermined.

Our *rpoB*-based protocol on human blood mixed with MAP was accomplished through contaminating normal human blood with MAP strain 18, and extracting bacterial DNA directly from the blood mixture. As a result, a sufficient amount of bacterial genomic DNA was obtained for successful amplification of our regions of interest within *rpoB* (data not shown). The purpose of this approach was to assess the effectiveness of our protocol on CD patient blood.

Information regarding patient history may explain a rationale for the observed results. Ironically, the patients' medical history indicated that none of them was on anti-MAP treatment. Instead these patients had received a variety of anti-inflammatory and immunosuppressants. However, alarming new reports suggest that some of these drugs may contain antimicrobial activity, especially when tested against few strains of MAP<sup>[47]</sup>. Hence, it is inconclusive to rule out the possibility of antibiotic resistance development *via* alternative drugs.

In conclusion, through the application of our protocol on CD patient samples, we may assist in the determination of RFB and RIF susceptible MAP strains for the treatment of CD. The inconclusive results from the recent Australian clinical trial using RFB, calrithromycin and clofazamine for treatment of patients with CD<sup>[9]</sup> suggested either the absence of MAP or the presence of drug resistance MAP in non-responders. Therefore, detection of drug resistance in pathogens like MAP is now necessary. Our protocol may address the rationale for MAP resistance to RFB in these patients. Based upon the *in vitro* selection of a RFB and RIF resistant MAP strain (UCF5-RIF16r), it is likely that this trend occurs *in vivo*, as supported by the data from MAP strain 18. Furthermore, as RFB is applied more towards the treatment of CD, our protocol will be of utmost significance for the optimization of CD treatment with related antibiotics.

### Abstract

**AIM:** To characterize the mitochondrial dysfunction in experimental cirrhosis and to study whether insulin-like growth factor- I (IGF- I) therapy (4 wk) is able to induce beneficial effects on damaged mitochondria leading to cellular protection.

**METHODS:** Wistar rats were divided into three groups: Control group, untreated cirrhotic rats and cirrhotic rats treated with IGF- I treatment (2 µg/100 g bw/d). Mitochondrial function was analyzed by flow cytometry in isolated hepatic mitochondria, caspase 3 activation was assessed by Western blot and apoptosis by TUNEL in the three experimental groups.

**RESULTS:** Untreated cirrhotic rats showed a mitochondrial dysfunction characterized by a significant reduction of mitochondrial membrane potential (in status 4 and 3); an increase of intramitochondrial reactive oxygen species (ROS) generation and a significant reduction of ATPase activity. IGF- I therapy normalized mitochondrial func-

tion by increasing the membrane potential and ATPase activity and reducing the intramitochondrial free radical production. Activity of the electron transport complexes I and III was increased in both cirrhotic groups. In addition, untreated cirrhotic rats showed an increase of caspase 3 activation and apoptosis. IGF- I therapy reduced the expression of the active peptide of caspase 3 and resulted in reduced apoptosis.

**CONCLUSION:** These results show that IGF- I exerts a mitochondrial protection in experimental cirrhosis leading to reduced apoptosis and increased ATP production.

### INTRODUCTION

Insulin-like growth factor- I (IGF- I) is an anabolic hormone produced mainly in the liver in response to growth hormone (GH) stimulation<sup>[1]</sup>. In cirrhosis, the reduction of receptors for GH in hepatocytes and the reduced ability of synthesis of the hepatic parenchyma cause a progressive decrease in serum IGF- I levels<sup>[2,3]</sup>. We have shown previously that short courses of treatment with IGF- I in rats with carbon tetrachloride-induced cirrhosis induced many systemic beneficial effects<sup>[4-11]</sup> and showed hepatoprotective, antioxidant and antitubrogenic properties<sup>[12-15]</sup>. However, these mechanisms of IGF- I activities regarding the improvement of liver function and fibrosis are not fully understood. We have suggested previously that the described hepatoprotection by IGF- I therapy in rats with carbon tetrachloride-induced cirrhosis

could be related to mechanisms of mitochondrial protection<sup>[12]</sup>.

Mitochondria are a major source of reactive oxygen species (ROS) under physiologic conditions, because 2% to 3% of the O<sub>2</sub> consumed is converted to O<sub>2</sub><sup>•</sup>. Intramitochondrial ROS production increases after peroxidation of mitochondrial membrane lipids<sup>[16-20]</sup>. Mitochondria are particularly sensitive to ROS-induced injury in the pathogenesis of disease. Oxidative stress exerts deleterious effects on mitochondrial function by directly impairing oxidative phosphorylation through direct attack of proteins or membrane lipids. ROS can also induce mitochondrial DNA deletions and mitochondrial membrane permeability transition (MMPT)<sup>[21]</sup>. MMP pore opening activates caspases which is an endpoint to initiate cell death. Furthermore, it has been implicated in the pathogenesis of many fibroproliferative diseases including liver fibrogenesis<sup>[22]</sup>. Recently, a large number of studies have associated mitochondrial dysfunction caused by ROS to both accidental cell death (necrosis) and programmed cell death (apoptosis)<sup>[19,23,24]</sup>. In order to give a better insight into the mechanisms by which IGF- I exerts an hepatoprotective action on damaged liver and supposing that mitochondria could be one of the main cellular target of IGF- I, the aims of the present study were: (1) to characterize the mitochondrial dysfunction in experimental liver cirrhosis and (2) to study whether IGF- I (4 wk) induces beneficial effects on damaged mitochondria leading to cellular protection. Thus, we have extended our study to analyze the effect of IGF- I on mitochondrial function (Mitochondrial Potencial Membrane, intramitochondrial free radical production and “*in vitro*” complex activities), caspase 3 activation and apoptosis. In this series we included three experimental groups of Wistar rats: healthy control group (CO); untreated cirrhotic rats (CI) and cirrhotic rats treated with IGF- I at low doses (2 µg/100 g bw/d, CI + IGF- I).

## MATERIALS AND METHODS

### Animals, liver cirrhosis induction

All experimental procedures were performed in conformity with The Guiding Principles for Research Involving Animals<sup>[25]</sup>. Cirrhosis was induced as previously described<sup>[5,12]</sup>. Briefly, male Wistar rats (3 wk old, 130-150 g) were subjected to CCl<sub>4</sub> inhalation (Merck, Darmstadt, Germany) twice a week for 11 wk with a progressively increasing exposure time from 1 to 5 min. From that time since 12 wk until the 16 wk rats were exposed to CCl<sub>4</sub> once a week for 2 min (5 additional doses of CCl<sub>4</sub>).

During the whole period of cirrhosis induction animals received phenobarbital (Luminal, Bayer, Leverkusen, Germany) in the drinking water (400 mg/L). Both food (standard semipurified diet for rodents; B.K. Universal, Sant Vicent del Horts, Spain) and water were given *ad libitum*. Healthy, age and sex-matched control rats were maintained under the same conditions, but received neither CCl<sub>4</sub> nor phenobarbital.

### Study design

IGF- I therapy or saline was administered the last 4 wk

(13th-16th wk, 28 d), cirrhotic rats were randomly assigned to receive either vehicle (saline) (group CI, *n* = 6) or recombinant human IGF- I (Chiron Company, San Francisco, CA) (20 µg/kg per day in two divided doses, subcutaneously) (Group CI + IGF- I, *n* = 6) for 4 wk. Healthy control rats (Group CO, *n* = 6) received saline during the same period.

In the morning of the 29th day (after 4 wk of treatment), rats were weighed, blood was obtained from the retroocular plexus and animals were killed by decapitation. After the abdominal cavity was opened, the livers were dissected and weighed. No animals developed ascites in this series that was considered as compensated cirrhosis. A sample from the left major liver lobe and the testes was processed for histological examination (fixed in Bouin's solution) and the right lobe was placed in ice-cold isolation buffer. Bouin-fixed tissues were processed and sections (4 µm) were stained with haematoxylin and eosin and Masson's trichrome. Liver cirrhosis was confirmed in all animals treated with CCl<sub>4</sub> following the criteria previously reported<sup>[12,15]</sup>.

### Analytical methods

Liver function tests were determined by routine laboratory methods using a Hitachi 747 autoanalyzer (Boehringer Mannheim, Mannheim, Germany).

### 4-Hydroxynonenal determination

Lipid peroxidation is a well-established mechanism of cellular injury in animals and is used as an indicator of oxidative stress in cells and tissues. Lipid peroxides are unstable and decompose to form a complex series of compounds including reactive carbonyl compounds.

Polyunsaturated fatty acid peroxides generate malondialdehyde (MDA) and 4-hydroxynonenal (4-HNE) upon decomposition. Measurement of malondialdehyde and 4-hydroxyalkenals have been used as an indicator of lipid peroxidation<sup>[26]</sup>. The LPO-586 method (Biotech, Oxis International Inc, USA) is designed to assay MDA in combination with 4- hydroxynonenal.

The LPO-586<sup>TM</sup> assay is based on the reaction of a chromogenic reagent, N-methyl-2-phenylindole, with MDA and 4-HNE at 45°C. One molecule of either MDA or 4-hydroxyalkenal reacts with 2 molecules of reagent N-methyl-2-phenylindole to yield a stable chromophore with maximal absorbance at 586 nm. For simultaneous determination of MDA and 4-HNE, one must use the procedure utilizing methanesulfonic acid (MSA) as the acid solvent.

### Protein carbonyl content (PCC) determination

PCC was determined by the method of Levine *et al*<sup>[27]</sup>. The sample was divided into two portions containing 1-2 mg protein each. To one portion, an equal volume of 2 mol/L HCl was added and incubated at room temperature for one hour, and shaken intermittently. The other portion was treated with an equal volume of 10 mmol/L DNPH in 2 mol/L HCl and incubated for one hour at room temperature. After incubation, the mixture was precipitated with 10% TCA and centrifuged. The precipitate was washed with ethanol:ethyl acetate (1:1), twice dissolved in 1 mL of 6 mol/L guanidine HCl, centrifuged at low speed and

the supernatant was taken. The difference in absorbance between the DNPH-treated and HCl-treated samples was determined at 366 nm.

### Isolation of liver mitochondria

Liver mitochondrial fraction was prepared according to the method described by Schneider and Hogeboom with modifications. Liver samples were homogenized (1:10 w/v) in an ice-cold isolation buffer pH 7.4, containing sucrose 0.25 mmol/L,  $\text{KH}_2\text{PO}_4$  5 mmol/L, MOPS 5 mmol/L, and 0.1% BSA. The homogenate was centrifuged at 800 *g* for 10 min. The resulting supernatant was centrifuged at 8500 *g* for 10 min. The supernatant was discarded and the pellet was diluted in cold isolation buffer and centrifuged at 8500 *g* for 10 min three times. The final mitochondria pellet was resuspended in a minimal volume and aliquots were stored at -80°C until use in enzyme assays. All procedures were conducted at 4°C.

### Flow cytometry analysis

Mitochondrial membrane potential was evaluated using rhodamine 123 dye (RH123) obtained from Molecular Probes, Inc. (Eugene, OR). It has an absorbance maximum of 500 nm and an emission maximum of 523. Mitochondrial suspensions (40-50 µg mitochondrial prot/mL) were incubated in isolation buffer for 5 min in the dark with RH123 (0.5 µg/mL), after adding various agents. For state 4 conditions, mitochondrial samples were incubated with rotenone 25 µmol/L and energized with sodium succinate 5 mmol/L, and with rotenone 25 µmol/L, sodium succinate 5 mmol/L + ADP 200 µmol/L for state 3 conditions. The uncoupler CCCP 10 µmol/L was added to confirm that the uptake of RH123 was related to mitochondrial membrane potential.

The mitochondrial free radical production was measured by RH123 production, a fluorescent molecule derivated from DihydroRh123 without charge (DHR123) (Molecular Probes Inc.) employing the cytometry method performed by O'Connor<sup>[28]</sup> with a small modification.

The mitochondrial homogenates (100 µg/mL) were incubated with DHR123 8.2 nmol/L and radish peroxidase 7 U/mL for 5 min, at room temperature. Fluorescence values from the substrates were normalized with that obtained with peroxidase + uncoupler CCPC.  $\text{H}_2\text{O}_2$  1 mmol/L was employed as positive control.

After incubation, the suspensions were analyzed immediately. Gated mitochondrial population was chosen by flow cytometry, based on forward scatter (FS) and side scatter (SS) within mitochondria samples.

Cytofluorometric analysis was performed by using a flow cytometer EPICS XL (Beckman-Coulter, CA). Green fluorescence was detected with a wide band filter for RH123 centred in  $525 \pm 20$  nm (FL1).

The fluorescence intensity of dyes reflecting a minimum of 15000 individual mitochondria per sample were analyzed in an Epics XL flow cytometer (Beckman-Coulter, CA) using System II version 3.0. Software.

### In vitro mitochondrial activities

Mitochondrial suspensions were thawed and diluted with

potassium phosphate. Activities of the respiratory chain enzymes were measured at 37°C in Cobas Mira (ABXMicro, Alemania). *In vitro* mitochondrial activities were assessed as follow.

**Complex I NADH-ubiquinone oxidoreductase (E.C. 1.6.99.3.):** The activity was measured by following the decrease in absorbance due to oxidation of NADH to NAD at 340 nm<sup>[29]</sup>. The reaction mixture contained potassium phosphate 1.0 mol/L (pH 8),  $\text{NaN}_3$  0.1 mol/L, EDTA 1 mmol/L, NADH 10 mmol/L, Coenzyme Q1 1 mmol/L. The reaction was initiated by the addition of the mitochondrial suspensions and was monitored for 10 min.

**Complex II Succinate-ubiquinone oxidoreductase (E.C. 1.3.5.1.):** The activity was measured by following the decrease in absorbance due to coupled reduction of 2,6-dichlorophenolindophenol (DCPIP) at 600 nm. The reaction mixture contained sodium succinate 1.0 mol/L, potassium phosphate 1.0 mol/L (pH 7), 10% Triton X-100, EDTA 1 mmol/L, NADH 10 mmol/L, 0.1% DC-PIP, Coenzyme Q<sub>2</sub> 0.01 mg/mL. The reaction was initiated by the addition of the mitochondrial suspensions and was monitored for 10 min.

**Complex III Ubiquinol-ferricytochrome c oxidoreductase (E.C.1.10.2.2.):** The activity was measured by following the increase in absorbance due to the reduction ferricytochrome c at 550 nm. The reaction mixture contained sodium succinate 1.0 mol/L, potassium phosphate 0.04 mol/L (pH 7.4),  $\text{NaN}_3$  0.02 mol/L, EDTA 0.1 mmol/L, 0.1% bovine serum albumin, (CoQ<sub>2</sub>)  $\text{H}_2$  0.05 mg/mL. Mitochondrial sample was added and reaction was initiated by the addition of ferricytochrome c 3 mg/mL and was monitored for 2 min. Ferricytochrome c was prepared according to Trounce *et al*<sup>[30]</sup>.

**Complex IV Ferrocytochrome c-oxygen oxidoreductase (E.C.1.9.3.1.):** The activity was measured by following the decrease in absorbance due to the oxidation of ferrocytochrome c at 550 nm. The assay mixture consisted of potassium phosphate 0.1 mol/L (pH 7.4) and 1% ferrocytochrome c. The reaction was initiated by the addition of mitochondria and the reaction was monitored for 2 min. Ferrocytochrome c was prepared according to Trounce *et al*<sup>[30]</sup>.

**Complex V ATPase (E.C: 3.6.1.34.):** The activity was assayed by coupling the reaction to the pyruvate kinase and lactate dehydrogenase systems and measuring NADH oxidation at 340 nm. The assay system contained Tris-HCl buffer 65 mmol/L (pH 7.5), sucrose 300 mmol/L,  $\text{MgCl}_2$  4.75 mmol/L, ATP 4 mmol/L, NADH 0.4 mmol/L, phosphoenolpyruvate 0.6 mmol/L, KCN 5 mmol/L, PK 700 U/mL and LDH 1000 U/mL.

### Measurement of caspase-3 processing

Frozen livers (1 g) were homogenized (Ultra-turrax T25; Janke & Kunkel IKA-laboratory) in lysis solution (1% SDS, Tris-HCl 10 mmol/L, EDTA 50 mmol/L, PMSF

Table 1 Analytical data in the three experimental groups before and after treatment

1 mmol/L, aprotinin 1 µg/mL and leupeptin 1 µg/mL) pH 7.4 at 4°C for 10 min, transferred to Eppendorf tubes and centrifuged at 20800 *g* at 4°C for 5 min. Proteins (100 µg) were separated by 12% SDS-PAGE and transferred to nitrocellulose. The membranes for measuring caspase-3 activation were incubated with anti-caspase-3 (dilution 1:150) rabbit polyclonal antibodies (Santa Cruz Biotechnology, Inc., California, USA) as primary antibodies and anti-rabbit-IgG-alkaline phosphatase (Sigma Chemical Co.) as secondary antibodies using BCIP-NBT as alkaline phosphatase substrate.

#### Apoptosis assessment by TUNEL at the Light-Microscopic Level

TUNEL was performed in deparaffinized 4-µm-thick sections of liver from the three experimental groups with an ApopTag kit (Oncor Gaithersburg, Maryland) according to the supplier's instructions. Sections were counterstained with hematoxylin. The number of TUNEL-positive hepatocytes was recorded in the whole preparation (at × 200 magnification). The results were expressed as stained cells per area (arithmetic mean of 4 areas).

#### Statistical analysis

Data are expressed as mean ± SEM. Statistical significance was estimated with paired or unpaired *t*-test as appropriate. A *P*-value of < 0.05 was considered significant. All analyses were performed by using the SPSS version 10.0. (SPSS Inc, Chicago, USA) statistical package.

## RESULTS

At baseline, before the onset of IGF- I treatment, groups CI and CI + IGF- I showed similar serum levels of alanine aminotransferase, aspartate aminotransferase, glucose, cholesterol, alkaline phosphatase, bilirubin, total protein and albumin which were all of them significantly abnormal when compared to those in control rats (Table 1). According to previous data, the biochemical results in this series

**Figure 1** Histopathological comparative study (4 µm sections; Masson's trichrome stain). An evident reduction of fibrosis was found in the cirrhotic group treated with IGF-I in agreement with previous studies<sup>[12,14,15]</sup>.

showed an improvement of liver function tests as it is summarized in Table 1.

In agreement with previous results, a reduction of fibrosis (Figure 1) and liver oxidative products were also observed in CI-IGF group: 4-hydroxynonenal, CO = 0.64 ± 0.05; CI = 0.78 ± 0.03; CI + IGF- I = 0.73 ± 0.04 (nmol/mg prot.); Protein carboxyl content (nmol/mg prot.): CO = 6.48 ± 0.71; CI = 8.15 ± 0.60; CI + IGF- I = 6.80 ± 0.64 (*P* < 0.05 CI vs CO), although the reduction was less notable than in previous studies because in this series (see Methods) cirrhotic animals received CCl<sub>4</sub> doses also during the 4 wk of treatment (with IGF- I or saline).

#### Mitochondrial membrane potential

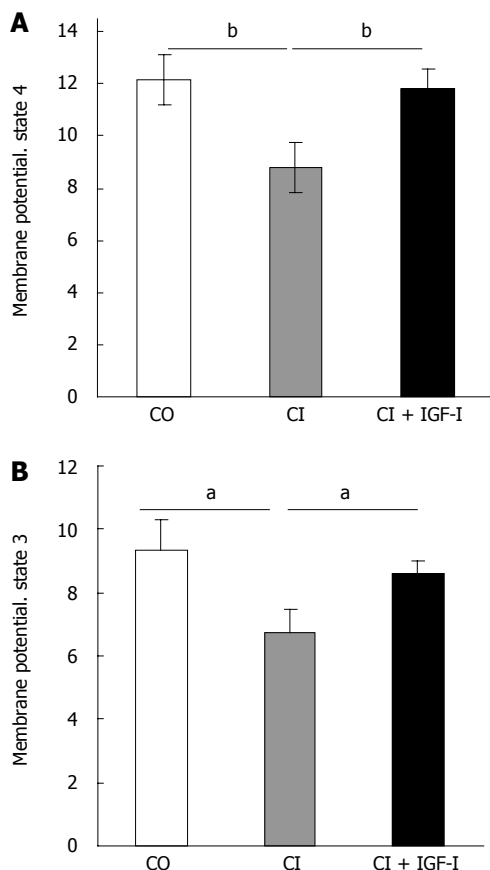

Gated mitochondrial population was chosen by flow cytometry (FCM), based on forward scatter (FS) and side scatter (SS) within mitochondria samples.

The membrane potential was monitored by fluorescence

Table 2 Activities of the electron transport complexes ( $n = 6$ )

	CO, healthy control group	CI, untreated cirrhotic group	CI + IGF, cirrhotic rats treated with IGF- I
I -NADH-ubiquinone oxidoreductase (nmol/min per mg prot)	7.68 ± 2.19	11.01 ± 1.60 <sup>c</sup>	16.10 ± 2.03
II -Succinate-ubiquinone oxidoreductase (μmol/min per mg prot)	0.38 ± 0.02	0.33 ± 0.04	0.35 ± 0.03
III -Ubiquinol-ferricytochrome oxidoreductase (nmol/min per mg prot)	89.57 ± 6.54	148.75 ± 23.26 <sup>a</sup>	163.15 ± 21.38 <sup>b</sup>
IV -Ferrocycytochrome c-oxygen oxidoreductase (pmol/min per mg prot)	3.91 ± 0.85	5.22 ± 1.01	5.66 ± 0.97

mean ± SEM; <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs CO groups; <sup>c</sup> $P < 0.05$  vs CI + IGF.

**Figure 2** Mitochondrial Membrane Potential (MMP): the MMP was evaluated by flow cytometry with Rhodamine 123 under respiratory conditions (with succinate), state 4 (A) and with ADP state 3 (B). MMP is expressed as fluorescence arbitrary units (FAU). mean ± SEM; <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$ .

quenching of RH123 in mitochondria from liver rats under respiratory state 4. Under these conditions, the mitochondrial membrane potential is an index of mitochondrial energy status. Figure 2A shows that the membrane potential in state 4 was significantly decreased in the CI animals compared to control, and was restored upon IGF- I treatment (CO, healthy controls =  $12.18 \pm 0.96$ , CI, untreated cirrhotic rats =  $8.83 \pm 0.88$ , CI + IGF- I, cirrhotic rats treated with IGF- I =  $11.80 \pm 0.85$  Fluorescence Arbitrary Units -FAU-).

In a similar way, in the state 3 (addition of ADP as substrate), expressed as fluorescence arbitrary units, both the control rats and the CI + IGF- I rats showed significantly higher values than untreated cirrhotics rats treatment (CO =  $9.33 \pm 0.97$ , CI =  $6.71 \pm 0.58$ , CI + IGF- I =  $8.62 \pm 0.45$  FAU) (Figure 2B).

**Figure 3** Intramitochondrial ROS production in isolated mitochondria: mitochondria from untreated cirrhotic rats showed an increased production of free radicals as compared to healthy controls (CO) and cirrhotic rats treated with IGF- I (CI + IGF). mean ± SEM; <sup>a</sup> $P < 0.05$ .

### Free radical production

Mitochondria from untreated cirrhotic rats showed a significant increase in ROS generation (CI =  $0.58 \pm 0.03$  FAU,  $P < 0.05$  vs CO) when compared to controls (CO =  $0.47 \pm 0.02$  FAU) and cirrhotic rats treated with IGF- I (CI + IGF- I =  $0.45 \pm 0.01$  FAU,  $P < 0.05$  vs CI): see Figure 3.

### Activities of the electron transport complexes

Table 2 summarizes the activities of the electron transport complexes in mitochondria from the three experimental groups. As shown in Table 2, activities of complex I and III increased significantly in cirrhotic animals. This increase was significantly higher in the CI + IGF- I group. Therefore, activity of complex IV was slightly increased in CI and CI + IGF- I groups.

By contrast, complex II activity was slightly decreased in cirrhotic rats when compared to control group.

As shown in Figure 4, ATPase activity declined in untreated cirrhotics rats. However, there was no significant difference between the CO and CI + IGF- I groups in complex V activity treatment (CO =  $4.52 \pm 0.23$ , CI =  $3.43 \pm 0.21$ , CI + IGF- I =  $3.83 \pm 0.31$  nmol/min per mg prot).

### Measurement of caspase-3 activation

Western blotting for fragment-17 of caspase 3 showed a significant increase of caspase 3 activation in untreated cirrhotic rats when compared to healthy controls (Figure 5). However a notable reduction in the expression of this

Table 3 TUNEL positive hepatocytes in the three experimental groups

	CO, healthy control group	CI, untreated cirrhotic group	CI + IGF, cirrhotic rats treated with IGF- I

mean ± SEM; <sup>b</sup>*P* < 0.01 vs other groups; <sup>c</sup>*P* < 0.05 vs CI.

**Figure 4** Complex V ATPase activity: ATPase activity was significantly reduced in mitochondria from untreated cirrhotic rats (*P* < 0.05 vs CO group). IGF-therapy induced a little increase of ATPase activity (*P* = no significant vs CO group). mean ± SEM; <sup>a</sup>*P* < 0.05.

**Figure 5** Active fragment of caspase 3 by Western blot in liver homogenates: untreated cirrhotic rats showed an increment of caspase activation. IGF- I replacement therapy induced an inhibition of caspase 3 activation. <sup>b</sup>*P* < 0.01; <sup>d</sup>*P* < 0.001.

**Figure 6** Apoptosis by TUNEL in the liver from the three experimental groups: the number of TUNEL positive hepatocytes was increased in untreated cirrhotic rats (CI) as compared to healthy controls (CO). IGF- I therapy reduced significantly apoptosis in hepatocytes.

fragment was observed in cirrhotic animals treated with IGF- I.

### Apoptosis assessment by TUNEL

The number of TUNEL-positive hepatocytes was significant increased in untreated cirrhotic group as compared to controls. IGF- I treatment reduced apoptosis in hepatocytes as shown in Figure 6 and Table 3.

## DISCUSSION

This study analyzes the effect of IGF- I on mitochondrial damage, caspase 3 activation and hepatocyte apoptosis in rats with CCl<sub>4</sub>-induced cirrhosis. In previous studies, we have shown that low doses of IGF- I improved liver function and reduced oxidative liver injury and

fibrosis, suggesting a mitochondrial protection<sup>[12,14,15]</sup>. The mechanisms of this hepatoprotection are understood only partially; but, data in this paper give some insight.

When compared to healthy rats, untreated cirrhotic rats showed altered liver function tests and increased hepatic lipid peroxidation and protein carbonyl content (PCC) which was in agreement with previous data<sup>[12,14,15]</sup> and improved with IGF- I substitution.

The present work shows that mitochondrial dysfunction in rats with CCl<sub>4</sub>-induced cirrhosis is characterized by a significant depletion of the mitochondrial membrane potential (MMP), a reduction of ATPase activity, and a significant increase of intramitochondrial ROS generation.

In addition, these results indicate that the activities *in vitro* (in optimal conditions) of complex I and III were highest in cirrhotic animals when compared to control

animals. It would be an adaptive mechanism as in fact it is not possible to produce a normal proton gradient (Figure 2) in untreated cirrhotic rats. The increased mitochondrial production of  $O_2^{\cdot -}$  at complexes I and III and consequently of  $H_2O_2$  is a common finding in oxidative mitochondrial damage<sup>[31,32]</sup>. Uncontrolled mitochondrial formation of ROS promotes the activation of the mitochondrial membrane permeability transition<sup>[31]</sup>.

Several research groups have tried to characterize the effect of chronic ethanol consumption and CCl<sub>4</sub>-induced liver injury showing morphological alterations in mitochondria and deficient substrate oxidation, ADP phosphorylation, cytochrome c and enzyme content<sup>[16,31,33-37]</sup>. On the other hand, other authors have concluded that in chronic CCl<sub>4</sub>-treated rats, liver mitochondria are morphologically and functionally intact<sup>[38]</sup>. In the present work, the described alteration in mitochondrial function occurred at least after 16 wk of CCl<sub>4</sub> exposure.

The major finding of this work is that mitochondrial dysfunction leading to hepatocyte apoptosis is improved by IGF- I therapy. These results give new evidence of the hepatoprotective properties of IGF- I in experimental cirrhosis<sup>[12,15]</sup>.

In the present work, oxygen consumption by isolated mitochondria was not assessed and consequently proton leak data (oxygen consumption/MMP) are not available. However, the observed reduction of MMP with an increased generation of ROS suggests that oxygen is wasted by damaged mitochondria producing  $H_2O_2$  instead of a normal proton gradient, driving force of ATP synthesis through the proton pumping  $F_1F_0$  adenosine triphosphate synthase (ATP synthase)<sup>[31]</sup>.

The described mitochondrial dysfunction in this paper is corrected by IGF- I therapy since mitochondria from IGF- I treated cirrhotic rats showed a normal MMP and a recovered ATPase activity resulting in increased activity of complex I and III, but reduced ROS generation. Taken together, all of these data suggest an extramitochondrial protection of mitochondria by IGF- I.

Previously, we have reported that IGF- I treatment restored the expression of several protease inhibitors such as alpha-1-antichymotrypsin, the serine protease inhibitor 2<sup>[13]</sup>, that could contribute to the described mitochondrial protection. Further studies are necessary to elucidate all mechanisms involved in the hepatoprotection induced by IGF- I. In the previously mentioned work, we provided evidence that IGF- I treatment in cirrhotic rats modulates gene expression, reverting the global hypomethylation of the genomic DNA observed in cirrhosis<sup>[13]</sup>.

On the other hand, the mitochondrial dysfunction in the present study was associated with an overexpression of the active fragment of caspase 3 and an increased number of TUNEL positive hepatocytes in untreated cirrhotic rats. In accordance with the improvement of the mitochondrial function described in CI + IGF- I group, IGF- I treated animals showed a significant reduction of caspase 3 activation and apoptosis of hepatocytes.

In recent years, mitochondria have been recognized as regulators of cell death<sup>[39,40]</sup>. Cellular dysfunction induced by intra- or extracellular insults converge on mitochondria

and induce a sudden increase in permeability on the inner mitochondrial membrane, the so-called mitochondrial membrane permeability transition (MMPT). MMPT is caused by the opening of pores in the inner mitochondrial membrane, matrix swelling and outer membrane rupture. The MMPT is an endpoint to initiate cell death and a putative target for cellular protection since MMPT and the release of mitochondrial cytochrome c activate the apoptotic pathway by which initiator caspases (i.e. caspase 8 and 9) are converted to their active forms, which in turn activate downstream effector caspases (i.e. caspases 3, 6 and 7). Finally, cellular targets of the effector caspases include endonucleases and cytoskeletal proteins<sup>[41]</sup>.

These results show that IGF- I induces cell resistance to apoptosis by oxidative stress through mitochondrial protection. Mitochondria seem to be the main cellular targets of IGF- I action. Likewise, our data are in agreement with the observation that the effect of serum withdrawal on the autophagy of dysfunctional mitochondria is prevented by the addition of IGF- I<sup>[42]</sup>.

Accordingly, it has been reported that IGF- I inhibited the reduction of MMP, cytochrome c release, caspase 3 activity and apoptosis in several cell lines and experimental procedures<sup>[43-45]</sup>.

The described improvement of mitochondrial function in cirrhotic rats by IGF- I therapy resulted in an increment of the ATP synthesis. Interestingly, a recent trial with cirrhotic patients showed that the IGF- I therapy induced an improvement in albumin and metabolism increasing resting energy expenditure (REE) (kcal/d)<sup>[46]</sup>. Although the mechanism by which IGF- I influences REE in cirrhotic patients remains to be clarified, it could be related with an increment of ATP availability after IGF- I therapy.

In conclusion, these results show that IGF- I exerts a mitochondrial protection in experimental cirrhosis leading to reduced caspase activation and apoptosis and increasing ATP production. This work provides new evidence of the beneficial effect of IGF- I supplementation in experimental liver cirrhosis and experimental basis for further studies at exploring the potential of IGF- I in the treatment of human cirrhosis.

## ACKNOWLEDGMENTS

The authors wish to express their gratitude to Dr. Bruce Scharschmidt, Chiron Company (USA), for granting the rhIGF- I used in this study. We are as well deeply indebted to Dr. Jorge Quiroga, Mrs Cristina Chocarro and Ms Yolanda Rico for their generous help.

## COMMENTS

### Background

Liver cirrhosis is a condition of "IGF- I deficiency". The endogenous administration of low doses of insulin-like growth factor I (IGF- I) exerts a mitochondrial protection in experimental cirrhosis leading to reduced apoptosis and increased ATP production.

### Research frontiers

Liver cirrhosis. Antioxidant therapies. New strategies in chronic liver diseases. Axis GH/IGF- I in liver cirrhosis.

## Innovations and breakthroughs

Mitochondrial dysfunction in cirrhosis. Mitochondrial protection induced by IGF- I at low doses.

## Applications

This work provides new evidence of the beneficial effect of IGF- I supplementation in experimental liver cirrhosis and experimental basis for further studies at exploring the potential of IGF- I in the treatment of human cirrhosis.

## Peer review

This paper provides evidence in order to give a better insight into the mechanisms by which IGF- I exerts an hepatoprotective action on damaged liver and demonstrates that mitochondria are one of the main cellular targets of IGF- I . This study contributes to the characterization of mitochondrial dysfunction in experimental liver cirrhosis and shows the beneficial effects on damaged mitochondria leading to cellular protection induced by IGF- I therapy.

Hepatic reconstruction from fetal porcine liver cells using a radial flow bioreactor. *World J Gastroenterol* 2008; 14(17): 2740-2747 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2740.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2740>

### Abstract

**AIM:** To examine the efficacy of the radial flow bioreactor (RFB) as an extracorporeal bioartificial liver (BAL) and the reconstruction of liver organoids using embryonic pig liver cells.

**METHODS:** We reconstructed the liver organoids using embryonic porcine liver cells in the RFB. We also determined the gestational time window for the optimum growth of embryonic porcine liver cells. Five weeks of gestation was designated as embryonic day (E) 35 and 8 wk of gestation was designated as E56. These cells were cultured for one week before morphological and functional examinations. Moreover, the efficacy of pulsed administration of a high concentration hepatocyte growth factor (HGF) was examined.

**RESULTS:** Both cell growth and function were excellent after harvesting on E35. The pulsed administration of a high concentration of HGF promoted the differentiation and maturation of these fetal hepatic cells. Microscopic examination of organoids in the RFB revealed palisading and showed that bile duct-like structures were well developed, indicating that the organoids were mini livers. Transmission electron microscopy revealed microvilli on the luminal surfaces of bile duct-like structures and junctional complexes, which form the basis of the cytoskeleton of epithelial tissues. Furthermore, strong expression of connexin (Cx) 32, which is the main protein of hepatocyte gap junctions, was observed. With respect to liver function, ammonia detoxification and urea synthesis were shown to be performed effectively.

**CONCLUSION:** Our system can potentially be applied in the fields of BAL and transplantation medicine.

### INTRODUCTION

Although organ transplantation has become an established treatment, the shortage of donor organs remains a serious problem, for which tissue engineering is a possible solution. A bioartificial liver (BAL) system consists of three components: cells, a scaffold for the cells, and growth-regulating factors. Ideally, the cells for a BAL will exhibit similar functions to normal human mature hepatocytes while maintaining long-term viability and proliferative activity. However, a method of culturing human hepatocytes for a prolonged period has not been established so far.

We have developed a radial flow bioreactor (RFB), which is a 3-dimensional culture system that can be used for high-density culture<sup>[1-4]</sup>, achieving a cell density 10 times greater than that obtained with hollow-fiber culture<sup>[5,6]</sup>. A cylindrical bioreactor is filled with porous cellulose beads that act as microcarriers, and culture medium flows from the periphery toward the center of the reactor (Figure 1A)<sup>[2,7]</sup>. To achieve a high-density cell culture, it is essential to minimize any variations in the distribution of oxygen and nutrients between the culture medium at the inlet and outlet of the reactor. If medium flows from the periphery towards the center, a high perfusion rate can provide an adequate supply of oxygen and nutrients to cells at the center of the bioreactor even though oxygen and nutrients are consumed by cells at the periphery. Thus, there are similarities between the RFB and the anatomy of hepatic lobules (Figure 1B)<sup>[2,7]</sup>.

Because of the easy availability, recent reports point out a clinical use of BAL systems that utilize animal cells<sup>[8,9]</sup>. Fetal porcine hepatocytes have a high proliferative potential *in vitro*. Previous studies have shown that minimal immunogenicity is exhibited by tissues harvested at the

earliest available gestational age<sup>[10-12]</sup>. Thus, the earliest time after organogenesis is established appears to be preferable for human transplantation. In fact, Friedman *et al.*<sup>[13]</sup> have shown that maximal liver growth and function were achieved at the earliest teratoma-free gestational age of embryonic day (E) 28. In this study, the possibility of teratoma development was also taken into consideration, and construction of a BAL system was achieved with a RFB and fetal porcine livers obtained on E35 as the cell source, while E56 cells were also examined for comparison. Furthermore, this study also focused on the effect of hepatocyte growth factor (HGF), which was originally reported as a hepatocyte-specific mitogen with an important role in liver regeneration<sup>[14]</sup>.

## MATERIALS AND METHODS

### Isolation of fetal hepatocytes and nonparenchymal epithelial cells

Pregnant mini swines (CSK-MS) weighing 30 to 35 kg were purchased from Chugai Institute of Medical Science (Nagano, Japan). Fetal hepatic cells were isolated from the porcine livers of embryos at 5 and 8 wk of gestation (NIBS strain) by the two-step liver perfusion method of Seglen with some modifications<sup>[15-17]</sup>. Five weeks of gestation was designated as E35 and 8 wk of gestation was designated as E56. For controls, mature porcine liver cells were used. After intraportal infusion of collagenase (0.05%) and dispase (1000 U/mL), the hepatic tissue was minced into pieces and shaken in collagenase solution. Then the collagenase-digested liver cell suspension was centrifuged at 50 *g* for 1 min. The E35 cells were divided into 3 fractions and the E56 cells were divided into 2 fractions. The hepatocyte fraction (lowest fraction) was maintained on ice in serum-free ASF 104 medium (Ajinomoto, Tokyo). The one and two upper fractions, respectively, were centrifuged once at 350 *g* for 5 min, and the cell pellet (containing non-parenchymal cells) was also maintained on ice in serum-free ASF 104 medium.

### Oxygen consumption in the RFB

An RFB system with a 15-mL capacity was placed in an aseptic room maintained at 37°C. The system was composed of an RFB and a conditioning vessel connected to a tank containing fresh medium and a recovery tank. The system was automatically controlled by a computer that monitored pH, glucose, and oxygen consumption. The oxygen tension in the culture medium was measured both within the reservoir and at the outlet of the bioreactor, and the oxygen consumption was monitored on the basis of the oxygen tension gradient ( $Do_{in} - Do_{out}$ :  $\Delta O_2$  ppm). Oxygen consumption was used as an index of the activity of the cells in the RFB system.

### Culture of cells in the RFB

The RFB (Biott, Tokyo, Japan) is a cylindrical bioreactor with a capacity of 15 mL that contains cellulose beads (Asahi Kasei, Tokyo, Japan). The RFB is attached to a reservoir containing culture medium and an automatic controller that maintains the oxygen content and pH of the

**Figure 1** The principle of RFB system. **A:** A cylindrical bioreactor is filled with porous cellulose beads that act as microcarriers and culture medium flows from the periphery toward the center of the reactor. Biases in distribution of oxygen and nutrients between the culture medium at the inlet and outlet of the reactor are minimized; **B:** The RFB system is similar to the organization of the hepatic primary lobe Figure 1B is reproduced from reference 7.

medium. Both hepatocytes ( $5 \times 10^7$ ) and non-parenchymal cells ( $5 \times 10^7$ ) were inoculated into the reservoir, which was filled with ASF104 medium containing 2% fetal bovine serum (FBS). The bioreactor was perfused in a closed circuit fashion for 2 h to maximize the efficiency of cell attachment to the cellulose beads, after which the reactor was switched to the open-circuit mode and the medium was changed to ASF104 without FBS. For this study, incubation in the RFB system was performed for one week before morphological and functional examinations.

### Factor mix and HGF

The factor mix (FM) that we formulated consists of  $10^{-7}$  mol/L insulin,  $10^{-7}$  mol/L dexamethasone, 100 ng/mL oncostatin M (OSM), 25 ng/mL epidermal growth factor (EGF), 1  $\mu$ g/mL L-ascorbic acid phosphate magnesium salt, 0.1 mmol/L nicotinamide, and antibiotics, which was added to the culture medium. HGF was also added at 20 ng/mL (low-dose group) or 100 ng/mL (high-dose group). HGF was administered three times (d 1, 3, and 5) by closed-circuit perfusion for 2 h.

### Experimental groups

The following groups were studied: FME35 group (ASF104 + FM), LFE35 group (ASF104 + FM + HGF 20 ng/mL: low-dose), and HFE35 group (ASF104 + FM + HGF 100 ng/mL: high-dose) for E35 cells, with corresponding groups for E56 cells. Two other groups, i.e., the FMH group (Adult: group H, ASF104 + FM) and the HFH group (Adult: group H, ASF104 + FM + HGF 100 ng/mL), were studied as control groups. Each group was set at  $n = 3$ .

### Ammonia loading test

In order to assess the performance of hepatocyte functions, the ammonia ( $NH_3$ ) loading test was performed. In consideration of the results of oxygen consumption and morphological features, the  $NH_3$  loading test compared the

**Figure 2** Histological findings of fetal porcine liver (HE staining). **A:** Extramedullary hematopoiesis was observed (arrow) and the cells are largely immature at embryonic d 35 (x 100); **B:** A definite lobular structures and a decrease of extramedullary hematopoiesis were observed at embryonic d 56 (x 100).

HFE35 group, FME35 group, and HFE56 group. After incubation for one week (d 7) in the RFB, ammonium chloride ( $\text{NH}_4\text{Cl}$ ) was added at three concentrations (1 mmol/L + 2 mmol/L + 3 mmol/L) every 8 h for 24 h, followed by 3 mmol/L for a further 24 h<sup>[4]</sup>. Then  $\text{NH}_3$  and urea levels were measured on d 8 and d 9 using an automatic high-speed amino acid analyzer JLC-300 (JEOL Ltd., Tokyo).

### Immunohistochemistry

For immunochemical study of cytokeratin 19 (CK19) (DakoCytomation), the streptavidin-biotin (SAB) technique was used<sup>[18,19]</sup>. Specimens of RFB cultures were fixed with Methacarn solution (methanol:chloroform:glacial acetic acid = 6:3:1), embedded in paraffin, cut into 3  $\mu\text{m}$  sections, and deparaffinized with graded xylene series. Endogenous peroxidase was inhibited by adding 0.3%  $\text{H}_2\text{O}_2$  methanol.

For immunofluorescence study of connexin 32 (Cx32), specimens of RFB cultures were fixed in cold absolute acetone for 10 min. Immunohistochemistry with a rabbit polyclonal anti-Cx32 (Zymed, South San Francisco, CA) was performed. Cx32 was visualized using Alexa Fluor 488-conjugated goat anti rabbit immunoglobulin G (Molecular Probes, Eugene, OR). For comparison, immunohistochemical staining as also performed on parenchymal cells and non-parenchymal cells in monolayer cell culture. Samples were examined with an epifluorescence microscope (Nikon, Tokyo, Japan) and a laser-scanning confocal microscope (MRC 1024; Bio-Rad, Hercules, CA).

### Transmission electron microscopy (TEM)

For TEM, cultured cells were fixed with 2.0% glutaraldehyde in 0.1 mol/L phosphate buffer (PB) for 1 h and postfixed with 1%  $\text{OsO}_4$  in 0.1 mmol/L PB for 1 h at 4°C. Specimens were dehydrated in ethanol and embedded in a mixture of Epon-Araldite. Thin sections (60 nm) were cut with a diamond knife mounted on an LKB ultratome, and stained with aqueous uranyl acetate. Then the sections were examined under a JEOL 1200EX electron microscope (JEOL Ltd., Tokyo, Japan).

### Statistical analysis

The oxygen consumption, the  $\text{NH}_3$  and urea levels were reported as a mean  $\pm$  SD. For individual parameters, differences between groups were assessed by repeated measures ANOVA<sup>[20,21]</sup> and Bonferroni's multiple

**Figure 3** Changes of the oxygen consumption in the HFE35, LFE35, and FME35 groups. HFE35 group vs FME35 group ( $P < 0.01$ ), HFE35 group vs LFE35 group ( $P < 0.05$ ), LFE35 group vs FME35 group (no significant). The data show the mean values, while error bars represent corresponding standard deviations. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$ .

comparison test. All calculations were performed using Stat View-J statistical software (SAS Institute, Cary, NC) with  $P < 0.05$  considered significant.

## RESULTS

### Morphological features of fetal porcine liver cells

Figure 2A demonstrates the histological features of E35 porcine liver. Although the hepatic lobular structure is present, extramedullary hematopoiesis was also observed and the cells are largely immature. On the other hand, the E56 liver shows a definite lobular structure and a decrease of extramedullary hematopoiesis, so it more closely resembles the adult porcine liver (Figure 2B). Liver cells isolated on E56 were divided into two layers (parenchymatous cells and non-parenchymatous cells) after centrifugation of the cell suspensions in accordance with these histological findings; but, E35 liver cell suspensions were divided into three layers. The upper layer, the middle layer, and the lower layer consisted of parenchymal cells, extramedullary-hematopoiesis cells including immature hepatic cells, and non-parenchymal cells, respectively.

### Oxygen consumption

Changes in the oxygen consumption in each group, which is an index of cellular activity in RFB culture, are shown in Figure 3. Although viability of the FME35 group was maintained for one week, viability of the FMH group

**Figure 4** Histological findings of cultured cells in the RFB (hematoxylin-eosin staining and immunohistochemistry). **A:** Cultured cells formed layers on the cellulose beads. Non-parenchymal cells had a flat shape and existed on the surface of the perfused side (arrow); **B:** A palisading structure was observed in cell clumps; **C:** Bile duct-like structures were also observed in cell clumps; **D:** The expression of cytokeratin 19 (CK19) was observed in bile duct-like structures.

was difficult to maintain (data not shown). Although the LFE56 group did not show a significant change of oxygen consumption over time compared with the FME35 group ( $P = 0.2792$ ), the HFE35 group showed a significant change of oxygen consumption with time ( $P < 0.01$ ). Also compared to the LFE35 group, the HFE35 group showed a significant change over time ( $P < 0.05$ ). E56 cells gave the same results as E35 cells when cultured under the same conditions (data not shown). The HFH group, which was treated with a high concentration of HGF, also maintained viability for one week (data not shown).

#### Architecture of cells cultured in the RFB

In the bioreactor, cultured cells formed layers on the cellulose beads. Non-parenchymal cells had a flat shape and existed on the surface of the perfused side (Figure 4A). Moreover, cell clumps of 0.4 to 0.8 cm<sup>3</sup> separated from the cellulose beads to float in the RFB. In particular, these clumps were conspicuous in the HFE35 group. On histological examination of these clumps, a palisading structure (Figure 4B) and bile duct-like structures were also observed (Figure 4C), so reconstruction of a “mini-liver organoid” was achieved. Furthermore, CK19 which is the marker of a bile duct was also observed in bile duct-like structures (Figure 4D). TEM images revealed microvilli inside bile duct-like structures (Figure 5A). Moreover, junctional complexes were well-developed and tight junctions were also observed (Figure 5B). Immunohistochemical staining for Cx32, which is the main protein of gap junctions in hepatocytes of the organoid, showed expression in a whirl-shaped pattern (Figure 5C). These morphological characteristics were more notable in the HFE35 group. The expression of Cx32 in the parenchymal cells in monolayer culture was reduced

compared to that of the clump in RFB (Figure 5D). Furthermore, the expression of Cx32 in non-parenchymal cells in monolayer culture was not observed (Figure 5E).

#### Ammonia loading test

The ammonia loading test was performed in the HFE35 group, which showed good oxygen consumption and morphological reconstruction of a mini liver, the FME35 group, and the HFE56 group. Compared with the FME35 group, the NH<sub>3</sub> concentration of the HFE35 group was decreased significantly ( $P < 0.01$ ) (Figure 6), and the urea concentration increased significantly along with a reduction of NH<sub>3</sub> ( $P < 0.01$ ) (Figure 7). Moreover, a significant reduction of the NH<sub>3</sub> concentration was seen in the HFE35 group compared with the HFE56 group ( $P < 0.05$ ) (Figure 6). On the other hand, the change of the urea concentration in the HFE35 group was marked, but there was no significant difference with the HFE56 group (Figure 7).

## DISCUSSION

In this study, fetal porcine hepatic cells with proliferative capacity were cultured in a RFB system that allowed high-density, three-dimension culture<sup>[1-4]</sup>, and the usefulness of the RFB system as a BAL and the possibility of liver reconstruction with implantable organoids were examined. Although the high proliferative capacity of embryonic cells is well known, it has been unclear at which gestational age the fetal liver cells show optimal proliferation and functional capacity when used as a source of cells for a BAL or for organoid reconstruction. In this study, fetal porcine livers (E35 and E56) were selected based on the findings of Friedman *et al.*, who examined the timing

**Figure 5** A: Transmission electron microscopic images revealed microvilli inside bile duct-like structures; B: Junctional complexes were well developed and tight junctions were also observed; C: Connexin 32 (Cx32) in liver organoid, showed expression in a whirl-shaped pattern; D: Cx32 in parenchymal cells in monolayer culture was fewer than that of the organoid; E: Cx32 in non-parenchymal cells in monolayer culture was not observed.

**Figure 6** The  $\text{NH}_3$  loading test compared the HFE35 group, FME35 group, and HME56 group. HFE35 group vs FME35 group ( $P < 0.01$ ), HFE35 group vs HFE56 group ( $P < 0.05$ ). FME35 vs HFE56 (no significant). <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$ .

**Figure 7** Changes of urea concentration in the HFE35, HFE56, and FME35 groups. HFE35 group vs FME35 group ( $P < 0.01$ ), HFE35 vs HFE56 and HFE56 vs FME35 (no significant). <sup>a</sup> $P < 0.01$ .

of liver organogenesis in embryonic swines<sup>[13]</sup>. They determined distinct gestational time windows for the embryonic porcine liver and precursor cells, with maximal liver growth and function being achieved at the earliest teratoma-free gestational age of E28. In their tissue transplantation experiment, no development of teratomas was seen on E28 (0/23 transplants)<sup>[13]</sup>. Examination of hepatocyte function based on the serum albumin level also showed that E28 is the optimal gestational age for transplantation, and albumin secretion was decreased at E56 and E80<sup>[13]</sup>. Although this study was performed *in vitro*

using the RFB system, in consideration of the possibility of the teratoma development because the environment was similar to that *in vivo*, E35 was chosen as a safe gestational age and comparison with E56 was also performed.

At present, using cells from the fetal human liver is ethically problematic and great difficulties in obtaining such cells are expected. For this reason, fetal porcine liver cells were used in the present study. The following three points are also worth considering: (1) The anatomical and physiological characteristics of the porcine liver are similar to those of the human liver; (2) The gestation period of

pigs is comparatively short (about 112–116 d), and breeding is easy; (3) Breeding of specific-pathogen-free animals is also possible, so zoonoses can be avoided<sup>[22,23]</sup>. However, the swine is immunologically different from humans and hyperacute rejection of porcine organs by human recipients is mediated *via* antibodies directed against Gal $\alpha$ -1, 3-Gal on porcine cells, posing an immediate barrier to successful clinical xenotransplantation<sup>[24–26]</sup>. In addition, infection of the human host by porcine endogenous retroviruses poses a major problem<sup>[27]</sup>. It was reported that infection can be avoided by breeding GalT KO swines that show no infectivity for human cells *in vitro*<sup>[28,29]</sup>. Thus, porcine organs may be used for xenotransplantation in donors with no alternative.

With respect to growth factors, the factors that were considered to be necessary for organogenesis by inducing proliferation, differentiation, and maturation of co-cultured fetal hepatic parenchymal cells and non-parenchymal cells were added to the culture medium<sup>[30–35]</sup>. Hamazaki *et al.*<sup>[35]</sup> demonstrated that the important growth factors for hepatogenesis are fibroblast growth factor (FGF) at an early stage, HGF in the middle stage, and OSM, insulin, and dexamethasone at the late stage. OSM and dexamethasone are especially important for the maturation of hepatoblasts to hepatocytes<sup>[31,36]</sup>. On the other hand, it is generally accepted that HGF/scatter factor (SF) is an important paracrine mediator of epithelial-mesenchymal cell interactions, with potential involvement in organogenesis and angiogenesis<sup>[37,38]</sup>. In particular, a morphogenic effects of HGF/SF on the organization of focal contacts and cellular junctions has been documented<sup>[39]</sup>.

Morphological examination of each group showed that fetal hepatic parenchymal cells were adherent to the cellulose beads, while fetal hepatic non-parenchymal cells existed on side of perfusion (Figure 4A)<sup>[2]</sup>. Also, small organoids that had separated from the beads were observed floating in the RFB. In the HFE35 group, larger organoids were observed. Microscopic examination of the organoids from a high-HGF groups revealed a palisading architecture and bile duct-like structures with the expression of CK19, so the organoids could be called mini livers. Furthermore, TEM showed microvilli on the luminal surfaces of bile duct-like structures and junctional complexes, the basis of the cytoskeleton of epithelial tissue. Finally, strong expression of Cx32, which is the main protein of hepatocyte gap junctions, was observed<sup>[40,41]</sup>. These findings were considered to be the features of organoids which had adhered to the beads firmly until reaching a certain size.

Oxygen consumption was used as an index of cellular activity and it showed a significant change over time in the HFE35 group compared to the FME35 group, and a high level of oxygen consumption was maintained in the HFE35 group. Although the LFE35 group also showed a high consumption at the time of HGF addition compared to the FME35 group, there was no significant change over time. The E56 group also showed similar changes of oxygen consumption under the same conditions. The ammonia loading test was performed for evaluation of functionality of mature hepatocytes. Among 3 groups tested, the reduction of NH<sub>3</sub> and the increase of urea

production were highest in the HFE35 group, suggesting that the urea cycle was activated by elevation of the ammonia concentration. Although similar changes were observed in the HFE56 group, the extent of change was smaller than in the HFE35 group. These results showed that the organoids possessed some of the functions of mature hepatocytes.

Both proliferative activity and differentiation of cells are needed as an ideal source for a BAL. In this study, the combination of embryonic porcine liver (E35) cells and pulsing with a high concentration of HGF in our RFB provided a system for which clinical application may eventually be possible in the fields of BAL and transplantation medicine.

## ACKNOWLEDGMENTS

We are grateful to Dr. T Matsuura of Department of Internal Medicine at the Jikei University School of Medicine and Mrs. H Maehashi of Department of Biochemistry I at the Jikei University School of Medicine for their excellent technical and practical support.

## COMMENTS

### Background

As an alternative to liver transplantation, numerous researchers have been working towards the goal of development of a fully functional artificial liver. Researchers are, therefore, concentrating their efforts on hybrid systems incorporating human- or animal-derived cells. While research on bioartificial liver (BAL) system is still in its infancy, the urgent goal is to develop a sophisticated BAL suitable for clinical applications.

### Research frontiers

The flow bioreactor (RFB) system is a 3-dimensional culture system that can be used for high-density culture, achieving a cell density 10 times greater than that obtained with hollow-fiber culture. The culture medium flows from the periphery toward the center of the reactor. When medium flows from the periphery towards the center, a high perfusion rate can provide an adequate supply of oxygen and nutrients to cells at the center of the bioreactor even though oxygen and nutrients are consumed by cells at the periphery. This system simulates the anatomy of hepatic lobules. On the other hand, both proliferative activity and differentiation of cells are needed as an ideal source for a BAL. Fetal cells have a high proliferative potential *in vitro* and we selected the fetal porcine hepatocytes as a cell source. Furthermore, we examined the earliest teratoma-free gestational age of embryonic day. Furthermore, the efficacy of pulsed administration of a high concentration hepatocytes growth factor (HGF) was examined.

### Innovations and breakthroughs

In this study, the combination of embryonic porcine liver (embryonic d 35: E35) cells and pulsing a high concentration of HGF in our RFB provided a system for which clinical application may eventually be possible in the fields of BAL and transplantation medicine.

### Applications

Our RFB system may be able to perform clinical application as extracorporeal BAL for acute hepatic failure. Furthermore, the liver organoids in RFB have the potential future *in vivo* application (implantable bioartificial liver *etc.*).

### Peer review

The manuscript reports the hepatic reconstruction from fetal porcine liver cells using a radial flow bioreactor. The authors evidenced that cells organized in organoids with the presence of bile duct-like structure. They also showed that HGF favored differentiation and survival of cells in the bioreactor. Despite the fact that this bioreactor was described useful from maintenance of expression of CYP3A4

by human hepatocytes and that the use of pig cells is ethically problematic for tissue engineering and development of extracorporeal bioartificial liver, the results are interesting and well documented.

### Abstract

**AIM:** To investigate the expression and activity of leukotriene C4 (LTC4) synthesis enzymes and their underlying relationship with cysteinyl leukotriene (cys-LT) generation in a rat fulminant hepatic failure (FHF) model induced by D-galactosamine/lipopolysaccharide (D-GalN/LPS).

**METHODS:** Rats were treated with D-GalN (300 mg/kg) plus LPS (0.1 mg/kg) for 1, 3, 6, and 12 h. Enzyme immunoassay was used to determine the hepatic cys-LT content. Reverse transcription-polymerase chain reaction (RT-PCR), Western blot or immunohistochemical assay were employed to assess the expression or location of LTC4 synthesis enzymes, which belong to membrane associated proteins in eicosanoid and glutathione (MAPEG) metabolism superfamily. Activity of LTC4 synthesis enzymes was evaluated by determination of the products of LTA4 after incubation with liver microsomes using high performance liquid chromatography (HPLC).

**RESULTS:** Livers were injured after treatment with D-GalN/LPS, accompanied by cys-LT accumulation at the prophase of liver injury. Both LTC4 synthase (LTC4S) and microsomal glutathione-S-transferase (mGST) 2 were expressed in the rat liver, while the latter was specifically located in hepatocytes. Their mRNA and protein expressions were up-regulated at an earlier phase after treatment with D-GalN/LPS. Meantime, a higher activity of LTC4 synthesis enzymes was detected, although the

activity of LTC4S played the main role in this case.

**CONCLUSION:** The expression and activity of both LTC4S and mGST2 are up regulated in a rat FHF model, which are, at least, partly responsible for cys-LT hepatic accumulation.

### INTRODUCTION

Leukotriene (LT) is a potent lipid mediator with biological activities related to inflammation and allergy<sup>[1]</sup>. It was reported LT is involved in a variety of diseases, such as allergic airway disease, dermatological disease, cardiovascular disease and liver injury<sup>[2-5]</sup>. Fulminant hepatic failure (FHF) is a severe liver injury accompanying hepatic encephalopathy<sup>[6]</sup> and causes multi-organ failure with an extremely high mortality rate, even if intensive care is provided. Treatment is directed at an early recognition of the complications and general supportive measures. The only proven therapy for those who are unlikely to recover is liver transplantation<sup>[7,8]</sup>. Although it has been considered to be caused by several hepatitis viruses, various drugs, toxins, and metabolic disorders, its pathogenesis is extremely complicated, with indeterminate mechanisms<sup>[9,10]</sup>. There is evidence that inflammatory response and microcirculatory disturbances contribute to FHF<sup>[11-14]</sup>. Suppression of the inflammatory process in the liver is an effective therapy for fulminant or severe acute hepatic failure<sup>[15]</sup>. An experimental model of FHF induced

by D-galactosamine (D-GalN)/lipopolysaccharide (LPS) well simulates the situation in clinical FHF<sup>[11]</sup>. D-GalN can deplete liver UTP, disrupt protein synthesis and sensitize hepatocytes to challenging agents such as LPS<sup>[10,16]</sup>. It was reported that arachidonate metabolism is changed and LT formation is stimulated in D-GalN/LPS-induced acute liver injury<sup>[17,18]</sup>. Inhibition of LT biosynthesis or blocking binding of LT at the receptor level could also prevent liver injury induced by D-GalN/LPS<sup>[19,20]</sup>. Therefore, LT as an inflammatory factor is probably involved in the pathogenesis of FHF.

LT is a metabolite of arachidonic acid synthesized *via* the 5-lipoxygenase pathway<sup>[21]</sup>. LTC4 synthase (LTC4S) catalyzes LTA4 and reduced glutathione (GSH) generating LTC4 is the first committed step in the synthesis of cysteinyl leukotrienes (cys-LT), including LTC4, LTD4, and LTE4<sup>[22]</sup>. Like LTC4S, members of membrane associated proteins in eicosanoid and glutathione metabolism (MAPEG) superfamily, namely microsomal glutathione-S-transferase 2 (mGST2) and mGST3 also catalyze LTC4 synthesis<sup>[23-25]</sup>. However, it was reported that rat mGST3 is unable to synthesize LTC4 even in the presence of the conserved Arg/Try catalytic pair<sup>[26]</sup>. LTC4S is a pivotal enzyme for cys-LT biosynthesis in human lung membranes and platelet homogenates where it is prevalently expressed<sup>[27,28]</sup>. A recent study in LTC4S knockout mice suggested that LTC4S is a predominant *in vivo* source for cys-LT synthesis<sup>[29]</sup>. Its crystal structure that was recently interpreted provides structural insights into the mechanism of LTC4 formation<sup>[30,31]</sup>. It is up-regulated in LPS-induced systemic inflammatory reactions<sup>[32]</sup>. Our previous study showed that hepatic ischemia/reperfusion (I/R) injury up-regulates the mRNA and protein expression of LTC4S and its activity<sup>[33]</sup>. However, other studies reported that mGST may account for LTC4S-like activity in non-inflammatory cells<sup>[24]</sup>. mGST2, 44% identical to LTC4S in primary structure, is the principal enzyme responsible for LTC4 production in human liver microsomes and endothelial cells<sup>[34,35]</sup>.

However, no reports are available on the alterations in both mRNA and protein of LTC4 synthesis enzymes including LTC4S and mGST2, their activities, and the cell types responsible for their expression during the FHF course. The mechanism underlying cys-LT generation at the early phase of FHF has not been extensively elucidated. Therefore, the present study aimed to investigate the expression and activity of LTC4 synthesis enzymes and the possible mechanism underlying cys-LT generation in a rat FHF model induced by D-GalN/LPS.

## MATERIALS AND METHODS

### Animals and experimental protocol

Male Sprague-Dawley rats, weighing  $200 \pm 20$  g, were obtained from Experimental Animal Center, Zhejiang University. The animal study protocol, in compliance with the Guidelines of China for Animal Care, was approved by the Ethics Committee of Zhejiang University and conformed to the internationally accepted principles in the care and use of experimental animals.

Rats were randomly divided into five groups. Vehicle rats (control) were injected with saline, and decapitated immediately after the second injection. Other animals were intraperitoneally injected with D-GalN (300 mg/kg), followed by LPS (0.1 mg/kg) 1 h later. Rats were decapitated at 1, 3, 6 and 12 h, respectively, after LPS administration. Sera and liver tissue were collected for further evaluation.

### Aminotransferase determination and histological evaluation

Serum ALT and AST were measured with an automatic analyzer (Hitachi 7600, Tokyo, Japan). The right lobe of liver was fixed in 4% paraformaldehyde for hematoxylin and eosin or immunohistochemistry staining. The left lobe of liver was snap-frozen in liquid nitrogen and stored at  $-80^{\circ}\text{C}$  until further preparation.

Paraffin-embedded liver tissue was cut into  $5\text{-}\mu\text{m}$  thick sections, deparaffinized in xylene, and rehydrated through a series of decreasing concentrations of ethanol. The sections were stained with hematoxylin and eosin and analyzed under a light microscope.

### Enzyme immunoassay

An aliquot of liver tissue (0.4 g) was individually homogenized in Dulbecco's phosphate-buffered saline and de-proteined with two volumes of ice-cold acetonitrile. Supernatant was collected before extraction with Sep-pak C18 cartridges (Water Corporation, USA). Methanol fraction was collected and evaporated to dryness under nitrogen for cys-LT measurement.

Cys-LT content in liver tissue was quantified with an enzyme immunoassay (EIA) kit (Cayman Chemical Company, USA) which recognizes LTC4, LTD4 and LTE4 for a combined quantitative value.

### RNA isolation and reverse transcription-polymerase chain reaction (RT-PCR)

Total RNA was isolated from rat liver tissues using the TRIzol reagent (Sanggon) according to its manufacturer's instructions and quantified by measuring the ultraviolet absorption at 260 nm. For the synthesis of cDNA, 3  $\mu\text{g}$  of total RNA from each sample was reverse-transcribed. Primers (Shanghai Sanggon, China) and application parameters for PCR analysis of LTC4S, mGST2 and  $\beta$ -actin are listed in Table 1. PCR products were analyzed by electrophoresis, visualized by ultraviolet transillumination of ethidium bromide-stained gels.

### Western blotting analysis

Total protein was harvested from liver tissues. An aliquot of protein (80  $\mu\text{g}$ ) was electrophoresed on 12.5% SDS-polyacrylamide gels. After separation, proteins were transferred onto a pure nitrocellulose blotting membrane (Pall, Dreieich, Germany). Membranes were incubated with their corresponding antibody (1:200 for LTC4 synthase antibody from Santa Cruz). Blots were then exposed to the corresponding secondary antibody (horseradish peroxidase-conjugated IgG, Beijing Zhongshan Biotechnology Company, 1:4000). Immunocomplexes

Table 1 Primers and application parameters for PCR analysis of the respective genes

Gene	Primer	Designed size (bp)	Annealing temperature (°C)	Mg <sup>2+</sup> (mmol/L)	Cycles
LTC4S	Sense 5'-GAAGAACTTTCCACGTGTCG-3' Antisense 5'-GTGCAGCCATTGCCACTAGC-3'	282	55	2.0	35
mGST2	Sense 5'-TTCAATCAAGTTTTTGCAACC-3' Antisense 5'-TCTTGGCAACATGAAAGTCC-3'	204	57	1.5	35
β-actin	Sense 5'-TGACGGGGTACCCACACTGTGCCCATCTA-3' Antisense 5'-CTAGAAGCAATTGCGGTGGACGATGGAGGG-3'	660	58	1.5	28

were visualized autoradiographically with an enhanced chemiluminescent substrate (ECL, Pierce, USA), and scanned using a bio-imaging analyzer (Bio-Rad, USA).

### Immunohistochemistry

Immunohistochemistry was performed to determine the localization and protein expression of LTC4S or mGST2. Liver tissue was cut into 5-μm thick sections with a microtome and the sections were then mounted on slides. Streptavidin-biotin-complex (SABC, Boster Co, China) immunohistochemistry was used to explore the expression of mGST2. Briefly, endogenous peroxidase was inactivated. After treated with 5% BSA for 30 min, specimens were incubated at 4°C overnight with primary antibody (mGST2 antibody from Abnova Corporation, Taiwan, final dilution 1:100; LTC4S antibody from Santa Cruz, USA, final dilution 1:200). Diaminobenzidine (DAB) was used for peroxidase reaction and the slides were counterstained with hematoxylin.

### Reverse-phase HPLC analysis of LTC4 synthesis enzyme activity

Activity of LTC4 synthesis enzymes was assayed by measuring the amount of LTC4 and its isomer produced after incubation with liver microsomal fraction and LTA4-free acid. LTA4 was saponified in acetone with 50 mmol/L NaOH (20% v/v) for 40 min at room temperature (RT) from LTA4 methyl ester (Cayman Chemical Co., USA). Microsomal fraction was harvested from liver tissue homogenates. An aliquot (100 μg) of microsomal fraction was incubated with 60 μmol/L LTA4-free acid, 10 mmol/L GSH and 0.2% BSA for 5 min at 37°C. The reaction was terminated by adding 100 μL stop solution (acetonitrile/methanol/acetic acid, 150:50:0.3, v/v) containing a defined amount of internal standard prostaglandin B2 (PGB2). Metabolites of LTA4 were resolved by isocratic RP-HPLC on an Agilent Zorbax SB-C18 column (4.6 mm × 250 mm, 5 μm). The mobile phase was at 1.0 mL/min comprised of acetonitrile: water: acetic acid (38:62:0.3, v/v, pH adjusted to 5.6 with NH<sub>3</sub>H<sub>2</sub>O). LTC4 and LTC4 isomer peaks were identified by comparing the retention time of LTC4 standard and on-line analysis of UV absorbance spectra. The amount of products formed was calculated by comparing the internal standard.

### LC/MS assay

LTC4 generation was further identified by LC/MS. Assay was performed on a HP 1100 HPLC system with an Esquire-LC 00075 quadrupole mass spectrometer

detection system. Agilent Zorbax SB-C18 column (4.6 mm × 250 mm, 5 μm) was used. The mass spectrometer was equipped with an electrospray ionization source. Typical source conditions were as follows: positive ionization mode, capillary 3.5 kV, skimmer 38.3 V, dry inert gas N<sub>2</sub> (10 L/min), temperature of the capillary 350°C, scan beginning at 200 m/z, scan ending at 700 m/z.

### Statistical analysis

All data were expressed as mean ± SD. The results in different groups were compared by one-way analysis of variance (ANOVA) with SPSS 10.0 for WINDOWS. *P* < 0.05 was considered statistically significant.

## RESULTS

### Serum ALT and AST examination and histological evaluation

Rat liver injury was evaluated histologically and serologically after D-GalN/LPS treatment. As shown in Figure 1B, serum ALT and AST levels were continuously elevated and peaked at 12 h (392.2 ± 104.6 IU/L and 888.2 ± 190.8 IU/L respectively in the 12 h group, and 116.8 ± 39.4 IU/L and 156.2 ± 15.5 IU/L in the control group). ALT at 6, 12 h and AST at 3, 6, 12 h were significantly elevated in the D-GalN/LPS treatment group than those in the control group (*P* < 0.05).

Liver sections from the control group showed cord-like arrangement of hepatocytes with clear nucleus and intact endothelium in central veins without vascular congestion, observed with HE staining. Liver inflammation, found at 1 and 3 h after treatment with D-GalN/LPS, was characterized by congested central vein, infiltrated inflammatory cells and swollen hepatocytes. Dramatic injuries occurred in liver 6 and 12 h after treatment with D-GalN/LPS, and were characterized by disarranged hepatocytes, appearance of massive necrosis and broken cytolemma (Figure 1).

### Hepatic cys-LT accumulation after D-GalN/ LPS treatment

Cys-LT in liver, determined with a cys-LT EIA kit, was significantly higher at 1 h in the D-GalN/LPS treatment group than in the control group (1167.9 ± 340.5 pg/g *vs* 236.3 ± 88.5 pg/g, *P* < 0.05), increased to 4.9 folds at 3 h, and gradually returned to its basal values at 12 h (Figure 2), suggesting that D-GalN/LPS injection at an early stage could lead to accumulation of cys-LT, which may play an important role in the onset of FHF.

**Figure 1** Histology and enzyme evaluation of rat livers treated with D-galactosamine/lipopolysaccharide (D-GalN/LPS). **A:** Histological examination of the liver at indicated times after GalN/LPS treatment (hematoxylin-eosin staining, bar = 100  $\mu$ m). Arrow heads indicate congested central veins. The arrow in the control group **A1** indicates cord-like arrangement of hepatocytes with clear nucleoli. The arrows in the 1 h group **A2** indicate infiltrated inflammatory cells. The arrow in the 3 h group **A3** indicates swollen hepatocytes. The arrow in the 6 h group **A4** indicates disarranged hepatocytes. The arrow in the 12 h group **A5** indicates massive necrosis and broken cytolemma; **B:** Time course of serum ALT and AST in rats received intraperitoneal injection of D-GalN/LPS. Data are represented as mean  $\pm$  SD,  $n = 6$ ,  $^aP < 0.05$  and  $^bP < 0.01$  vs control group.

**Figure 2** Time course of hepatic cys-LT content in D-GalN/LPS-injured rats. Rats were treated with D-GalN/LPS as described. Cys-LT was quantified with an enzyme immunoassay kit which recognizes LTC<sub>4</sub>, LTD<sub>4</sub> and LTE<sub>4</sub> for a combined quantitative value. Each value represents the mean obtained from six rats in each group.  $^aP < 0.05$ ,  $^bP < 0.01$  vs control group.

### Expressions of LTC<sub>4</sub>S and mGST2 in liver tissues

mRNA and protein expressions of LTC<sub>4</sub>S and mGST2 were detected in D-GalN/LPS-injured liver tissues.

Figure 3A shows a representative of hepatic mRNA expression of LTC<sub>4</sub>S and mGST2 in rat liver during FHF. Densitometric analysis of their PCR products revealed that mRNA expressions of LTC<sub>4</sub>S and mGST2 were significantly increased at 1 h after treatment with D-GalN/LPS ( $P < 0.05$ ).

Considering the above changes in hepatic cys-LT content and the gene expressions of LTC<sub>4</sub> synthesis enzymes, we examined their protein levels in rat liver tissues by Western blotting analysis. The protein level of mGST2 was not detectable by Western blotting analysis because the proper antibody was not commercially available. As shown in Figure 3B, the protein expression of LTC<sub>4</sub>S was obviously increased after D-GalN/LPS treatment.

### Immunohistochemical localization of LTC<sub>4</sub> synthesis enzymes in liver tissue

To clarify what cell types increased the expression of LTC<sub>4</sub> synthesis enzymes in the rat FHF model, we performed immunohistochemical staining for paraffin-embedded liver sections from control and D-GalN/LPS treated rats.

**Figure 3** mRNA and protein expressions of LTC4S and mGST2 in D-GalN/LPS-treated liver tissues. **A:** mRNA expression of LTC4S and mGST2 detected by RT-PCR. cDNA synthesized from total RNA (3 μg) was used for PCR amplification with 35 cycles for LTC4S and mGST2. PCR products were electrophoresed on a 1.5% agarose gel. The intensity of each band was quantified by computer-assisted densitometry, and the data were compared to those of the corresponding band of β-actin (Right panel); **B:** Protein expression of LTC4S detected by Western blotting. An aliquot of total protein (80 μg) was subjected to immunoblot analysis as described in Methods. Left panel: Immunoreactive bands corresponding to LTC4S and β-actin in D-GalN/LPS-injured liver; right panel: Densities of the products quantified by computer-assisted densitometry, and the data were normalized to β-actin expression. Data are represented as mean ± SD, <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs control group.

In normal liver, liver cells exhibited a low immunological staining for LTC4S (Figure 4A). In D-GalN/LPS treated rats, LTC4S was detected in endothelial cells and most hepatocytes which were strongly stained, exhibiting a heterogeneous intralobular distribution. However, no positive infiltrated inflammatory cells or Kupffer cells were found. As shown in Figure 4B, mGST2 was mainly located in hepatocytes and its expression was increased in D-GalN/LPS-injured rat livers.

#### Activity of LTC4 synthesis enzymes in D-GalN/ LPS-treated rats

The activity of LTC4 synthesis enzymes in liver microsomal fraction were determined by RP-HPLC. A peak at the retention time of 6.06 min in the indicated mobile phase appeared using an LTC4 standard (Figure 5A), which was also detected at the same retention time in lung microsomes, as a positive control, when the microsomal fraction was incubated with LTA4 and GSH (Figure 5B). MS analysis of the peak displayed a protonated molecular ion at  $m/z$  625.8, corresponding to the LTC4 ion form (Figure 5C). We assessed the activity of mGST2 by identifying the isomer of LTC4, since mGST2 may produce not only LTC4, but also an isomer of LTC4 when incubated with LTA4 which is different from LTC4S<sup>[23,34]</sup>. A peak assessed as the LTC4 isomer was observed when the rat liver microsomal fraction was incubated with exogenous LTA4. The time course of LTC4 production in incubated samples is illustrated in Figure 5D. LTC4 production was increased after treatment with D-GalN/

LPS, suggesting that the activity of LTC4 synthesis was strengthened ( $P < 0.05$ ). The activity of isomer of LTC4 was also increased, indicating that the activity of mGST2 was also initiated, demonstrating that the activity of both mGST2 and LTC4S in rat liver microsomes was increased after D-GalN/ LPS treatment.

## DISCUSSION

Cys-LT has a wide variety of physiological and immunological effects on liver function and disease<sup>[36-39]</sup>. Cys-LT, as an inflammatory factor, is involved in the pathogenesis of FHF<sup>[17,18]</sup>, which has attracted the interest of clinicians<sup>[40]</sup>. However, the mechanism of cys-LT alteration during FHF has not been well elucidated yet. Thus, we employed a D-GalN/LPS-induced rat model of FHF to explore the possible reason of LTC4 alteration in the pathogenesis of FHF.

In the present study, we evaluated the inflammatory cell infiltration, hepatocytes damage and structure disorder after D-GalN/LPS treatment. Serological data further confirmed the impairment of liver function at a later phase of treatment. However, the hepatic cys-LT content was transiently increased before the occurrence of liver injuries. It was reported that inhibiting cys-LT biosynthesis or blocking binding of cys-LT at the receptor level can prevent liver injury<sup>[19,20]</sup>. D-GalN not only acts directly on hepatocytes by depleting liver UTP and disrupting protein synthesis, but also sensitizes hepatocytes to challenging agents such as LPS<sup>[10,16]</sup>. In addition, liver injury induced by D-GalN/LPS well simulates the situation in clinical FHF<sup>[11]</sup>. Our results suggested that cys-LT accumulation plays a role in D-GalN/LPS-induced FHF.

To elucidate whether cys-LT accumulation is related to LTC4 synthesis enzymes in the rat FHF model, we examined their expression and activity owing to lack of enough information in this model. The committed step in cys-LT biosynthesis in rats is catalyzed by LTC4 synthesis enzymes, but not by mGST3<sup>[22-24]</sup>. It was reported that mRNA expression of LTC4S in liver is so low that Northern blotting analysis is not sufficiently sensitive to detect it<sup>[29,41]</sup>. In the present study, the mRNA expression of mGST2 was significantly higher than that of LTC4S by RT-PCR. Protein expression of LTC4S was detected in rat liver instead of purified hepatocytes by Western blotting assay. Immunohistochemical staining was used to clarify which cell types expressed LTC4 synthesis enzymes and whether the expression was changed in the rat FHF model. The results showed that LTC4S was expressed in hepatocytes and sinusoidal endothelial cells, while mGST2 was only located in hepatocytes. Unlike the report of Schröder<sup>[32]</sup> that mGST2 remained unchanged after a single dose of LPS-induced systemic inflammatory reaction, our results showed that both LTC4S and mGST2 were increased in liver after D-GalN/LPS treatment. The result suggested that mGST2 may play a special role in the pathogenesis of FHF. The discrepancy may be due to the pretreatment with D-GalN and the different treatment time or dose of LPS<sup>[42]</sup>. D-GalN, as a specific hepatotoxic agent, renders hepatocytes sensitive to LPS.

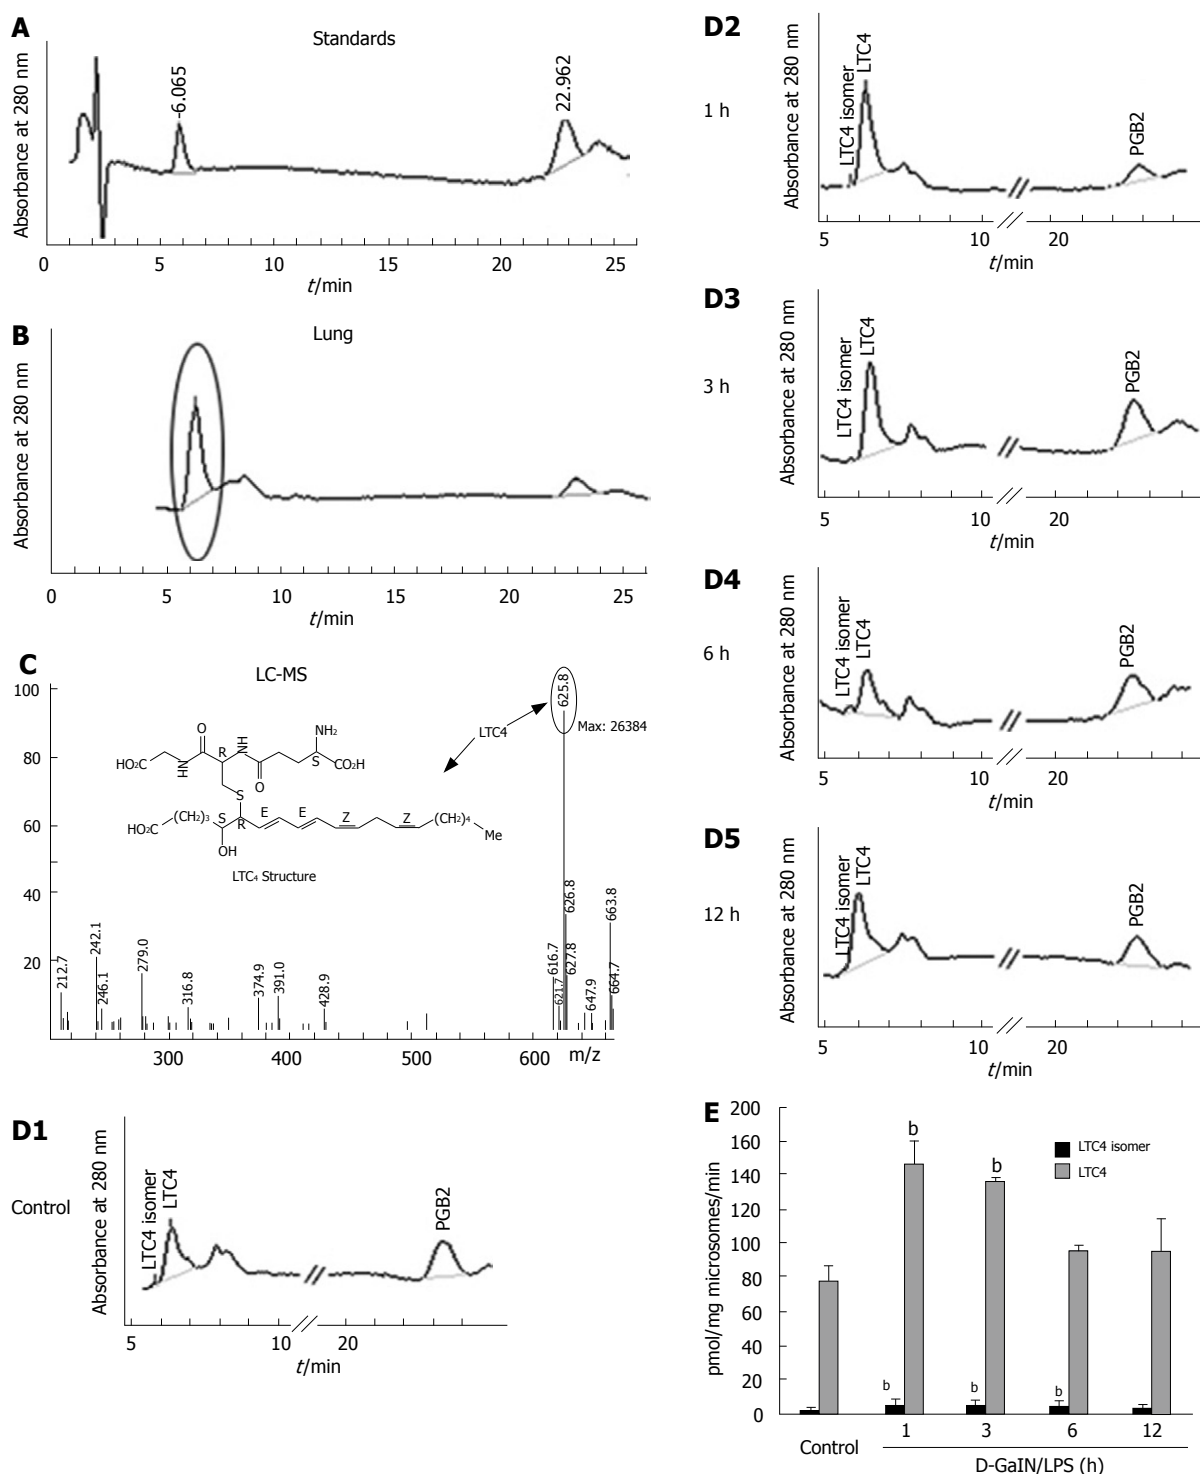

**Figure 4** Immunohistochemical assay of the expression and localization of LTC<sub>4</sub>S (A) and mGST2 (B) in control and D-GalN/LPS-treated liver tissues. Immunohistochemical staining for paraffin-embedded liver sections from the control and D-GalN/LPS-treated rats was examined as described in Materials and Methods. Arrows indicate the representative positive cells expressing the brown granules. 1: Absence of staining on omission of primary antibody; 2: Control; 3-6: Groups treated with D-GalN/LPS at 1, 3, 6 and 12 h, respectively. Bar = 100  $\mu$ m.

Pretreatment with D-GalN creates a different pathogenesis of liver injury. Different treatment time or dose of LPS could also produce different effects. For instance, LPS is usually thought to be a potent stimulus for LT production *in vivo*<sup>[43,44]</sup>. However, it was reported that LPS down-regulates cys-LT release and LTC<sub>4</sub>S gene expression in mononuclear phagocytes<sup>[45]</sup>. In the present study, LTC<sub>4</sub>S and mGST2 expressions were up-regulated after treatment with D-GalN (300 mg/kg) and LPS (0.1 mg/kg). Further

more, the liver not only plays a major role in metabolism and elimination of LT, but also produces cys-LT<sup>[46]</sup>. It was reported that hepatocytes generate cys-LT when co-cultured with Kupffer cells<sup>[47,48]</sup>. Therefore, increased expression of LTC<sub>4</sub> synthesis enzymes in liver may partly contribute to cys-LT accumulation.

The activity of LTC<sub>4</sub> synthesis enzymes was subsequently detected in D-GalN/LPS-induced rat FHF. The appearance of isomer of LTC<sub>4</sub> in HPLC traces

**Figure 5** LTC<sub>4</sub> synthesis enzyme activity in rat liver microsomal fraction. **A:** HPLC traces showing standard LTC<sub>4</sub> and internal standard PGB<sub>2</sub>; **B:** HPLC traces showing the main products when 100 000 × g pellets from lung incubated with LTA<sub>4</sub> (60 μmol/L) and glutathione (10 mmol/L); **C:** MS assay of the product showing its peak at the retention time of 6.06 min in HPLC; **D:** HPLC traces showing generated LTC<sub>4</sub> and isomer of LTC<sub>4</sub> by a microsomal fraction from D-GalN/LPS treated rat livers with indicated times; **E:** The amount of generated LTC<sub>4</sub> and isomer of LTC<sub>4</sub> was calculated by an area peak compared with the internal standard PGB<sub>2</sub> and then plotted. Each value represents the mean obtained from duplicate experiments with liver tissue from six rats in each group. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 vs control group.

suggested the activity of mGST2 in rat liver, since the isomer was used to distinguish between mGST2 and LTC<sub>4</sub>S activities involved in the biosynthesis of LTC<sub>4</sub><sup>[23,34]</sup>. According to Scoggan *et al.*<sup>[34]</sup>, a ratio of LTC<sub>4</sub>/LTC<sub>4</sub> isomer < 50 is typical for a system containing mostly mGST2 whereas a ratio > 50 is seen in tissues containing mostly LTC<sub>4</sub>S. The minimal ratio in our study was 32,

suggesting that mGST2 and LTC<sub>4</sub>S have activities in liver microsomes, but LTC<sub>4</sub>S takes the main responsibility in this case. The mGST2 activity was simultaneously increased, as demonstrated by the increased LTC<sub>4</sub> isomer. mGST2 in liver is a functional enzyme and plays a role in LTC<sub>4</sub> biosynthesis. Since mGST2 was not changed after a signal dose LPS treatment, the synergistic effect of D-GalN and

LPS may be the reason why the expression and activity of mGST2 were increased, which may partly contribute to the pathogenesis of FHF.

In conclusion, the expressions and activities of both LTC4S and mGST2 are up-regulated in a rat FHF model, which are, at least, partly responsible for cys-LT hepatic accumulation.

## ACKNOWLEDGMENTS

## COMMENTS

### Background

Cysteinyl leukotriene (cys-LT), as an inflammatory factor, is probably involved in fulminant hepatic failure (FHF). LTC4 synthesis enzymes catalyze LTA4 to generate LTC4. However, no report on the alterations in mRNA and protein of LTC4S and mGST2 and their activities during FHF is available. The mechanism underlying cys-LT generation at an early phase of FHF has not been elucidated. Therefore, we focused on the expression and activity of LTC4 synthesis enzymes and their relationship with cys-LT generation in a rat FHF model induced by D-galactosamine/ lipopolysaccharide (D-GalN/LPS).

### Research frontiers

LTC4S is a pivotal enzyme for cys-LT biosynthesis in human lung membranes and platelet homogenates where it is prevalently expressed. Studies in the LTC4S knockout mice suggest that LTC4S is a predominant *in vivo* source for cys-LT synthesis. Its crystal structure was recently interpreted, which provides structural insights into the mechanism of LTC4 formation. It is up-regulated in LPS-induced systemic inflammatory reactions. Our previous study showed that hepatic infusion/reperfusion (I/R) injury can up-regulate mRNA and protein expression of LTC4S and enhance its activity. However, other studies reported the mGST may account for LTC4S-like activity in non-inflammatory cells. mGST2, 44% identical to LTC4S in primary structure, is the principal enzyme responsible for LTC4 production in human liver microsomes and endothelial cells.

### Innovations and breakthroughs

Increased expression of LTC4 synthesis enzymes may partly contribute to cys-LT accumulation and liver injury in a rat FHF model. mGST2 and LTC4S contribute to the pathological process of this model.

### Applications

The results provide a rationale for the pathophysiological process of FHF and potential drug molecular targets.

### Terminology

Cysteinyl leukotriene: A potent lipid mediator with biological activities related to inflammation and allergy. LTC4 synthesis enzymes include LTC4S, mGST2 and mGST3.

### Peer review

The authors showed that cys-LT accumulation in FHF was due to enhanced expression and activity of LTC4S and mGST2. The present study is interesting and instructive. The data are well described in this paper. The paper provides useful information on the daily management of patients with viral hepatitis.

### Abstract

**AIM:** To verify the validity of the International Ascites Club guidelines for treatment of spontaneous bacterial peritonitis (SBP) in clinical practice.

**METHODS:** All SBP episodes occurring in a group of consecutive cirrhotics were managed accordingly and included in the study. SBP was diagnosed when the ascitic fluid polymorphonuclear (PMN) cell count was  $> 250$  cells/mm<sup>3</sup>, and empirically treated with cefotaxime.

**RESULTS:** Thirty-eight SBP episodes occurred in 32 cirrhotics (22 men/10 women; mean age:  $58.6 \pm 11.2$  years). Prevalence of SBP, in our population, was 17%. Ascitic fluid culture was positive in nine (24%) cases only. Eleven episodes were nosocomial and 71% community-acquired. Treatment with cefotaxime was successful in 59% of cases, while 41% of episodes required a modification of the initial antibiotic therapy because of a less-than 25% decrease in ascitic PMN count at 48 h. Change of antibiotic therapy led to the resolution of infection in 87% of episodes. Among the cases with positive culture, the initial antibiotic therapy with cefotaxime failed at a percentage (44%) similar to that of the whole series. In these cases, the isolated organisms were either resistant or with an inherent insufficient susceptibility to cefotaxime.

**CONCLUSION:** In clinical practice, ascitic PMN count is a valid tool for starting a prompt antibiotic treatment and

Efficacy of current guidelines for the treatment of spontaneous bacterial peritonitis in the clinical practice. *World J Gastroenterol* 2008; 14(17): 2757-2762 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2757.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2757>

### INTRODUCTION

Spontaneous bacterial peritonitis (SBP) is a frequent and severe complication of cirrhotic patients with ascites<sup>[1]</sup>. It is defined as an infection of ascites in the absence of a contiguous source of infection, such as abdominal abscesses or intestinal perforations.

The prevalence of SBP in unselected, hospitalized, cirrhotic patients with ascites has been reported to range between 10% and 30%<sup>[1,2-6]</sup>. Following the first episode of SBP, the cumulative recurrence rate within one year of follow up is approximately 70%<sup>[7]</sup>.

In an initial series published in the 1970s, when SBP was first described, the mortality rate associated with an episode of SBP exceeded 80%<sup>[8]</sup>. This short-term prognosis has, however, considerably improved during the last decades. In more recent prospective studies, in fact, the mortality rate related to this complication was estimated to be around 20%-30%<sup>[9-11]</sup>. An early diagnosis and the promptness of an effective therapy are the most likely rea-

sons for this improvement in prognosis.

Symptoms of SBP may be insidious; in addition, by using conventional culture techniques, the ascitic fluid culture outcome is negative in up to 60% of patients with SBP. Since a rapid diagnosis and an early treatment have a crucial role, the antibiotic treatment cannot, therefore, be delayed to the moment when the microbiological results are available<sup>[12,13]</sup>.

In 2000, the International Ascites Club published the guidelines for the diagnosis and treatment of SBP in cirrhotic patients<sup>[12]</sup>. These guidelines suggested that a diagnosis of SBP should be based on polymorphonuclear (PMN) cell count in the ascitic fluid and that a PMN cell count greater than 250 cells/mm<sup>3</sup> should be considered highly suspicious of SBP, thus representing an indication to empirically initiate an antibiotic treatment. The gold standard treatment consists of third-generation cephalosporins, especially cefotaxime, given intravenously at a dose of 4-8 g/d for a minimum duration of 5 d. A repeat diagnostic paracentesis to document the response by a greater-than 25% decrease in ascitic fluid neutrophil count at 48 h after initiation of antibiotics is recommended. With this regimen, resolution of SBP is achieved in approximately 90% of patients and 30-d survival is at least 80%<sup>[12]</sup>. This recommendation is, however, based on the results of randomized controlled trials and its validity and applicability need to be verified in the clinical practice. Moreover, there have been suggestions that the type and etiology of bacterial infections in cirrhosis may have changed during recent years<sup>[14,15]</sup>. An increasing incidence of SBP caused by Gram-positive bacteria in cirrhotic patients with ascites has been observed by different authors<sup>[16,17]</sup>. In addition, an increased frequency of bacteria resistant to multiple antibiotics has been shown<sup>[18]</sup>. This may be due to the extensive use of quinolones, and, in particular, to the employment of norfloxacin for SBP prophylaxis, as well as an increasing use of invasive procedures for the complications of cirrhosis.

The recent changes in its microbial etiology may have several important implications for the management and treatment of SBP and suggest the need for verifying the efficacy of current guidelines.

The aim of our study was, therefore, to verify validity, applicability, and efficacy of the International Ascites Club guidelines for the treatment of SBP and assess the results of such approach in an unselected group of consecutive cirrhotic patients with SBP admitted to our Gastroenterology Unit during a three-year period (January 2004-January 2007).

## MATERIALS AND METHODS

### Materials

All the episodes of SBP occurring in cirrhotic patients admitted to our Gastroenterology Unit from January 2004 to January 2007 were managed according to the International Ascites Club guidelines<sup>[12]</sup> and included in the study.

The diagnosis of liver cirrhosis was based on clinical, biochemical, and/or histopathological data. The severity

of the liver disease was classified in each patient at entry according to the Child-Pugh's<sup>[19]</sup> and the model for end-stage liver disease's (MELD) scores<sup>[20]</sup>. The MELD score was assessed using the Mayo Clinic website calculator. The main cause of admission was recorded for each patient.

According to our routine clinical practice, a detailed medical history, a complete physical examination, standard laboratory tests (including a complete blood cell count, prothrombin time, biochemical tests of liver and kidney function, and fresh urine sediment), a chest x-ray film, a diagnostic paracentesis, and an ascitic fluid culture were performed in all the cirrhotic patients with ascites on the day of admission and whenever they developed symptoms and signs suspicious for SBP (i.e. fever, change in mental status, abdominal pain, peripheral leukocytosis, development of renal failure, hypotension, *etc.*) during hospitalization. In some patients re-admitted for recurrent ascites, a diagnostic paracentesis was also repeated.

The ascitic fluid samples were collected under aseptic conditions in tubes containing ethylenediamine tetraacetic acid anticoagulant and then tested to determine white blood cell (WBC) and PMN counts by automated cell blood counter (Technicon System H\*1; Bayer Diagnostics, Milan, Italy), as described elsewhere<sup>[21]</sup>. All the specimens were analyzed within one hour. Additional samples of ascitic fluid were collected for the determination of glucose, albumin, and total protein concentrations. Moreover, 10 mL of ascitic fluid were inoculated directly at the patient's bedside into aerobic and anaerobic blood culture bottles for bacteriological examination<sup>[22]</sup>. Bacterial identification and antimicrobial susceptibility testing were carried out by the VITEK2 system (bioMérieux SA, Marcy-l'Etoile, France). Double-disk synergy tests were used for the confirmation of extended-spectrum-lactamase (ESBL) producers.

### Patients' management

Those patients with a diagnosis of SBP (when the PMN cell count in the ascitic fluid was greater than 250 cells/mm<sup>3</sup>) were included in the study. Those with bacteriascites (i.e. positive ascitic fluid culture with < 250 neutrophils/mm<sup>3</sup>) or with clinical and laboratory data suggesting secondary peritonitis were excluded. All the patients were managed according to the International Ascites Club guidelines<sup>[12]</sup>. SBP was empirically treated with third-generation cephalosporins (intravenous cefotaxime, 2 g/8 h, for a minimum of 5 d), regardless of the positivity of the culture. The antibiotic dosage was adjusted to the renal function throughout the treatment period.

In those cases not responding to the initial antibiotic regimen, the therapy was appropriately changed, either according to the *in vitro* susceptibility of the isolated bacteria, or empirically. For this purpose, a further paracentesis was always performed 2 d after the beginning of the antibiotic treatment. Treatment failure was established when the condition of the patients rapidly deteriorated within the first hour of the antibiotic therapy (i.e. with development of shock), or when no significant decrease in the ascitic PMN count was observed in the follow-up paracentesis. A reduction in the PMN count of

less than 25% as compared with the pre-treatment value was considered as suggestive of failure of the antibiotic treatment.

Clinical signs and symptoms of infection (fever, abdominal pain, mental status change, hypotension, *etc.*) were recorded daily. Arterial pressure, heart rate, body temperature, and weight were measured daily. WBC count, serum urea, creatinine, and sodium levels were determined before the initiation of treatment, every 2 d during treatment, and 24 h after therapy completion.

Diuretics were routinely withdrawn at the time of diagnosis of SBP and therapeutic paracenteses were not allowed until the resolution of infection.

SBP was considered resolved when all the clinical signs of infection disappeared, the PMN count in the ascitic fluid decreased to less than 250 cells/mm<sup>3</sup>, total and differential WBC count normalized, and blood and ascitic fluid cultures were negative.

If signs or symptoms of infection developed after discontinuation of antibiotics, a paracentesis for PMN cell count was also repeated.

SBP was considered as “community-acquired” when it was present at admission, and as “nosocomial” when it developed during hospitalization in patients with a normal ascitic fluid at admission<sup>[14]</sup>.

SBP-related mortality was defined as a death caused by bacterial infection of the ascitic fluid, with clinical and bacteriologic evidence of uncontrolled infection.

After discharge from the hospital, most of the patients were followed as outpatients for continued care. All were prescribed norfloxacin for prophylaxis of SBP recurrence.

### Statistical analysis

Results are expressed as mean  $\pm$  SD. The differences between groups were determined by student's *t* test. The chi-square test was used when appropriate to determine the differences in proportions. The independent role of factors selected by the univariate analysis was assessed by stepwise regression analysis. The statistical significance was established at a *P* value of less than 0.05. Calculations were performed by using a statistical software program (Number Cruncher Statistical System 97, Kaysville, Utah, USA).

## RESULTS

From January 1, 2004 through December 31, 2006, 38 consecutive episodes of SBP occurred in 32 cirrhotic patients with ascites (22 men and 10 women, mean age 58.6-11.2 years) hospitalized in our Gastroenterology Unit.

In the same period, a total of 228 diagnostic paracenteses were performed in 129 cirrhotic patients with ascites consecutively admitted to our Unit. The prevalence of SBP, in our patient population, was therefore calculated as 17%.

Demographic and clinical characteristics of our patient population are reported in Table 1. The etiology of cirrhosis was alcoholic in 13 (41%) cases. All the patients had advanced cirrhosis with high serum bilirubin (9.5-10.5 mg/dL), low prothrombin activity (57%-18.8%), and high Child-Pugh's (10.2-1.9) and MELD's (19.4-8.5) scores.

SBP presented without symptoms and signs in most

**Table 1** Demographic, clinical, and biochemical characteristics of the patients (mean  $\pm$  SD)

	Patients
<i>n</i>	32
Age (yr)	58.6 $\pm$ 11.2
Gender (male/female)	22/10
Alcoholic origin (yes/no)	13/19
MELD score	19 $\pm$ 9
Child-Pugh class (A/B/C)	0/11/21
Bilirubin (mg/dL)	9.5 $\pm$ 10.5
Albumin (g/dL)	2.6 $\pm$ 0.5
Prothrombin time (%)	55.7 $\pm$ 18.8
Creatinine (mg/dL)	1.3 $\pm$ 0.5

WBC (mm <sup>3</sup> )	8867.1 $\pm$ 6504

cases: at the time of hospital admission, fever was present in 12 cases, abdominal pain in six, and blood leukocyte counts were higher than 10 000/mm<sup>3</sup> in only 11 cases. At hospitalization, renal failure was recorded in 14 (37%) cases and hepatic encephalopathy in eight (21%).

In 16 of the 38 episodes, the presence of a risk factor for SBP occurrence was identified: there were seven cases with a previous episode of SBP (six of them were receiving antibiotic prophylaxis for SBP at inclusion), three patients had gastrointestinal bleeding, and six had undergone invasive procedures.

The ascitic fluid culture was positive in only nine (24%) of the 38 SBP episodes. The isolated organisms were Gram-negative bacilli in five cases (two *E. coli*, two *Klebsiella pneumoniae*, and one *Enterobacter*) and Gram-positive cocci in four (two *Enterococcus species*, one *Staphylococcus aureus*, and one *Streptococcus viridans*).

Eleven (29%) episodes were nosocomial and 71% were community-acquired. There was no significant difference in terms of resolution of infection and mortality between these two sub-groups.

Cefotaxime was used as an initial empirical therapy in 29 cases. In the remaining nine cases, a different antibiotic therapy was started for the following reasons: five developed SBP despite the antibiotic treatment with cephalosporins initiated for other reasons (i.e. as a prophylaxis before an invasive procedure or for bleeding), and four patients were allergic to cephalosporins. These nine patients were included only in the analysis for the identification of predictors of mortality.

The treatment was successful in 17 of the 29 episodes initially treated with cefotaxime (59%), while in 12 (41%) episodes the initial antibiotic therapy with cefotaxime was changed because of a less-than 25% decrease in the ascitic fluid of PMN cell count at paracentesis performed after 48 h. In these patients, the antibiotic therapy was changed to imipenem-cilastatin in six cases, piperacillin-tazobactam in two, ampicillin-sulbactam in two and amoxicillin-clavulanic acid in one. The last patient died 48 h after the beginning of the antibiotic therapy. In five cases, a further change in the antibiotic treatment was necessary.

Among the nine episodes of SBP in whom the culture of ascitic fluid was positive, the initial antibiotic therapy

with cefotaxime failed in four cases, a percentage (44%) similar to that of the whole series. In these four episodes, the isolated organisms were either resistant to cefotaxime (ESBL-positive *E. coli*, *Enterobacter*, and *Enterococcus*), or had an inherent insufficient susceptibility to cefotaxime (*Staphylococcus aureus*).

SBP resolved in 26/29 episodes initially treated with cefotaxime, while three patients died with signs of active infection. Two further deaths due to SBP occurred among the nine patients not treated initially with cefotaxime. At multivariate analysis, the only variables that showed an independent relationship with mortality for SBP were the presence, at entry, of renal failure (defined as an increase in serum urea and/or creatinine to greater-than 30 mg/dL or 1.2 mg/dL respectively) and a mean arterial pressure < 70 mmHg (R-squared = 0.35).

## DISCUSSION

The aim of our study was to verify the validity, applicability, and efficacy of the guidelines proposed in 2000 by the International Ascites Club for the treatment of SBP. The applicability in the clinical practice of a guideline derived from randomized controlled investigations is very important. Moreover, such analysis is also justified by the evidence that the type and etiology of bacterial infections in cirrhosis may have changed during recent years<sup>[14-18]</sup>. For this purpose, the results of patients' management according to these guidelines were evaluated in an unselected group of cirrhotic patients with SBP consecutively observed in the last three-year period.

Our study suggests that, in clinical practice, an approach to SBP based on ascitic fluid PMN cell count is correct and valid for starting the antibiotic treatment and evaluating its efficacy as well. On the other hand, the suggestion of using third-generation cephalosporins (cefotaxime) as the first-line antibiotic treatment is not equally valid, since a switch to another antibiotic was necessary in more than 40% of our cases.

Infections may frequently occur in patients with liver cirrhosis, especially when decompensated, and may be a cause of death *per se*; but, they can also act as a trigger for a number of severe complications, such as hepatic encephalopathy and renal failure<sup>[23]</sup>. Moreover, infection has been related to variceal bleeding both in terms of pathogenesis of portal pressure increment and severity of bleeding episodes<sup>[24,25]</sup>, since the related mortality was reduced by prompt antibiotic therapy<sup>[26]</sup>. SBP is one of the most frequent infections in patients with cirrhosis<sup>[6]</sup>. Fever, leukocytosis, and abdominal symptoms are rare (recorded in 20% only of our series); the identification of the infection of ascitic fluid is, therefore, based only on the result of the diagnostic paracentesis. A PMN cell count > 250 cell/mm<sup>3</sup> has been proposed as the most important parameter for the diagnosis of SBP, as we isolated responsible bacteria in the ascitic fluid culture very infrequently (recorded in only 24% of the episodes observed in our cohort). The low proportion of positive ascitic fluid cultures is probably due to the relatively low concentration of bacteria in the ascitic fluid as compared with the infections in other organic flu-

ids (e.g. urine)<sup>[12]</sup>. For the same reason, a therapy based on the isolation of the responsible bacteria is seldom achievable and the antibiotic treatment cannot be delayed to the moment when microbiological results are available<sup>[12,13]</sup>. In these conditions, the efficacy of the empiric antibiotic treatment can rarely be based on the amelioration of the symptoms or on microbiological results. Therefore, a reduction of PMN cell count below 250 cell/mm<sup>3</sup> or of 25% of the initial value has been suggested as the main criterion for establishing the efficacy of the antibiotic and the need for switching the therapy. Our study confirms the validity of such an approach. Based on PMN cell count, we were, in fact, able to identify the failure of the initial therapy on time, and the consequent change of the antibiotic therapy allowed us to control the infection in the majority of cases, with in-hospital mortality rate of less than 15%. This result is similar to that reported in the literature and is particularly good when considering the severe conditions of our patients.

In our study, the presence of arterial hypotension or renal failure at admission was the only independent predictor of mortality for SBP. To our knowledge, this observation is similar to the findings of other studies<sup>[27]</sup>. According to the 2000 Ascites Club guidelines the use albumin, as suggested by the paper of Sort *et al*<sup>[28]</sup>, was not included in our protocol for SBP management. Even the most recent guidelines for the prevention and treatment of HRS<sup>[29]</sup> suggest that albumin administration may reduce the incidence of renal failure and mortality in patients with SBP, but recommended further studies to define the optimal doses and the subgroup of patients for whom albumin is highly indicated. In our study, renal dysfunction was independently related with mortality and this finding supports the importance of improving the systemic hemodynamics and, thus, of renal function during the treatment of SBP.

According to the PMN cell count carried out at 48-h diagnostic paracentesis, cefotaxime-suggested as the first-line empiric antibiotic treatment-failed in more than 40% of SBP episodes. The need for changing antibiotic treatment is higher than that reported in previous studies<sup>[30-35]</sup>.

Although the cases with a positive culture were few (only 9 out of 29 patients), in these episodes the percentage of treatment failure of the initial therapy with cefotaxime was similar to that of the entire series (44%). In these patients, cefotaxime failed because the isolated organisms were intrinsically resistant to cefotaxime (as enterococci) or capable of degrading the expanded-spectrum cephalosporins (as ESBL-producing *E. coli* or Amp C  $\beta$ -lactamase producing *Enterobacter* species) or bacteria with a inherent insufficient susceptibility to cefotaxime (as *Staphylococcus aureus*). If this small subgroup is to be considered representative of the organisms currently involved in the development of SBP, our study supports the possibility that, in recent years, the microbial etiology of SBP is changing, as it seems to have more generally occurred for bacterial infections of these kinds of patients<sup>[14]</sup>. In our hospital, a recent survey<sup>[36]</sup> on 4769 samples collected for bacterial isolation from April to September 2006, showed a high prevalence of ESBL-producing enterobacteriaceae as an emergent cause of infections. In particular, among the ESBL-positive

*E. coli*, strains with CTX-M  $\beta$ -lactamases, specifically able to hydrolyze cefotaxime, were the most diffused. It is interesting to note that, although in the majority of our patients SBP was defined as “community-acquired” and nosocomial infections-defined as an infection of ascitic fluid diagnosed after a first negative ascitic fluid analysis-were not prevalent in the group resistant to cefotaxime, the above organisms are typically nosocomial. In other words, the episodes of SBP resistant to cefotaxime may be considered as healthcare-related infections<sup>[37]</sup>, probably due to the fact that compromised patients, as the cirrhotic patients included in the present study, have the frequent need of hospital assistance including outpatient visits, diagnostic invasive examinations, day-hospital admissions, *etc.*, which may facilitate contact with nosocomial antibiotic-resistant pathogens. These considerations should induce a change in our approach aimed not only at changing the first line antibiotic therapy in SBP, but also at reducing and making the patients’ access to the hospital more appropriate and rational.

In conclusion, an approach to SBP based on ascitic fluid PMN cell count is correct and valid in the clinical practice for both starting promptly the antibiotic treatment and evaluating its efficacy. However, the initial treatment with cefotaxime failed more frequently than expected. These results should promote investigations aimed at identifying different approaches. The antibiotics used for the empiric initial treatment should be chosen among those able to control infections which are often healthcare-related and thus sustained by antibiotic-resistant bacteria. The characteristics of bacterial infection in a given geographical area and community should be taken into account. Therefore, the generalization of our findings, which are derived by a monocentric study, deserves further investigations.

## COMMENTS

### Background

Spontaneous bacterial peritonitis (SBP) is a severe complication of cirrhotic patients with ascites. A prompt diagnosis and an early treatment are crucial for the outcome of these patients.

### Research frontiers

In 2000, the International Ascites Club published the guidelines for the diagnosis and treatment of SBP in cirrhotic patients. This recommendation is, however, based on the results of randomized controlled trials and its validity and applicability need to be verified in clinical practice.

### Innovations and breakthroughs

In agreement with the International Ascites Club guidelines, the study confirms the importance of performing a second paracentesis at 48 h after the initiation of the antibiotic therapy as well as the utility of the cut-off of PMN count in ascitic fluid for establishing treatment failure. The suggestion of using third-generation cephalosporins (cefotaxime) as the first-line antibiotic treatment is arguable, since a switch to another antibiotic was necessary in more than 40% of cases.

### Applications

The study supports the possibility that, in recent years, the microbial etiology of SBP is changing as well as the sensibility of pathogens to antibiotic therapy. The characteristics of bacterial infection in a given geographical area and community should, therefore, be taken into account and each hospital should performed studies on bacterial sensibility and design their antibiotic strategy for SBP.

## Peer review

It is a well-designed and well-written paper. The study adds important information on the management of cirrhotic patients with SBP.

### Abstract

**AIM:** To identify patients with persistent acute diverticulitis who might benefit from an early colonoscopy during their first hospitalization.

**METHODS:** All patients hospitalized between July 2000 and December 2006 for acute diverticulitis who underwent colonoscopy were included in the study. Patients were followed during hospitalization and after discharge. Patients were considered to have a persistent course of acute diverticulitis if symptoms continued after 1 wk of conventional treatment with IV antibiotics, or if symptoms recurred within 2 mo after discharge. Patients were considered to benefit from an early colonoscopy if the colonoscopy was therapeutic or if it changed a patient's outcome.

**RESULTS:** Three hundred and six patients were hospitalized between July 2000 and December 2006 with the diagnosis of acute diverticulitis. Two hundred and twenty four of these were included in the study group. Twenty three patients (10.3%) fulfilled the criteria for a persistent course of acute diverticulitis. Of them, four patients (17.4%) clearly benefited from an early colonoscopy; these patients' clinical course is described. None of the patients with a regular non-persistent course demonstrated any benefit from colonoscopy.

**CONCLUSION:** Early colonoscopy detected other significant pathology, which accounted for the clinical presentation in 17% of patients with persistent acute diverticulitis. Therefore, we believe an early colonoscopy should be considered in all patients with a persistent clinical course.

### INTRODUCTION

Diverticular disease of the colon is a common condition in Western societies. The incidence rises with age. By the age of 85 two thirds of the population in developed countries will have developed colonic diverticula<sup>[1,2]</sup>. Most patients will remain asymptomatic. Only a minority will have complications. The most common complication is acute diverticulitis which occurs in 10%-25% of patients<sup>[2-6]</sup>. In most patients, the disease is mild, responds well to antibiotic therapy and does not recur<sup>[7]</sup>. However, there are patients who suffer from a persistent disease course. This relatively small group of patients does not respond well to conventional therapy, usually suffers from longer disease duration and might experience recurrent exacerbations. These patients often require a more aggressive therapeutic approach.

Colonoscopy is advised after an attack of acute diverticulitis in order to completely evaluate the colonic lumen and exclude a potential malignancy. However, it is a common practice to postpone colonoscopy until symptoms have fully subsided and perform it at least six wk after discharge, in order to avoid the potential risk of converting a sealed perforation into a free perforation<sup>[8-12]</sup>.

In two previous studies, we have shown that performing an early colonoscopy during hospitalization for acute diverticulitis is feasible and safe<sup>[13,14]</sup>. Early in-hospital colonoscopy was associated with better patient compliance, but a lower rate of cecal intubation. Patients with persistent diverticulitis seemed to benefit most from having early colonoscopy. The aim of this study was, therefore, to assess the yield of performing an early colonoscopy on patients with persistent acute diverticulitis, and to try to identify the subgroup of patients with persistent acute diverticulitis who might benefit from an early colonoscopy during their first hospitalization.

## MATERIALS AND METHODS

### Patients

All patients who were hospitalized between July 2000 and December 2006 for acute lower abdominal pain, fever above 38°C and leukocytosis above 12000, and who were suspected of having acute diverticulitis, were prospectively studied. All patients underwent abdominal CT and only those with CT findings compatible with acute diverticulitis were included in the study group. CT criteria for acute diverticulitis included the presence of colonic diverticuli, thickening of the colonic wall at the site of the diverticuli and peri-colic fat infiltration.

During hospitalization, patients were treated with IV antibiotics suitable to cover abdominal flora (usually ampicillin and garamycin) at the appropriate dosages.

Patients were considered to have a persistent course of acute diverticulitis if symptoms continued after 1 wk of conventional treatment with IV antibiotics, or if symptoms recurred within 1 mo after discharge.

All patients enrolled in the study underwent colonoscopy. Early colonoscopy was defined as colonoscopy performed during hospitalization on symptomatic patients or within 6 wk of the initial presentation. Late colonoscopy was defined as when the procedure was performed at least 6 wk after discharge, and when the patient was asymptomatic. The timing of the colonoscopy was based upon randomization protocols, as described in our previous two studies<sup>[13,14]</sup>.

All patients were closely followed during hospitalization and after discharge. Their follow-up after discharge was done by regular phone calls, conducted by the study coordinator as to their well being.

Patients enrolled in this study belong to a database of patients with acute diverticulitis. This database was used in our previous publications as well<sup>[13-15]</sup>.

Patients were considered to benefit from an early colonoscopy if the colonoscopy was therapeutic or if it changed the patient's outcome. Excluded from the study group were patients who refused to undergo colonoscopy (either early or late), patients with a history of colonoscopy within one year prior to the current episode of acute diverticulitis, patients operated on due to colonic perforation and patients lost to follow-up. The study was approved by the local ethics committee.

### Statistical analysis

Patients' characteristics were analyzed by the  $\chi^2$  test with Yates correction. Statistical analyses were conducted by using Statsoft software (Tulsa, OK, USA).

## RESULTS

Three hundred and six patients were hospitalized at the Chaim Sheba Medical Center between July 2000 and December 2006 with the diagnosis of acute diverticulitis. Eighty two patients did not undergo colonoscopy and, therefore, only 224 patients were included in the study group (Figure 1).

Twenty three patients (10.3%) fulfilled the criteria for a persistent course of acute diverticulitis. Fourteen patients underwent an early colonoscopy and the other

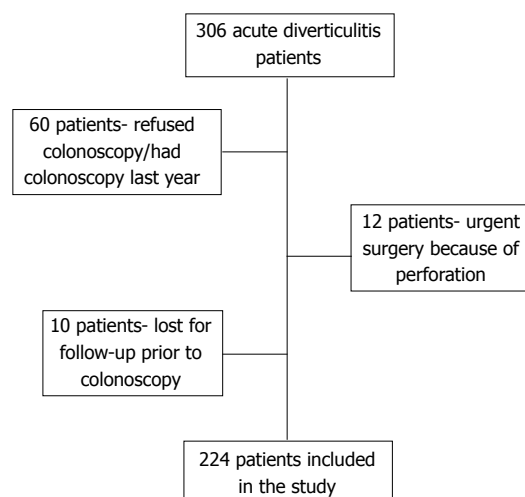

Figure 1 Study scheme.

Table 1 Beneficial and non-beneficial colonoscopies

Colonoscopy	Protracted course (n = 23)	Non-protracted course (n = 201)
Beneficial	4 (17.4%) <sup>b</sup>	0
Non-beneficial	19 (82.6%)	201

<sup>b</sup>P < 0.01 vs non-beneficial colonoscopies.

nine a late colonoscopy. Four patients (17.4%) clearly benefited from an early colonoscopy, whereas the remaining 19 patients underwent colonoscopy with no significant findings apart from the detection of diverticula and occasionally inflammation. Twelve of these patients eventually underwent sigmoidectomy because of recurrent episodes of diverticulitis, and their symptoms resolved. An additional two patients were offered sigmoidectomy, but refused. They continued to experience recurrent episodes of acute diverticulitis. The remaining five patients recovered completely with no further symptoms during a mean follow up period of 2.2 years. Interestingly, none of the patients with a regular non-persistent course demonstrated any benefit from colonoscopy (Table 1). Thus, colonoscopy was found to be beneficial only in patients with a persistent course of diverticulitis. The 4 patients in whom early colonoscopy seemed to be beneficial are described here.

### Patient No. 1

A 55-year-old man was admitted to another hospital 2 mo earlier with a clinical picture of acute diverticulitis. The patient was treated conservatively with IV antibiotics and was discharged after his symptoms subsided. Due to recurrent abdominal pain and fever he was readmitted to our hospital. In-hospital colonoscopy detected an obstructive mass in the sigmoid colon. Histology showed an adenocarcinoma. The patient underwent a sigmoidectomy.

### Patient No. 2

A 50-year-old woman was hospitalized due to left lower quadrant pain, fever and weight loss of 6 kg over a 4 mo period. CT was interpreted as compatible with acute

diverticulitis (Figure 2). After conservative treatment with IV antibiotics her symptoms improved and she was discharged. However, her symptoms did not resolve and she continued to have left lower quadrant pain. A colonoscopy, performed 2 mo later, revealed an obstructing mass in the sigmoid colon. Histology confirmed the diagnosis of adenocarcinoma. While waiting for her operation, she developed a free perforation and underwent emergency surgery with tumor resection and a temporary colostomy. Earlier colonoscopy could probably have enabled her to undergo elective surgery with primary closure of the colon.

#### **Patient No. 3**

A 60-year-old man was transferred from another hospital where he was hospitalized because of acute diverticulitis with an abscess in the left lower abdominal quadrant. The abscess was treated with IV antibiotics, but with no clinical response. A CT-guided drainage of the abscess was performed. Symptoms persisted, and the patient underwent colonoscopy. On colonoscopy, a 2-cm polyp was detected at the beginning of the inflamed area, 15 cm from the anus. Histology demonstrated a moderately differentiated adenocarcinoma arising in a tubulovillous adenoma. The tumor infiltrated the submucosa as well. No diverticuli were seen. The mucosa of the colonic segment between 15–30 cm looked irregular and biopsies showed nonspecific chronic inflammation. The patient underwent sigmoidectomy with resolution of his symptoms.

#### **Patient No. 4**

A 73-year-old woman was admitted with symptoms suggestive of acute diverticulitis. CT showed a thickened bowel wall of the sigmoid colon with multiple diverticula. The patient was treated with IV antibiotics for 10 d, with no improvement. On the 10th d of her hospitalization she underwent colonoscopy. On colonoscopy, a small chicken bone was found trapped in the diverticulum, with a purulent discharge from that diverticulum.

Removal of the bone during the colonoscopy produced complete recovery, and the patient was discharged asymptomatic and afebrile 1 d following the procedure.

## **DISCUSSION**

In this prospective study, we assessed the value of performing an early colonoscopy in a selective group of patients with a persistent course of acute diverticulitis.

Our data showed 17.4% of such patients will benefit from an early colonoscopy. We believe non-responders to conventional therapy form a special subgroup of patients with acute diverticulitis. These patients have a more severe disease and worse prognosis, as demonstrated by the fact that sixty-five percent of these patients eventually underwent a sigmoidectomy.

In our previous publications, we showed the main disadvantage of performing an early colonoscopy during hospitalization is the higher rate of incomplete examinations (18%)<sup>[13,14]</sup>. However, in this small but important group of patients with a persistent disease course, an early colonoscopy seemed to be beneficial. Therefore, the main

**Figure 2** Abdominal CT of patient No. 2. The arrow indicates the tumor misinterpreted as acute diverticulitis.

question is whether in cases of persistent course of acute diverticulitis the benefit of performing an early colonoscopy prevails over the risk of an incomplete examination. Identifying the patients from this group in whom a benefit is expected from an early colonoscopy would probably contribute to decision making. Therefore, in this study we focused on patients with a persistent course of acute diverticulitis in whom colonoscopy was beneficial. Three of the four patients (patient No. 1, 3, 4) were briefly mentioned in our previous publications<sup>[8,9]</sup>. In this paper we concentrated on those patients and added an additional patient to our series.

However, we were unable to determine predictors for the subgroup of patients who may benefit from early colonoscopy. The reasons for this might be the small number of patients involved, or, simply, because there are no such predictors.

Nevertheless, in the light of the significant findings in this small group of patients, we believe colonoscopy should be offered to all patients with a protracted disease course. However, it is not advocated for patients with a non-protracted course.

In conclusion, early colonoscopy should be considered in all patients with a protracted clinical course. In this small group of patients, 17% of the patients will benefit from the procedure with no additional risk of complications.

## **COMMENTS**

### **Background**

Patients with persistent acute diverticulitis have longer disease duration and do not respond to conventional therapy. In previous studies we showed that early in-hospital colonoscopy is feasible and safe in patients with acute diverticulitis.

### **Research frontiers**

This study was designed to investigate the benefit from performing an early colonoscopy during hospitalization in patients with persistent acute diverticulitis.

### **Applications**

Persistent acute diverticulitis affects about 10% of acute diverticulitis patients. This study showed that in this special group of patients, performing an early colonoscopy had a therapeutic benefit of 17%. Considering that performing an early colonoscopy during an attack of acute diverticulitis was shown to be safe in previous studies, this study suggests an early in-hospital colonoscopy should be considered in all patients with a persistent course of acute diverticulitis.

**Peer review**

In this prospective study, the authors focused on the yield of performing an early colonoscopy in a well defined group of patients with acute diverticulitis - patients who suffer from a persistent disease course. Study results suggest that in this small group of patients early colonoscopy will detect other significant pathology which will change patient's management in 17% of cases. Therefore, performing an early colonoscopy in patients with persistent diverticulitis is well advised.

### Abstract

**AIM:** To find the precautions against the safety in caudate lobe resection.

**METHODS:** The clinical data obtained from 11 cases of primary liver cancer in caudate lobe who received hepatectomy successfully were retrospectively analyzed. Four safe procedures were used in resection of primary liver cancer in caudate lobe: (1) selection of appropriate skin incision to obtain excellent exposure of operative field; (2) adequate mobilization of the liver to allow the liver to be displaced upwards to the left or to the right; (3) preparatory placement of tapes for total hepatic vascular exclusion, so that this procedure could be used to control the fatal bleeding of the liver when necessary; (4) selection of the ideal route for hepatectomy based on the condition of the tumor and the combined removal of multiple lobes if necessary. Among the 11 cases, simple occlusion of vessels of porta hepatis was used in caudate lobectomy for 6 cases, while in the other cases, the vessels were intermittently occluded several times or total hepatic vascular isolation was used in the caudate lobectomy. Combined partial right hepatectomy was done for 3 cases, combined left lateral lobectomy for 2 cases and caudate lobectomy alone for 6 cases.

**RESULTS:** Operation was successful for all the 11 cases. Intermittent inflow occlusion was performed for all patients for 15 min at 5-min intervals. Blockade was performed twice in 3 patients and total hepatic vascular exclusion was performed in one of the three patients. Blockade was performed three times in one patient, including a total hepatic vascular exclusion. Total hepatic vascular exclusion was performed only in one patient. The mean blood loss was 300 mL. Ascites and pleural effusion occurred in 4 patients, jaundice in 1 patient. Six

patients died of tumor recurrence in 6, 11, 12, 13, 15, 19 mo after operation, respectively. The other 5 patients have survived more than 16 mo since the operation.

**CONCLUSION:** Caudate lobectomy for liver cancer in candidate lobe can be safely performed with the above procedures.

Wen ZQ, Yan YQ, Yang JM, Wu MC. Precautions in caudate lobe resection: Report of 11 cases. *World J Gastroenterol* 2008; 14(17): 2767-2770 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2767.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2767>

### INTRODUCTION

Caudate lobe is the first segment of liver in the Couinaud's classification<sup>[1-3]</sup>, and because of its unique anatomical site, its resection has a high risk<sup>[4-7]</sup>. If appropriate surgical procedures are used, it can be safely and successfully resected<sup>[8]</sup>.

### MATERIALS AND METHODS

#### Patients

From 2003 to 2005, four safe procedures were used in resection of primary liver cancer in caudate lobe. Eleven cases of primary liver cancer in caudate lobe received resection successfully at the First Department of Hepatic Surgery of the Eastern Hepatobiliary Surgery Hospital, Second Military Medical University. Among the 11 cases, 9 were males and 2 females (age range, 32-65 years, and mean age 53 years). All the patients were diagnosed with primary liver cancer. Nine patients were positive for hepatitis B surface antigen and their liver cirrhosis was confirmed by histologic examination of the resected specimens. The primary liver cancer was originated from the caudate lobe in 9 cases and from the adjacent lobe in 2 cases. Three cases received liver lobe resection ago. Nine cases were diagnosed with hepatocellular carcinoma and 2 cases with biliary cell carcinoma.

**Figure 1** A reversed T-shaped skin incision (A), ligated short hepatic veins (B), tapes around the infrahepatic IVC (C), tapes around the suprahepatic IVC (D), hepatic hilum pulled aside (E), inversed left lobe (F). IVC: Inferior vena cava.

### Surgical procedures

**Skin incision:** A reversed T-shaped skin incision was made (bilateral oblique incision under costal arch) (Figure 1A). The costal arch was hauled and secured with a special liver hook. The whole abdominal cavity was explored to rule out intra-abdominal metastasis.

**Dividing ligaments:** The falciform ligament was divided up to the front of the suprahepatic inferior vena cava (IVC), then the coronary, triangular, hepatorenal and hepatogastric ligaments were cut off, making the whole liver moveable.

**Dissecting blood vessels of caudate lobe:** The liver was pulled upward to exposure the infrahepatic IVC. The short hepatic veins of the caudate lobe were dissected and ligated (Figure 1B). Three thin and short hepatic veins were divided. The caudate portal triads were ligated and divided. Thus, the caudate lobe was isolated completely. The caudate lobe was detached from the neighboring liver parenchyma where large branches must be ligated if there are any.

**Preparing tapes:** As a safety precaution, tapes were preplaced around the infrahepatic and suprahepatic IVC (total hepatic vascular exclusion) (Figure 1C and 1D).

**Pringle maneuver:** The resection was begun with the occlusion of the first hepatic hilum (Pringle maneuver). The hepatic hilum was pulled aside to obtain the excellent exposure of caudate lobe (Figure 1E). Total vascular exclusion was used only when the patient had laceration

of the infra vena cava or liver vein. Such a maneuver could achieve hemodynamic instability.

**Resection:** In our series, the left lobe was removed in 9 patients and the liver was inversed without removing the left lobe in 9 patients (Figure 1F), the right lobe was removed in 2 patients. The anterior entry approach was not used in any patients. The caudate lobe was resected in 6 patients. However, additional right hemihepatectomy was performed for 3 patients and left hemihepatectomy for 2 patients. The left lateral lobe or the right lateral lobe was resected to release the space, and then the caudate lobe was resected.

### RESULTS

Intermittent inflow occlusion at the hepatoduodenal ligament was performed for all patients for 15 min at 5-min intervals. Six patients finished the operation. Blockade was performed twice in 3 patients and total hepatic vascular exclusion was performed in one of the three patients. Blockade was performed three times in one patient, including a total hepatic vascular exclusion. Total hepatic vascular exclusion was performed only in one patient. Among the patients undergoing total hepatic vascular exclusion, the infra vena cava was repaired in one patient, the liver vein was repaired in one patient, and the caudate lobe was resected with the right suprarenal gland in one patient.

It was reported that there are more intraoperative blood loss, longer operation time and more postoperative

complications in resection of the caudate lobe than for other lobes<sup>[9,10]</sup>. In our study, blood loss varied from 100 to 800 mL. The mean blood loss was 300 mL. Ascites and pleural effusion occurred in 4 patients, jaundice in 1 patient. Two patients with severe cirrhosis were cured and drainage occurred in the right thoracic cavity of 2 patients with hydrothorax.

Intrahepatic recurrence was noted in 5 patients and lung metastasis was found in one patient. The 6 patients died of tumor recurrence 6, 11, 12, 13, 15, 19 mo after operation, respectively. The other 5 patients have survived more than 16 mo since the operation.

## DISCUSSION

### *Unique anatomy and resection risk of caudate lobectomy*

The first segment of caudate lobe is divided into three sub-segments: Spiegel lobe, paracaval portion, and caudate process<sup>[11,12]</sup>. The Spiegel lobe is located behind the lesser omentum, just to the left of intrahepatic IVC. The paracaval portion is in front of the intrahepatic IVC, just to the right of the Spiegel lobe, and is closely attached to the right and middle hepatic veins. The caudate process is a tongue-like projection between the IVC and the adjacent portal vein, just to the right of the paracaval portion.

There are three porta hepatis in a liver<sup>[13,14]</sup>. The first porta hepatis denotes the hilum in a general sense; the second porta hepatis denotes the confluence of major hepatic veins, and the third porta hepatis denotes the segment of retrohepatic IVC with a series of short hepatic veins. Caudate lobe is, thus, surrounded by the three porta hepatis, all of which consist of important and potentially dangerous structures in terms of performing operation<sup>[15,16]</sup>. In view of the unique anatomical location, caudate lobe resection is technically challenging, especially for isolated caudectomy because it is easy to damage the hilum and bile duct in dissecting the anterior of caudate lobe, the inferior vena cava and cause uncontrolled bleeding when the posterior of caudate lobe is dissected as well as most difficult to remove the tumor near the protruded portion or inferior vena cava portion.

### *Clinical significance of caudate lobectomy*

Carcinoma, originating from the caudate lobe, cannot be treated effectively with trans-arterial chemotherapy embolization (TACE)<sup>[17,18]</sup>, because the supply vessels of caudate lobe are different from those of other lobes. Caudate lobe has many supply blood vessels from the right and left portal veins and hepatic arteries, many veins outflow the caudate lobe into the inferior vena cava and hepatic veins. It is not easy to completely embolize so many arteries. Percutaneous ethanol injection therapy (PEIT)<sup>[19]</sup> and percutaneous radiofrequency ablation (PRFA)<sup>[20]</sup> are also limited in the treatment of caudate lobe tumor, because injection or penetration can easily damage the adjacent blood vessels or other important structures. Therefore, caudate lobectomy may be the only effective method to cure the cancer.

### *Safe surgical precautions*

**Surgical approach to caudate lobe:** The choice

of procedures is essential to the success of caudate lobectomy<sup>[21]</sup>. There are different procedures of caudate lobectomy, but only three are effective. (1) Anterior procedure: resection of the hepatic parenchyma from the middle line with the right and left porta hepatis pulled aside to expose the caudate lobe. This method is complicated and causes huge injuries. We do not consider anterior procedure in caudate lobectomy resection. (2) Right procedure: resection of the 6 segments to expose the caudate lobe. This procedure resects more normal tissues. It is thus, not suitable for cirrhosis. If partial right lobe is not resected, it is difficult to dissect the protruded right portion of caudate lobe. (3) Left procedure: if the carcinoma is close to the left and upside of the lobe, resection of the left lateral lobe can expose the caudate lobe. It is better not to dissect the left lateral lobe. Otherwise, it causes liver failure if cirrhosis is severe. After the left lateral lobe is removed and the liver is inversed to the right and upwards, it is easy to perform the procedure. This procedure is commonly used to resect the caudate lobe.

**Preparation of infra vena cava occlusion belt:** Preparation of infra vena cava belt is to block intraoperative vital bleeding caused by laceration of the infra vena cava and hepatic vein<sup>[22]</sup>. If bleeding occurs, the mortality would be high. We think that infra vena cava block belt should be prepared for all patients<sup>[23]</sup>. In practice, only few patients need infra vena cava block<sup>[24]</sup>. We stress that infra vena cava block belt secures the safety of operation. When total hepatic vascular exclusion is used, the block time should be controlled. The authors think that the preferable block time is less than 15 min in order to reduce complications after operation, because patients with liver cirrhosis have insufficient liver function.

### *Repair of laceration of infra vena cava or hepatic vein:*

Once much blood emerges through the wound, laceration of the infra vena cava is diagnosed<sup>[25]</sup>. We should make a prompt decision without any hesitation to perform total hepatic vascular exclusion, in order to remove the tumor quickly and repair the laceration. However, if the laceration is small and can be located, it is not necessary to perform total hepatic vascular exclusion. We can use the finger press method to stanch bleeding and repair the vessels quickly<sup>[26]</sup>.

## COMMENTS

### *Background*

Primary liver cancer originating from the caudate lobe is not rare. It is difficult to remove it because of its unique anatomical location. We presented a safe technique of caudate lobectomy for liver cancer.

### *Applications*

Caudate lobectomy can be safely performed when appropriate skin incision is made, liver ligaments are adequately cut off, tapes for total hepatic vascular exclusion are placed and the ideal section route is selected.

### *Peer review*

This is an interesting paper describing caudate lobe resection and the precautions against the safety in caudate lobe resection. The authors suggest that caudate lobectomy for liver cancer in caudate lobe can be safely performed when proper procedures are used.

### Abstract

**AIM:** To evaluate the protective effect of inactivated hepatitis A vaccine (Healive®) against hepatitis A outbreak in an emergency vaccination campaign.

**METHODS:** During an outbreak of hepatitis A in Honghe Town, Xiuzhou District, Jiaxing City, Zhejiang Province, two nonrandomized controlled trials were conducted in September 2006. The first trial was to vaccinate 108 anti-HAV negative individuals with close contacts of the patients from September with 1 dose of an inactivated hepatitis A vaccine, Healive®. The control group comprised of 115 individuals with close contacts of the patients before September. The second trial was to vaccinate 3365 primary and secondary school students who volunteered to receive a dose of Healive® and 2572 students who did not receive Healive® serving as its controls. An epidemiological survey was conducted to evaluate the protective efficacy of the vaccine.

**RESULTS:** A total of 136 hepatitis A cases were reported during an outbreak that started in June, peaked in August and September, and ended after December of 2006. After a massive vaccination of school children in September, the number of cases declined significantly. No hepatitis A was detected in the 108 vaccinated individuals with close contacts of patients, whereas 4 cases of hepatitis A were found in the controls. The infection rate of hepatitis A was not significantly different in the individuals with close contacts of patients whether or not they received the vaccine ( $P = 0.122$ ). No hepatitis A was detected in the 3365 students who received the vaccine, four cases of hepatitis A were found in the controls. The infection rate of students with or without vaccination was significantly different in the students who received the vaccine (0/3365 vs 4/2572,  $P = 0.035$ ). The protective efficacy of the vaccine was 100%.

**CONCLUSION:** Inactivated hepatitis A vaccine demonstrates a good protective effect against an outbreak of hepatitis A.

### INTRODUCTION

Hepatitis A is an acute, usually self-limited disease of the liver caused by hepatitis A virus (HAV). Although it is often a benign infection, up to 15% of the infected persons have a protracted relapsing disease course lasting up to 6 mo<sup>[1]</sup>. Hepatitis A infection may lead to acute liver failure with a mortality rate of 0.43‰-0.58‰ in 2005 and 2006 according to China Center for Disease Control and Prevention<sup>[2]</sup>. An estimated 1.5 million clinical cases of hepatitis A occur globally each year. Since HAV is transmitted from person to person, primarily through the faecal-oral route, the incidence of hepatitis A is closely related to the socioeconomic development and hygienic conditions. In China, the incidence of hepatitis A was above 100/100 000 in the 1980s. With the economic growth in the past decade, especially with the usage of live attenuated hepatitis A vaccine and inactivated hepatitis A vaccine<sup>[3,4]</sup>, its incidence has decreased from 20/10 000 in 1996 to 5/10 000 in 2006<sup>[5]</sup>. Local outbreaks, however, are often reported in small cities and rural areas. In a previous study to investigate the prophylactic use of attenuated hepatitis A vaccine during an outbreak in a village, the live vaccine did not show protective effect, as the infection rate was not significantly different between the vaccinated and control groups<sup>[6]</sup>. The reason for this might be that the antibody induction period of the attenuated hepatitis A

vaccine is relatively long and the seroconversion reaches a peak 2 or 3 mo after injection<sup>[7]</sup>. In contrast, the antibody induction period of inactivated hepatitis A vaccine is as short as 2 wk<sup>[8]</sup>, and the seroconversion reaches a peak one month after delivery<sup>[9]</sup>. It is generally recognized that inactivated hepatitis A vaccine could provide good protection against hepatitis A after exposure to HAV<sup>[10,11]</sup>. Until now, the protective efficacy of inactivated hepatitis A vaccine has not been documented as an emergency vaccination in Chinese population.

Honghe Town, which belongs to the Xiuzhou District, Jiaxing City, Zhejiang Province, is an open rural community in southeastern China. Hepatitis A has been periodically epidemic in this area before vaccines were commonly used, and its incidence has been brought down to the national level with the introduction of hepatitis A vaccination programs. A serological survey in 2002 showed that the anti-HAV positive rate is 67.13% in this area<sup>[12]</sup>. Great changes have taken place in recent years, as the number of migrants now exceeds that of the local population. Many immigrants live in cramped dwellings and have limited access to appropriate hygienic conditions. Their sewage is drained directly into farmlands and streams without any proper treatment. Moreover, food safety is not guaranteed, as many people get food from unauthorized street stands. Infectious diseases are, thus, very likely to develop and get circulated.

Honghe Town consists of 9 villages with a population of 59700, including a local population of 27000 and a migrant population of 32700. In August and September 2006, a hepatitis A outbreak was detected by the Xiuzhou District Center for Disease Control and Prevention. An emergency vaccination program was implemented for those with close contacts of patients and all school children in Honghe Town to interrupt the outbreak. Here, we report the protective effect of vaccination with Healive<sup>®</sup>, an inactivated hepatitis A vaccine developed and manufactured in China, on the control of hepatitis A in an open rural community.

## MATERIALS AND METHODS

### *Surveillance of hepatitis A cases*

Routine surveillance data on hepatitis A cases were obtained from the reports of physicians, laboratories, and hospitals. The major diagnostic criteria for hepatitis A were nausea, abdominal discomfort, jaundice, dark urine, presence of IgM antibody, and elevated serum alanine aminotransferase (ALT) level.

Considering two weeks needed for antibody induction with inactivated hepatitis A vaccine<sup>[6]</sup> and a 15-50 d incubation period of hepatitis A, we defined 15 d post-vaccination as the window period. Any case occurring within the window period was excluded from the vaccine protective efficacy analysis.

### *Composition of the vaccine*

The inactivated hepatitis A vaccine, Healive<sup>®</sup>, developed and manufactured by Sinovac Biotech Co. Ltd. (Beijing, China), was licensed in China in 2002. The vaccine is

prepared from the TZ84 strain of HAV. The virus used for vaccine production can grow in human fetal lung diploid fibroblast 2BS cells. Whole viruses were extracted from tissue culture, purified, formalin inactivated, and then adsorbed onto aluminum hydroxide. The pediatric dose contains 250 U/0.5 mL HAV antigen, and the adult dose contains 500 U/1.0 mL HAV antigen. Other ingredients include aluminium hydroxide, sodium dihydrogen phosphate, disodium hydrogen phosphate, sodium chloride, and water for injection.

### *Study populations and vaccination programs*

During the outbreak of hepatitis A in Honghe Town, Xiuzhou District, Jiaxing City, Zhejiang Province, two nonrandomized controlled trials were conducted. Both trials were approved by the Medical Ethics Committee of Xiuzhou District.

Starting in September 2006, anti-HAV tests were performed in individuals with close contacts of hepatitis A patients, of them 108 were negative for HAV. In the first trial, inactivated hepatitis A vaccine, Healive<sup>®</sup> was emergently delivered to the 108 individuals with close contacts of hepatitis A patients as a post-prophylactic measure after informed consent was obtained. Subjects younger than 16 years old received one injection of a pediatric dose of vaccine containing 250 U/0.5 mL hepatitis A virus antigen and those older than 16 years received one injection of an adult dose of vaccine containing 500 U/1.0 mL hepatitis A virus antigen. These 108 subjects served as the intervention group. Meanwhile, a retrospective investigation and follow-up study were conducted among 44 patients from June to August, who had 115 close contacts and none of them had a previous hepatitis A vaccination. Because the vaccination program was not implemented until September, these 115 close contacts formed a natural non-intervention group. All those with close contacts in the intervention and non-intervention groups were observed for 60 d.

The second trial of the vaccination program was carried out from September 2 to 8 in primary and secondary school students. A written consent form (which provided information about the burden of the disease, the role of vaccine, and the cost of vaccine) was given to each student in the primary and secondary schools in Honghe Town. After the consent forms were signed by the students' parents, 3365 students who consented to receive the vaccination served as the vaccine group, and 2572 students who did not choose to receive served as the control group. Students having either a history of hepatitis A infection or contraindications for hepatitis A vaccination were excluded from inoculation. One dose of Healive<sup>®</sup>, containing 250 U/0.5 mL hepatitis A virus antigen, was delivered to all students in the vaccine group.

### *Data analysis*

The protective rate was calculated from the formula: (incidence of non-intervention group-incidence of intervention group)/incidence of non-intervention group. Fisher's exact test was used to compare the incidence between the intervention and non-intervention groups. Z-test was used to analyze the number of cases. A two-tailed

**Figure 1** Number of hepatitis A cases by month in Honghe Town during the outbreak of hepatitis A in 2006.

*P* value less than 0.05 was considered statistically significant. Statistical analysis was carried out using SPSS 11.5 software.

## RESULTS

### Epidemiology of the hepatitis A outbreak

The outbreak of hepatitis A started in June 2006 and ended in January 2007 (Figure 1). A total of 136 cases of hepatitis A were reported. The first wave peaked in August and September in 67.65% (92/136) of the total cases. Forty-four cases of hepatitis A occurred in the second wave of outbreak, accounting for 32.35% (44/136) of the cases. The incidence was 227.86/100 000. Among the 136 reported cases, 64 patients were immigrating population while 72 patients were local population.

The cases had a different age distribution within the two populations. In the local population, most of the cases [81.9% (59/72)] were found at the age of 20-49 years, while 37.5% (24/64) and 32.8% (21/64) of the cases were found in the migrant population at the ages of 0-10 and 30-39 years, respectively.

### Protective efficacy of the vaccine in those with close contacts of the patients

Within the 60-d observation period, 4 subjects in the non-intervention group during the first trial developed clinical symptoms and were diagnosed with hepatitis A. In the intervention group, the earliest and latest emergency injection of the vaccine was given 1 d and 31 d post-contact (the median was 12 d). No hepatitis A clinical symptoms were observed in the intervention group during the 60-d observation period. The statistical test showed the difference in the infection rates between those with close contacts who received vaccination (0/108) and those who did not receive vaccination (4/115) was not significant ( $P = 0.122$ ). The protective efficacy was 100% in those with close contacts.

### Protective efficacy of the vaccine in students

To evaluate the ability of a massive vaccination of students to prevent the outbreak, students were enrolled in the vaccine group or the control group, according to their willingness to receive the vaccine. After the vaccination for 3365 students in early September 2006, one hepatitis

**Figure 2** Hepatitis A cases by age group in Honghe Town before and after intervention. The vaccination was implemented in early September 2006.

**Table 1** Hepatitis A incidence in vaccination and control groups

Group	No. of subjects	No. of cases	Incidence (1/100 000)
Vaccine	3365	0	0
Control	2572	4	155.5

A case was reported 3 d after injection. Another 5 cases were detected between September and December 2006 in the control group of 2572 students, on September 16 and 30, October 5, November 1, and December 10. The single case in the vaccine group and September 16 case in the control group were excluded from the incidence analysis. The incidence of hepatitis A in the vaccine and control groups was calculated (Table 1). Fisher's exact test indicated that the incidence of hepatitis A in the control group was significantly higher than that in the vaccine group ( $P = 0.035$ ). The protective efficacy was 100% in students who received vaccination.

### Effect of vaccination program on reducing the number of cases

After vaccination, the number of cases was reduced dramatically in the student group (5-19 years old) and in other age groups (Figure 2). Compared with the number of cases before the vaccination program, the number of cases in the student group (5-19 years old) decreased by 70% after the vaccination program (20 cases in July-September *vs* 6 cases in October-December) ( $Z = 2.746$ ,  $P < 0.01$ ). The number of cases decreased by 22.22% (54 cases in July-September *vs* 42 cases in October-December, ( $Z = 1.224$ ,  $P > 0.05$ ) among those outside the student group.

## DISCUSSION

We report a vaccination program in certain populations of an open rural community using an inactivated hepatitis A vaccine as an intervention to a hepatitis A outbreak. This is the first study to demonstrate the protective

**Table 2** Anti-HAV sero-positive rate in the community of Honghe Town

	Age group (yr)							Total
	0-	5-	10-	20-	30-	40-	50-	
Number of tested persons	8	19	97	136	160	71	41	532
Number of positive results	4	16	78	103	120	59	34	414
Positive rate (%)	50	84.2	80.4	75.7	75	83.1	82.9	77.8

effect of inactivated hepatitis A vaccine (Healive<sup>®</sup>) on a Chinese population, and the vaccine was shown to have a 100% protective efficacy, suggesting that the vaccination program reduced the incidence of new hepatitis A cases after a massive vaccination in school children. The precise contribution of the vaccine campaign to the control of the outbreak of hepatitis A is difficult to quantify because the outbreaks are often on the wane over time.

The outbreak of hepatitis A showed a typical epidemic mode: a weak second wave appeared a couple of months after the first wave. One possible reason for the second wave is that 30% of the patients were not hospitalized, and the HAV transmission might have resulted from a delayed quarantine. The appearance of the second wave could also be explained by the fact that the vaccinated population was not large enough to form immunity. In this vaccination campaign, 3365 students and 108 individuals with close contacts of hepatitis A patients were inoculated, leading to a vaccine coverage of 56.7% [ $3365/(3365 + 2572)$ ] in students and an average vaccine coverage of 5.82% [ $(3365 + 108)/59700$ ] in the whole community. As vaccination was targeted mainly at students, the vaccination campaign only increased seroconversion in the student group, and hepatitis A virus could still circulate among the susceptible individuals in preschool children and adults. We believe that incomplete interruption of HAV is the consequence of a lack of vaccination coverage in preschool children and adults.

A corroborative survey was conducted to investigate the anti-HAV positive rate when the outbreak occurred in the community (Hai-Tao He, Xiuzhou District Center for Disease Control and Prevention, personal communication, 2006) (Table 2). The anti-HAV positive rate was low in those at the age of 0-4 and 20-39 years, suggesting that a large number of susceptible individuals are the preschool children and adults. These data provide evidence that a low anti-HAV seropositive rate and the lack of a vaccination campaign in preschool children and adults might be the cause of the aforementioned second wave of hepatitis A epidemic.

It was reported that inactivated hepatitis A vaccine was used in prevention of community-wide outbreaks of hepatitis A<sup>[13]</sup>. Studies showed that an epidemic of hepatitis A could end eight weeks after 80% of susceptible children and adults received one dose of hepatitis A vaccine<sup>[14]</sup>; the epidemic may persist for up to 30 wk in another location where less than 50% of the susceptible individuals were vaccinated<sup>[15]</sup>. It is still unknown what level of vaccination coverage is required to curtail a community-wide outbreak of hepatitis A.

It was difficult to promote vaccination in the local

community, as vulnerable individuals besides the students refused to receive the vaccination in spite of our recommendation. Since inactivated hepatitis A vaccine is at expense of the recipients and whole-family vaccination is still unaffordable for many households, school children enjoy the priority in receiving the vaccination. We hope that the government and public health authorities can allocate a larger budget to support emergency vaccination programs to control outbreaks of hepatitis A more rapidly and effectively, especially in areas with a high incidence of HAV infection.

## ACKNOWLEDGMENTS

The authors thank Ye Ning (European Molecular Biology Laboratory, Heidelberg) for helpful suggestions and comments.

## COMMENTS

### Background

Hepatitis A is an acute, usually self-limited disease of the liver caused by hepatitis A virus. Although the use of inactivated hepatitis A vaccine as a prophylactic treatment has been reported in Europe and USA, little is known about the application of such a vaccine in control of hepatitis A in China.

### Research frontiers

Although hepatitis A is regarded as a benign infection, it may cause serious symptoms. The disease can be prevented by vaccination and hepatitis A vaccine has been proved effective in controlling its outbreak worldwide.

### Innovations and breakthroughs

Our study showed that inactivated hepatitis A vaccine demonstrating a good protective effect against outbreak of hepatitis A could be used for emergency vaccination. The study reports the first clinical study evaluating inactivated hepatitis A vaccine in an emergency vaccination campaign during an outbreak of hepatitis A in China.

### Applications

Hepatitis A vaccine has several advantages over immune globulin, including long-term protection effect, ease of administration, and widespread availability. Substitution of immunoglobulin by inactivated hepatitis A vaccine and its application in both routine and emergency vaccination during an outbreak of hepatitis are proposed.

### Terminology

Hepatitis A: an acute infectious disease of the liver caused by hepatitis A virus. Emergency vaccination: vaccination used during an outbreak of hepatitis A.

### Peer review

The present study demonstrated the protective effect of inactivated hepatitis A vaccine against hepatitis A during the outbreak in an open rural community. It provides an interesting insight into the control and prevention of hepatitis in a rural community of China.

## Abstract

Hemosuccus pancreaticus is a rare cause of intermittent upper gastrointestinal bleeding. We report two cases of hemosuccus pancreaticus with multiple episodes of upper gastrointestinal bleeding. The causes of hemorrhage were rupture of pseudoaneurysm of the splenic artery and bleeding from the wall of pancreatic pseudocyst. Interventional radiology is the first modality for early diagnosis and possible treatment of hemosuccus pancreaticus. When angiography shows no abnormal findings or interventional radiological therapy can not be successful, surgery should be considered without delay. Our patients herein underwent surgery without recurrence or sequelae. Intraoperative ultrasonography and pancreatoscopy were helpful modalities for confirming the source of hemorrhage and determining the cutting line of the pancreas. When we encounter intermittent upper gastrointestinal bleeding with an obscure source, hemosuccus pancreaticus should be included in differential diagnoses especially in patients with chronic pancreatitis, which would lead to a prompt and proper treatment.

## INTRODUCTION

Hemorrhage from the papilla of Vater *via* the pancreatic duct, known as hemosuccus pancreaticus, is a rare cause of intermittent upper gastrointestinal bleeding. This condition was first reported in 1931 by Lower and Farrell who mentioned bleeding from an aneurysm of the splenic artery<sup>[1]</sup>. The expression "hemosuccus pancreaticus" was named by Sandblom in 1970<sup>[2]</sup>. Until now, reports on hemosuccus pancreaticus have been quite limited. Difficulties in determining the location of bleeding sometimes cause delay of treatment and critical condition of patients.

We herein report two cases of hemosuccus pancreaticus and discuss problems and pitfalls for managing this disease.

## CASE REPORTS

### Case 1

A 75-year-old woman had been followed up for epigastric discomfort and anemia for 3 years, but no abnormality had been elucidated by either upper gastrointestinal series or endoscopic examinations. She developed sudden hematoemesis and was emergently admitted to a referral hospital. Upper gastrointestinal endoscopy revealed fresh bleeding from the papilla of Vater (Figure 1A), and she was transferred to our institute. A CT scan showed a 2.0 cm × 1.8 cm cystic mass at the tail of the pancreas without remarkable findings of chronic pancreatitis (Figure 1B). Angiography identified aneurysms at the distal portion of the splenic artery and the right hepatic artery (Figure 1C). The patient came down with a pre-shock condition with continuous bleeding, and a diagnosis of the rupture of aneurysm of the splenic artery and/or the right hepatic artery was confirmed emergently. Intraoperative ultrasonography revealed a 2.0 cm × 2.0 cm low echoic mass at the body of the pancreas suspected as a hematoma (Figure 1D). Distal pancreatectomy and splenectomy were performed for the rupture of aneurysm of the splenic artery. The pancreas was diffusely hard and compatible with chronic pancreatitis. It seemed that this might be caused by obstruction of main pancreatic duct due to blood from hematoma. Pathological examination confirmed peripancreatic hematoma and pseudoaneurysm

of the splenic artery communicated with the pancreatic duct: hemosuccus pancreaticus (Figure 2). Postoperative course was uneventful without recurrence.

## Case 2

A 44-year-old man was hospitalized at a referral hospital developing tarry stool with severe anemia. Upon the first upper gastrointestinal endoscopy, a small amount of fresh blood was observed in the duodenum, but the source of bleeding was not identified. Colorectal endoscopy, angiography (Figure 3A) and scintigraphy failed to detect the bleeding source. A CT scan revealed multiple calcifications at the whole pancreas and dilatation of main pancreatic duct compatible with chronic pancreatitis and pancreatolithiasis (Figure 3B). Endoscopic retrograde pancreatography and magnetic resonance cholangio-

pancreatography revealed a dilated branch of pancreatic duct at the head of the pancreas (Figure 3C). Finally, bleeding from the papilla of Vater was seen by the upper gastrointestinal endoscopy (Figure 3D). He was transferred to our hospital and was electively explored with a diagnosis of hemosuccus pancreaticus and alcoholic chronic pancreatitis. The pancreas was macroscopically compatible with chronic pancreatitis and the bleeding source remained unclear because the stricture of the main pancreatic duct at the head of the pancreas prevented the endoscopic examination *via* the papilla of Vater. The pancreas was then divided right above the portal vein, and the bleeding source was identified at the tail of the pancreas by endoscopic examination (Figure 4A and B). Distal pancreatectomy and splenectomy were performed. Pathological examination demonstrated a pseudocyst filled with hematoma at the tail of the pancreas (Figure 4C).

## DISCUSSION

Hemosuccus pancreaticus (HP), a rare cause of upper gastrointestinal bleeding from the papilla of Vater *via* the pancreatic duct, is most commonly caused by the rupture of aneurysm of the splenic artery associated with acute or chronic pancreatitis. Pseudoaneurysm of the hepatic, gastroduodenal or pancreaticoduodenal artery have also been reported as sources of bleeding<sup>[3-5]</sup>. Other uncommon causes are pancreatolithiasis and pseudocyst of the pancreas<sup>[6,7]</sup>. Our two patients demonstrated different pathogenetic mechanisms of HP: (1) a rupture of splenic arterial pseudoaneurysm communicating to the pancreatic duct (case 1), and (2) a communication between the peripancreatic artery and pancreatic pseudocyst (case 2).

It is difficult to make HP diagnosis because of intermittent hemorrhage from a source that is not

**Figure 3** Case 2. Pseudoaneurysm in pancreatic pseudocyst. **A:** Angiography failed to detect a bleeding point; **B:** CT scan shows multiple calcifications at the whole pancreas and dilatation of main pancreatic duct; **C:** Endoscopic retrograde pancreatography displays a dilated branch of pancreatic duct at head of pancreas (arrow); **D:** Endoscopy reveals bleeding from papilla of Vater.

**Figure 4** Case 2. Intraoperative pancreatoscopy and specimen. **A:** Pancreatic head by pancreatoscopy; **B:** Pancreatic tail by pancreatoscopy, and bleeding source was seen; **C:** Bleeding source at pancreatic tail.

readily accessible by endoscopy. Moreover, some patients underwent operations elsewhere of questionable benefit before establishment of the correct diagnosis<sup>[8]</sup>. Therefore, if patients present with obscure source of repeated upper gastrointestinal bleeding, especially underlying

chronic pancreatitis, repeated examinations and careful observations should be performed for the diagnosis of these conditions and HP should be included in differential diagnosis<sup>[9]</sup>. Koizumi *et al*<sup>[10]</sup> reported that MRI successfully identified the fistula and bleeding. However, MRI was not helpful for the diagnosis of HP in our cases, and reasons remain unknown.

The management for HP should be aimed to eradicate the source of bleeding completely. There are two choices for the treatment of HP: (1) surgery (e.g. resection of the pancreas head or tail), and (2) interventional radiological therapy<sup>[11-14]</sup>. Most HP cases can receive angiography. If the source of hemorrhage is found by arteriography, interventional radiological therapy should be done following this examination. Recently, Benz *et al*<sup>[13]</sup> reported the interventional radiological therapy of HP by implantation of an uncoated metal Palmaz stent across the aneurysmal segment of splenic artery. This interventional radiological treatment may be useful for the rupture of arterial pseudoaneurysm to the pancreatic duct so as to prevent emergency operation. However, surgical treatment is required when angiography shows no abnormal findings and interventional radiological therapy is not successful. For the patient with HP who has a pancreatic disease such as pancreatic pseudocyst, surgical treatment may be appropriate. However, it is very difficult to confirm the source of bleeding and determine the cutting line of pancreas. Therefore, intraoperative sonography and pancreatoscopy should be performed to confirm the origin of hemorrhage. They have also been frequently used during hepatobiliary and pancreas surgery. There has been no report about intraoperative ultrasonography

and pancreatoscopy in this disease. Case 1 in our report had two aneurysms of splenic artery and right hepatic artery. Preoperative angiography did not reveal fistula either between aneurysm and pancreatic duct or between aneurysm and bile duct. On intraoperative ultrasonography, no abnormality in hepatobiliary system was seen, but a hematoma could be seen in the pancreatic body. Finally, the diagnosis of a rupture of aneurysm of splenic artery was established. Case 2 in our study was diagnosed with bleeding from the pseudocyst at the pancreatic head by ERCP and MRCP. However, on intraoperative ultrasonography and pancreatoscopy, the bleeding point turned out to be a pseudocyst at the pancreatic tail. Intraoperative pancreatoscopy was also useful in finding the origin of bleeding.

In summary, we had experienced two cases of HP. Repeated examinations and careful observations should be performed to find the obscure source of repeated upper gastrointestinal bleeding and HP should be included in the differential diagnosis. Interventional radiological therapy should be tried at first for HP. Only when angiography shows no abnormal findings and interventional radiological therapy is not successful, surgical treatment is considered. Intraoperative ultrasonography and pancreatoscopy are often performed at surgery to confirm the origin of hemorrhage.

## Abstract

Hepatic injury is rarely associated with undifferentiated connective tissue diseases (UCTD). We report, here, a case of a middle-aged woman with UCTD-related hepatic injury, including its case history, clinical manifestations, laboratory findings, treatment and its short-term effect. The patient was admitted to the hospital with symptoms of fatigue, anorexia, low-grade fever and skin rashes. She had a past history of left knee joint replacement. Laboratory tests showed elevated levels of serum transaminase, IgG and globulin, accelerated erythrocyte sedimentation rate, eosinophilia and a high titer of antinuclear antibodies (1:320). Imaging studies showed interstitial pneumonitis and hydropericardium. Liver biopsy showed the features which were consistent with those of connective tissue diseases-related polyangitis. After treatment with a low-dose of oral prednisone, both symptoms and laboratory findings were significantly improved. UCTD-related hepatic injury should be considered in the differential diagnosis of connective tissue diseases with abnormal liver function tests. Low-dose prednisone may effectively improve both symptoms and laboratory tests.

## INTRODUCTION

The term of undifferentiated connective tissue disease (UCTD) is used to define conditions characterized by the presence of signs and symptoms suggestive of a systemic autoimmune disease that do not satisfy the classification criteria for defined connective tissue diseases (CTD), such as systemic lupus erythematosus (SLE), Sjögren's syndrome (SS), rheumatoid arthritis (RA) and others. Patients may present with systemic symptoms, such as fatigue, fever, or weight loss, preceding any organ involvement. The most common symptoms include arthralgias, unexplained or undifferentiated polyarthritides, Raynaud syndrome, mucocutaneous manifestations, and sicca symptoms. However, it is unusual for a patient with UCTD to have major organ involvement<sup>[1]</sup>. Here, we report a case of UCTD-related hepatic injury.

## CASE REPORT

A 58-year-old woman was admitted to our hospital with chief complaints of fatigue, anorexia, low-grade fever and skin rashes for two months. At physical examination, she had a BP of 118/79 mmHg, a pulse of 82 beats/min, a respiratory rate of 16, and a temperature of 37.3°C. BMI was 25.2. Red maculae and desquamation were found on her face, upper limbs and buttocks. Family history was negative for rheumatic or inherited liver disease. She had a past medical history of psoriasis, hypertension, acute hepatitis A and blood transmission, but no history of ethanol consumption, no exposure to possible hepatotoxic drugs. She accepted left knee joint replacement three years ago because of osteoarthritis. Abdominal ultrasonography revealed echo enhancement of the liver and mild splenomegaly, no ascites was detected. Chest CT examination revealed interstitial pneumonia and hydropericardium. Laboratory analysis revealed a white blood cell count of  $9.86 \times 10^9/L$ , eosinophile of 10.1%, hemoglobin of 108 g/L, ESR of 90 mm/h, aspartate aminotransferase level of 157 U/L, alanine aminotransferase level of 141 U/L, albumin of 27.1 g/L, globulin of 34.7 g/L, pre-albumin of 69 mg/L, seropositivity for antinuclear antibodies with a titer of 1:320. Total bilirubin, prothrombin time, renal function and urine routine test were within normal range. Investigations for the underlying cause of her hepatic injury including alfa-fetoprotein, CEA, thyroid function, cytomegalovirus, EB virus, adenovirus antinephrotic cytoplasmic antibody, antibodies to liver/kidney microsome, smooth muscle antibodies, anti-neutrophil cytoplasmic antibody,

**Figure 1** Biopsy of the liver showing dense fibrosis of intrahepatic portal tracts with obliteration of portal vein channels, consistent with connective tissue diseases-related polyangitis with HE staining (A) and Masson trichrome staining (B).

immunoglobulin pattern, hepatitis B, C and E serology were all negative or within the normal range. Liver biopsy showed the features consistent with those of connective tissue diseases-related polyangitis (Figure 1). These findings suggested that she had UCTD-related hepatic injury. The patient was treated with a low dose of oral prednisone (40 mg/d) at the beginning. Three weeks later, the dose of oral prednisone was decreased to 30 mg/d. Her symptoms and laboratory tests improved markedly four weeks later. The levels of hemoglobin, albumin and pre-albumin were elevated to 107 g/L, 31.7 g/L and 158 mg/L, respectively. The levels of white blood cells, eosinophile, PLT, ESR, ALT and AST were decreased to  $8.72 \times 10^9$ /L, 6.4%,  $356 \times 10^9$ /L, 44 mm/h, 100 U/L, and 86 U/L, respectively. She was discharged on the 40th d. Twenty-eight days after discharge, follow-up laboratory tests showed that the levels of ESR and eosinophiles were decreased to their normal range. The levels of ALT and AST were also decreased to 60 U/L and 70 U/L, respectively.

## DISCUSSION

The most characteristic symptoms of UCTD are arthritis, arthralgias, Raynaud's phenomenon, and leukopenia. It is clear that the clinical profile of UCTD is characterized by the absence of major organ involvement. During follow-up, the symptoms may improve or mildly flare spontaneously. A positive ANA is common, with a positive rate ranging from 60%-100%, and a stable profile over time<sup>[2]</sup>. After reviewing the UCTD literature, Mosca *et al*<sup>[3]</sup> proposed that the preliminary classification criteria for UCTD include: (1) signs and symptoms suggestive of a connective tissue disease, but not fulfilling the criteria for any defined CTD, (2) positive antinuclear antibodies, and (3) a disease course of at least 3 years. As these are mild and benign conditions, only a small number of UCTD patients are treated. The most widely used drugs are NSAID (40%), corticosteroids (30%-50%) and antimalarials at a low dose (10%-30%)<sup>[4,5]</sup>. Our patient was treated with a low dose of prednisone. Four weeks later, both symptoms and laboratory findings were improved markedly. According to the above findings, the diagnosis of UCTD was established.

Our report was evaluated for hereditary (Wilson's disease,  $\alpha$ -1 antitrypsin deficiency, and genetic hemochromatosis), infections (hepatitis B, C and CMV,

EBV), drinking history and drug-induced liver injury, some of which may have autoimmune features. These possible causes for liver damage can be excluded. Likewise, although echogram of the liver showed fatty change, histological findings did not show steatosis in hepatocytes. However, even after careful exclusion of the above stated etiologies, the question remains whether the patient should be diagnosed having a primary liver disease associated with autoimmune or clinical and laboratory features and liver involvement should be considered manifestations of UCTD. The main pathogenetic dilemma is autoimmune hepatitis (AIH) and UCTD-related hepatic injury, although they have some common features of autoimmune syndrome. In this paper, we present a case of a patient with hepatic injury. UCTD is a systemic autoimmune condition characterized by a mild clinical profile and a simplified autoimmune repertoire. Although UCTD is generally benign, it may progress to CTD and changes in the disease course may occur. A small number of patients presenting with an undifferentiated profile will develop CTD during the first year follow-up. However, an average of 75% patients will maintain an undifferentiated clinical course. These patients may be defined having a stable UCTD. Bodolay *et al*<sup>[6]</sup> followed up 665 Hungarian patients with UCTD and found that most of the UCTD patients do not develop a definite CTD, but have new clinical and serological manifestations during the follow-up period and UCTD progresses to different types of specific CTD in one-third of them. Margaret *et al*<sup>[7]</sup> reviewed 11 patients meeting the diagnostic criteria for AIH. Of these 11 patients, three with a definitive diagnosis of AIH developed systemic CTD, one developed systemic lupus erythematosus (SLE) with vasculitis and peripheral neuropathy, 2 developed limited scleroderma, and 3 developed UCTD and interstitial lung disease. There appears to be a shared susceptibility of alleles to AIH and CTD in addition to the shared positive autoantibodies. Therefore, it is necessary to exclude the possibility of AIH if the definite diagnosis of UCTD-related hepatic injury is made. In the present case, the possibility of a diagnosis of AIH should be considered. The criteria for the diagnosis of AIH in adult patients have been established by the International Autoimmune Hepatitis Group (IAIHG)<sup>[8]</sup>. The diagnosis of UCTD-related hepatic injury is based on the presence of characteristic laboratory and liver histology features and the exclusion of conditions that

resemble AIH. Interface hepatitis is the hallmark of AIH<sup>[9]</sup>. However, the liver biopsy did not show interface hepatitis, which is essential for the diagnosis of AIH. Therefore, the diagnosis of AIH cannot be established. Instead, the diagnosis of UCTD-related hepatic injury can be established. Laing *et al*<sup>[10]</sup> reported that potential risk factors for UCTD are found in women implanted medical devices, of which, non-silicone-containing devices, non-silicone-containing artificial joints (OR = 5.01, 95% CI = 1.60-15.71) and orthopedic metallic fixation devices (OR = 1.95, 95% CI = 1.05-3.60) are associated with UCTD. Laing *et al*<sup>[10]</sup> have also reviewed the intervals between surgical implantation of artificial joints and diagnosis of UCTD (mean, 4.5 years; range, 3.0-6.9 years). Our patient received left knee joint replacement because of a 3-year history of osteoarthritis. Whether this plays a role in the pathogenesis of UCTD needs further study.

Just as most of other connective-tissue diseases, the pathogenesis of UCTD is unclear. Like most connective-tissue diseases, the theory and research have been concentrated on genetically susceptible hosts, T- and B-cell abnormalities, and environmental triggers, such as ultraviolet light or infection. In general, activities are not restricted unless specific functional limitations, such as interstitial lung disease, associated with UCTD are present<sup>[11]</sup>. Therefore, UCTD-related hepatic injury is an auto-reactive tissue injury which may arise *via* either the TH<sub>1</sub> pathway (leading to cell-mediated cytotoxic reactions) or the TH<sub>2</sub> pathway (resulting in antibody-mediated cell damage). These processes are under a certain form of immunoregulatory control which normally maintains self-tolerance by “switching off” the autoimmune response, although whether this involves discrete subsets of “suppressor” T lymphocytes is still controversial<sup>[12]</sup>. Whether the above factors induce UCTD-related hepatic injury is uncertain, in part because the pathogenetic mechanism underlying the development of these two conditions is poorly understood.

In conclusion, we report this case for its unusual hepatic injury after UCTD. UCTD-related hepatic injury should be considered in the differential diagnosis of connective tissue diseases with abnormal liver function tests. Low-dose prednisone can effectively improve both symptoms and laboratory findings of UCTD.

### Abstract

Eosinophilic cholecystitis is caused by the accumulation of eosinophils in the gallbladder wall and diagnosis is usually made based on histopathologic studies. The purpose of this paper is to comment on a case report published in *World J Gastroenterol* 2007 July; 13 (27): 3760-3762, about eosinophilic cholecystitis along with pericarditis without histopathological studies, which are considered necessary for its diagnosis.

**Key words:** Eosinophilic cholecystitis; *Ascaris lumbricoides*; Pericarditis

**Peer reviewers:** Xian-Ming Chen, MD, Associate Professor, Department of Medical Microbiology and Immunology, Creighton University, 2500 California Plaza, Omaha NE 68178, United States; Richard A Kozarek, MD, Department of Gastroenterology, Virginia Mason Medical Center, 1100 Ninth Avenue, PO Box 900, Seattle 98111-0900, United States

Montiel-Jarquín A. Eosinophilic cholecystitis caused by *Ascaris lumbricoides*. *World J Gastroenterol* 2008; 14(17): 2783 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2783.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2783>

### TO THE EDITOR

Regarding the article eosinophilic cholecystitis along with pericarditis caused by *Ascaris lumbricoides*: A case report<sup>[1]</sup>, a coproparasitoscopic test should have been conducted to demonstrate the presence of the parasite in the digestive tract of the patient, since the presence of the *A. lumbricoides*'s antigen in the blood is nonspecific and only refers to the contact of the patient with the parasite<sup>[2-4]</sup>. It is likely that the parasitosis is the cause both of the eosinophilia and the cholecystitis. Nevertheless, because the histopathological study to demonstrate an increase of eosinophils in the gallbladder wall was not conducted<sup>[1]</sup>, the following doubt remains: did eosinophilia cause the cholecystitis? Because of clinical improvement with medical treatment with albendazole, surgery was not performed and the acute cholecystitis that went into remission following administration of the drug may be a consequence of migration of the parasite from the biliary tract<sup>[2]</sup>.

## ACKNOWLEDGMENTS

# Acknowledgments to Reviewers of *World Journal of Gastroenterology*

Many reviewers have contributed their expertise and time to the peer review, a critical process to ensure the quality of *World Journal of Gastroenterology*. The editors and authors of the articles submitted to the journal are grateful to the following reviewers for evaluating the articles (including those published in this issue and those rejected for this issue) during the last editing time period.

## Meetings

### Events Calendar 2008-2009

#### FALK SYMPOSIA 2008

January 24-25, Frankfurt, Germany  
 Falk Workshop: Perspectives in Liver Transplantation

International Gastroenterological Congresses 2008  
 February 14-16, Paris, France  
 EASL-AASLD-APASL-ALEH-IASL Conference Hepatitis B and C virus resistance to antiviral therapies  
[www.easl.ch/hepatitis-conference](http://www.easl.ch/hepatitis-conference)

February 14-17, Berlin, Germany  
 8<sup>th</sup> International Conference on New Trends in Immunosuppression and Immunotherapy  
[www.kenes.com/immuno](http://www.kenes.com/immuno)

February 28, Lyon, France  
 3<sup>rd</sup> Congress of ECCO - the European Crohn's and Colitis Organisation Inflammatory Bowel Diseases 2008  
[www.ecco-ibd.eu](http://www.ecco-ibd.eu)

March 10-13, Birmingham, UK  
 British Society of Gastroenterology Annual Meeting  
 E-mail: [BSG@mailbox.ulcc.ac.uk](mailto:BSG@mailbox.ulcc.ac.uk)

March 14-15, HangZhou, China  
 Falk Symposium 163: Chronic Inflammation of Liver and Gut

March 23-26, Seoul, Korea  
 Asian Pacific Association for the Study of the Liver  
 18<sup>th</sup> Conference of APASL: New Horizons in Hepatology  
[www.apaslseoul2008.org](http://www.apaslseoul2008.org)

March 29-April 1, Shanghai, China  
 Shanghai - Hong Kong International Liver Congress  
[www.livercongress.org](http://www.livercongress.org)

April 05-09, Monte-Carlo (Grimaldi Forum), Monaco  
 OESO 9<sup>th</sup> World Congress, The Gastro-esophageal Reflux Disease: from Reflux to Mucosal Inflammation - Management of Adeno- carcinomas  
 Email: [robert.giuli@oeso.org](mailto:robert.giuli@oeso.org)

April 18-22, Buenos Aires, Argentina  
 9<sup>th</sup> World Congress of the International Hepato-Pancreato Biliary Association  
 Association for the Study of the Liver  
[www.ca-ihpba.com.ar](http://www.ca-ihpba.com.ar)

April 23-27, Milan, Italy  
 43<sup>rd</sup> Annual Meeting of the European

Association for the Study of the Liver  
[www.easl.ch](http://www.easl.ch)

May 2-3, Budapest, Hungary  
 Falk Symposium 164: Intestinal Disorders

May 18-21, San Diego, California, USA  
 Digestive Disease Week 2008  
 June 4-7, Helsinki, Finland

The 39<sup>th</sup> Nordic Meeting of Gastroenterology  
[www.congrex.com/ngc2008](http://www.congrex.com/ngc2008)  
 June 6-8, Prague, Czech Republic  
 3<sup>rd</sup> Annual European Meeting: Perspectives in Inflammatory Bowel Diseases  
 Email: [meetings@imedex.com](mailto:meetings@imedex.com)

June 13-14, Amsterdam, Netherlands  
 Falk Symposium 165: XX International Bile Acid Meeting, Bile Acid Biology and Therapeutic Actions

June 25-28, Barcelona, Spain  
 10<sup>th</sup> World Congress on Gastrointestinal Cancer  
 Imedex and ESMO  
 Email: [meetings@imedex.com](mailto:meetings@imedex.com)

June 25-28, Lodz, Poland  
 Joint Meeting of the European Pancreatic Club (EPC) and the International Association of Pancreatology (IAP)  
 E-mail: [office@epc-iap2008.org](mailto:office@epc-iap2008.org)

### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (WJG, ISSN 1007-9327 CN 14-1219/R) is a weekly open access peer-reviewed journal supported by an editorial board consisting of 1208 experts in gastroenterology and hepatology from 60 countries. The aim of the journal is to deliver the most clinically relevant original and commentary articles to readers, and to make the full text publicly available to all clinicians, scientists, patients and biomedical students on an unrestricted platform, so that they can access and learn about the most recent key advances in the field.

In addition to the open access nature, another key characteristic of WJG is its reading guidance for each article which includes background, research frontier, related reports, breakthroughs, applications, terminology, and comments of peer reviewers for the general readers.

WJG publishes articles on esophageal, gastrointestinal, hepatobiliary and pancreatic tumors, and other esophageal, gastrointestinal, hepatic-biliary and pancreatic diseases in relation to epidermiology, immunology, microbiology, motility & nerve-gut interaction, endocrinology, nutrition & obesity, endoscopy, imaging and advanced hi-technology.

The main goal of WJG is to publish high quality commentary articles contributed by leading experts in gastroenterology and hepatology and original articles that combine the clinical practice and advanced basic research, to provide an interactive platform for clinicians and researchers in internal medicine, surgery, infectious diseases, traditional Chinese medicine, oncology, integrated Chinese and Western medicine, imaging, endoscopy, interventional therapy, pathology and other basic medical specialties, and thus eventually improving the clinical practice and healthcare for patients.

### Indexed and abstracted in

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, Index Medicus, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology and Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

### Published by

The WJG Press

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297 mm × 210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or

damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjgnet.com>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjgnet.com](mailto:submission@wjgnet.com), or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. font with ample margins. The preferred font is Book Antiqua. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was carried out; author contributions; disclosure of any financial support for the research; and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (remove all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s), and full family name.

**Author contributions:** The format of this section should be like this: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed research; Wang CL, Zou CC, Hong F and Wu XM performed research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed data; and Wang CL, Liang L and Fu JF wrote the paper.

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in WJG, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

#### Abstract

An informative, structured abstract of no more than 350 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipment, and the experimental procedures should be included. RESULTS: The observed and experimental results, including data, effects, outcome, *etc.* should be included. Authors should present *P* value where necessary, and also include any significant data. CONCLUSION: Accurate view and the value of the results should be included.

The format for structured abstracts can be found at: <http://www.wjgnet.com/wjg/help/11.doc>.

**Key words**

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

**Text**

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, should be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

**Illustrations**

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

**Tables**

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

**Notes in tables and illustrations**

Data that are not statistically significant should not be noted. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P* < 0.05 and <sup>d</sup>*P* < 0.01 are used. A third series of *P* values can be expressed as <sup>e</sup>*P* < 0.05 and <sup>f</sup>*P* < 0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

**Acknowledgments**

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

**REFERENCES****Coding system**

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

**PMID requirement**

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information for journal citations is very important. Using the reference testing system, the authors and editor should check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in an ASP file so that the readers can immediately access the abstract of the citations online.

**DOI requirement**

A CrossRef DOI® (Digital Object Identifier) name is a unique string created to identify a piece of scholarly content in the online environment. The author should supply the DOIs for journal citation (doi:10.3748/wjg.13.6458). This link (<http://www.crossref.org/SimpleTextQuery/>) allows you to retrieve Digital Object Identifiers (DOIs) for journal articles, books, and chapters by simply cutting and pasting the reference list into the box. You may use the form with any reference style, although the tool works most reliably if references are formatted in a standard style such as shown in this example: Assimakopoulos SF, Scopa CD, Vagianos CE. Pathophysiology of increased intestinal permeability in obstructive jaundice. *World J Gastroenterol* 2007; 13(48): 6458-6464

The accuracy of the information of journal citations is very important. We will interlink all references with DOI in ASP file so that readers can access the abstracts of cited articles online immediately.

**Style for journal references**

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

**Style for book references**

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

- 16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

### Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those linked with a hyphen when the difference between the two numbers is greater than five. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered inappropriate references. Authors should not cite their own unrelated published articles.

### Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

### Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as *v* (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

### Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5  $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: <http://www.wjgnet.com/wjg/help/15.doc>.

### Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless

they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

### Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindIII*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *H pylori*, *E coli*, etc.

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

### Editorial Office

#### World Journal of Gastroenterology

Editorial Department: Room 903

Ocean International Center, Building D

No. 62 Dongsihuan Zhonglu

Chaoyang District, Beijing 100025, China

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

Telephone: +86-10-59080039

Fax: +86-10-85381893

### Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

### Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/9.doc>.

### Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/10.doc>.

### Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

### Links to documents related to the manuscript

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

### Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

### Publication fee

Authors of accepted articles must pay a publication fee.

EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

## Abstract

Recent discovery of occult hepatitis C virus (HCV) infection persisting after spontaneous or antiviral therapy-induced resolution of hepatitis C was made possible by the introduction of nucleic acid amplification assays capable of detecting HCV RNA at sensitivities superseding those offered by clinical tests. Although individuals with this seemingly silent HCV infection are usually anti-HCV antibody reactive and have normal liver function tests, occult HCV infection has also been reported in anti-HCV-negative individuals with persistently elevated liver enzymes of unknown etiology. Studies have shown that HCV RNA can persist for years in serum, lymphomononuclear cells and liver in the absence of clinical symptoms, although histological evidence of a mild inflammatory liver injury can be occasionally encountered. Furthermore, while HCV RNA can be detected in circulating lymphoid cells in approximately 30% of cases, a short-term culture under stimulatory conditions augments HCV replication in these cells allowing detection of virus in otherwise HCV-negative cases. HCV infects different immune cell subsets, including CD4<sup>+</sup> and CD8<sup>+</sup> T lymphocytes, B cells and monocytes. Studies employing clonal sequencing and single-stranded conformational polymorphism analyses have revealed unique HCV variants residing in immune cells, further strengthening the notion of HCV lymphotropism. Overall, the data accumulated suggest that occult HCV infection is a common consequence of resolution of symptomatic hepatitis C and that examination of the cells of the immune system is an effective approach to diagnosis of HCV infection and its long-term persistence. Further work is required to fully realize pathogenic and epidemiological consequences of occult HCV persistence.

Pham TNQ, Michalak TI. Occult persistence and lymphotropism of hepatitis C virus infection. *World J Gastroenterol* 2008; 14(18): 2789-2793 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2789.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2789>

## INTRODUCTION

Hepatitis C virus (HCV) is an important human pathogen which infects over 170 million people world-wide and causes symptomatic chronic hepatitis in up to 85% of those inflicted. In a significant number of patients, chronic hepatitis C (CHC) eventually progresses to fibrosis, cirrhosis and hepatocellular carcinoma (HCC). In fact, it is estimated that cirrhosis can manifest in up to 35% of patients with CHC, of whom approximately 3% would develop HCC<sup>[1,2]</sup>. End-stage liver disease due to CHC is currently the number one reason for liver transplantation in many parts of the world. The global socioeconomic burden of HCV infection is further magnified by hundreds of thousands of infections identified each year.

HCV is a positive single-stranded RNA virus which belongs to the *Flaviviridae* family and replicates by making the so-called negative strand, which is also referred to as the anti-genomic strand. The virus genome of approximately 9600 base pairs in length contains an internal ribosomal entry site (IRES) located at the 5'-untranslated region (5'-UTR), which drives the translation of the viral RNA transcript. Subsequent processing of the polyprotein precursor gives rise to over ten proteins, including structural proteins which form the viral nucleocapsid and envelope, as well as several non-structural proteins which are essential to replication<sup>[3]</sup>.

The current standard treatment for CHC is a combination of pegylated-interferon alpha and Ribavirin (P-IFN $\alpha$ /RBV), which is administered for 24 wk to patients infected with HCV genotype 2 or 3 and for 48 wk

to those with genotype 1 or 4<sup>[4,5]</sup>. At present, patients who are serum HCV RNA non-reactive for at least 6 mo after completion of treatment, as determined by clinical laboratory assays, of which the sensitivities range between 9.6 and 615 IU or 30 and 1000 virus genome copies (also referred to as virus genome equivalents, vge) per mL, are considered to have achieved a sustained virological response (SVR) and would clinically be deemed “cured” of HCV. Thus, by this definition, SVR is attainable in approximately 40%-45% of patients infected with genotype 1<sup>[6,7]</sup> and in up to 69% of those carrying genotype 4<sup>[5]</sup>. HCV genotypes 2 and 3 are generally easiest to treat with up to 80% of patients afflicted with these strains achieving a SVR, as defined above<sup>[6,7]</sup>.

## IDENTIFICATION OF OCCULT HCV INFECTION

In the past four years, the identification of a new entity of HCV infection termed as occult HCV infection was made possible by the introduction of research assays which are capable of detecting HCV RNA at lower quantities ( $\leq 2$  IU or  $\leq 10$  virus genome copies per mL) than those used in clinical laboratories. One such research assay sequentially involves: (1) a reverse transcription (RT) of high quality intact total RNA extracted from serum or plasma, peripheral blood mononuclear cells (PBMC) or, when feasible, hepatic tissues; (2) a two-round (i.e., direct and nested) amplification of the resulting cDNA by polymerase chain reaction (PCR) using primers spanning different regions of the HCV genome; and (3) validation of the amplified products by nucleic acid hybridization (NAH) to recombinant HCV DNA probe<sup>[8]</sup>. By employing this assay or those with comparable sensitivities, low levels of HCV RNA can be detected in individuals for many years after clinical and biochemical recovery from hepatitis C<sup>[9-12]</sup>. In our studies, HCV RNA loads, as determined by the aforementioned method, in individuals who were followed for up to 7 years after SVR, were usually below 100 virus copies per mL of plasma or serum and, in most cases, ranged 100-1000 virus copies per  $10^7$  circulating lymphoid cells<sup>[9,13]</sup>. Comparable levels of HCV genomes were also observed by others<sup>[10]</sup>. Furthermore, longitudinal analyses of serum or plasma and PBMC samples obtained from the same patients at different time points of SVR duration or after spontaneous recovery from hepatitis C revealed that HCV RNA typically would not fluctuate by more than ten-fold between collections and that screening sequential samples enhanced identification of occult HCV persistence<sup>[8,13,14]</sup>. In this regard, when serum samples collected 12 mo after the first one were analyzed, the overall HCV RNA positivity was increased by as much as 15% of the cases examined<sup>[13]</sup>.

The discovery of occult HCV infection has, in essence, directly challenged the accepted paradigm that apparent complete resolution of hepatitis C, either spontaneously or therapeutically-induced, would be indicative of eradication of HCV<sup>[8]</sup>. It should be pointed out that although HCV persistence after resolution of CHC was first made evident from studies using the RT-PCR/NAH or equivalent

research assays, data from more recent studies suggested that this form of clinically unapparent, but molecularly evident HCV infection could also be identified when clinical assays of enhanced sensitivity are employed. On this note, it was reported that using the Roche Cobas-Amplicor assay (sensitivity: 50 virus copies/mL), HCV RNA was detected in freshly isolated blood mononuclear cells of approximately 20% of individuals with clinical SVR<sup>[12]</sup>. Furthermore, in another study conducted by another group, over 11% of CHC patients who initially failed IFN $\alpha$  monotherapy, but achieved clinical SVR after successful completion of P-IFN $\alpha$ /RBV were also found to carry residual HCV RNA when their sera were tested by the Cobas-Amplicor assay<sup>[15]</sup>.

In addition to the documentation of HCV RNA in serum or plasma, PBMC and hepatic tissue in patients with resolved hepatitis C in whom alanine aminotransferase (ALT) levels were deemed repeatedly normal, HCV genomes were also identified in the same three aforementioned compartments in patients with persistently elevated liver enzymes, who were consistently negative for serological markers typical of a *bona fide* HCV infection<sup>[11,16-18]</sup>.

## LYMPHOTROPISM OF HCV

Although hepatocytes are considered to be primary targets of HCV, clinical and experimental evidence strongly indicates that the virus also invades and replicates in cells of other organs, particularly the immune system<sup>[19-21]</sup>. In doing so, HCV may effectively equip itself with one of the most efficient mechanisms to establish long-term, if not life-long, persistence, as it has been documented for other viruses equally capable of inducing protracted infections<sup>[22-24]</sup>. The notion of HCV lymphotropism is further supported by a greater representation of disorders of the lymphatic system in patients with CHC than in those without, including type II mixed cryoglobulinemia<sup>[25]</sup> and non-Hodgkin's lymphoma<sup>[26]</sup>.

Recent findings from our studies with different cohorts of patients with either spontaneous or therapy-induced resolution of hepatitis C showed that HCV RNA, on average, is detectable in freshly isolated PBMC in about 30% of cases, at levels ranging 100-1000 virus copies per  $10^7$  cells. However, in approximately 10% of such individuals, HCV RNA can reach  $10^4$  virus copies per  $10^7$  cells or higher, a level which is typically observed in patients with CHC<sup>[13]</sup>. In individuals where PBMC were apparently negative for HCV RNA, the use of mitogen cocktails supplemented with interleukin-2 (IL-2) and IL-4 to stimulate T and B lymphocytes and monocytes in 72-h cultures, augments HCV replication in the respective cells leading to enhanced detection of the residing virus<sup>[9,13,27]</sup>. Using this approach, HCV RNA positive strand could be identified in approximately 75% of seemingly HCV-negative cases<sup>[9,13,14,27]</sup>. Of note, the presence of HCV RNA positive strand in mitogen-treated cells is nearly always accompanied by that of HCV RNA negative (replicative) strand, indicative of authentic viral replication. Moreover, non-structural HCV proteins, such as NS5A, are also

detectable in circulating immune cells, as our recent study clearly documented<sup>[14]</sup>. Interestingly, in many cases of occult infection, HCV RNA expression was found to be higher in cells treated with a cocktail of mitogens, which simultaneously stimulated different immune cell types, compared to those treated with single mitogens<sup>[13,27]</sup>. This implied that within a given individual, different immune cell subsets may be infected with HCV. Indeed, this observation was unequivocally confirmed in our most recent study<sup>[14]</sup> in which different affinity-purified immune cell types, e.g. CD4<sup>+</sup> and CD8<sup>+</sup> T lymphocytes, B cells and monocytes, were found to be infected to a varying extent in different individuals. We have also established that HCV infection can be confined to a specific immune cell subtype, as evidenced by the presence of replicating HCV in affinity-purified cell types but not in total PBMC. This finding highlights the need to screen individual immune cell populations, in addition to PBMC, for possible HCV presence before occult infection can be irrefutably excluded.

The use of clonal sequencing and highly sensitive single-stranded conformational analysis (SSCP), which allows for identification of even single nucleotide polymorphisms, has enabled the identification of HCV variants which appeared unique to immune cells. For example, sequence polymorphisms located at the IRES of the 5'-UTR and the hypervariable region (HVR) of the second envelope glycoprotein (E2) were observed in lymphoid cells of individuals with occult persistent HCV infection<sup>[10,12-14,28]</sup>. The fact that these variants were different from those found in the serum or liver obtained in parallel further strengthened the notion of HCV lymphotropism<sup>[10,12-14]</sup>. Additional support for the inherent propensity of HCV to infect and propagate in cells of the immune system came from *in vitro* studies documenting that certain substitutions found in individuals with occult HCV infection<sup>[10,12,14]</sup> were identical to those that emerged from wild-type HCV passaged through untransformed T cell and lymphoblastoid cell cultures<sup>[29,30]</sup>.

## POTENTIAL CLINICAL CONSEQUENCES OF OCCULT HCV INFECTION

As of now, clinical data pertinent to the clinical significance of occult HCV persistence are still in its infancy. However, it is hypothesized that persistent HCV replication in hepatocytes and lymphoid cells would likely lead to continuous antigenic stimulation of the immune system in immunocompetent patients, which in turn, allows the host to keep this silent infection under relative control. This concept has been supported by demonstration of sustained HCV-specific T cell cytotoxic and proliferative responses in patients years after recovery from hepatitis C<sup>[31-33]</sup>. Similarly, T cell responses to HCV antigens were also evident in patients with persistently elevated liver enzymes of unknown etiology who were HCV RNA reactive in both lymphoid cells and the liver<sup>[34]</sup>. On the other hand, such prolonged HCV replication associated with the continuous presentation of HCV antigens by infected B cells and monocytes may contribute to the

immune tolerance of HCV, hence, favouring even further virus persistence. At present, it remains unknown whether and how infection of the immune cells by HCV may alter their functions, although impairment in the allostimulatory capacity of HCV-infected dendritic cells derived from patients with CHC has been reported<sup>[35]</sup>.

In certain scenarios, including immunosuppression, immunomodulatory therapy or co-infection, instead of eliciting desirable T cell responses in the host, persistent replicating HCV could represent a potential source for virus reactivation, as it has been shown in other viruses, including hepatitis B virus<sup>[8]</sup> and human herpesvirus 6<sup>[36]</sup>. In this regard, corticosteroid-induced immunosuppression has been shown to affect HCV reactivation years after spontaneous resolution of acute hepatitis C<sup>[37]</sup>. Along this line, recurrent HCV infection has been reported in liver transplant recipients who were deemed free of HCV RNA at the time of transplantation, as evidenced by negativity of HCV RNA in serum and the explanted liver tissue assessed by Cobas Amplicor assay with a sensitivity of 50 copies/mL<sup>[38]</sup>. Furthermore, HCV replication was found to be frequent among patients positive for antibodies to HCV (anti-HCV) who received HCV-negative kidney<sup>[39]</sup>. In this study, HCV became detectable around 30 d with the viremia peaking on d 62 post-transplantation. Similarly, approximately 18% of bone marrow recipients who were HCV seropositive prior to transplantation became reactive to HCV RNA after receiving a transplant from an apparently HCV-negative donor<sup>[40]</sup>.

## CONCLUDING REMARKS

The availability of research assays capable of detecting HCV RNA at sensitivities superior to those offered by clinical assays significantly contributed to the recent discovery of occult HCV infection in individuals years after having been clinically deemed to have cleared the virus. Interestingly, when HCV reactivity in both plasma/serum and peripheral lymphomononuclear cells is taken into consideration, nearly all individuals with apparent complete resolution of hepatitis C can be found to carry low levels of HCV RNA. The fact that the HCV RNA replicative strand and viral proteins are detectable in immune cells, as well as that certain HCV variants are unique to immune cells, lends strong support to the existence of an extrahepatic compartment of HCV replication. Overall, the data accumulated in recent years highlight not only the need for development and implementation of more sensitive HCV RNA diagnostic assays but also the importance of screening both serum and peripheral immune cells for HCV RNA<sup>[8]</sup>. At present, the data pertinent to pathogenic and epidemiological consequences of occult HCV infection remain very sparse. Further research in this area is of significant clinical relevance in which, as works from our and other groups have shown, an involvement of the infected immune system should not be neglected.

### Abstract

*Clostridium difficile* (CD), specifically its toxins, have been implicated as a risk factor for exacerbation of the inflammatory process in up to 5% of patients with ulcerative colitis or Crohn's disease. Typical evidence of colonic changes with CD infection, including pseudomembranous exudate, are often not present; however, a severe clinical course may result, including precipitation of toxic colitis and toxic megacolon. Recently, hypervirulent CD strains have been reported raising concern for a more severe disease process in patients with underlying inflammatory bowel disease. Moreover, small bowel involvement or CD enteritis has been increasingly described, usually in those with a history of a prior colectomy or total proctocolectomy for prior severe and extensive inflammatory bowel disease. Finally, refractory or treatment-resistant pouchitis may occur with CD infection.

### INTRODUCTION

Considerable information has emerged on the intriguing relationship between the intestinal luminal microflora and the pathogenesis of inflammatory bowel disease<sup>[1]</sup>. While not believed to play an etiologic role, one particular organism, *Clostridium difficile* (CD) has become increasingly recognized as a risk factor for exacerbation of the inflammatory process in ulcerative colitis or Crohn's colitis<sup>[2]</sup>. In recent years, there has also been a marked increase in the apparent severity of disease associated with CD per se, especially with a hypervirulent strain (e.g. B1/NAP1/027) that exhibits fluoroquinolone resistance and has been detected in spite of metronidazole treatment. There have also been reports showing increased mortality and more complex CD disease with this hypervirulent strain, initially in Quebec, an eastern province of Canada, and later from other centers in North America and Europe<sup>[3-5]</sup>.

### CD TOXINS AND CD DISEASE

After 1977, evidence rapidly accumulated to show that toxins produced by the microbial agent, CD, rather than the organism, were responsible for significant and sometimes severe inflammatory changes in the colon, particularly pseudomembranous colitis. This usually occurred after antibiotic use that was thought to alter the normal intestinal microflora so that CD could colonize the intestine. Larson *et al*<sup>[6]</sup> made the initial observation during attempts to isolate a virus from stool of a 12-year-old female with penicillin-associated pseudomembranous colitis. Diluted fecal ultrafiltrates were toxic to tissue-cultured cells; however, this effect was not due to a viral agent. In addition, toxin concentration decreased with improved clinical status. Others examined clindamycin-induced cecitis in a hamster model and showed that vancomycin was protective, further implicating a bacterial cause<sup>[7]</sup>. Rifkin *et al*<sup>[8]</sup> showed that stool toxin from patients with the disease could be specifically neutralized in tissue culture by antitoxin. Later, toxigenic CD was cultured from fecal material of patients with antibiotic-associated pseudomembranous colitis and CD toxin was also neutralized by antitoxin.

CD causes diarrhea, often watery, rather than bloody, developing within 48 to 72 h after infection. In some, symptoms may be delayed for 2 to 3 mo, usually after an

antimicrobial agent had been administered. In some, only a single antibiotic tablet may lead to severe disease. Over time, the clinical spectrum has become better appreciated with illness severity noted to be broad ranging from an asymptomatic carrier state (without detectable toxin) to severe and life-threatening pseudomembranous colitis with toxic megacolon<sup>[2]</sup>. In others, persistent symptoms or recurrent bouts of disease develop, in part, likely reflecting the capability of the CD organism to form spores.

CD produces at least two distinct toxins<sup>[9]</sup>. These have been labeled toxin A and toxin B. Although initially thought to have distinctive actions, both now appear to be cytotoxic and enteropathic. These disrupt the actin cytoskeleton of intestinal epithelial cells by uridine diphosphate-glucose dependent glycosylation of Rho and Ras proteins<sup>[10]</sup>. Other toxins have been described, but their significance is not clear<sup>[11,12]</sup>. The most widely used laboratory assays for CD involve toxin A and/or toxin B detection and both are usually detected if diarrhea is present. Atypical toxin variant strains that may cause symptoms have also been described from Asia<sup>[13]</sup>. So far, there is no widely available clinical detection method for hypervirulent strains. Treatment for hypervirulent CD strains, however, appears to be no different from other CD infections, including oral vancomycin<sup>[14]</sup>. Recent evidence suggests that PCR (rather than the widely used ELISA assays) may not only permit detection of toxins, but also identify virulent strains, including epidemic strains<sup>[14]</sup>.

## CD AND INFLAMMATORY BOWEL DISEASE

CD toxin was later detected in patients with inflammatory bowel disease, especially with symptomatic relapse<sup>[15-23]</sup>. In some, no prior antibiotic administration was recorded and symptoms responded to vancomycin. Previously, some “relapses” may have been assumed to be due to “disease activity” of the underlying inflammatory bowel disease. Some thought that drugs used in medical treatment (e.g. sulfasalazine) might alter the intestinal flora and promote CD colonization<sup>[20]</sup>. Others theorized that altered immune status, possibly related to therapeutic agents, or nutritional status might be important. Pseudomembranous exudates were not always present with underlying colitis<sup>[15,17]</sup>. Also, CD toxin was detected in ileostomy fluid with symptomatically increased ileostomy output; this resolved with vancomycin. This finding suggested that CD, under special circumstances, might be able to cause small bowel as well as colonic disease<sup>[15]</sup>. Another report described toxic megacolon with CD toxin in two patients that resolved with metronidazole<sup>[23]</sup>. In both, underlying inflammatory bowel disease was noted, including Crohn’s colitis and ulcerative colitis. Thus, early recognition of CD in those with known colitis might permit antibiotic treatment and reversal of toxic megacolon.

More recent investigations have confirmed and extended these early reports<sup>[24,25]</sup>. CD was the most common infecting organism in hospitalized patients with inflammatory bowel disease, recently estimated to occur in up to 5% of patients<sup>[25]</sup>. Their numbers also appear to be increasing and account for a large proportion of all

patients in hospital with CD infections<sup>[24,25]</sup>. This may be due to several factors<sup>[2]</sup>: first, increased awareness of the need to test for CD toxins, particularly soon after hospital admission as many CD infections in colitis patients are community acquired; second, increased detection, due to the sensitivity of modern toxin tests; third, many hospitalized patients (including those with Crohn’s or ulcerative colitis) may have other co-morbidities or reduced resistance to infection; and finally, increased use of proton pump inhibitors, antibiotics and immune modulators may also alter the normal intestinal microbial flora.

Reports have also noted the occurrence of CD enteritis usually with colitis, but very rarely as an independent small intestinal infection in the absence of colitis<sup>[26-32]</sup>. In the latter, this usually occurs after substantive colon resections, often for underlying severe and extensive colitis<sup>[28]</sup>. This is not entirely surprising since prior autopsy studies and cultures of jejunal aspirates have suggested that the small bowel per se may be a reservoir for CD<sup>[33,34]</sup>. Most often, these have been identified in elderly patients and pseudomembranous enterocolitis was found<sup>[32]</sup>. Most patients had prior gastrointestinal surgery, especially colonic resections, and usually these were patients that had a colectomy or total proctocolectomy for severe ulcerative colitis. Often, the CD infection occurred soon after colectomy, but in some, the colon resection was done even years earlier<sup>[32]</sup>. In most, a severe, often fatal, clinical course was initially noted<sup>[32]</sup>, although this may now be reduced<sup>[35]</sup>.

The pathogenesis has not been precisely defined. Most had prior use of broad spectrum antibiotics. As CD usually affects the colon, the factors that predispose to small bowel disease are not known. Changes in the small intestinal flora after colectomy may lead to development of a small intestinal environment similar to the colon, susceptible to CD overgrowth following antibiotic usage. Some have shown the colonic-type bacteria grow rapidly in the distal small bowel after ileocolonic resection<sup>[36]</sup>. Others have reported that the phenotypic histological changes develop in distal ileum so that colonic epithelial characteristics are seen<sup>[37]</sup>. CD toxin has also been detected in patients that have undergone pelvic pouch reconstruction<sup>[38-40]</sup>. In these, pouchitis or refractory pouchitis may be present.

## CONCLUSION

The diagnosis of CD-related disease with a positive toxin assay as a cause for new or worsening symptoms in patients with underlying inflammatory bowel disease is significant as it may lead to antibiotic treatment that entirely reverses the exacerbation of clinical symptoms. Usually, disease affects the colon, but, interestingly, in patients with underlying Crohn’s colitis or ulcerative colitis, pseudomembranous changes may not occur. In addition, the ileal mucosa may be at increased risk for inflammatory disease in a specific subset of patients that have undergone a prior colectomy. As a result, CD enteritis may result, possibly because the residual ileum has developed phenotypic features of the colonic luminal environment or the colonic mucosa per se. Similarly, chronic or refractory pouchitis may result from CD toxin after colectomy due

to CD colonization of the proximal small bowel, pouch mucosa or the residual rectal cuff mucosa. In these pouch patients, CD treatment may resolve the pouchitis.

## Abstract

Hepatocellular carcinoma (HCC) is one of the most common malignancies worldwide, including Japan. Although the development of imaging modalities has made the early diagnosis of HCC possible, surgically resectable cases are relatively uncommon because of hepatic function reserve and/or an advanced stage at presentation. Several modalities, such as transcatheter arterial chemoembolization, percutaneous ethanol injection, microwave coagulation therapy and radiofrequency ablation are reportedly useful in treating patients with non-resectable disease. However, unfortunately, many HCC patients have tumor recurrence. The overall prognosis of patients with HCC is very poor, and treatment of the advanced form is still problematic. In this article, we review the clinical efficacy and toxicity of enteric-coated tegafur/uracil in the treatment of patients with advanced non-resectable HCC.

## INTRODUCTION

Chronic liver disease predisposes patients to hepatocellular

carcinoma (HCC), therefore, a high-risk group can be identified<sup>[1]</sup>. Progress in diagnostic imaging studies has facilitated the relatively early diagnosis of HCC. In many patients, however, the disease is already advanced at the time of detection. Patients with recurrence after local treatment and those with far-advanced HCC should receive effective systemic chemotherapy. In this review, we outline the mechanism of action and outcomes of enteric-coated tegafur/uracil (UFT-E Taiho Pharmaceutical, Co. Ltd., Tokyo, Japan) used as systemic chemotherapy in patients with HCC.

## DEVELOPMENT OF UFT

Heidelberger *et al*<sup>[2]</sup> synthesized 5-fluorouracil in 1957. Since that time, fluoropyrimidine antimetabolites have been used as broad-spectrum anticancer drugs to treat various types of tumors. However, the serum half-life of 5-fluorouracil is very short (8-12 min)<sup>[3,4]</sup>. Therefore, many derivatives have been developed to maintain high serum concentrations of 5-fluorouracil, enhance response, and reduce toxicity. In 1968, Hiller *et al*<sup>[5]</sup> synthesized tegafur, a prodrug of 5-fluorouracil, which is gradually converted to 5-fluorouracil by cytochrome P450 2A6. Subsequently, UFT was developed to enhance the tumor specificity and effectiveness of 5-fluorouracil. In 1978, Fujii *et al*<sup>[6]</sup> conducted a series of experiments on combination therapy with fluoropyrimidines and pyrimidines and reported that the antitumor activity of tegafur was most strongly enhanced by uracil. They also found that combinations of tegafur and uracil in certain ratios enhanced the antitumor activity of tegafur, without increasing toxicity. A combination of tegafur and uracil in a molar ratio of 1:4 was experimentally shown to be optimal.

These findings led to the development of UFT. This preparation produces and maintains high concentrations of 5-fluorouracil and its active metabolites in tumors, and has specific characteristics not obtained with tegafur or 5-fluorouracil alone. In some patients, however, the conventional formulation of UFT capsules is associated with adverse upper gastrointestinal effects such as loss of appetite, nausea and vomiting, and requires dose reduction or treatment withdrawal. To reduce such adverse effects, UFT-E was developed from 1987 to 1988. Subsequently, the therapeutic usefulness of UFT-E has been confirmed in clinical studies<sup>[7,8]</sup>. In 1990, a new drug application was submitted. UFT-E was approved in 1992 and is now widely used.

Figure 1 Mechanism of action of UFT.

## MECHANISM OF ACTION OF UFT

The mechanism of action of UFT is shown in Figures 1 and 2. The anticancer activity of UFT is derived from 5-fluorouracil, to which tegafur is gradually converted. As for the mechanism of action of 5-fluorouracil, 5-fluoro-2'-deoxyuridine 5'-monophosphate (FdUMP), the active metabolite of 5-fluorouracil, competes with 2'-deoxyuridine 5'-monophosphate (dUMP) and inhibits thymidylate synthase, thereby blocking DNA synthesis. 5-fluorouridine 5'-triphosphate (FUTP) is incorporated into RNA, which disrupts RNA function (*in vitro*)<sup>[9,10]</sup>. The antitumor activity of 5-fluorouracil depends mainly on inhibition of DNA synthesis. 5-fluorouracil is a time-dependent anticancer drug; therefore, prolonged exposure of cancer cells to even low concentrations of 5-fluorouracil results in antitumor activity. Dihydropyrimidine dehydrogenase (DPD), the main metabolizing enzyme of 5-fluorouracil, is present throughout the body, including the liver, epithelium of the gastrointestinal tract, and peripheral leukocytes, but is most abundant in the liver<sup>[11]</sup>. After intravenous administration, > 90% of the dose of 5-fluorouracil is metabolized during the first pass through the liver<sup>[12]</sup>. Tumors contain DPD, which metabolizes 70% of the 5-fluorouracil that enters tumor tissue. Therefore, outcomes of 5-fluorouracil monotherapy in patients with HCC are poor. On the other hand, uracil is a pyrimidine-based analogue, a component of nucleic acids. Uracil alone has no appreciable antitumor activity or toxicity, but has a high affinity for DPD in the liver and tumors, thereby inhibiting DPD and preventing the metabolism of 5-fluorouracil. This mechanism provides the theoretical basis for UFT, a combination of uracil and tegafur that produces prolonged concentrations of 5-fluorouracil in serum, thereby enhancing antitumor activity against HCC and reducing toxicity<sup>[13]</sup>. Previous studies have reported that  $\gamma$ -hydroxy butyrate (GHB), the metabolite of the protecting group of tegafur,  $\gamma$ -butyrolactone (GBL), and high-dose tegafur inhibit neovascularization<sup>[14]</sup>. UFT-E is thus expected to be effective against HCC.

## REGIMENS OF UFT

Recent controlled studies have reported the usefulness of postoperative adjuvant chemotherapy with UFT, given continuously in a high daily dose (400 mg/m<sup>2</sup>) for 1-2 years.

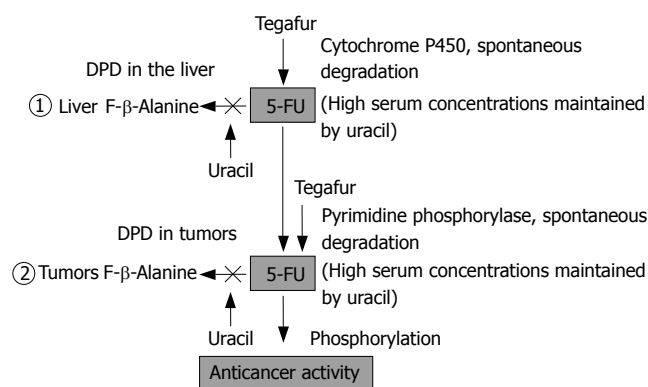

Figure 2 Biochemical modulation of UFT.

In a representative study of patients with resected rectal cancer, the 3-year recurrence-free survival rate was 78% in patients who received postoperative adjuvant chemotherapy with UFT (400 mg/m<sup>2</sup> per day) for 1 year, and 60% in those who underwent surgery alone. The 3-year survival rate was 91% in the UFT group and 81% in the surgery alone group. The rates of recurrence-free and overall survival were significantly improved by postoperative adjuvant chemotherapy with UFT<sup>[15]</sup>. In this study, because UFT was given at a high dose of 400 mg/m<sup>2</sup> per day (in two divided doses), adequate concentrations of 5-fluorouracil in serum might have been maintained, which inhibited the growth of small amounts of residual tumor cells. Severe myelosuppression and gastrointestinal disorders associated with 5-fluorouracil were rare. This was attributed to the fact bone marrow cells and gastrointestinal mucosal cells were rescued by treatment with UFT, given for five consecutive days followed by two days rest. However, in patients with HCC, long-term treatment with oral anticancer drugs may negatively affect liver function as a side effect because of underlying chronic liver disease. Oral anticancer drugs should thus be administered cautiously. The next section describes the use of a reduced dose of UFT-E, equivalent to two-thirds to less than half of the usual dose, in patients with HCC.

## TREATMENT OF HCC WITH UFT-E

### Effectiveness of UFT-E for stage IVA HCC

We have previously described our own experience with a patient who had stage IVA HCC, in whom all tumors disappeared after monotherapy with UFT-E, with no evidence of recurrence<sup>[16]</sup>. Subsequently, we assessed the usefulness of monotherapy with UFT-E in 28 patients with stage IVA HCC who could not undergo hepatectomy, interventional radiology, or intra-arterial infusion chemotherapy<sup>[17]</sup>. In a study that compared patients who received UFT-E with those who did not, the survival rate was significantly higher in the UFT-E group (Figure 3). Moreover, survival was significantly longer in the UFT-E group than in the untreated group among patients who had a complete or partial response, as well as among those with no change or progressive disease (Figure 4)<sup>[17]</sup>.

**Figure 3** Cumulative survival rates in patients with stage IVA HCC who received UFT-E and those who did not.

**Figure 4** Cumulative survival rates in patients with stage IVA hepatocellular carcinoma according to response to treatment. CR: Complete response; PR: Partial response; NC: No change; PD: Progressive disease.

Although patients with clinical disease progression tended to have poor outcome, multivariate analysis showed that treatment with UFT-E contributes to improved survival, which indicates UFT-E is effective (Table 1)<sup>[17]</sup>. These results indicate administration of UFT-E improves the survival time by inducing a cytostatic phase, rather than by tumor reduction<sup>[18]</sup>.

### Effectiveness of UFT-E for far-advanced HCC

**HCC with portal vein tumor thrombosis (PVTT):** We have previously reported that UFT-E is therapeutically useful in patients with stage IVA HCC<sup>[16,17]</sup>. However, in patients with advanced HCC accompanied by PVTT, outcome is extremely poor, and UFT-E monotherapy is apparently not beneficial. Combination therapy with UFT-E has, therefore, been tried. Recently, Kusunoki *et al*<sup>[19,20]</sup> have reported that pharmacokinetic modulating chemotherapy, based on the concept that the benefit of continuous venous 5-fluorouracil infusion can be potentiated by low-dose oral UFT, is useful for a variety of cancers.

We have previously reported on patients with various types of cancer who had a complete response to pharmacokinetic modulating chemotherapy with UFT-E and continuous intravenous infusion of 5-fluorouracil<sup>[21-27]</sup>.

**Table 1** Multivariate analysis of prognostic factors in patients with stage IVA hepatocellular carcinoma

Variable	No. of patients	Risk ratio	95% CI	P value

NS: Not significant.

Such regimens have recently been used to increase tissue 5-fluorouracil concentrations in patients with advanced gastric cancer or colorectal cancer. We, therefore, modified the regimen for intra-arterial infusion chemotherapy with epirubicin, etoposide, and cisplatin (EEP therapy) described by Takayasu *et al*<sup>[28]</sup> to treat HCC patients with PVTT. Our modified EEP regimen consisted of intra-arterial infusion chemotherapy with epirubicin (30 mg), carboplatin (200 mg), and etoposide (60 mg), given once weekly, followed by a 24-h infusion of 5-fluorouracil (500 mg) as standard therapy, plus continuous treatment with UFT-E (200 mg/d). We have previously described a patient with UFT-E who had a complete response to this regimen. We then studied outcomes in several similar patients. Despite PVTT, all patients could receive chemotherapy on an outpatient basis. The mean survival from the beginning of intra-arterial infusion chemotherapy, excluding the period of previous treatment, was 457.2 d (Figure 5). Further studies are needed to determine the optimal dosage and treatment intervals. However, preliminary evidence indicates modified EEP therapy, including oral anticancer treatment with UFT-E, might be a useful treatment strategy for advanced HCC accompanied by PVTT (Vp3, Vp4)<sup>[29]</sup>.

**Effectiveness of UFT-E against stage IVB HCC with extrahepatic metastasis:** Systemic chemotherapy is usually given to patients who have HCC with extrahepatic metastasis. However, drug recommendations based on

**Figure 5** Cumulative survival rates in patients with tumor occlusion of the portal vein who received modified EEP therapy.

scientific evidence are currently not available. Although the effectiveness of UFT-E has been confirmed in patients with stage IVA HCC, monotherapy with UFT-E does not improve outcome in patients who have stage IVB disease with distant metastasis, usually an indication for systemic chemotherapy. We have previously reported a case of HCC with multiple lung metastases that had a complete response to combination therapy with UFT-E plus docetaxel/cisplatin<sup>[30]</sup>. At present, additional patients with distant metastasis are being studied. Long-term studies of larger numbers of patients are needed to assess the clinical significance of combination therapy including oral anticancer drugs.

## TOXIC EFFECTS OF UFT

Toxic effects of UFT include severe liver dysfunction and diarrhea. Leukoencephalopathy has been reported as a neurological effect, and pigmentation as a skin symptom. Loss of appetite, nausea and vomiting commonly occur in clinical practice. These adverse signs and symptoms may require a reduction in the dose of UFT or even the cessation of treatment in some patients<sup>[31]</sup>. In a study that compared the incidence of toxicity between UFT capsules and UFT-E granules, which were developed to reduce upper gastrointestinal symptoms and thereby improve compliance, patients who received UFT-E granules had a lower incidence of adverse upper gastrointestinal symptoms<sup>[31]</sup>. Grade 1 stomatitis developed in three patients with stage IVA HCC who received monotherapy with UFT-E. However, hepatic function reserve was undisturbed. Monotherapy with UFT-E thus contributed to an improved quality of life. Ikeda *et al*<sup>[32]</sup> conducted a controlled study to compare outcome between patients who received UFT-E adjuvant chemotherapy before transcatheter arterial embolization and those who did not. Outcomes did not significantly differ between the groups, but ascites and hepatic encephalopathy developed in the UFT-E group. However, in our studies, no patient had UFT-E-induced liver failure. In patients with tumor occlusion of the portal vein, who received combination chemotherapy, toxic effects such as stomatitis and leukopenia developed, but treatment could be continued after a rest period.

## CONCLUSION

The effectiveness of UFT-E should be evaluated at different stages of HCC. At the same time, different dosages and treatment with UFT-E regimens, including rest periods, should be assessed, rather than administering anticancer drugs continuously. Unlike other types of cancer, HCC is usually associated with cirrhosis. Long-term treatment with anticancer drugs may therefore adversely affect liver function. Further studies are needed to determine optimal regimens, doses, and treatment periods for anticancer drugs. Other clinical questions, such as whether systemic chemotherapy with UFT-E is an effective adjuvant therapy after liver transplantation, remain to be answered.

### Abstract

**AIM:** To explore the correlation between the mRNAs and protein expression of gastrin (GAS), somatostatin (SS) and apoptosis index (AI), apoptosis regulation gene Fas/FasL and caspases in large intestinal carcinoma (LIC).

**METHODS:** Expression of GAS and SS mRNAs were detected by nested RT-PCR in 79 cases of LIC. Cell apoptosis was detected by molecular biology *in situ* apoptosis detecting methods (TUNEL). Immunohistochemical staining for GAS, SS, Fas/FasL, caspase-3 and caspase-8 was performed according to the standard streptavidin-biotin-peroxidase (S-P) method.

**RESULTS:** There was a significant positive correlation between mRNA and protein expression of GAS and SS ( $r_s^{\text{GAS}}=0.99, P < 0.01$ ;  $r_s^{\text{SS}}=0.98, P < 0.01$ ). There was significant difference in positive expression rates of GAS, SS mRNAs and protein among different histological differentiation, histological types and Dukes' stage of LIC. The AI in GAS high and moderate expression groups was significantly lower than that in low expression groups ( $3.75 \pm 2.38$  vs  $7.82 \pm 2.38, P < 0.01$ ;  $5.51 \pm 2.66$  vs  $7.82 \pm 2.38, P < 0.01$ ), and the AI in SS high and moderate expression groups was significantly higher than that in low expression groups ( $9.03 \pm 1.76$  vs  $5.35 \pm 3.00, P < 0.01$ ;  $7.44 \pm 2.67$  vs  $5.35 \pm 3.00, P < 0.01$ ). There was a significant negative correlation between the integral ratio of GAS to SS and the AI ( $r_s = -0.41, P < 0.01$ ). The positive expression rate of FasL in GAS high and moderate expression groups was higher than that

in low expression group (90.9% and 81.0% vs 53.2%,  $P < 0.05$ ). The positive expression rates of Fas, caspase-8 and caspase-3 in SS high (90.0%, 90.0% and 100%) and moderate (80.0%, 70.0%, 75.0%) expression groups were higher than that in low expression group (53.1%, 42.9%, 49.0%) (90.0% and 80.0% vs 53.1%,  $P < 0.05$ ; 90.0% and 70.0% vs 42.9%,  $P < 0.05$ ; 100.0% and 75.0% vs 49.0%,  $P < 0.05$ ). There was a significant positive correlation between the integral ratio of GAS to SS and the semiquantitative integral of FasL ( $r_s = 0.32, P < 0.01$ ).

**CONCLUSION:** GAS and SS play important roles in the regulation and control of cell apoptosis in LIC, and the mechanism may be directly related to the aberrant expression of Fas/FasL. The GAS and SS will be valuable targets of the biological behavior of LIC.

### INTRODUCTION

Large intestinal cancer (LIC) is one of the most common digestive tract malignant tumors in the world, with a high incidence rate in North America, Western Europe, Australia, New Zealand and France, and is the second leading cause of gastrointestinal cancer-related mortality worldwide<sup>[1-4]</sup>. In China, it now ranks fourth<sup>[5]</sup>. Although great progress in understanding the molecular aspects of LIC has been made and several therapeutic agents have been developed, it is still difficult to cure the tumor. It is posing a serious threat to public health and remains a major killer among Chinese patients. The general survival rate

of LIC patients does not exceed 40%. Thereby, it is very important to know what kind of cell factor can influence cell apoptosis, which will enrich the etiology theory of tumor. In addition, while studying the mechanism of loss of control of tumor cell apoptosis from signal transduction pathway, we may find a new way to treat malignant tumors. Previous studies have demonstrated that the occurrence of LIC is directly related to the abnormal expression of gastrointestinal hormones such as gastrin (GAS), somatostatin (SS), *etc*<sup>[6,7]</sup>. Some studies found that GAS was able to promote growth and inhibit apoptosis of LIC cells, but the role of SS was opposite<sup>[8-10]</sup>. However, the detailed molecule mechanism by which GAS and SS mediate cell apoptosis of LIC is not fully known. We used nested RT-PCR method to detect the expression of GAS and SS mRNAs in LIC tissues, and TUNEL method to detect cell apoptosis, and immunohistochemical staining S-P method to detect the protein expression of GAS, SS, Fas/FasL, caspase-3 and caspase-8. The aim of this study was to explore the correlation between the mRNAs and protein expression of GAS and SS, and between the protein expression of GAS, SS and apoptosis index (AI), and apoptosis regulation gene Fas/FasL and caspases in LIC, and to further confirm whether GAS and SS could mediate LIC cell apoptosis mainly via affecting the expression of Fas/FasL.

## MATERIALS AND METHODS

### Clinical data

Seventy-nine cases of cancer tissue samples were randomly and retrospectively selected from patients with LIC hospitalized in our hospital from January 2004 to October 2006. All patients were confirmed as having LIC by clinical pathology. Among them, 36 were cases of rectum cancer, and 43 were cases of colorectal carcinoma. Thirty-seven were females and 42 were males. The median age was  $50.8 \pm 11.2$  years, with a range of 21-79 years. There were 27 patients with well differentiated carcinoma, 28 patients with moderately differentiated carcinoma, and 24 patients with poorly differentiated carcinoma (inclusive of undifferentiated carcinoma). Among them, there were 40 cases of ulcerative type, 32 protruded type, 7 infiltrating type, 19 papillary adenocarcinoma, 35 glandular adenocarcinoma, 10 mucoid carcinoma, 6 signet-ring cell carcinoma and 9 undifferentiated carcinoma. The clinical stage was determined according to the Dukes' stage. Dukes' stages A and B were found in 36 patients, and stages C and D in 43 patients.

### Main reagents

The polyclonal rabbit antibodies against human SS protein and human GAS, monoclonal rabbit antibodies against human Fas and FasL, caspase-3, caspase-8, and immunohistochemical staining kit and *in situ* cell apoptosis detection kit II were all purchased from Beijing Zhongshan Biological Technology Co, Ltd. Trizol liquid, M-MLV reverse transcriptase, SK312, Taq DNA polymerase, RNasin, oligo (dT) 15 and dNTPs primers were purchased from Shanghai Sangon Biological Engineering Technology

and Service Co. Ltd and PCR primers were synthesized by the same company.

### Total RNA extraction and cDNA synthesis

Total RNA was extracted from frozen tissue specimens (50-100 mg) using TRIzol reagent according to the protocol provided by the manufacturer. Total RNA was primed with an Oligo (dT) 15 oligonucleotide and reverse-transcribed following the manufacturer's instructions.

### PCR amplification

The primers of GAS, SS and  $\beta$ -actin were synthesized according to the primer design principles, all primers spanned an intron to control against amplification of genomic DNA sequences. Two point five  $\mu$ L first strand cDNA was amplified in 25  $\mu$ L total volume. The first PCR amplifications were performed in a UNO II thermocycler (Perkin-Elmer, USA) under the following conditions. After an initial denaturation for 5 min at 94°C, samples were subjected to 30 cycles, each amplification consisting of denaturation at 94°C for 30 s, primer annealing at 60°C for 45 s, extension at 72°C for 45 s, followed by a final extension of 6 min 72°C. Conditions and parameters of the second PCR amplifications were the same with the first PCR amplifications except for primers. The length of final PCR products was 174 base pair (bp) (GAS) and 231 bp (SS), respectively. At last, 6  $\mu$ L of reaction product was analyzed by electrophoresis on a 1.5% agarose gel followed by ethidium bromide staining and digital camera photography (Table 1, Figure 1).

### Detection of cell apoptosis

Cell apoptosis was detected using molecular biology *in situ* apoptosis detecting methods (TUNEL). The sections were fixed and embedded conventionally. Dnase (1 mg/L) was used to digest the positive control specimen for 10 min before put into TUNEL response mixture. Only label liquor was added into the negative control response mixture. The detailed manipulation was conducted according to the introductions for users. Cells with brown or yellow nuclei were assumed as apoptotic cells. The number of apoptotic cells and total cancer cells was counted under light microscope at  $400 \times$  magnification in 10 fields of vision and the average values were obtained for the calculation of apoptosis index (AI) according to the formula:  $AI = (\text{apoptotic cells} / \text{total cancer cells}) \times 100\%$ .

### Immunohistochemical staining

Specimens obtained at surgery were routinely fixed in 10% neutral formalin and embedded in paraffin. Serial 4  $\mu$ m thick sections were cut. Immunohistochemical staining for Fas, FasL, caspase-3, caspase-8, GAS and SS was performed by the standard streptavidin-biotin-peroxidase (S-P) method. Positive pancreatic tissue and stomach antrum mucous membrane were used as a positive control for SS and GAS. Positive controls for Fas, FasL, caspase-3 and caspase-8 were purchased from Shanghai Sangon Biological Engineering Technology and Service Co. Ltd. PBS 0.01 mol/L as a negative control replaced the primary antibody. The detailed

Table 1 Primers used for nested RT-PCR amplification of GAS and SS

manipulation of S-P immunohistochemical method was used according to its manual.

### Evaluation of scores

Brown-yellow staining mainly in cell plasma, partly in cell membranes was considered positive SS and GAS protein expression. When SS and GAS protein expression was scored, both the extent and intensity of immunopositivity were considered. The intensity of staining was scored as follows: 0, no staining; 1, weak-yellow; 2, brown-yellow; and 3, brown-black. The extent of positive cells was scored as follows (100 cells were counted by two independent observers, who did not know the clinicopathological features of these LIC): 1, positive staining cells < 5%; 2, positive staining cells in 5%-10%; 3, positive staining cells in 10%-20%; and 4, positive staining cells > 20%. The final score was determined by multiplying the intensity and extent of positivity scores, yielding a range from 1 to 12. According to the semi-quantitative integral evaluation, SS and GAS were divided into three groups: Scores 1-3 was defined as the low expression group, 4-6 as the moderate expression group, and 7-12 as the high expression group (Figure 2A and B).

The positive Fas and FasL protein expression was defined with brown-yellow staining mainly in cell membranes, or cell plasma, while positive caspase-3 and caspase-8 protein expression was defined with brown-yellow staining mainly in cell plasma. The degree of Fas, FasL, caspase-3 and caspase-8 staining was estimated by semi-quantitative evaluation and

categorized by the extent and intensity of staining<sup>[11]</sup>. The intensity of staining was scored as: 0, negative; 1, weak-yellow; 2, brown-yellow; and 3, brown-black. The extent of positive cells was scored as: 0 = positive staining cells in 0%-5%, 1 = positive staining cells in 6%-25%, 2 = positive staining cells in 26%-50%, 3 = positive staining cells in 51%-75%, and 4 = positive staining cells > 75%. Combined staining score was used to evaluate the results of Fas, FasL, caspase-3 and caspase-8 staining. The final score was determined by adding the intensity and extent of staining scores, yielding a range from 0 to 7. Scores 1-2 were defined as negative expression (-), 3 as weak staining (+), 4 as moderately staining (++), and  $\geq 5$  as strong staining (+++) (Figure 2C-F).

### Statistical analysis

Statistical evaluation was performed using Chi-square test and  $q$  test to differentiate the positive rates of different groups, and using Spearman test to analyze the correlation between the ratio of GAS to SS and the integral of Fas, FasL, caspase-3 and caspase-8. All data were analyzed with statistical package for social science (SPSS) version 10.0.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Expression of GAS, SS mRNA and protein

The positive expression rates of GAS and SS mRNA were 46.8% (36/79), 41.8% (33/79), respectively. The positive expression rates of GAS and SS protein were 40.5% (32/79) and 38.0% (30/79), respectively. There was a significant positive correlation between mRNA and protein expression of GAS and SS ( $P < 0.01$ ,  $r_{\text{GAS}} = 0.99$ ;  $P < 0.01$ ,  $r_{\text{SS}} = 0.98$ ). There was significant difference in positive expression rates of GAS, SS mRNAs and protein among different histological differentiation, histological types and Dukes' stage of LIC, as shown in Table 2.

### Apoptosis index

The AI in GAS high and moderate expression groups was significantly lower than in low expression groups ( $q_{\text{high vs low}} = 6.71$ ,  $P < 0.01$ ;  $q_{\text{middle vs low}} = 4.60$ ,  $P < 0.01$ ), and the AI in SS high and moderate expression groups was significantly higher than in low expression groups ( $q_{\text{high vs low}} = 5.66$ ,  $P < 0.01$ ;  $q_{\text{middle vs low}} = 4.21$ ,  $P < 0.01$ ). There was a significant negative correlation between the integral ratio of GAS to SS and the AI ( $r_s = -0.41$ ,  $P < 0.01$ ) (Table 3).

**Figure 2** Strong expressions of GAS, SS, Fas, FasL, caspase-3 and caspase-8 in LIC tissues. **A:** Strong GAS expression in LIC. S-P  $\times$  400; **B:** Strong SS expression in LIC. S-P  $\times$  400; **C:** Strong Fas expression in SS high expression group. S-P  $\times$  400; **D:** Strong FasL expression in GAS high expression group of colorectal carcinoma. S-P  $\times$  400; **E:** Strong caspase-3 expression in SS high expression group. S-P  $\times$  400; **F:** Strong caspase-8 expression in SS high expression group. S-P  $\times$  400.

#### **Fas, FasL, caspase-3 and caspase-8 expression in GAS and SS high, moderate and low expression groups of LIC**

The positive expression rate of FasL in GAS high (10/11) and moderate (17/21) expression groups was higher than

that in low expression group (26/47) ( $\chi^2_{\text{high vs low}} = 6.24$ ,  $P < 0.05$ ;  $\chi^2_{\text{moderate vs low}} = 4.74$ ,  $P < 0.05$ ). There were no significant differences in positive expression rates of Fas, caspase-3 and caspase-8 among GAS high, moderate and

**Table 3** Comparison of AI in GAS and SS high, moderate and low expression groups of LIC (mean  $\pm$  SD)

Groups	<i>n</i>	AI (mean $\pm$ SD)	<i>F</i>	<i>P</i>
SS

Low	47	7.82 $\pm$ 2.38	16.08	< 0.01
Moderate	21	5.51 $\pm$ 2.66 <sup>d</sup>		
High	11	3.75 $\pm$ 2.38 <sup>d</sup>		

<sup>b</sup>*P* < 0.01 vs low SS group; <sup>d</sup>*P* < 0.01 vs low GAS group.

low expression groups (*P* > 0.05). The positive expression rates of Fas, caspase-8 and caspase-3 in SS high (9/10, 9/10 and 10/10) and moderate (16/20, 14/20 and 15/20) expression groups was higher than that in low expression group (26/49, 21/49 and 24/49) ( $\chi^2_{\text{high}}$  vs low = 5.48, 5.62 and 6.89, *P* < 0.05;  $\chi^2_{\text{middle}}$  vs low = 4.32, 4.19 and 3.91, *P* < 0.05). There was no significant difference in positive expression rate of FasL among SS high, moderate and low expression groups (*P* > 0.05) (Table 4). There was a significant positive correlation between the integral ratio of GAS to SS and the semi-quantitative integral of FasL ( $r_s = 0.32$ , *P* < 0.01). But, there was no correlation between the integral ratio of GAS to SS and Fas, caspase-3 and caspase-8 (*P* > 0.05).

## DISCUSSION

LIC arises mainly from mutations in somatic cells. However, conversion of normal to cancer cells is not the result of a single mutation. It is achieved through a multi-step process that is closely associated with the accumulation of multiple gene changes including both oncogenes and tumor suppressor genes<sup>[12-16]</sup>. Uncontrolled cell proliferation and apoptosis are the main hallmarks of LIC. Apoptosis is a unique physiological mechanism that it can not only eliminate discrete cells in normal development, host defense and maintain the body in well stable condition, also play an important role in regulating and controlling tumor occurrence, development and treatment<sup>[17,18]</sup>. Impaired apoptosis has been implicated in the development of many human diseases, including cancer. It has been proved that occurrence of cancers is due to the loss of control of normal apoptosis and the disturbance of balance between cell proliferation and apoptosis<sup>[19-21]</sup>. Two main signaling pathways initiate the apoptotic program in mammalian cells<sup>[22]</sup>. The cell-extrinsic pathway, namely, death receptor signaling pathway triggers apoptosis in response to activation by their respective ligand of the tumor necrosis factor (TNF) family of death receptors, including TNF-RI for TNF $\alpha$ , Fas or CD95 for FasL, and death receptor 4 (DR4) or 5 (DR5) for TNF-related apoptosis-inducing ligand (TRAIL). On the other hand, the cell-intrinsic pathway, namely, mitochondria signaling pathway triggers apoptosis in response to DNA damage, loss of survival factors, or other types of cell distress. Both pathways involve the activation of cysteine proteases called caspases, which

**Table 4** Comparison of positive rates of Fas, FasL, caspase-3 and caspase-8 protein in GAS and SS high, moderate and low expression groups of LIC

Groups	<i>n</i>	Fas		FasL		Caspase-3		Caspase-8		
		+	(%)	-	+	(%)	-	+	(%)	-
GAS										
High	11	7	(63.6)	4	10	(90.9) <sup>a</sup>	1	9	(81.8)	2

Low	49	26	(53.1)	23	32	(65.3)	17	24	(49.0)	25

<sup>a</sup>*P* < 0.05 vs GAS low expression group; <sup>c</sup>*P* < 0.05 vs SS low expression group.

are constitutively expressed in the cytosol as proenzymes, and are activated to mature proteases by cleavage, which triggers the activation of the caspase-8 and caspase-9, followed by the activation of caspase-3. Caspase-3 is one of the key executioners in the apoptosis pathway. Caspase-3 activation is thought to be a major step in the apoptotic signal transduction cascade that commits cells to suicide. Caspase-3 cleavage during apoptosis leads to the proteolysis of several cytosolic and nuclear proteins and precedes DNA fragmentation. However, some recent studies have shown that activation of Fas/FasL signaling pathway is regulated by many kinds of cell factors, including GAS and SS<sup>[23-25]</sup>.

Many studies have pointed out that some tissue growths are regulated by hormones, and these tissues turned into tumors are still controlled by hormones<sup>[26-28]</sup>. Gastrointestinal hormones such as GAS and SS regulate the secretion, motility, absorption, blood flow and cell nutrition of the digestive tract. Abnormality of their secretion often affected the normal functions of digestive tract, even produced clinical symptoms or syndromes<sup>[29]</sup>. Xie *et al*<sup>[30]</sup> found that the disordered gastrointestinal hormones play a crucial role in the pediatric chronic gastritis and duodenal ulcer. There seems to be an increasing tendency in the expressions of GAS and SS in children with chronic gastritis and duodenal ulcer. In recent years, some studies have demonstrated that there is a high correlation between the aberrant expressions of GAS, SS and the occurrence and development of LIC<sup>[31-33]</sup>. D'Onghia *et al*<sup>[34]</sup> found that GAS serum levels were slightly higher in patients with colorectal cancer than in healthy controls. GAS levels were higher in patients carrying left colorectal cancer than the others, and higher in early stage than in late stage. Cao *et al*<sup>[35]</sup> found that GAS 17 can increase colorectal cancer cells' invasion, the mechanism of which is probably that GAS 17 makes FAK-Tyr397 to be phosphorylated and localized to lamellipodia, causing the formation of FAK-Src-p130 (Cas)-Dock180 signaling complex when it is bound to its receptor CCK-2 and activation of Rac. In this study, we found that there was a significant positive correlation between mRNA and protein expression of GAS and SS. The positive expression rate of GAS and SS mRNA and protein varied greatly in different histological type, differentiation degree, and Dukes' stage. The higher mRNA and protein expression of GAS was, the poorer of tissue differentiation degree and clinical stages.

For example, the expression GAS in poorly differentiated LIC, in particular, in mucinous adenocarcinomas and signet-ring cell carcinoma was prominently higher than the others, with poor prognosis. However, the action of SS was opposite. The results indicate that the expressions of GAS and SS were closely related to the biological behavior of LIC. It is obvious that the GAS and SS will be valuable targets of the biological behavior of LIC.

Tumor escape mechanisms in LIC result from dysregulation of the cell apoptosis signaling pathways, which are mediated by death ligands. Recently, great progress has been made in understanding the regulated signaling pathway mechanisms of GAS and SS. Some studies showed that the abnormal expressions of GAS and SS were closely related to cell apoptosis of LIC. GAS could promote cell proliferation and inhibit cell apoptosis. However, the action of SS was opposite in LIC<sup>[36,37]</sup>. Our studies showed that the expression of GAS protein in LIC was higher and the AI was lower, and the higher expression of SS protein, the higher AI. Despite abundant evidence that GAS may play an integral role in promoting tumor growth in the stomach and malignancies in the GI tract, the precise mechanisms about gastrin-restrained, somatostatin-induced apoptosis are still largely unknown. To elucidate the mechanisms by which GAS and SS might influence apoptotic signaling pathway, we analyzed their effects on the expression of Fas, FasL, caspase-3 and caspase-8 protein in human LIC tissue.

GAS is a gastrointestinal (GI) peptide that possesses potent trophic effects on most of the normal and neoplastic mucosa of the GI tract. GAS is mainly secreted from GAS secreting cells (G cells) in the antrum mucosa or upper small intestine and large intestine. Medulla oblongata and dorsal nuclei of vagus nerves in central nervous system also secrete GAS<sup>[38,39]</sup>. Recent reports indicate that chronic hypergastrinaemia increases the risk of colorectal cancer and cancer growth, and that interruption of the effects of GAS could be a potential target in the treatment of colorectal cancer<sup>[40]</sup>. Recent data have shown that GAS is not only able to induce cell proliferation, but also inhibit LIC cell apoptosis. However, the underlying mechanisms that GAS inhibits cell apoptosis, is still worthy of further elucidation. Wu *et al.*<sup>[41]</sup> recent studies found that down-regulation of GAS gene expression results in the activation of caspase 9 and 3 in gastrin-dependent human colon cancer cells inducing cell apoptosis. Cui *et al.*<sup>[42]</sup> found that GAS can induce apoptosis in gastric epithelial cells via GAS/CCK-2 receptor and synergized with FasL stimulation and contribute to the development of gastric carcinogenesis. In this study, we found that the level of GAS protein expression was higher and the positive expression rate of FasL was higher in LIC tissues, and expression of GAS protein was not related to expression of Fas, caspase-3 and caspase-8. The results indicate that the mechanisms of GAS inhibiting LIC cell apoptosis might be *via* up-regulation of expression of FasL inducing apoptosis with Fas-expressing T cells, making LIC cells escape from immune surveillance and immunocyte attack.

SS is a multifunctional hormone, which is secreted from SS secreting cells (D cells). D cells are distributed mainly in human central and peripheral nervous system, and in the gastrointestinal tract, including the large intestine. SS

inhibits multiple functions, including exocrine and endocrine secretions, inflammation, and angiogenesis, as well as cell proliferation and tumorigenesis, as shown in normal or tumoral cell models<sup>[43-46]</sup>. SS acts as an inhibitory peptide of various secretory and proliferative responses. The diverse biological effects of SS are mediated through a family of five SS receptors (sst1-sst5) that belong to the family of G-protein-coupled receptors and that regulate diverse signal transduction pathways including adenylate cyclase, phospholipase C- $\beta$ , phospholipase A2, guanylate cyclase, ionic conductance channels, and tyrosine phosphatase<sup>[47,48]</sup>. The mechanisms of the inhibition are the combined interaction of SS and its analogs with SST1-5R in tumor tissues, either directly inhibiting division and proliferation of tumor cells or inhibiting the activities of growth factors such as vascular endothelial growth factor (VEGF), insulin-like growth factor (IGF), *etc.*<sup>[49-51]</sup>, thus counteracting tumorigenesis and tumor cell proliferation. The ability of SS and its stable analogues to promote tumor cell apoptosis has been demonstrated in various cell types including mammary, prostatic, gastric, pancreatic, colorectal, and small cell lung cancer cells. However, the underlying mechanisms of SS induced cell apoptosis are still poorly understood. Guillermet *et al.*<sup>[52]</sup> showed that sst2-dependent activation and cell sensitization to death ligand-induced apoptosis involved activation of the executioner caspases are key factors in both death ligand-or mitochondria-mediated apoptosis. Sst2 affected pathways by up-regulating expression of TRAIL and TNF $\alpha$  receptors, DR4 and TNFRI, respectively, and sensitizing the cells to death ligand-induced initiator caspase-8 activation; by down-regulating expression of the antiapoptotic mitochondrial Bcl-2 protein; and by enhancing TNF $\alpha$ -mediated activation of NF- $\kappa$ B, resulting in JNK inhibition and subsequent executioner caspase activation and cell death. Kang *et al.*<sup>[53]</sup> found that SS was able to induce peritoneal macrophages apoptosis by a Bax- and NO-independent p53 accumulation, and through Fas and caspase-8 activation pathways. Recent reports have demonstrated that SS analogs octreotide was able to induce human somatotroph tumor cell apoptosis by activating SST2 and also induce an increase in caspase-3 levels<sup>[54,55]</sup>. In this study, we found that the higher the integral of SS was, the higher the positive expression rate of Fas, caspase-3, caspase-8, and expression of SS protein was foreign to expression of FasL. Our results indicated that SS was able to induce over-expression of Fas, caspase-3 and caspase-8 protein, and the mechanisms of SS promoting LIC cell apoptosis can be *via* up-regulation of expression of Fas or through increasing caspase-3 levels and sensitivity of death receptor signaling pathway.

In this study, we found that the ratio of GAS to SS had an effect on biological characteristics such as malignant type, tissue differentiation and clinical stages of LIC. The increased ratio of GAS to SS is an event of significance in LIC occurrence and development<sup>[56,57]</sup>. Our results indicated that there was a positive correlation between the ratio of GAS to SS and the semi-quantitative integral of FasL, and negative correlation between the integral ratio of GAS to SS and the AI. Furthermore, the expression of GAS and SS proteins was directly related to the expression of Fas, FasL, caspase-3, 8 in LIC.

In conclusion, the regulation and control of GAS and SS in LIC cell apoptosis may be directly related to the aberrant expression of Fas/FasL. The GAS and SS will be valuable targets of the biological behavior of LIC.

## COMMENTS

### Background

Although great progress in understanding the molecular aspects of large intestinal cancer (LIC) has been made and several therapeutic agents have been developed, it is still difficult to cure the tumor. The general survival rate of LIC patients does not exceed 40%. Thereby it is highly important to know that what kind of cell factor can influence cell apoptosis, which will enrich the etiology theory of tumor. Despite abundant evidence that gastrin may play an integral role in promoting tumor growth in the large intestine, the precise mechanisms about gastrin-restrained and somatostatin-induced apoptosis are still largely unknown.

### Research frontiers

Recent some studies have shown that activation of Fas/FasL signaling pathway is regulated by many kinds of cell factors, including gastrin (GAS) and somatostatin (SS).

### Innovations and breakthroughs

Some studies found that GAS was able to inhibit apoptosis in LIC cell, but the role of SS was opposite. However, the detailed molecule mechanism by which GAS and SS mediate cell apoptosis of LIC is not fully known. In this study, the authors analyzed their effects on the expression of Fas, FasL, caspase-3 and caspase-8 protein. To further confirm whether GAS and SS could mediate LIC cell apoptosis mainly via affecting the expression of Fas/FasL, will help us find a new way to treat malignant tumors.

### Applications

The GAS and SS will be valuable targets of the biological behavior of LIC.

### Terminology

GAS: It is mainly secreted from GAS secreting cells (G cells) in antrum mucosa or upper small intestine and large intestine. Medulla oblongata and dorsal nuclei of vagus nerves in central nervous system also secrete GAS. SS: It is secreted from SS secreting cells (D cells). D cells are distributed mainly in human central and peripheral nervous system, and in the gastrointestinal tract. Fas/FasL: It belongs to the ligand of the tumor necrosis factor (TNF) family of death receptors. Caspase: Mammalian cysteine aspartate proteases (caspase) can be divided into initiator (e.g. caspases 2, 8, 9, 10) and effector (caspases 3, 4, 5, 6, 7, 11, 12, and 13) enzymes.

### Peer review

This paper demonstrates that GAS and SS play important roles in the regulation and control of cell apoptosis in LIC, and the mechanism may be directly related to the aberrant expression of Fas/FasL, which will enrich the etiology theory of LIC. In addition, it also provides a way to evaluate targets of the biological behavior of LIC.

Pseudomonas exotoxin antisense RNA selectively kills hepatitis B virus infected cells. *World J Gastroenterol* 2008; 14(18): 2810-2817 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2810.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2810>

## Abstract

**AIM:** To present an approach for selectively killing retrovirus-infected cells that combines the toxicity of Pseudomonas exotoxin (PE) and the presence of reverse transcriptase (RT) in infected cells.

**METHODS:** PE antisense toxin RNA has palindromic stem loops at its 5' and 3' ends enabling self-primed generation of cDNA in the presence of RT. The RT activity expressed in retrovirus-infected cells converts "antisense-toxin-RNA" into a lethal toxin gene exclusively in these cells.

**RESULTS:** Using cotransfection studies with PE-expressing RNAs and  $\beta$ -gal expressing reporter plasmids, we show that, in HepG2 and HepG2.2.15 hepatoma cells as well as in duck hepatitis B virus (DHBV) infected cells, HBV or DHBV-polymerase reverse transcribe a lethal cDNA copy of an antisense toxin RNA, which is composed of sequences complementary to a PE gene and eukaryotic transcription and translation signals.

**CONCLUSION:** This finding may have important implications as a novel therapeutic strategy aimed at the elimination of HBV infection.

## INTRODUCTION

Hepatitis B virus (HBV) infection results in a broad spectrum of clinical manifestations, ranging from asymptomatic course to acute self-limited or fulminant hepatitis or chronic hepatitis that may progress to liver cirrhosis and hepatocellular carcinoma (HCC). The individual host immune response as well as viral mutations largely determines the natural course of HBV infection.

Infection with retroviruses causes among others leukemias (HTLV-1) or AIDS (HIV)<sup>[1,2]</sup>. Because retroviruses encode a reverse transcriptase (RT), one therapeutic strategy is inhibition of RT. RT inhibitors such as lamivudine, adefovir, entecavir and other nucleotide analogues are presently being used to treat HBV infection<sup>[3-6]</sup>.

RT inhibitors are of limited efficacy, however, due to the development of viral resistance<sup>[7,8]</sup>. An alternative therapeutic approach for retroviral infection is to target infected cells by recombinant toxins or immunotoxins that bind to surface antigens<sup>[9-13]</sup> and kill the cells by the toxin moiety, as shown for HIV-infected cells<sup>[9,10]</sup>. One example is the CD4-Pseudomonas exotoxin (PE), composed of a CD4 binding domain fused to a truncated derivative of PE<sup>[14,15]</sup>, which is an extremely potent toxin. Because only few PE molecules are required to kill a cell, the full-length or truncated PE results in the death of eukaryotic cells<sup>[16]</sup>. The fusion of the HIV-binding domain CD4 to a truncated PE derivative proved extremely effective in HIV infection<sup>[17,18]</sup>.

Here, we describe a strategy for the selective killing of retrovirus-infected cells that combines the extreme toxicity of PE and the presence of RT in infected cells. The RT activity of HBV is recruited to selectively convert PE antisense toxin RNA into a lethal toxin gene exclusively in HBV infected cells. This experimental strategy was first evaluated in uninfected COS and MCF7 cells and

in RT positive MM5MT (murine mammary tumor) and HUT102 (human T-cell leukemia) cells (data not shown). Transfection of sense toxin RNA kills cells independently of RT, whereas antisense toxin RNA requires reverse transcription for toxin expression. In COS monkey kidney or MCF7 human breast carcinoma cells in which RT cannot be detected, antisense toxin RNA was not toxic, because it does not express a sense toxin. However, it reduces cell viability when transfected into RT positive HUT102 or MM5MT cells, infected with a human (HTLV1) and a murine (M-MLV) retrovirus, respectively. Here, we demonstrate that HBV RT converts PE antisense RNA into a cDNA expressing PE that selectively eliminates HBV infected cells. The antisense toxin RNA is complementary to the PE gene, flanked by eukaryotic transcription and translation signals. In addition, antisense toxin RNA has palindromic stem loops at its 5' and 3' ends enabling self-primed generation of cDNA in the presence of RT. Antisense toxin RNA does not affect uninfected cells but is lethal for RT containing cells and may therefore represent a novel antiviral strategy.

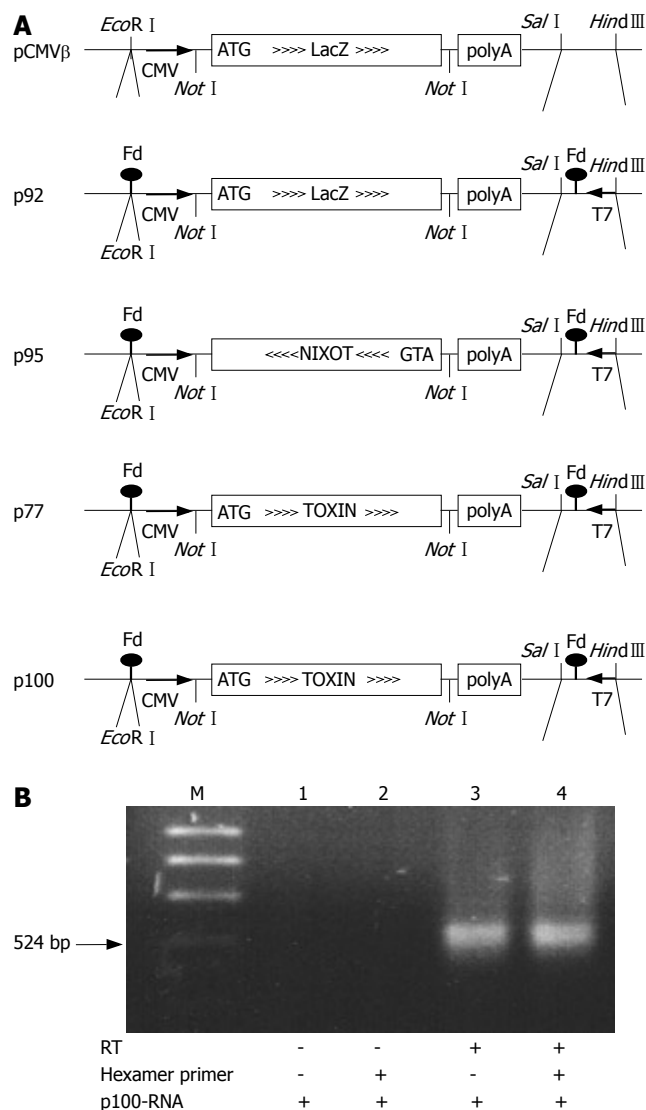

## MATERIALS AND METHODS

### Cell lines

HepG2 and HepG2.2.15 cells (American Type Culture Collection, ATCC, Manassas, VA, USA) were maintained as described<sup>[19]</sup>. HepG2.2.15 is a hepatoblastoma cell line based on Hep G2 cells transfected with a plasmid carrying the gene that confers resistance to G418 and four 5'-3' tandem copies of the HBV genome positioned such that two dimers of the genomic DNA are 3'-3' with respect to one another<sup>[19]</sup>.

### Plasmids for toxin expression and RNA production

The plasmids for PE expression and production of RNA are derived from pCMV $\beta$  (Clontech, Palo Alto, CA, USA)<sup>[17]</sup> which contain the *E. coli* LacZ gene under the control of the CMV promoter for expression of  $\beta$ -galactosidase ( $\beta$ -Gal) in eukaryotic cells, and SV40 splice and polyadenylation signals (Figure 1A). We introduced the T7 phage gene 10 promoter, the and 5'-stem loop sequence<sup>[20]</sup> and the Fd-phage transcription terminator<sup>[21]</sup> in opposite direction to the CMV expression cassette behind the polyadenylation signal and in front of the CMV promoter of pCMV $\beta$ , respectively. This generates a T7-transcription cassette that contains, and is complementary to, the CMV- $\beta$ Gal expression cassette (p92). p92 has the promoter and stem loop sequence of the T7 phage gene 10, obtained by PCR with the primers 5'-GTTCTTTCCAAAGCTTGTGAATTGAT-3' and 5'-GGGCGGAGTCGACCCCGCTAGAGGGAAA-3' inserted between the *Sal*I and *Hind*III restriction sites of pCMV $\beta$  and, in addition, the Fd phage transcription terminator inserted in the *Eco*R I site. The annealed terminator oligos, 5'-AATTACAAAATTAAGGCTCTTTTGAGCCTLTITG-3' and 5'-AATTCAAAAAAGGCTCCAAAAGGAGCCTTTAATTTTGT-3' are *Eco*R I compatible at both ends but reconstitute the site after ligation in the plasmid only at the 3'-end of the terminator.

**Figure 1** A: p92 has the promoter and stem loop sequence of the T7 phage gene 10 and the Fd phage transcription terminator. In p95, p100 and p77, the LacZ-gene *Not*I -fragment of p92 is replaced by fragments containing truncated mutated forms of *Pseudomonas* exotoxin (PE38). p92 represents the control  $\beta$ -Gal expressing plasmid. p95 contains the gene for PE38 in reverse orientation to the CMV promoter. p77 expresses a non-functional frameshift mutant of PE38. p100 expresses the fully active PE38. B: Reverse transcription of toxin antisense RNA *in vitro*. Ethidium bromide stained nondenaturing 2% agarose gel. PCR fragments indicate the presence of toxin cDNA; templates were p100 RNA incubated with (1) no M-MLV RT, no random hexamer primers, (2) no M-MLV RT, random hexamer primers, (3) M-MLV RT, no random hexamer primers, (4) M-MLV RT, random hexamer primers.

The T7 transcription cassette generated by these insertions is in opposite orientation to the CMV promoter. Toxin sense or antisense RNA coding plasmids were generated by replacing LacZ of the modified pCMV $\beta$  by a truncated but enzymatically fully active PE (PE35KDEL)<sup>[22]</sup>. We also constructed a PE frameshift mutation (p77) in which the active site of the toxin (Glu553) is inactivated<sup>[23]</sup>. In p95, p100 and p77, the LacZ gene *Not*I -fragment of p92 is replaced by fragments containing a translation initiation signal (Kozak) and ATG start codon at the 5'-end of truncated mutated forms of PE obtained by PCR with 5'-ACCCGTCATCGCGGCCGCCACCATGGGCTGGGAACAACCTGGA-3' and 5'-TCGGGCTTTTGCGGCC

GCCGAATTCCTTAGAGCTCG-3'; an *EcoR* I site in the latter primer was later filled in by polymerase, religated and thereby removed. p9 (active toxin)<sup>[23]</sup> was used as template for PE38KDEL; the introduction of an additional (fill-in) frameshift mutation in the *Bam*H I site located in the enzymatically active domain III of the toxin gene provided the template for p77.

### Conversion of antisense toxin RNA to a lethal toxin gene by self primed cDNA synthesis

The Fd-terminator stem loop at the 3' end of the RNAs (SL1, ..ACAAAATTAAAGGCTCCCTTTTGGAGCCTTTTTCG-3') can prime the first strand synthesis, the 3' end of which forms a stem loop (SL2, previous RNA-5'-stemloop 5'-GGGAGACCACAACGGTTTCCC..) initiating second strand synthesis. cDNA multimers might also be obtained by repeated flip-over polymerizations around the stem loops. The cDNAs would represent functional and lethal toxin expression cassettes. Depending on the orientation of the toxin coding region in the T7/CMV promoter cassette, these plasmids contain either a functional eukaryotic toxin expression cassette (p100) or no toxic activity (p77), or a cassette in which the toxin is encoded by the opposite strand (p95). In this latter plasmid p95, the CMV promoter driven expression generates nonsense RNA in eukaryotic cells. Since the T7 and CMV promoters are in opposite orientation, this situation is inverted for the RNAs from T7-promoter driven *in vitro* transcription: RNA produced in vitro from p100 and p77 is nonsense RNA (T7-nixot) while RNA from p95 (T7-Toxin) encodes the toxin.

### Construction of plasmid pCH-391mt

Plasmid pCH-391wt contains the complete HBV2 (ayw) genome (infectious in chimpanzees) under control of a CMV promoter. The CMV promoter allows transcription of an authentic pregenomic RNA. Plasmid pCH-391mt is derived from pCH-391wt. pCH-391mt contains a G2024C mutation that inactivates the endogenous polymerase because the active polymerase motif YMDD in pCH-391mt is mutated to YMDH<sup>[24]</sup>. In pCH-391mt a new *Nsi* I restriction site is created. pCH-391mt was cloned by restriction digest of pCH-391wt with *Xba* I and *Bsr*G I, removing the wild-type *Xba* I / *Bsr*G I fragment and insertion of a PCR fragment containing the YMDH motif using primers HBV-pol G2024C Rev (5'-CTCAAGATGCTGTACAGACTTGCCCCCAATACCACATCATGCA TATACTG-3') and HBV-pol 1400 For (5'-GTCAATCTTCTCGAGGATTGGGGACCCT-3') and pCH-391wt as template for PCR amplification. The mutation was verified by sequencing as well as *Nsi* I digestion.

### Synthesis of antisense toxin RNA by reverse transcription *in vitro*

Templates for *in vitro* transcription were linearized with *EcoR* I to eliminate read-through transcripts. Transcription was performed using a large-scale RNA synthesis kit (RiboMAX, Promega, Mannheim, Germany) without Cap analog. RNA was incubated for 1 h at 37°C with 10 units RNase free DNase I (Promega, Mannheim, Germany) to

remove template DNA, extracted with phenol, phenol/chloroform and chloroform, precipitated with ethanol, dissolved in DEPC-treated water and stored at -70°C. For reverse transcription 1 µg p100 RNA (r100) was incubated for 30 min in 20 µL RT buffer (Advantage RT-PCR-Kit, Clontech, Palo Alto, CA, USA) with or without random hexamer primers and M-MLV RT and subsequently treated with 1 µg RNase A for 1 h at 37°C. One µL of the reaction mixture was used to PCR amplify [25 × (95°C, 1 min; 60°C, 2 min; 72°C, 3 min)] a PE gene fragment with the primers 5'-ATGGTCTCCAGGCGCCCGCCTTCCTC-3' and 5'-GCTATGTGTTTCGTCGGCTACCACGGC-3'. Ethidium bromide stained nondenaturing 2% agarose gel-electrophoresis was performed to identify the PE cDNA PCR fragments.

### Transfection of HepG2 and HepG2.2.15 cells with toxin expression plasmids

Transfections were performed using the calcium phosphate transfection kit (GIBCO, Heidelberg, Germany).  $1.5 \times 10^5$  cells were plated 24 h prior to transfections. Transfections were performed with 7.5 µg β-Gal expressing plasmid p92 and 7.5 µg toxin expressing plasmid. β-Gal activities obtained after cotransfection with the β-Gal expressing plasmid p92 (7.5 µg) and p92 plasmid without insert (7.5 µg) were set to 100%. Activities resulting from coexpression of toxin plasmids (p77, p95, p100) and β-Gal expressing plasmid p92 are expressed as relative levels. RT dependent toxicity was determined by β-Gal activity staining.

In RNA transfection experiments, 7.5 µg β-Gal expression plasmid p92 and 7.5 µg of r95, r100, r77 or r92-RNA obtained by *in vitro* transcription were transfected. In experiments determining the sensitivity of HepG2 cells to sense toxin and antisense RNA a further plasmid (7.5 µg) expressing either wild-type (pCH-391wt) or mutant HBV polymerase (pCH-391mt) was transfected. β-Gal activity was assessed using the β-Gal activity staining set (Invitrogen, Groningen, Netherlands). To assess the sensitivity of Hep G2 cells to sense and antisense toxin RNA in the presence and absence of the RT inhibitor adefovir, Hep G2 cells were transfected with 7.5 µg β-Gal expressing plasmid p92 and 7.5 g of r95, r100, r77 or r92-RNA. After transfection of plasmid p92 and the respective RNA adefovir was added to a final concentration of 10 µmol/L. In addition, a plasmid expressing wild-type or mutant HBV polymerase was transfected (7.5 µg).

### PCR of genomic DNA of HepG2 cells after transfection with *in vitro* transcribed toxin RNA

To demonstrate that HBV polymerase reverse transcribed p100 RNA in HepG2 cells only that were transfected with the HBV polymerase encoding plasmid DNA pCH-391wt, genomic DNA was extracted and purified using the QIA-amp-DNA mini Kit (QIAGEN, Hilden, Germany) according to the manufacturer's protocol, following transfection with β-Gal expression plasmid p92 and r100 PE expressing RNA. Genomic DNA was stored at -70°C. For reverse transcription 1 µL of the genomic DNA was used to PCR amplify [25 × (94°C, 1 min; 58°C, 2 min;

72°C, 3 min)] a gene fragment with the primers PE-FOR (5'-GCTATGTGTTTCGTCGGC-3') and 4648 REV (5'-ATTAATGTGAGTTAGCTCACTCAT-3').

#### **Transfection of DHBV infected primary duck hepatocytes with toxin expression plasmids**

DHBV was obtained from the serum of 2-wk to 3-wk-old Pekin ducks congenitally DHBV-infected. One day after hatching, Pekin ducks were infected by intravenous injection of 100 L DHBV DNA positive serum ( $10^9$  virions/mL). Ten days later the ducks were sacrificed. Hepatocytes were obtained by liver perfusion. After the ducks were anesthetized with pentobarbital sodium, the livers were perfused *via* the portal vein with 200 mL of 0.5 mmol/L EGTA [ethyleneglycol-bis ( $\beta$ -aminoethyl ether)-N,N,N',N'-tetraacetic acid] in Swimms 77 medium (GIBCO Heidelberg, Germany) that was buffered with 20 mmol/L HEPES (N-2-hydroxyethylpiperazine-N'-2-ethanesulfonic acid) followed by 200 mL of 0.5 mg of collagenase type 1 (Sigma, Munich, Germany) per mL, 2.5 mmol/L  $MgCl_2$  in Swimms 77 medium. To maintain the perfusion at 37°C, all solutions were kept at 39°C, and the livers were removed and cells dispersed in Williams' medium (GIBCO Heidelberg, Germany) containing 5% fetal bovine serum (FBS), 20 mmol/L HEPES (pH 7.4), 300 mg of penicillin per liter, 1.5 mg of glucose per liter,  $10^{-5}$  mol/L hydrocortisone-hemisuccinate (Sigma, Munich, Germany), and nystatin (10 U/mL). Cells were filtered through gauze and centrifuged at  $50 \times g$  for 4 min. The cell pellet was washed three times with Williams' medium supplemented 20 mmol/L HEPES (pH 7.4), 5 mmol/L glutamine, 0.066 mmol/L insulin, 10 mmol/L dexamethasone, 100  $\mu$ g/mL penicillin, 100  $\mu$ g/mL streptomycin and 1.5% dimethyl sulfoxide containing 5% FBS. Cells were counted in a hemacytometer, and 60 mm dishes were seeded with  $1.5 \times 10^5$  cells per dish in Williams' medium containing the above mentioned supplements. Cultures were incubated at 37°C and 5%  $CO_2$  in a humidified incubator.

Transfections were performed using the calcium phosphate transfection kit (GIBCO, Heidelberg, Germany). DNA and RNA transfections were performed identical to "Transfection of HepG2 and HepG2.2.15 cells with toxin expression plasmids".

## **RESULTS**

#### **Transfection of human HepG2 cells with PE antisense expression constructs and HBV reverse transcription**

To study the ability of a RT to reverse transcribe an antisense toxin RNA, we first constructed a series of PE expression plasmids allowing primer-independent synthesis of cDNA by RT. RNA was obtained by *in vitro* transcription from the T7 promoter. The 5' end of the RNA can form 5-end stem loop of T7 gene 10 promoter transcripts<sup>[20]</sup>. The 3' end consists of the Fd-terminator<sup>[21]</sup> followed by a residual *EcoR* I sequence (used to linearize the plasmid templates prior to *in vitro* transcription) that can participate in a 3' stem loop. Primer independent cDNA synthesis was used to verify that these secondary

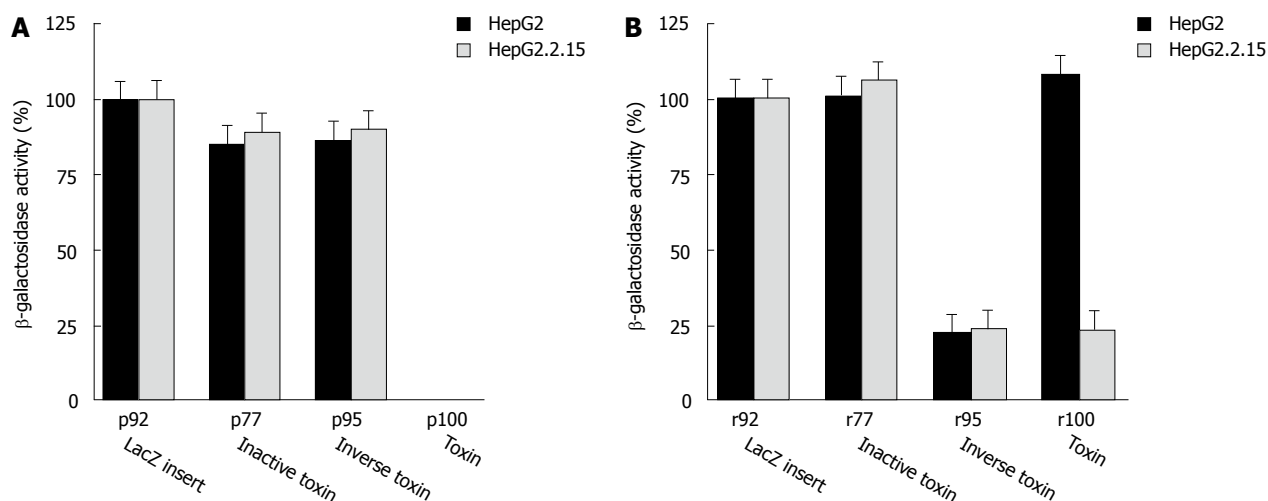

structures at the 5'- and 3'- ends of the RNA allow self-primed, i.e., primer-independent synthesis of cDNA by RT. Figure 1B shows the conversion of these RNAs to cDNA when incubated with dNTPs and RT either with or without primers. The self-primed *in vitro* cDNA synthesis is as effective as random-primed cDNA synthesis under otherwise identical conditions.

Expression of PE or truncated active PE derivatives in animal cells leads to cell death resulting in lack of viable PE expressing transfectants<sup>[16]</sup>. The analysis of cell viability is based upon transfection of toxin expression plasmids, sense or antisense toxin RNA, and a LacZ reporter plasmid (p92) followed by colorimetric quantitation of the LacZ gene product  $\beta$ -galactosidase ( $\beta$ -Gal). The  $\beta$ -Gal activity correlates with the number of transfectants as well as cell viability, because  $\beta$ -Gal protein is synthesized in viable cells only. Thus, reduced  $\beta$ -Gal activity reflects cell death induced by intracellular PE expression. Our data indicate that plasmids expressing an active toxin (p100) kill cells independent from RT (Figure 2A). By contrast, a plasmid expressing a mutated inactive toxin gene (p77) is not toxic. p95 is not toxic, because the PE cassette has an inverse orientation to the CMV promoter resulting in synthesis of nonsense RNA. We conclude that transfection and expression of a fully active or only partially active sense PE gene kills target cells. By contrast, a PE gene inactivated by a frameshift mutation or inversion of the cassette is not toxic.

Next, we analyzed whether PE sense RNA synthesized *in vitro* can be transfected and expressed in target cells resulting in cytotoxicity. The T7 *in vitro* transcription cassette of p95 is in the same orientation as the CMV eukaryotic expression cassette encoding the toxin. Indeed, RNA derived from p95 is cytotoxic even though transfected DNA plasmid itself is not toxic. Cell viability after transfection of r95 toxin RNA is reduced in both HepG2 and HepG2.2.15 cells (Figure 2B compare to p100 DNA in Figure 2A) as well as in DHBV infected cells (Figure 3). These data show that transfected PE RNA is expressed in cells, resulting in cytotoxicity. By comparison transfection of r95 (inverse orientation of PE cassette) is less toxic than transfection of p100.

#### **Reverse transcription of PE antisense RNA by HBV and DHBV**

Transfection of sense RNA kills HBV expressing target cells as well as normal cells in a non-specific manner. Using PE antisense RNA we analyzed the effect of HBV-mediated reverse transcription on cytotoxicity. PE antisense RNA was synthesized by *in vitro* transcription of the plasmids p77 and p100. It contains stem loop sequences at both ends, a toxin gene, poly A signals and CMV promoter sequences, all in inverse orientation to the toxin reading frame and transcription/translation signals (Figure 1A). Antisense RNA should be nontoxic to cells because, similarly to p95 the toxin gene has an inverse orientation. However, if antisense toxin RNA is reverse transcribed in RT positive cells, similar to M-MLV RT *in vitro* (Figure 1B), an active toxin should be synthesized resulting in cell death of RT positive cells only. Indeed,

**Figure 2 A:** Cytotoxicity of toxin expression plasmids to HepG2 and HepG2.2.15 cells.  $\beta$ -Gal activities obtained after cotransfection with the  $\beta$ -Gal expressing DNA plasmid p92 (7.5  $\mu$ g) and p92 plasmid without insert (7.5  $\mu$ g) were set to 100%. Activities resulting from coexpression of toxin plasmids (p77, p95, p100) and  $\beta$ -Gal expressing plasmid p92 are expressed as relative levels. p95, coexpression of p95 with the toxin gene in opposite orientation to the CMV promoter; p100, coexpression of p100 with the active toxin fragment under control of the CMV promoter. Cell viability after cotransfection was determined by  $\beta$ -Gal activity from the  $\beta$ -Gal expressing plasmid. Reduced activity reflects cytotoxicity. **B:** Cytotoxicity of toxin of sense and antisense RNA. Transfection of PE sense and antisense RNA in HepG2 and HepG2.2.15 cells. RT dependent toxicity of antisense toxin RNA in HepG2 and HepG2.2.15 cells was determined. The  $\beta$ -Gal activities obtained after cotransfection with the  $\beta$ -Gal expressing DNA plasmid p92 (7.5  $\mu$ g) and *in vitro* transcribed r92 control RNA (7.5  $\mu$ g) were set to 100%. Activities resulting from coexpression of toxin RNA (r77, r95, r100) and  $\beta$ -Gal expressing plasmid p92 are expressed as relative levels. r77, antisense RNA of inactivated toxin from p77; r95, sense toxin RNA from p95; r100, antisense RNA of active toxin from p100.

transfection of antisense RNA into HepG2.2.15 cells or DHBV infected hepatocytes expressing HBV or DHBV polymerase (HBV or DHBV-RT) results in cell death (Figure 2B, Figure 4) while HepG2 cells expressing no HBV or DHBV polymerase are not affected. In contrast to transfection of sense toxin RNA r95 (or toxin genes, Figure 2A), that kills cells independent from the presence of RT, antisense toxin RNA r100 derived *in vitro* from p100 is selectively toxic in HBV or DHBV positive cells. We therefore conclude that HBV and DHBV RT reverse transcribes PE antisense RNA, resulting in cytotoxicity.

To further analyze the selective cytotoxicity to HBV infected cells, HepG2 cells were transfected with the HBV polymerase construct pCH-391wt expressing wild-type HBV polymerase or pCH-391mt encoding an inactive HBV polymerase with a mutation in the YMDD-motif (Figure 5A). A similar effect on cell viability was observed after transfection of HepG2 cells with r100 RNA and pCH-391wt or of HepG2.2.15 cells with r100 RNA (Figure 2B). Again, r95 RNA kills HepG2 cells independent from the cotransfection of pCH-391wt or pCH-391mt (Figure 5A). By contrast, markedly reduced cytotoxicity was observed after HepG2 cells were transfected with PE antisense RNA r100 and pCH-391mt. This finding indicates that cell death caused by toxin antisense RNA r100 depends on the presence of active HBV polymerase.

To further support this conclusion, HepG2 cells were transfected with antisense toxin RNA r100 and wild-type HBV polymerase pCH-391wt in the presence of adefovir - a potent inhibitor of HBV polymerase. Inhibition of HBV polymerase indeed results in reduced cytotoxicity (Figure 5B). A similar result was achieved when adefovir was added to DHBV infected cells after transfection with

**Figure 3** RT-PCR of genomic DNA from HepG2 cells transfected with a HBV polymerase expression plasmid. 7.5  $\mu$ g p77 RNA mixed with 7.5  $\mu$ g p92  $\beta$ -Gal expression plasmid were transfected in each experiment as well as plasmids expressing either wild-type or mutant HBV polymerase (7.5  $\mu$ g each). Genomic DNA was extracted and analyzed by non-denaturing 2% agarose gel electrophoresis. PCR fragments indicate the presence of toxin p77 cDNA. A: Bio-Rad marker 50-2000 base pairs; B: PCR amplified fragment of HepG2 cells cotransfected with pCH391wt and r100; C: PCR amplified fragment of HepG2 cells cotransfected with pCH391mt and r100; D: P77 DNA as control DNA.

antisense toxin RNA r100 (Figure 4). Taken together these findings demonstrate that the toxicity of r100 is dependent on HBV RT.

#### RT-PCR of genomic DNA from HepG2 cells transfected with HBV polymerase expression plasmid

To demonstrate that r100 is reverse transcribed in HBV-infected cells and to visualize the resulting p100 cDNA, genomic DNA was extracted from HepG2 cells transfected with either wild-type or mutant HBV

polymerase expression plasmid (pCH-391wt, pCH-391mt). RNA was transcribed from linearized p100 DNA. RT-PCR (Figure 3) demonstrates that r100 was reverse transcribed from p100 only in cells cotransfected with pCH-391wt, resulting in the amplification of a 901 bp DNA fragment. In cells cotransfected with pCH-391mt p100 DNA could not be amplified.

## DISCUSSION

HBV infection is a major cause of chronic hepatitis, liver cirrhosis and HCC worldwide. HCC develops 30-50 years after HBV infection and is a leading cause of death, especially in sub-Saharan Africa and South East Asia where up to 20% of the population are HBV infected.

The HBV genome replicates *via* reverse transcription of a RNA intermediate. This property has been used in a model system of HBV infection based on HBV transfected cell lines to study the selective cytotoxicity of a PE antisense toxin RNA.

Despite the availability of a safe and efficient vaccine, chronic HBV infection remains a major health problem. The problems of non-responding individuals and emergence of vaccine escape mutants are largely still unsolved. New treatment options with nucleotide analogues initially designed for HIV infection have become available. Lamivudine efficiently inhibits HBV infection but drug resistant mutations are frequent. Adefovir is an alternative for the treatment of chronic HBV infection. Different from lamivudine, viral resistance to adefovir is used lesser frequent. Viral variants may influence the course of disease and require special attention during antiviral therapy<sup>[8]</sup>. Antiviral agents such as lamivudine, adefovir, entecavir and others work directly inhibit HBV viral polymerase and thereby suppress viral replication<sup>[25]</sup>. The viral cccDNA template in the cell nucleus, however, is not affected by antiviral therapy. Therefore, HBV infection persists, because the turnover rate of hepatocytes is rather slow. Therefore, cessation of treatment or the development of breakthrough mutations promptly results in eradication of replication. HBV polymerase is highly error-prone and lacks proofreading activity, as do other RT such as HIV-RT. Thus, viral quasiespecies will develop during persistent HBV infection<sup>[26]</sup>. In this setting, the use of nucleotide chain terminators such as lamivudine, adefovir, entecavir and others carry the risk of selecting drug resistant viral mutants by suppressing the replication of the major wild-type population. These agents allow noncompetitive drug-resistant quasiespecies to replicate and become the dominant viral population.

To overcome the problem of drug resistance we explored a novel experimental strategy approach to eliminate HBV infected cells. PE has the advantage as a candidate gene for gene therapy, because only very few molecules are necessary to induce cell death<sup>[16]</sup>. It is widely used as an experimental therapeutic approach as part of immunotoxins for a variety of malignant diseases. A major requirement for *in vivo* gene therapy is to target the therapeutic gene expression to tissues of interest by selecting potent therapeutic genes. The mechanism of

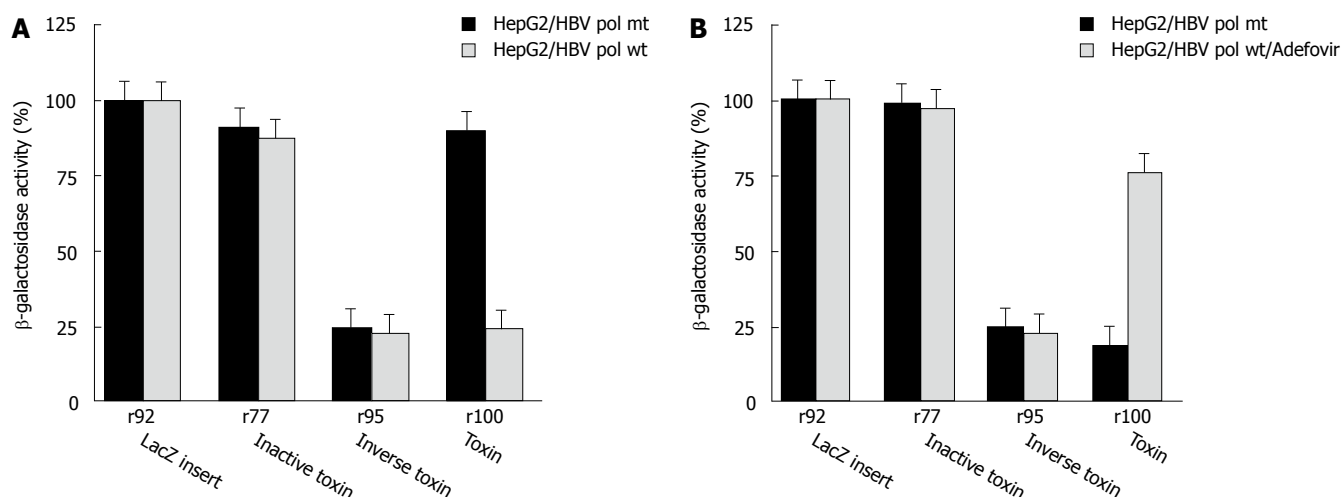

**Figure 4** Cytotoxicity of toxin sense and antisense RNA to DHBV infected duck hepatocytes in the presence or absence of 10 mmol/L adefovir. 7.5 µg RNA mixed with 7.5 µg p92 β-Gal expression plasmid were transfected in each experiment and β-Gal activities were quantified as described in legend to Figure 5. In addition, a wild-type HBV polymerase expression plasmid was transfected (7.5 µg). P92, control RNA from p92; p77, antisense RNA of inactivated toxin from p77; p95, sense toxin RNA from p95; p100, antisense RNA of active toxin from p100.

action of plant or bacterial toxins is internalization into an endosome, and translocation to the cytosol followed by enzyme induced modification or destruction of components critical for the cellular translation machinery resulting in lethal inhibition of protein synthesis or induction of programmed cell death<sup>[27,28]</sup>. An example for a retroviral disease is HIV infection where infected cells were selectively killed by an immunotoxin, consisting of a truncated PE joined to the variable region of a broadly neutralizing antibody (3B3) recognizing the viral envelope glycoprotein (env)<sup>[17]</sup>.

In our experiments PE antisense toxin RNA is less toxic to RT positive cells than toxin DNA (compare Figures 4 and 5: killing of HepG2 cells by p100 DNA *versus* r100 RNA). Possibly, intracellular reverse transcription of toxin antisense RNA is inefficient and the transfected RNA is degraded rather than expressed. Despite these limitations, our data clearly demonstrate that, in principle, it is possible to reverse transcribe a nontoxic RNA in RT positive cells to a toxic cDNA expressing active PE, resulting in cell death.

The elimination of retrovirus infected cells *in vivo* by antisense toxin RNA requires effective delivery to target cells. Thus, RNA instability and low transfection efficacy limit its usefulness and make even the analysis of antisense toxin RNA *in vitro* difficult. It might be possible to deliver such RNA, more effectively using liposomes or recombinant viruses<sup>[29,30]</sup>. Cells with retrotransposon activity could be affected by this approach when retroposon activity would be able to reverse transcribe the antisense-toxin RNA template.

Ultimately, retroviruses which naturally contain and stabilize RNA could be engineered to carry antisense toxin RNA and thus serve as a Trojan horse for the treatment of HBV infection.

**Figure 5** A: Cytotoxicity of toxin sense and antisense RNA to HepG2 cells in the presence or absence of transfected HBV polymerase expression plasmid. The  $\beta$ -Gal activities obtained after cotransfection with the  $\beta$ -Gal expressing DNA plasmid p92 (7.5  $\mu$ g), *in vitro* transcribed r92 control RNA (7.5  $\mu$ g) and plasmids expressing either HBV harbouring a wild-type or mutant HBV polymerase (7.5  $\mu$ g each) were set to 100%. Values resulting from coexpression of toxin RNAs (r77, r95, r100) with p92 and either wild-type HBV polymerase or mutant HBV polymerase expressing plasmids are expressed as relative levels. B: Cytotoxicity of toxin sense and antisense RNA to HepG2 cells in the presence or absence of 10 mmol/L adefovir. 7.5  $\mu$ g RNA mixed with 7.5  $\mu$ g p92  $\beta$ -Gal expression plasmid were transfected in each experiment and  $\beta$ -Gal activities were quantified as described in legend to Figure 3. In addition, a wild-type HBV polymerase expression plasmid was transfected (7.5  $\mu$ g). p92, control RNA from p92; p77, antisense RNA of inactivated toxin from p77; p95, sense toxin RNA from p95; p100, antisense RNA of active toxin from p100.

## COMMENTS

### Background

Hepatitis B virus (HBV) is the prototypic member of the Hepadnaviridae, a DNA-containing virus that replicates by reverse transcription of a pregenomic intermediate. Initiation of reverse transcription is thought to be strictly template specific. Here we present data showing that HBV-reverse transcription of the non-viral template coding for *Pseudomonas* exotoxin (PE) is possible. The RT-activity expressed in hepadnavirus-infected cells is recruited to convert an "antisense-toxin-RNA" into a lethal toxin exclusively in HBV-infected cells. We also present this approach for selectively killing retrovirus infected cells that combines the toxicity of *Pseudomonas* exotoxin (PE) and the presence of RT in infected cells.

### Research frontiers

Current therapies for chronic HBV infection are limited in their effect on viral gene expression and replication. Experimental therapies for HBV-infection are RNA interference (RNAi), ribozyme technology, target-dependent ribozymes, and gene therapeutic approaches using a variety of vectors to deliver therapeutic genes into HBV-infected cells. *Pseudomonas* exotoxin A kills cells either by direct inhibition of protein synthesis, or by concomitant induction of apoptosis.

### Innovations and breakthroughs

Here it is shown for the first time that HBV-and DHBV infected cells can be selectively killed by *Pseudomonas* exotoxin. The explanation for RT dependent toxicity is likely conversion of antisense-toxin-RNA to a toxin expression module by self-primed reverse transcription in the cell. This approach has been previously used by targeting HIV- infected cells by recombinant toxins that bind to HIV-surface antigens and kill infected cells by the toxin moiety. Moreover it is shown that HBV-polymerase can replicate a non-viral template. HBV polymerase can be active in trans outside the HBV nucleocapsid.

### Applications

The data demonstrate that, in principle, it is possible to generate a lethal cDNA copy of a per se nontoxic RNA in RT-containing infected cells. This principle is not limited to toxin genes but can probably be applied to other genes, e.g. inhibitors or ribozymes. The elimination of retrovirus infected cells *in vivo* by antisense-toxin-RNA requires effective delivery to target cells. It might be possible to deliver such RNA more effectively with liposomes or recombinant viruses. Ultimately, retroviruses which naturally contain and stabilize RNA could be loaded with antisense-toxin-RNA to serve as a "Trojan horse" in the battle against AIDS.

### Peer review

Cells with retrotransposon activity could be affected by this approach when retroposon activity would be able to reverse transcribe the antisense-toxin RNA template.

## Abstract

**AIM:** To investigate the role of estrogen on liver injury in an experimental obstructive jaundice model.

**METHODS:** Three groups of female rats were constituted; group 1 was oophorectomized and given E2 ( $n = 14$ ), group 2 was oophorectomized and given placebo ( $n = 14$ ), and group 3 was sham operated ( $n = 14$ ). Fourteen days following constitution of bile duct ligation, all groups were compared in terms of serum tests, histopathologic parameters, and tissue levels of IFN- $\gamma$  and IL-6.

**RESULTS:** The parameters representing both the injury and/or the reactive response and healing were more pronounced in groups 1 and 2 ( $\chi^2 = 17.2$ ,  $\chi^2 = 10.20$ ;  $\chi^2 = 12.4$ ,  $P < 0.05$ ). In the sham operated or E2 administered groups significantly lower tissue levels of IFN- $\gamma$  and higher IL-6 levels were found. In contrast, high IFN- $\gamma$  and low IL-6 tissue levels were found in the oophorectomized and placebo group ( $P < 0.001$ ). Kupffer cell alterations were observed to be more pronounced in the groups 1 and 3 ( $\chi^2 = 6.13$ ,  $P < 0.05$ ).

**CONCLUSION:** Our study indicates that E2 impaired liver functions, accelerated both the liver damage and healing. In the conditions of bile duct obstruction, estrogen significantly changed the cytokine milieu in the liver.

## INTRODUCTION

It has long been known that there are differences between the two sexes in the occurrence of some diseases or the response that they give to the same disease entity<sup>[1]</sup>, such as cardiovascular disease<sup>[2]</sup>, sepsis<sup>[3]</sup>, various autoimmune and collagen diseases including autoimmune thyroid disease<sup>[4]</sup>, or liver diseases<sup>[5]</sup>. These findings suggest that gender may determine the susceptibility to some diseases whereas it may be preventive to others, which is probably attributed to estrogen(s). The recent identification of estrogen receptor (ER)  $\beta$  in many tissues besides the target organs of estrogen, which mainly possess ER $\alpha$ <sup>[6,7]</sup>, has suggested that a larger tissue area, than previously known, is affected by estrogen through its specific receptors<sup>[8,9]</sup>. The demonstration of ER in the liver<sup>[10]</sup> has led studies to focus on the influence of steroid hormones, particularly estrogens, on liver disorders and regeneration<sup>[11]</sup>. In rats, liver injury induced by alcohol<sup>[12,13]</sup> or carbon tetrachloride<sup>[14]</sup> is more frequently seen in females. In transplanted liver<sup>[15]</sup> and hepatectomy models<sup>[16,17]</sup>, estrogen significantly increases regeneration and proliferation, and reverses inhibitory effect of the estrogen receptor antagonist, tamoxifen, on hepatocyte proliferation. These findings demonstrate that estrogens may aggravate injury or accelerate regeneration, depending on the model used.

The influence of estrogen on liver injury has not been studied in obstructive jaundice before. Biliary stones are found in 10% of adult population, and the risk of occurrence increases in women on oral contraceptives and with pregnancy. Each year 3%-5% of patients with

symptomatic biliary stones become complicated<sup>[18]</sup>. In patients with chronic extrahepatic bile duct obstructions, endotoxemia has been demonstrated and prolonged bile duct obstruction is harmful for phagocytic activity of reticuloendothelial system and increases the risk of mortality in the presence of endotoxemia<sup>[19,20]</sup>.

In this experimental study we have searched the effects of estrogens on liver injury and regeneration with the associated cytokine production using the bile duct ligation model. The aim of the study is to determine the differences, in terms of biochemical and histopathological parameters of liver injury in obstructive jaundice, between the groups of rats that represent women who are postmenopausal or oophorectomized with or without estrogen replacement therapy, and premenopausal; and to demonstrate the possible role of cytokines in these differences; and to assess the clinical importance of these data.

## MATERIALS AND METHODS

Female Wistar albino rats, 12-16 wk old and 180-200 g, were used. They were kept in temperature-controlled environment, and they had free access to standard rat food and water. The study was approved by Gazi University ethic committee.

### *The study design and administration of estrogen*

Forty-two female rats were randomly assigned to three groups of 14 each. In order to nullify the effect of ovarian estrogen, the first two groups, group 1 and 2 ( $n = 14$ ), underwent bilateral oophorectomy, as previously described<sup>[22]</sup> while group 3 ( $n = 14$ ) was sham operated to maintain physiological estrogen levels. Only laparotomy and ovary exploration was performed in group 3. Synthetic estrogen 17  $\beta$ -estradiol (Sigma Chemical Co., Steinheim, Germany) was dissolved in sesame oil (Sigma) and 5 mg/0.1 mL injection doses were prepared. Fourteen days after surgeries, during which effects of ovarian estrogen had disappeared, group 1 was given subcutaneous 5 mg/0.1 mL 17  $\beta$ -estradiol. Group 2 and group 3 were given 0.1 mL sesame oil subcutaneously as a placebo, meanwhile group 1 received 5 mg estrogen in 0.1 mL doses subcutaneous. Second and third doses were given 1 d and 5 d after the first dose.

The bile ducts were ligated 24 h after administration of the last dose of estrogen (or placebo), as previously described<sup>[20]</sup>. The animals were anesthetized by an intramuscular injection of ketamine hydrochloride (50 mg/kg of body weight) under semisterile conditions and through a 3 cm long upper midline abdominal incision, the common bile ducts were isolated, double ligated with 6-0 vicryl (Ethicon, Birmingham, UK) and transected between the sutures. Meticulous attention was paid not to damage the blood supply and neighboring organs.

Fourteen days after bile duct ligation, the abdominal incision was reopened following ketamine anesthesia. The animals were killed by cardiac puncture and blood withdrawn for the measurements of estrogen level and biochemical parameters. The liver was excised and the liver was divided into two samples; one sample was kept in 10% formaldehyde solution for histopathological evaluation and

**Table 1** Study design ( $n = 14$ )

Day	Group 1	Group 2	Group 3
0	Bilateral oophorectomy	Bilateral oophorectomy	Sham operation
15, 16, and 22	5 mg/0.1 mL E2 in sesame oil, SC	0.1 mL sesame oil, SC	0.1 mL sesame oil, SC
23	Bile duct ligation	Bile duct ligation	Bile duct ligation
37	Killed, blood and tissue samples obtained	Killed, blood and tissue samples obtained	Killed, blood and tissue samples obtained

SC: Subcutane.

the other was sent to the laboratory immediately as a fresh tissue for cytokine level measurements by ELISA (Table 1).

### *Measurements of blood biochemical parameters, estrogen and tissue cytokine levels*

Blood estrogen levels were measured by chemiluminescence method in pg/mL with Access Immunoassay System (Beckman Coulter, Inc., CA, USA) analyzer. To show altered liver functions, blood levels of bilirubin in mg/dL, alanine transaminase (ALT), and  $\gamma$ -glutamyl transpeptidase (GGT) in U/L were measured by Synchron CX-7 Clinical System (Beckman).

To assess the effect of estrogen on cytokines, liver IFN (interferon)- $\gamma$  and IL (interleukin)-6 levels were measured by ELISA in pg/mL, because of their significant role on liver injury and regeneration. For the measurements, 0.5 g of the fresh liver tissue was harvested and prepared for ELISA by homogenization as described previously<sup>[22]</sup>. Briefly, each specimen was homogenized for 60 s in 10 mL of phosphate buffered solution containing a cocktail of protease inhibitors including 2 mmol/L phenylmethyl-sulphonyl fluoride and 2  $\mu$ g/mL aprotinin, leupeptin and pepstatin A (Sigma) to inhibit proteolysis of cytokines. The homogenates were collected from the homogenizer (Jencons Scientific Ltd., Bedfordshire, UK), ultra-centrifuged at 10 000 r/min at 4°C for 45 min, the supernatants aliquoted and stored at -70°C. Cytokines were measured by ELISA with rat IFN- $\gamma$  and rat IL -6 kits (BioSource Int. Inc., CA, USA) as recommended.

### *Histopathological evaluation*

Liver fragments were kept in 10% formaldehyde solution for 6-48 h. Following treatment with various concentrations of alcohol and xylene, the specimens were embedded in paraffin blocks. After the preparation, the sections were stained with Hematoxylin & Eosin and Masson's trichrome stains. Evaluations were made by a pathologist, blinded, using the parameters described previously<sup>[20]</sup>. Each of the histopathological parameters listed in Table 2 were evaluated and scored for each slide in terms of the degree of change such that zero was given for no change, 1 for slight, 2 for moderate, and three for severe changes. For some of the parameters that could not be so scored, zero or two was assigned for absence or presence of the pathology, respectively (Table 2).

### *Statistical analysis*

For all parameters the means and standard deviations

Table 2 Histopathologic scoring of liver injury

	Parameters	Score
1	Necrosis	0, 1, 2, 3
2	Regenerative activity	0, 1, 2, 3
3	Portal PMNL infiltration	0, 1, 2, 3
4	Portal MNL infiltration	0, 1, 2, 3
5	Ductular proliferation	0, 1, 2, 3
6	Fibroblastic activity	0, 1, 2, 3
7	Kupffer cell abnormalities	0, 2
8	Sinusoidal PMNL infiltration	0, 2
9	Sinusoidal MNL infiltration	0, 2
10	Portal vascular congestion	0, 2
11	Sinusoidal vascular congestion	0, 2
12	Portal vascular thrombosis	0, 2
13	Sinusoidal vascular thrombosis	0, 2
14	Portal and central venous phlebitis	0, 2
15	Arterial wall changes	0, 1, 2, 3
16	Hydropic degeneration	0, 1, 2, 3
17	Decrease in hepatocyte glycogen content	0, 2

PMNL: Polymorphonuclear leukocytes; MNL: Mononuclear leukocytes.

were calculated. Kruskal-Wallis variance analysis and Chi-squared tests were used for all nonparametric comparisons.

## RESULTS

Blood estrogen levels were significantly different in all groups ( $P < 0.001$ ). The highest values were  $580 \pm 124.01$  in the group 1 in which oophorectomy and E2 replacement had been done, whereas the lowest values were  $61.5 \pm 15.97$  obtained in group 2 given placebo. Blood estrogen levels of group 3 was  $208 \pm 35.02$ .

Serum bilirubin, ALT, and GGT levels increased in all groups, as evidence of obstructive jaundice and liver damage. Serum bilirubin levels were not found to be different among the groups ( $P > 0.05$ ). Blood ALT and GGT levels generally were lower in group 2 given the placebo given group 2 than in the groups 1 and 3 in which blood estrogen levels were normal or high, respectively. The significant differences emerged with its lowest value for ALT in group 2 and its higher values for GGT only between groups 1 and 2 ( $P < 0.05$ , Table 3).

Liver specimens of all rats were examined histopathologically according to the parameters mentioned in table 2 and groups were then compared using the chi-squared test. Among 17 parameters necrosis, regenerative activity, ductular proliferation, fibroblastic activity, Kupffer cell abnormalities, sinusoidal congestion and portal-central venous phlebitis showed statistical difference among the groups ( $P < 0.05$ , Table 4). Progressive rounding, ruffling of cell surface, polarization, appearance of wormlike densities, vacuolization and degranulation were the abnormalities seen in Kupffer cells. The photos of ductal proliferation, fibrosis and sinusoidal congestion of specimens can be seen especially in group 1 and 3 (Figure 1). In terms of portal polymorphonuclear leukocyte and mononuclear leukocyte infiltration, sinusoidal polymorphonuclear leukocyte and mononuclear leukocyte infiltration, portal vascular congestion, portal and sinusoidal vascular thrombosis, arteriolar wall changes, hydropic degeneration,

Table 3 Comparison of liver function tests of the groups

Groups	ALT (U/L)	GGT (U/L)	Bilirubin level (mg/dL)
1	$347.85 \pm 61.12$	$65.35 \pm 20.98^a$	$6.83 \pm 1.32$
2	$256.57 \pm 54.19^a$	$46.50 \pm 12.0$	$5.90 \pm 2.12$
3	$360.50 \pm 65.22$	$58.78 \pm 7.47$	$6.30 \pm 1.57$

There are significant differences when compared with other groups ( $^aP < 0.05$ ).

and hepatocyte glycogen content, there was no significant difference among groups ( $P > 0.05$ , data not shown).

When necrosis was considered there appeared a significant difference, which was due to the lower values in group 2 ( $\chi^2 = 17.2$ ,  $P < 0.05$ , Table 4). Group 2 was also found to be significantly different with its lower regenerative activity ( $\chi^2 = 10.22$ ,  $P < 0.05$ , Table 4).

Ductular proliferation, a reactive response of liver to bile duct obstruction, was statistically more in groups 1 and 3 than in group 2 ( $\chi^2 = 12.43$ ,  $P < 0.05$ , Table 4).

In groups 1 and 3 with higher estrogen levels, fibroblastic activity was also significantly more pronounced ( $\chi^2 = 31.06$ ,  $P < 0.001$ , Table 4). There was a significant difference in terms of Kupffer cell abnormalities between groups 1 and 2 ( $\chi^2 = 6.13$ ,  $P < 0.05$ , Table 4).

Sinusoidal congestion and portal venous phlebitis were significantly lower in group 2 than in group 3 ( $\chi^2 = 8.17$ ,  $P < 0.05$ ,  $\chi^2 = 7.636$ ,  $P < 0.05$ , respectively, Table 4).

To summarize, in all groups, bile duct ligation produced histopathological changes in liver and there appeared a significant difference between group 2 with the lowest estrogen level and the others in terms of at least some of the parameters.

The groups were also compared according to the tissue cytokine measurements of IFN- $\gamma$  and IL-6 and were found to be statistically different. While IFN- $\gamma$  was significantly higher, IL-6 was lower in group 2 with the lowest estrogen level ( $P < 0.001$ , Table 4).

With Pearson's correlation analysis, IFN- $\gamma$  and IL-6 levels were tested and found to be inversely related to each other when group 2 was compared with groups 1 and 3 ( $r = -0.36$ ,  $P < 0.001$ , Figure 2).

## DISCUSSION

Differences exist between the two sexes of humans and animals<sup>[1]</sup>. It is known that in premenopausal period, female gender is a preventive factor against cardiovascular disorders<sup>[2,23]</sup>, peptic ulcer disease<sup>[24]</sup> and some others<sup>[3,23]</sup>, on the other hand, the risk of occurrence of autoimmune and collagen tissue disorders is more frequent in women<sup>[26]</sup>. It has been proposed that this fact may be due to the differences between the two sexes in hormone levels and tissue distribution of hormone receptors.

Because estrogen has influences on many tissues, other than its main target tissues, it has been speculated and shown that estrogen has a larger field of distribution than previously believed<sup>[7,27]</sup>. After the demonstration of estrogen receptors in liver, studies on the interaction of estrogen and its receptor in liver have accumulated<sup>[28,29]</sup>. Estrogen is thought to enhance regeneration after hepatectomy,

**Figure 1** A: Ductal proliferation and inflammation (HE, × 20); B: Fibrosis and ductal proliferation (Masson trichrom, × 10); C: Sinusoidal congestion (HE, × 40); D: Ductal proliferation and portal vascular congestion (HE, × 20).

due to its potentiative effect on proliferation, and studies have shown that estrogen increases regeneration<sup>[17]</sup> and mitotic activity of hepatocytes<sup>[15]</sup>, significantly. On the other hand, it potentiates liver injury with alcohol and carbon tetrachloride<sup>[4]</sup> administration<sup>[5,13,14,30]</sup>. Estrogen treatment also has an effect in cholangiocyte proliferation<sup>[31]</sup>.

Previous literature comprises data about the influence

of estrogen on various types of liver injury other than obstructive jaundice. In this experimental study, effects of estrogen on liver injury in bile duct ligation model were investigated.

Bile stones, 85% of which is cholesterol type, are frequent in surgical practice. Women are affected twice as much as men, and oral contraceptives and pregnancy increase the risk for biliary stone formation. Each year, 3%-5% of symptomatic biliary stones become complicated<sup>[18,32]</sup>. In general, benign and malignant bile duct obstructions are mostly seen in the elderly.

In our study, blood estrogen levels of groups were significantly different, as intended ( $P < 0.001$ , Table 3). While oophorectomized groups 1 and 2 had estrogen levels higher and lower than normal, respectively, group 3 maintained its physiological level. By this way, groups representing postmenopausal or bilaterally oophorectomized women with estrogen replacement (group 1), without

estrogen replacement (group 2) and premenopausal normal women (group 3) were constituted.

Increased serum bilirubin and liver enzyme levels after 14 d of bile duct obstruction proved that bile duct ligation had been successfully performed. The fact that the group with the lowest estrogen level (group 2) had significantly lower levels of liver enzymes than groups 1 and 3 suggested that estrogen enhanced liver injury. To test this, previously described parameters of liver injury were used for the comparison of groups (Table 2).

Histopathological changes were less significant in extent in group 2 with the lowest estrogen level than in the other groups, considering the seven parameters yielding statistical difference among groups (Table 4). This finding has shown that estrogen has an influence on liver injury. Reactive changes secondary to bile duct obstruction, like necrosis, ductular proliferation, Kupffer cell abnormalities, sinusoidal congestion, were significantly more pronounced in groups 1 and 3 than in group 2, which meant that both physiological and supraphysiological levels of estrogen potentiated, not only liver injury, but also reactive responses (Table 4). These data correlate well with the results of studies reporting that estrogen accelerates liver injury caused by alcohol and carbon tetrachloride<sup>[13,15,17]</sup>.

The fact that portal central venous phlebitis was more in both group 1 and 3, with statistical significance in the latter only, suggested that the occurrence of this change might be due to the influence of estrogen on coagulation and venous thromboemboli<sup>[33,34]</sup>.

Another striking result of this study was the statistically significant difference in cytokine levels among groups. There has been an inverse correlation between IFN- $\gamma$  and IL-6 ( $r < -0.5$ ). In group 2, with the lowest estrogen level, IL-6 was significantly lower ( $P < 0.001$ ) while IFN- $\gamma$  was significantly higher ( $P < 0.001$ ) than in the other groups in which IL-6 was higher and IFN- $\gamma$  lower (Table 4). This finding showed the possible strong effect of estrogen on liver cytokine pattern. It has been proposed that for regeneration, hepatocyte needs growth factors like hepatocyte growth factor, transforming growth factor- $\alpha$ , and epidermal growth factor; however, to be responsive to these growth factors, it must be sensitized with tumor necrosis factor- $\alpha$  and IL-6<sup>[35]</sup>. Kupffer cells have important effects on liver regeneration and in one study a decrease in that cell population, and hence in the production and the levels of many cytokines including IL-6, have been shown to slow down regeneration<sup>[36]</sup>. It has been accepted that IL-6 accelerates regeneration<sup>[35,37,38]</sup> and the most important synthesizers of IL-6 are Kupffer cells and macrophages infiltrating liver<sup>[39]</sup>. Besides, it has been suggested that IL-6 increases fibrosis because transforming growth factor- $\beta$ , that enhances fibrosis as a response to liver injury, seems to decrease in rats deprived of IL-6<sup>[40]</sup>. In this study, group 2 with low serum estrogen and liver IL-6 levels showed decreased regeneration and fibrotic activity unlike the other groups with higher IL-6 levels, and this supported the data about IL-6 in the literature.

IFN- $\gamma$  increases fibrosis in liver and in the absence of lymphocytes, responsible for the production of this cytokine, more intense fibrosis results<sup>[41,42]</sup>. In our study, IFN- $\gamma$  was found to be high in group 2 with the lowest

estrogen level and in group 2 regeneration and fibroblastic activity were decreased unlike the other groups with low IFN- $\gamma$  levels. This suggested that IFN- $\gamma$  had a role opposite to that of IL-6.

It has been reported that, estrogen suppresses<sup>[43-45]</sup>, stimulates<sup>[46]</sup> or is ineffective<sup>[3]</sup> on the secretion of IL-6 from various tissues or cells. The mentioned different effects of estrogen on IL-6 secretion probably are due to the distinct features of different tissues. Although it has been shown that, liver<sup>[47]</sup> and serum<sup>[48]</sup> IL-6 levels are increased transiently after obstructive jaundice, the effects of estrogen on liver tissue cytokine environment is not well understood. Influence of estrogen on IFN- $\gamma$  secretion is also contradictory; some reports have suggested suppression<sup>[49,50]</sup>, while others have claimed inhibition<sup>[51,52]</sup>.

In this study, we showed for the first time, even after 14 d of bile duct ligation, secretion of IL-6 was found to be increased while IFN- $\gamma$  was decreased in a reverse correlation under the influence of estrogen. Increased IL-6 and decreased IFN- $\gamma$ , together with the demonstration of accelerated regeneration and fibroblastic activity in liver, suggested the role of estrogen on liver injury might be mediated by these cytokines. Furthermore, determination of significantly more Kupffer cell changes in groups 1 and 3 with high level of estrogen, reminded us that changing of liver cytokine levels might be controlled by these cells. However, demonstration of higher degree of necrosis and other injury parameters in the groups with high level of estrogen, suggests that beside augmentation of regeneration, estrogen also increases existing injury.

As a result, our study indicates that in liver injury that is caused by bile duct obstruction, medications that contain estrogens should be avoided until the underlying cause of the liver damage is eliminated but, thereafter, they may be used because of possible effects of estrogen on liver regeneration. The existence and the considerable effects of estrogen receptors in liver may give rise to experiments studying on specific estrogen receptor modulators, at least, in some liver diseases. This study has also suggested that, in liver disease occurring before menopausal period, detrimental effects of physiological levels of estrogen(s) on the liver can perhaps be prevented by using specific estrogen blockers.

## COMMENTS

### Background

Different responses depend on differences in hormones between the sexes and have been the subject of several studies for several years. The main target hormone, estrogen, plays a critical role in several mechanisms in the body. Among these, estrogen receptors found in liver tissue have a key role for the estrogen effects on liver and related mechanisms. As women are more prone to bile stones and elderly postmenopausal patients have a higher incidence of bile obstruction, a role for estrogen must be considered in these pathologies.

### Research frontiers

It was shown that estrogen has a proliferative effect in partial hepatectomy; however, it increases the susceptibility of the liver to injury. On the other hand, bile duct obstruction, bile stasis and related cytokine changes by Kupffer cells have a distinct entity that must be investigated. Histopathological changes including Kupffer cells and cytokine release related to estrogen is still an unclear mechanism.

## Innovations and breakthroughs

As several studies mentioned the regenerative effect and increased injury due to hepatectomy, our study is performed in bile duct obstruction model. Not only the cholangiocyte proliferation, but also the cytokine levels, liver regeneration and liver function tests were also evaluated. Women are more prone to bile stones and the rate of bile duct obstruction increases with age. Bile duct obstruction related to bile stones is more likely to be seen in postmenopausal women. In this point of view, estrogen status and expected situations must be investigated.

## Applications

Although some points have been mentioned here, there are still unknown mechanisms for the actions of estrogen. Cytokine release, thromboemboli and coagulation are thought to be potential mechanisms. However, no clear definition has been made. We feel that this study will help in further clinical studies and will be an investigative source for other estrogen and bile duct obstruction related studies.

## Peer review

This is an interesting investigation of effects of estrogens on liver injury and regeneration using the bile duct ligation model. The presentation and readability of the manuscript is good. It indicates that E2 impaired the liver functions, accelerated both the liver damage and healing. In the conditions of bile duct obstruction, estrogen significantly changed the cytokine milieu in the liver.

### Abstract

**AIM:** To analyze gallbladder contractility in patients with black pigment stones (BPSs) and to compare this with patients with cholesterol stones (CSs) and healthy volunteers.

**METHODS:** The pattern of bile evacuation from the gallbladder was quantified by computer cholescintigraphy in 28 normal subjects, 22 patients with CSs and 14 with BPSs. The parameters of gallbladder contractility included ejection period (EP), ejection fraction (EF) and ejection rate (ER).

**RESULTS:** A significantly shorter EP was observed in patients with BPSs in comparison to those with CSs ( $t = 2.4$ ,  $P < 0.05$ ). EF in BPS patients significantly decreased in comparison to that in CS and normal subjects ( $t = 6.4$ ,  $P < 0.0001$ ;  $t = 2.1$ ,  $P < 0.05$ ). EF in CS patients also significantly decreased in comparison to that in normal subjects ( $t = -3.0$ ,  $P < 0.005$ ). Consequently, ER in patients with BPSs and CSs was significantly smaller than that in normal subjects ( $t = 3.1$ ,  $P < 0.005$ ;  $t = -3.5$ ,  $P < 0.001$ ). Moreover, in cases where postprandial reflux of a radioisotope into the common hepatic duct from the gallbladder was observed, EF and ER of either CS or BPS patients showed a significant reduction.

**CONCLUSION:** Bile evacuation from the gallbladder is reduced in patients with BPSs, in comparison to those with CSs and to healthy volunteers. Bile stagnation due to impaired gallbladder kinetics seems to be one of the predisposing factors for the development of BPSs.

### INTRODUCTION

The prevalence of gallstone disease has been increasing in Japan over the past five decades, with an increased incidence of cholesterol stones (CSs) as a leading cause<sup>[1-3]</sup>. In addition, the number of patients with black pigment stones (BPSs) has also been increasing, while the incidence of calcium bilirubinate stones is decreasing<sup>[1,2]</sup> and thus becoming less common in comparison to other Asian countries<sup>[2,3]</sup>.

Much effort has been directed to identify the mechanism of gallstone formation, especially in the case of cholesterol and calcium bilirubinate stones. The supersaturation of bile, caused by an increase in cholesterol concentration or a decrease in bile salt concentration, contributes to form a liquid crystalline phase of cholesterol<sup>[4-6]</sup>. Calcium bilirubinate stones (brown pigment stones) develop as the enzyme  $\beta$ -glucuronidase, possibly produced by bacteria such as *Escherichia coli*, generates unconjugated bilirubin, which precipitates as a calcium salt<sup>[5,7]</sup>. Therefore, bilirubinate calcium is closely related to biliary infection<sup>[3,5,7-9]</sup>.

However, the mechanism by which BPSs develop has not been fully elucidated. BPSs sometimes occur in patients with hemolytic anemia<sup>[8,10]</sup>, liver cirrhosis<sup>[5,11,12]</sup>, and histories of cardiac valve replacement<sup>[13]</sup> and gastrectomy<sup>[14-16]</sup>, but the majority of patients have no specific background<sup>[8]</sup>. Contrary to brown pigment stones, BPSs are not associated with biliary infection and almost all occur in the gallbladder<sup>[5,8,9]</sup>. Other reports have suggested that some unique structures of the gallbladder such as the Rokitsansky-Aschoff sinuses<sup>[17]</sup> and the cystic duct<sup>[18]</sup> might be predisposing factors for the formation of BPSs.

A change in gallbladder contractility is another possible mechanism of gallstone formation. Over the past century, many studies have been conducted to disclose a close

association with gallbladder dysmotility and gallstone diseases<sup>[11,19-29]</sup>. Previous studies, however, have yielded conflicting results. The majority of studies have reported impaired gallbladder emptying in patients with gallstones, while others have not. These conflicting results have derived in part from different methodology to assess gallbladder motility<sup>[22]</sup>, and also from the fact that these studies were conducted without taking into account the chemical characteristics of the stones. To date, there have been, according to the PubMed database, very few reports that describe gallbladder motility with special reference to the pathogenesis of BPS formation.

This study analyzed the pattern of postprandial bile evacuation from the gallbladder quantitatively in patients with BPSs, using a non-invasive technique with a radioactive marker <sup>99m</sup>Tc-PMT, and compared that pattern with that seen in patients with CSs and in healthy volunteers.

## MATERIALS AND METHODS

### Patients

From 1991 to 2005, 694 patients underwent cholecystectomy for cholelithiasis at Hirosaki University Hospital, Japan. Among these, 22 patients with CSs and 14 with BPSs were included. Patients with positive bile culture obtained at the time of surgery, any sign of cholecystitis, liver cirrhosis or hepatitis, diabetes mellitus, abnormal wall thickening of the gallbladder, and/or a previous surgical history were excluded from the study. The categories of the stones were determined according to the macroscopic characteristics of the specimens and their chemical analyses. Twenty-eight healthy volunteers without any surgical history were also analyzed and included as controls. There was no significant difference in age among the three groups ( $52.4 \pm 13.0$  in CS patients,  $55.8 \pm 14.4$  in BPS patients, and  $54.8 \pm 14.4$  in healthy volunteers,  $P = 0.74$ ). The male-to-female ratios were also comparable (6/16 in CS, 4/10 in PBS, and 15/13 in healthy volunteers,  $P = 0.11$ ). The nature of the study was explained to each subject before cholescintigraphy, and informed consent was obtained under the instruction of the ethical committee for human studies, and the study was approved by the Hirosaki University School of Medicine.

### Cholescintigraphy

The method was a modification of that previously described by Krishnamurthy *et al*<sup>[30]</sup>. All subjects were obliged to fast from 11:00 pm prior to the day of examination. Each subject was injected with 5 mCi <sup>99m</sup>Tc-N-pyridoxal-5-methyltryptophan (<sup>99m</sup>Tc-PMT) *via* the median cubital vein in the morning. After 60 min bed rest in a semi-reclining position, a scintillation camera with a low energy, high-resolution collimator was placed on the right hypochondrium and positioned to enable the separate visualization of the common hepatic duct, common bile duct, descending portion of the duodenum, and gallbladder. The radioactivity gradually increased and reached a plateau in 60 min. Serial views of the abdomen were obtained at 1-min intervals from this point up to 60 min. The information was simultaneously digitalized

**Figure 1** Definition of postprandial contractility indices of the gallbladder. Postprandial gallbladder contractility was expressed by EF, which is determined as a percentage decrease in radioactivity, and ER, which is determined by EF/EP. Radioactivity was measured in three regions of interest in the gallbladder and EP was determined as the time of decrease on the time-activity curve. CPS: Counts per second.

and recorded in the mode on  $64 \times 64$  computer matrices at 1 frame per 15 s. At 10 min, 200 mL Calorie Mate, which was composed of 33.4 g glucose, 6.7 g protein, 4.4 g fat, and 200 kcal (Otuka, Tokyo, Japan), was given to each patient as a test meal, and observation was continued for an additional 50 min. To avoid the effect of respiratory movement on images, each subject was instructed to breathe smoothly throughout the data collection.

### Computer data analysis

Serial images were created by a data-analyzing computer. Four regions of interest on a composite image were chosen. The first included the entire gallbladder; the second, the common hepatic duct; the third, the descending part of the duodenum; and the fourth, the liver as a background. Time-activity curves were generated for each region, background counts were subtracted, and net count decay was corrected and normalized. In a similar manner, time-radioactivity curves were obtained.

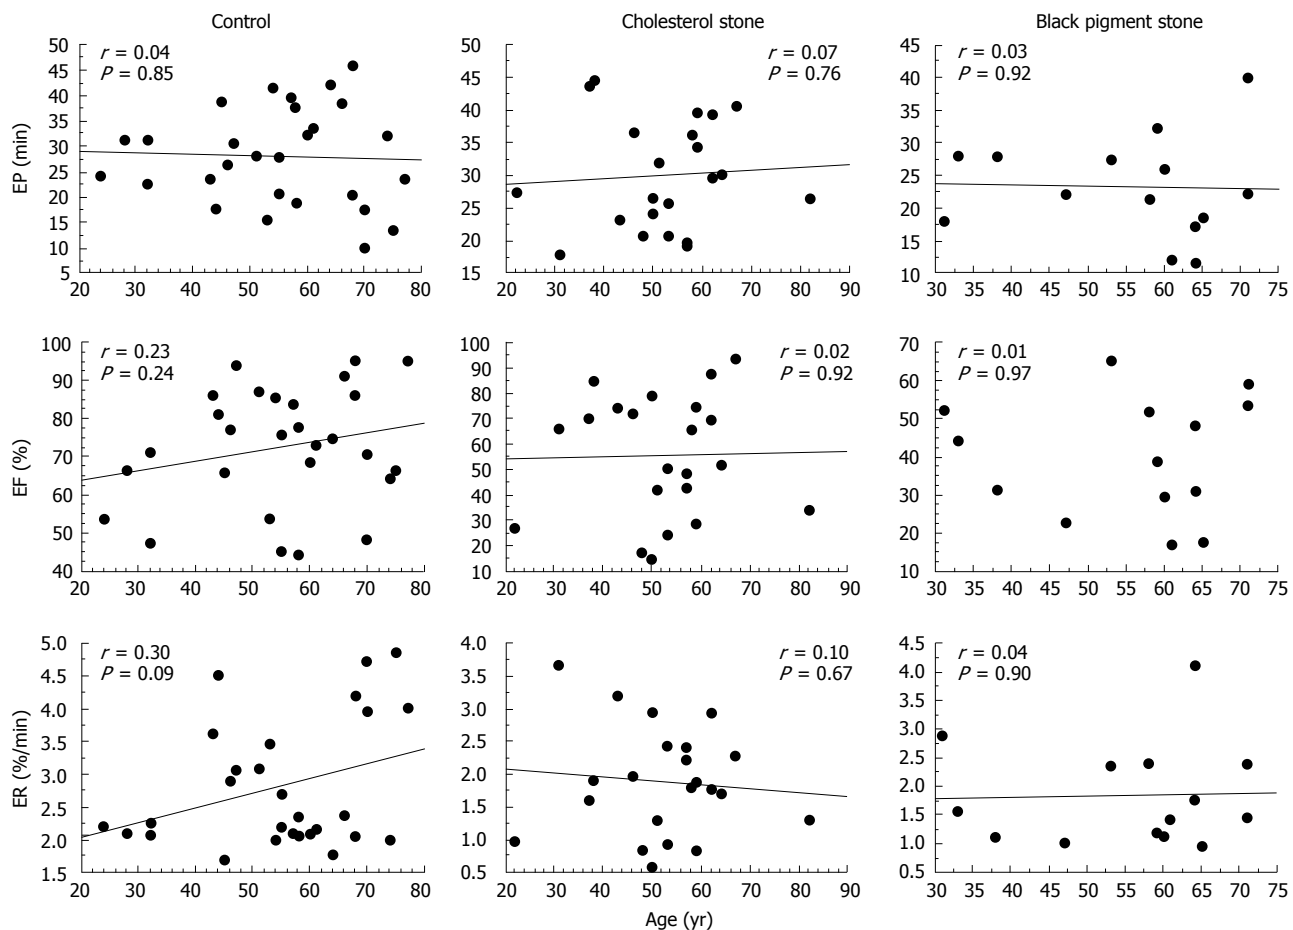

Next, the times when the gallbladder began ejecting ( $t1$ ) and when the gallbladder stopped ejecting ( $t2$ ), and their corresponding counts ( $c1$ ,  $c2$ ) were set (Figure 1). The ejection period (EP), ejection fraction (EF) and ejection rate (ER) were calculated according to the formulae below:  $EP = t2 - t1$  (min);  $EF = (c1 - c2)/c1$  (%);  $ER = EF/EP$  (%/min).

### Statistical analysis

For statistical examinations an analysis of variance, Student's *t* test,  $\chi^2$  test and linear regression analysis were all used appropriately, and the SPSS 11.0J software program for Windows was used for the analysis. The continuous variables were reported as the mean  $\pm$  SD.  $P < 0.05$  was considered to be significantly different.

## RESULTS

Gender did not affect EP, EF and ER in all three groups (Table 1). Age also showed no correlation with EP, EF and

**Figure 2** Correlation of age with contractility indices of the gallbladder. There was no correlation between age and EP, EF and ER in all three groups.

ER (Figure 2). Moreover, the size and the number of the stones correlated with none of the indices in either group with CSs or BPSs (Figures 3 and 4).

Postprandial changes in gallbladder contractility are summarized in Figure 5. The EP values of normal subjects ( $28.2 \pm 9.5$  min) and CS patients ( $30.0 \pm 8.4$  min) were comparable but the value in BPS patients ( $23.3 \pm 7.8$  min) was significantly shorter than that in CS patients ( $P < 0.05$ ). The EF of CS patients ( $55.5\% \pm 24.0\%$ ) was significantly smaller than that of normal subjects ( $72.5\% \pm 15.5\%$ ,  $P < 0.05$ ), and the value of BPS patients ( $40.2\% \pm 15.5\%$ ) was significantly reduced in comparison to that of CS patients ( $P < 0.05$ ), and to that of normal subjects ( $P < 0.0001$ ). Consequently, the ER in the CS group ( $1.9\% \pm 0.8\%/min$ ) and in the BPS group ( $1.9\% \pm 0.9\%/min$ ) significantly decreased in comparison to that of normal subjects ( $2.8\% \pm 1.0\%/min$ ,  $P < 0.001$ ,  $P < 0.005$ ). The ER values were comparable between the CS and BPS groups.

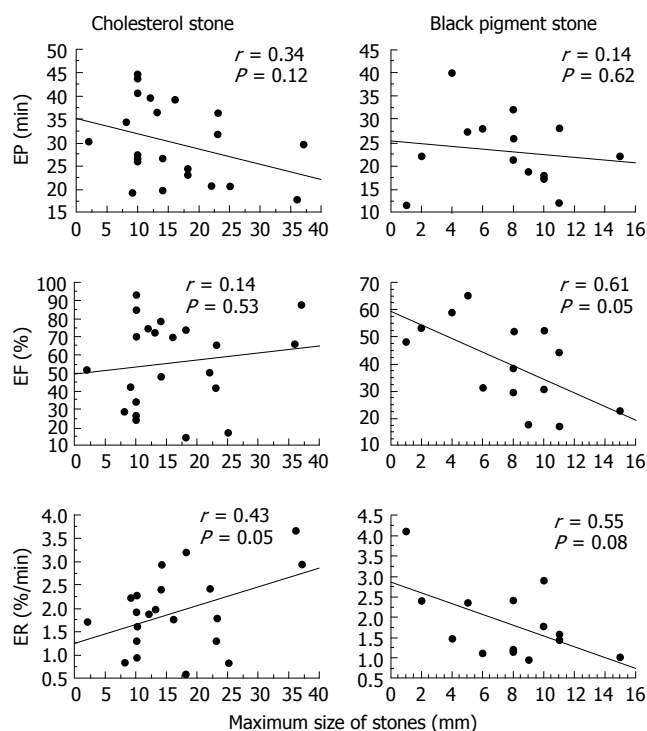

Postprandial bile reflux from the gallbladder to the common hepatic duct was observed in 22/28 (76%) normal subjects, 11/22 (50%) CS patients, and 8/14 (57%) BPS patients. Comparisons between the cases with and without reflux are summarized in Figure 6. In normal subjects, EP and ER were comparable between 22 reflux ( $28.5 \pm 9.5$  min,  $3.0\%/min$ ) and six non-reflux cases ( $27.0 \pm 10.0$  min,  $2.3\% \pm 1.0\%/min$ ), while EF was significantly larger in the reflux group ( $76.3\% \pm 13.6\%$ ) than in the non-reflux group ( $58.4\% \pm 14.3\%$ ,  $P < 0.01$ ).

**Table 1** Effects of gender on postprandial motility indices of the gallbladder

	Male	Female	P
Normal subjects (n)	15	13	
EP (min)	$26.6 \pm 10.3$	$30.1 \pm 8.4$	0.34
EF (%)	$68.7 \pm 14.6$	$77.1 \pm 15.9$	0.16
ER (%/min)	$2.9 \pm 1.2$	$2.7 \pm 0.7$	0.51
CS (n)	6	16	
EP (min)	$29.1 \pm 6.1$	$30.4 \pm 9.2$	0.76
EF (%)	$54.3 \pm 27.1$	$56.0 \pm 23.7$	0.89
ER (%/min)	$1.9 \pm 1.0$	$1.9 \pm 0.8$	0.99
BPS (n)	4	10	
EP (min)	$22.4 \pm 5.6$	$23.6 \pm 8.7$	0.80
EF (%)	$39.3 \pm 10.9$	$40.6 \pm 17.6$	0.89
ER (%/min)	$1.9 \pm 0.8$	$1.9 \pm 1.0$	0.99

In CS patients, EP was significantly longer in 11 reflux cases ( $33.5 \pm 7.4$  min) than in 11 non-reflux cases ( $26.6 \pm 8.1$  min,  $P < 0.05$ ). EF and ER were comparable between reflux and non-reflux groups. In BPS patients, EP, EF and ER were comparable, despite reflux state.

In a subgroup analysis limited to patients with postprandial bile reflux from the gallbladder to the common hepatic duct, EF and ER in the BPS CS groups were significantly smaller than those in normal subjects. EP in the BPS group was also significantly shorter than that in the CS group (Figure 6).

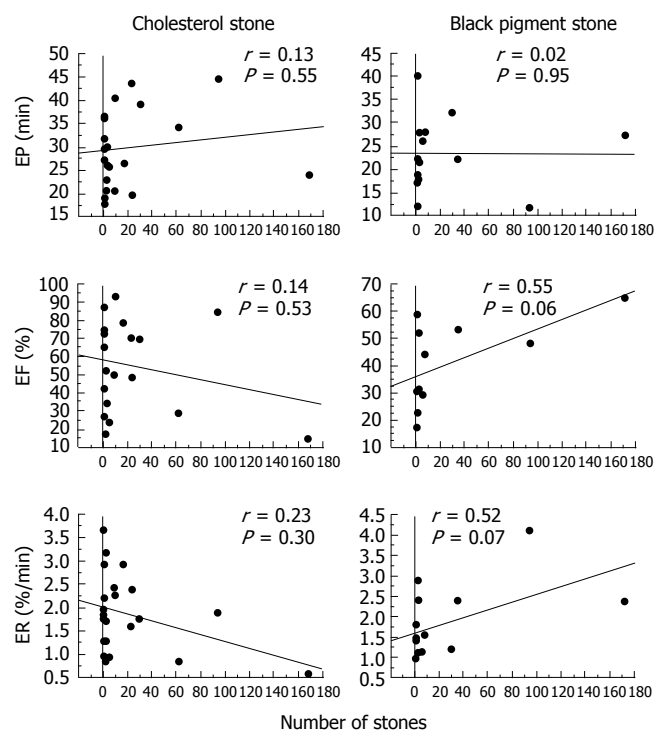

**Figure 3** Correlation of the size of stones with contractility indices of the gallbladder. There was no correlation between stone size and EP, EF and ER in all groups.

## DISCUSSION

Many studies have reported a high incidence of BPSs in patients with hemolytic jaundice<sup>[8,10]</sup>, heart valve replacement<sup>[13]</sup>, liver cirrhosis<sup>[5,11,12]</sup> and a previous history of gastrectomy<sup>[14-16]</sup>. The first two are primarily due to bilirubin overproduction, while the latter are not. However, despite similar biochemical and clinical features, many patients with hemolytic anemia do not develop BPSs. Moreover, Portincasa *et al*<sup>[10]</sup> have reported that impaired gallbladder motility is observed in patients with  $\beta$ -thalassemia major, and have suggested that hemolytic hyperbilirubinemia and dysmotility might contribute to the process of pigment stone formation. In patients with liver cirrhosis, Acalovshi *et al*<sup>[11]</sup> have reported that gallbladder contractility is impaired and hypomotility is proportional to disease severity. A close relationship between high incidence of gallstones and changes in gallbladder kinetics after gastrectomy has also been described<sup>[15]</sup>. Taking into consideration that BPSs also occur without these complications<sup>[17]</sup>, impaired gallbladder function may be associated with BPS formation. However, there have so far been very few reports on gallbladder kinetics and the mechanism of stone formation with special reference to BPSs.

In this study, biliary scintigraphy was used to analyze the postprandial dynamics of bile flow in patients with BPSs in comparison to those with CSs and normal subjects, because it was essentially risk-free, with very slight radiation exposure and yielded a precise assessment of the ejection fraction of the gallbladder motility, as previously reported<sup>[22,30]</sup>. First, the effects of age, gender and the characteristics of the stones on gallbladder

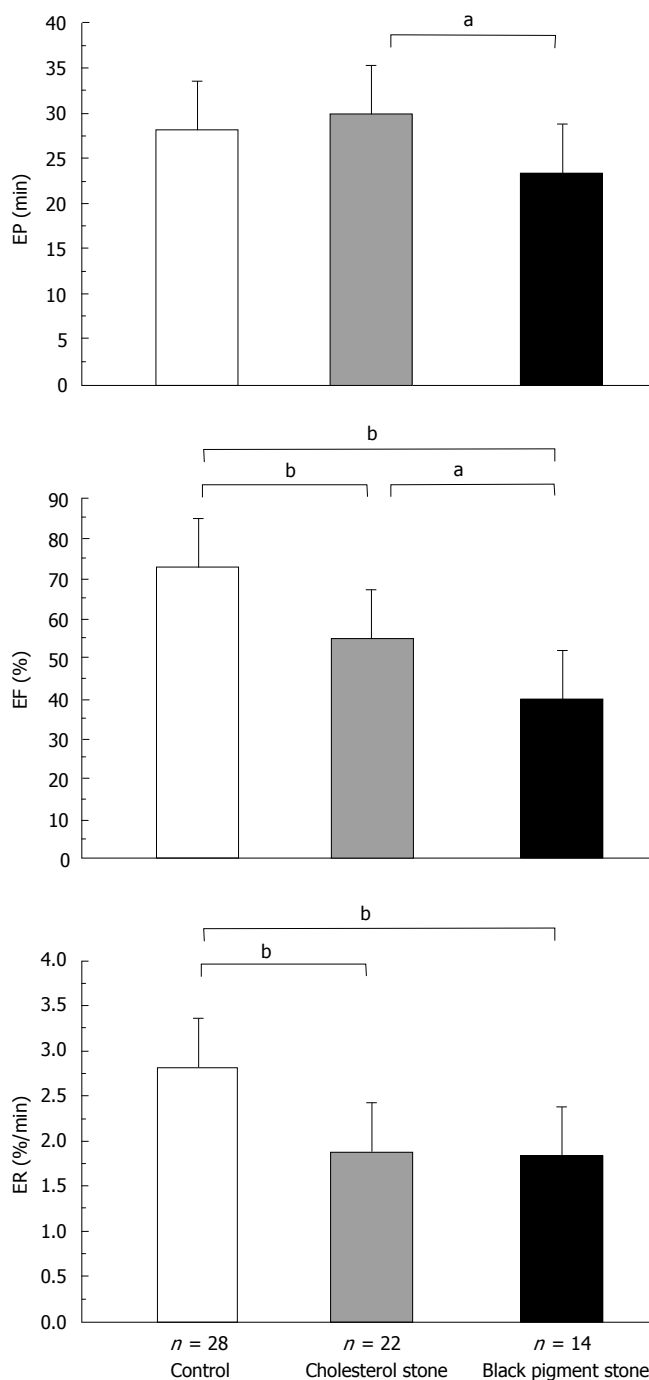

**Figure 4** Correlation between the number of stones with the contractility indices of the gallbladder. There was no correlation between the number of stones and EP, EF and ER in all groups.

contractility were analyzed, because there have been some previous studies on the effects of age and sex on gallbladder emptying<sup>[21,31]</sup>. In all groups, age and gender, and size and number of stones did not affect EP, EF and ER. Other studies have also found that size and number of stones have no influence upon postprandial gallbladder emptying<sup>[11,27]</sup>. Therefore, gallbladder contractility was analyzed without taking these backgrounds into consideration.

It has been reported that EF in normal subjects is 80% in response to postprandial intrinsic loading of cholecystikinin (CCK)<sup>[19]</sup>, and it ranges from 50%-80% in response to extrinsic administration of CCK<sup>[24,27]</sup>. In patients with gallstones, the contractility is reduced to 52% by intrinsic<sup>[19]</sup> and to 32%-50% by extrinsic stimulus of CCK<sup>[24,27]</sup>. These reports, however, included all kinds of gallstones with different etiology, while also neglecting the presence or absence of acute or chronic inflammatory processes, such as gallbladder-wall thickening. In this study, gallbladder contractility was analyzed according to the predominant chemical component of the gallstones. Patients with any sign of cholecystitis, liver cirrhosis or hepatitis, diabetes mellitus, abnormal gallbladder-wall thickening, and/or previous surgical history which might affect contractility were excluded from the study.

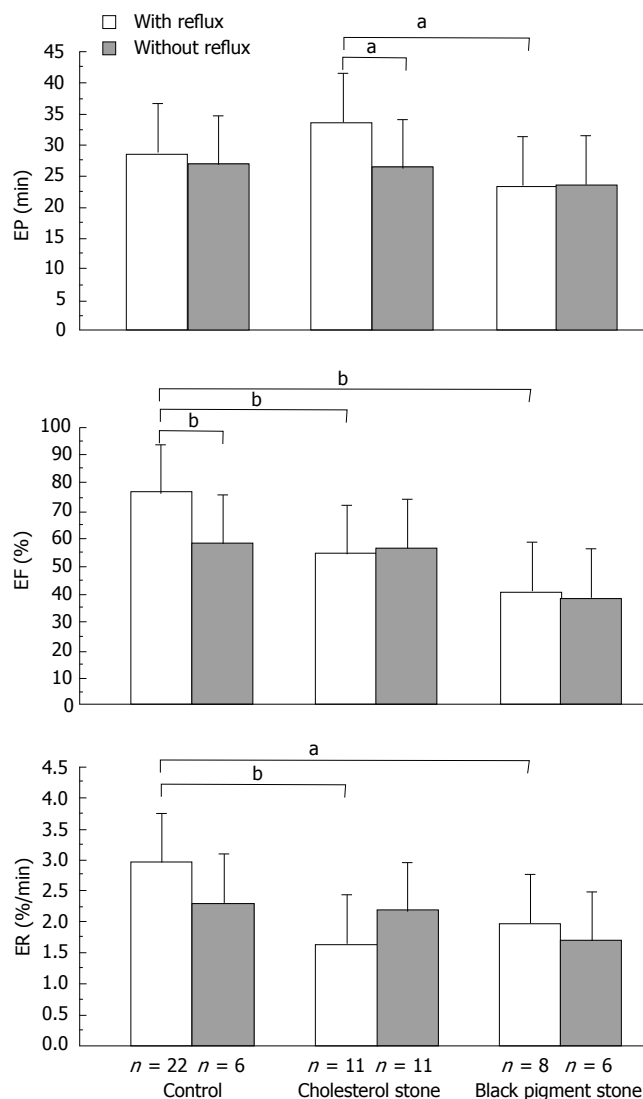

In BPS patients, EP was significantly shorter than that in CS patients. Simultaneously, EF was reduced significantly in BPS patients, in comparison to those with CSs and healthy volunteers. These findings suggested that bile clearance from the gallbladder was significantly reduced in patients with BPSs. Krishnamurthy *et al*<sup>[24]</sup> have reported that there is no difference in EP between

**Figure 5** Postprandial contractility indices of the gallbladder. A significantly shorter EP was observed in patients with BPSs than in those with CSs. EF in BPS patients was significantly decreased in comparison to that in CS patients and normal subjects. EF in CS patients also significantly decreased in comparison to that in normal subjects. Consequently, ER in patients with BPSs and CSs was significantly smaller than that in normal subjects. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$ .

gallstone patients and normal individuals, but they do not distinguish patients according to the chemical characteristics of their stones. Such results may come from an increased proportion of CSs in their study, because the EP of normal subjects and gallstone patients did not differ in the current study. Portincasa *et al.*<sup>[28]</sup> have conducted a comparative analysis of gallbladder contractility in patients with BPSs or CSs, and observed an increased fasting volume of the gallbladder in CS but not in BPS patients.

**Figure 6** Postprandial contractility indices of the gallbladder according to the reflux state of a radioisotope into the common hepatic duct. In normal subjects, EF was significantly larger in patients with reflux. In a subgroup analysis of such patients, EF and ER in those with either CSs or BPSs showed a significant reduction in comparison to those in normal subjects. <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$ .

Postprandial emptying was delayed and incomplete in both CS and BPS patients in comparison to control subjects. However, these observations were made based on the findings of ultrasonography, and not by biliary scintigraphy.

It has been demonstrated that CCK simultaneously induces contraction of the gallbladder and relaxation of the sphincter of Oddi, which facilitates secretion of the bile duct into the duodenum. If this contraction-relaxation coordination fails, bile reflux from the gallbladder to the common hepatic duct may occur because of transient resistance of the sphincter. Itoh *et al.*<sup>[32]</sup> have reported that this phenomenon is observed in patients with chronic pancreatitis and that the degree of reflux is proportional to disease progression. This means that one of the causes of such reflux is relative stenosis of the distal bile duct. Bile reflux, however, was observed in half of the patients with gallstones, in whom EF was significantly reduced in comparison to that in healthy volunteers. This phenomenon

suggests that minute discordance of gallbladder emptying and relaxation of the sphincter of Oddi predisposes to bile reflux and thus causes bile stagnation in the gallbladder.

Chemically, the structure of BPSs is polymerized bilirubin with copper, iron, calcium and other metals, and almost all the stones are formed in the gallbladder<sup>[33]</sup>. Therefore, an environment suitable for the formation of BPSs comprises conditions that allow chemical polymerization with sufficient time. In fact, EF was reduced in patients with gallstones, especially with BPSs in the present study. Moreover, bile reflux from the gallbladder to the common hepatic duct may cause subclinical transient bile stagnation, thereby contributing to stone formation.

In conclusion, bile evacuation from the gallbladder is reduced in patients with BPSs, in comparison to those with CSs and healthy volunteers. We therefore postulate that impaired gallbladder motor function and discordance of bile evacuation is not the result of the presence of gallstones, but instead it is considered to precede the development of BPSs.

## ACKNOWLEDGMENTS

The authors thank Professor R Hada and Emeritus Prof. M Konn, Hirosaki University Graduate School of Medicine, for their many and varied contributions throughout the study.

## COMMENTS

### Background

The incidence of BPSs and CSs is increasing in Japan. However, the mechanism of BPS formation is still not completely understood. The authors hypothesize that reduced motor function of the gallbladder and dysfunction of bile evacuation is associated with BPS formation.

### Research frontiers

To date, there have been very few reports that describe gallbladder motility with special reference to the pathogenesis of BPS formation. The authors found impaired gallbladder kinetics in patients with BPSs, in comparison to those with CSs and to healthy volunteers.

### Innovations and breakthroughs

The authors strictly selected the patients without any background diseases such as cholecystitis, liver cirrhosis or hepatitis, diabetes mellitus, abnormal gallbladder-wall thickening, and/or a previous surgical history, and then analyzed physiological patterns of bile evacuation from the gallbladder quantitatively by a less-invasive method of computer cholelscintigraphy.

### Applications

This research is expected to contribute to understanding the pathogenesis of gallstone diseases.

### Peer review

The authors analyzed gallbladder contractility in patients with BPSs in comparison to those with CSs and healthy volunteers. The study is very interesting.

### Abstract

**AIM:** To determine the effects of allopurinol, an inhibitor of xanthine oxidase, and apocynin, an inhibitor of NADPH oxidase, on oxidant stress and liver injury caused by hepatic ischemia/reperfusion (I/R) procedure in mice.

**METHODS:** Mice were pretreated with a xanthine oxidase inhibitor, allopurinol, or NADPH oxidase (NOX) inhibitor, apocynin before the hepatic I/R procedure. Then treated or untreated mice underwent the hepatic I/R procedure. The effects on hepatic injury and superoxide anions were determined after starting reperfusion.

**RESULTS:** A standard warm hepatic I/R procedure led to a marked increase in superoxide anion production as indicated by a superoxide anion tracer, MCLA. At the same time, the procedure caused profound acute liver injury, as indicated by elevated serum alanine aminotransferase and tumor necrosis factor- $\alpha$  levels, reduced liver glutathione levels and elevated malondialdehyde contents, as well as a high apoptotic cell count. All these changes were reversed by the use of apocynin or allopurinol prior to the hepatic I/R procedure.

**CONCLUSION:** Allopurinol and apocynin exerted protective effects on hepatic ischemia/reperfusion injury. The protection is associated with blocking the generation

### INTRODUCTION

Excessive reaction oxygen species (ROS) cause tissue damage and cell death by binding and altering cellular macromolecules, including DNA, proteins and lipids, and affect their function. One main chemical source which has been shown to contribute significantly to overall pronounced oxidant stress during hepatic ischemia/reperfusion (I/R) procedure is xanthine oxidase (XO), which generates superoxide anions ( $O_2^-$ ) during the conversion of hypoxanthine to xanthine. It is known from many studies that much of the sustained injury during organ transplantation, including the liver, is triggered by ROS *via* activated XO, because allopurinol, an XO inhibitor, provided some protection against the hepatic I/R-induced injury<sup>[1]</sup>.

NADPH oxidase (NOX), using NADPH as the source of electrons, catalyzes one electron reduction of molecular oxygen to generate  $O_2^{1-2}$ , which is a central and initial ROS molecule and may convert to more active and toxic ROS, such as hydrogen peroxide ( $H_2O_2$ ), hydroxyl radical ( $HO^\bullet$ ), or peroxide nitrite ( $ONOO^-$ ) in the presence of  $H^+$ ,  $H_2O_2$ , and nitric oxide ( $NO$ )<sup>[3]</sup>. These  $O_2^-$ -derived ROS participating in the inflammatory process, are thought to be key mediators for the activation of Kupffer cells<sup>[4]</sup> and thus, are crucial in the apoptotic and/or necrotic cell death of the parenchymal cells and sinusoidal endothelial cells (SEC) in the liver<sup>[5,6]</sup>. The generation of superoxide anions by NADPH oxidase serves as a host defense mechanism

against invading microorganism infection and the enzyme is present in phagocytic cells, such as monocytes and neutrophils<sup>[7]</sup>. Although the evidence exists that ROS generated by NOX participate in many cellular responses, and may be involved in many injuring processes, few studies are available that investigate the role of NOX in the contribution to pronounced oxidant stress during the ischemia/reperfusion-induced hepatic injury<sup>[7,8]</sup>. Apocynin is a naturally occurring methoxy-substituted catechol that effectively inhibits NADPH oxidase through preventing the assembly of its multi-subunits<sup>[9]</sup>. Thus, we used this inhibitor to explore the role of NADPH oxidase in the generation of superoxide anions during the hepatic I/R procedure and investigate whether apocynin confers any protection against the injury in a mouse model of warm ischemia/reperfusion-induced acute liver injury.

## MATERIALS AND METHODS

### Animals and treatments

ICR mice, from Charles River Laboratory, Wilmington, MA, were fed a pellet diet and water ad libitum and maintained on a 12 h-light/dark cycle. The animal experiment was performed according to a protocol approved by the UC Davis Institutional Animal Care and Use Committee (IACUC). The protocol was prepared in accordance with the National Institutes of Health animal use guidelines. Mice were pretreated with either an XO inhibitor, allopurinol (50 mg/kg, i.p. from Sigma Chemical Co. St. Louis, MO) or a NOX inhibitor, apocynin (3 mg/kg, i.p. from Acros Organics, Geel, Belgium) one day and one hour before the hepatic I/R procedure. A warm hepatic I/R procedure was performed as reported previously by us<sup>[10]</sup>. In brief, mice were anesthetized with pentobarbital sodium (60 mg/kg, i.p.). Laparotomy was made with a middle incision to expose the lobes of the liver. Following surgical exposure of the portal vein, mice were injected with heparin (100 unit/kg) *via* tail vein to prevent the formation of blood clot during the ischemia duration. The portal vein and hepatic artery were occluded for 30 min with a microaneurysm clamp to induce hepatic ischemia. Then, the clamp was removed to allow blood to flow through the liver again (reperfusion).

A total of six groups (6 mice in each group) were included in the experiment. Group A: sham-operated group, in which mice received normal saline (N.S.), and underwent a sham operation without I/R procedure; Group B (N.S. control group) in which mice underwent hepatic I/R procedure plus N.S. injection; Group C (allopurinol treatment group), in which animals received prior allopurinol injections and subsequent hepatic I/R procedure; Group D (apocynin treatment group), in which animals received prior apocynin injections and subsequent hepatic I/R procedure. Six and twenty four hours after starting the reperfusion, blood samples were collected from the vena cava before sacrifice. The liver was rapidly excised after drawing blood from the vena cava. Portions of liver tissue were fixed in 10% neutralized formalin for histological evaluation or snap frozen in liquid nitrogen, and maintained at -80°C until homogenization for the various biochemical assays.

### Serum alanine aminotransferase assay

Serum levels of alanine aminotransferase (ALT) served as an indicator of liver injury and were analyzed using a commercially available diagnostic kit (Catachem Inc. Bridgeport, Connecticut), and expressed as unit/L.

### Measurement of ROS generation in liver homogenates

2-Methyl-6-(P-methoxyphenyl)-3,7-dihydroimidazo(1,2- $\alpha$ )pyrazine-3-one (MCLA) enhanced chemiluminescence was used to determine  $O_2^-$  generation, as reported by us previously<sup>[10]</sup>. Approximately, 10 mg of frozen liver tissue was homogenized on ice in 1 mL of homogenization buffer containing 20 mmol/L of N-2-Hydroxyethylpiperazine-N'-2-ethanesulfonic acid (HEPES) and 10 mmol/L ethylene diamine tetraacetic acid (EDTA). The homogenate was subjected to low speed centrifugation (1000 g) for 10 min to remove debris. Luminometer vials containing 2 mL of prewarmed Krebs-HEPES buffer (99 mmol/L NaCl, 4.7 mmol/L KCl, 1.2 mmol/L  $MgSO_4$ , 1 mmol/L  $KH_2PO_4$ , 1.9 mmol/L  $CaCl_2$ , 25 mmol/L  $NaHCO_3$ , 11.1 mmol/L glucose, and 20 mmol/L HEPES, pH 7.4) with 1.0  $\mu$ mol/L of MCLA were placed in the dark for at least 20 min. After the dark adaptation, background readings were recorded in a luminometer (Lumat LB; Berthold Technologies, BmbH & Co. KG, Germany), and then 20  $\mu$ L of homogenate supernatant was added to each vial containing MCLA. Chemiluminescent emission in relative light units (RLU) was recorded during a plateau phase of each recording period, and corrected by subtracting the background reading. The calculated value was used to express the integrated values of chemiluminescence (RLU/second/ $\mu$ g protein).

### Assays of liver glutathione and malondialdehyde content

Levels of the reduced form of glutathione (GSH) and the lipid peroxidation product, malondialdehyde (MDA) in liver tissue were measured spectrophotometrically 6 h and 24 h after starting reperfusion by commercially available kits (OXIS Research, Portland, OR). The levels of GSH and MDA are expressed as nanomoles per milligram of protein.

### Histological examination

Fixed liver specimens were embedded in paraffin, sectioned in 4  $\mu$ m thickness, and stained with hematoxylin and eosin (HE) for the evaluation of liver injury. Photomicrographs were taken with a digital camera under a microscope. In addition, frozen sections of the livers were stained with the terminal deoxynucleotidyl transferase (TdT) for detecting of apoptotic cells by an *in situ* Apoptosis Detection Kit according to the manufacturer's instructions (Chemicon Inc., Temecula, CA), and reported previously by us<sup>[11]</sup>.

### Determination of serum tumor necrosis factor- $\alpha$ levels

Serum tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) levels after the hepatic I/R procedure were determined with an enzyme-linked immunosorbent assay (ELISA) kit (R&D Systems, Minneapolis, MN) and expressed as nanograms per milliliter.

**Figure 1** Attenuation of I/R-induced liver injury by apocynin and allopurinol in mice. **A-D**: Representative micrographs of liver histology ( $\times 100$ ). **A**: Normal liver; **B**: I/R-induced liver injury 6 h after starting reperfusion; **C** and **D**: Attenuation of liver injury with apocynin (APO) (**C**) or Allo (allopurinol) (**D**); **E**: Serum ALT levels in mice receiving apocynin or allopurinol and subsequently the hepatic I/R procedure. Serum ALT levels were determined 6 h and 24 h after starting reperfusion ( $n = 6$  each group), and expressed as mean  $\pm$  SEM.  $^*P < 0.01$  vs I/R procedure plus normal saline (N.S.) at 6 h or 24 h.

### Statistical analysis

Most data were expressed as mean  $\pm$  SD of the mean (SEM), and evaluated with an ANOVA analysis and Newman-Keuls tests for multiple comparisons among groups. A  $P$  value less than 0.05 was considered statistically significant.

## RESULTS

### Amelioration of I/R-induced acute liver injury

As shown in Figure 1E, the hepatic I/R procedure caused a marked increase in serum ALT levels 6 h to 24 h after starting the reperfusion. Prior intraperitoneal injection of either allopurinol or apocynin led to a marked decrease in serum ALT levels compared to animals with I/R plus N.S. injection at both 6-h and 24-h points ( $P < 0.01$ ). It appeared that either allopurinol or apocynin tended to exert an improved protection to the same extent, and that the differences were not statistically significant at both time points between these two groups. These findings

were consistent with the histological findings as shown in Figure 1A-D. The hepatic I/R procedure led to marked necrosis in the central lobule (Zone III) with significant inflammatory infiltration (Figure 1B). A significant reduction in necrosis was found in the livers of animals receiving injections of allopurinol or apocynin (Figure 1C and D) compared to the control group (Figure 1A). For controls, additional animals were injected with allopurinol or apocynin without the hepatic I/R procedure. Serum ALT levels in animals receiving apocynin ( $65 \pm 17$  unit/mL,  $n = 3$ ) or allopurinol ( $57 \pm 14$  unit/mL,  $n = 3$ ) were similar to levels in N.S. controls ( $46 \pm 27$  unit/mL,  $n = 3$ ). These data indicate that neither apocynin nor allopurinol is toxic to the liver.

### Enhanced apoptosis in hepatic I/R-induced liver injury

Apoptotic cells in liver sections were detected by in situ staining using TUNEL assay. As shown in Figure 2, 6 h after starting reperfusion, profound apoptotic cells with positive TUNEL red fluorescent staining in nuclei were

**Figure 2** Representative micrographs of *in situ* TUNEL staining of apoptotic cells in liver tissue after the hepatic ischemia/reperfusion procedure. **A-D:** The TUNEL staining assay was performed as described in the text, and the positive apoptotic cells were stained in red ( $\times 100$ ). **A:** Control; **B:** I/R procedure plus N.S. (6 h after starting reperfusion); **C:** I/R plus apocynin; **D:** I/R plus allopurinol. **E-H:** The corresponding liver sections stained with DAPI to illustrate nuclei as a cell number control.

**Figure 3** The hepatic I/R-induced superoxide anion production and the effects of apocynin or allopurinol in mouse liver. The superoxide anion production was determined in mouse liver homogenates with a superoxide anion tracer, MCLA, and the MCLA chemiluminescent emission was recorded in a luminometer and expressed as relative light unit per second per micrograms of protein (mean  $\pm$  SEM). <sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  vs the sham controls, <sup>d</sup> $P < 0.01$  vs the I/R procedure plus N.S. at 6 h time point.

visualized in animals with the hepatic I/R procedure (Figure 2B) compared to sham-operated controls (Figure 2A). Prior treatment of allopurinol or apocynin prevented apoptotic cell death caused by the hepatic I/R procedure (Figure 2C and D).

#### Enhanced superoxide anion release during the hepatic I/R procedure

We employed MCLA, which is proportional to levels of  $O_2^-$  and singlet oxygen, to investigate whether the hepatic I/R procedure enhanced the chemiluminescent emission from the liver homogenates. We found that light emission from the liver homogenates was elevated 3-fold 6 h after starting the perfusion, compared to animals with sham operation. The enhanced chemiluminescent emission, caused by the I/R procedure, was markedly inhibited by prior administration of allopurinol or apocynin (Figure 3).

This finding provides convincing evidence that NADPH oxidase or xanthine oxidase is the equally important source of superoxide anions, which contributes to pronounced oxidant stress during the hepatic I/R procedure.

#### Restored GSH and reduced MDA levels by allopurinol or apocynin treatment

Liver GSH and MDA levels were determined as indicators of oxidant stress and lipid peroxidation during the hepatic I/R procedure. As shown in Figure 4, both allopurinol or apocynin led to a restoration of decreased GSH levels and a reversion of elevated MDA levels in the liver ( $P < 0.05-0.01$ ). The GSH levels in the treated groups were close to controls 6 h after starting the reperfusion.

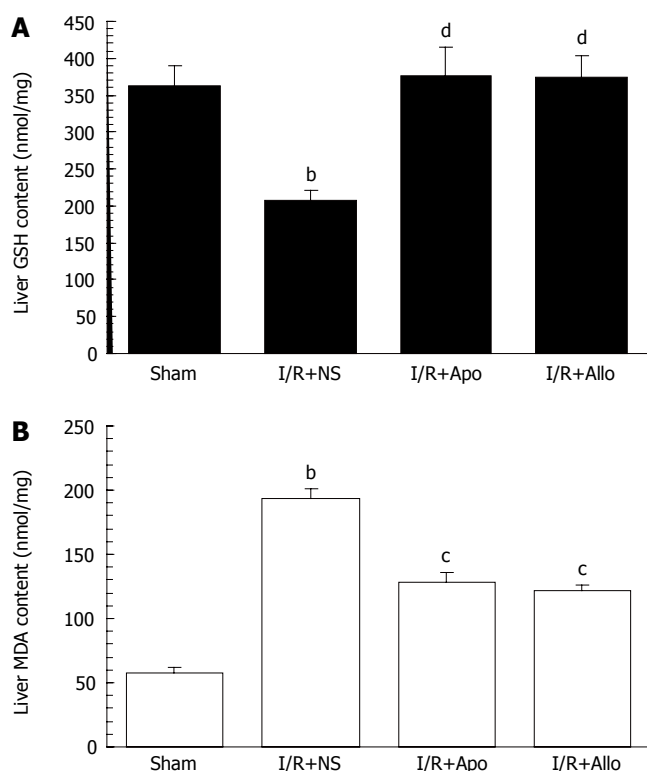

#### Serum TNF- $\alpha$ level

Serum TNF- $\alpha$  was determined using an ELISA kit 6 and 24 h after starting the reperfusion. It is clear that the hepatic I/R procedure caused an elevation of serum TNF- $\alpha$  levels, and that the prior administration of either allopurinol or apocynin reduced the TNF- $\alpha$  levels when compared to the I/R+N.S. controls ( $P < 0.05-0.01$ , Figure 5).

## DISCUSSION

In the present study, we demonstrated that prior administration of either allopurinol or apocynin prevented the hepatic I/R-induced acute liver injury in mice; the protection was due to a blockage of xanthine oxidase (XO) and NADPH oxidase (NOX) by allopurinol and apocynin, respectively. The findings indicate that both XO and NOX play a critical role in the generation of superoxide anion and superoxide anion-derived ROS during the hepatic I/R procedure. Thus, our findings further confirm the involvement of NOX activation in the hepatic I/R-induced acute injury.

Our previous study showed that pronounced oxidant stress is the major cause of the hepatic I/R injury, and the delivery of either extracellular superoxide dismutase or

**Figure 4** Hepatic I/R-induced depletion of reduced form of glutathione and enhanced lipid peroxidation, and effects of apocynin and allopurinol. **A:** Effect of apocynin or allopurinol on liver GSH levels with the hepatic I/R procedure. Liver MDA content was determined spectrophotometrically and expressed as nanomoles per milligram of tissue protein (mean  $\pm$  SEM). <sup>b</sup> $P < 0.01$  vs Sham controls; <sup>c</sup> $P < 0.05$ , <sup>d</sup> $P < 0.01$  vs the hepatic I/R procedure plus N.S. at 6 h time point ( $n = 6$  in each group).

catalase gene markedly attenuated the hepatic I/R-induced injury in mice<sup>[10]</sup>. It is known that XO plays a critical role in generating superoxide anions and administering allopurinol, a blocker of XO, reduced the injury. It is not clear whether other pathways of oxidative reactions also contribute to the enhanced oxidant stress based on the fact that allopurinol failed to improve the progression of remote hepatic parenchymal injury caused by hind limb I/R in mice<sup>[7]</sup>. This drove us to identify other possible pathologic pathways which lead to enhanced oxidant stress in the hepatic I/R process.

Apocynin is a potent inhibitor of NADPH oxidase by reacting with thiol groups required for enzyme assembly. Apocynin is thought to acquire activation by reacting with hydrogen peroxide and extracellular peroxidase. Active NADPH oxidase is comprised of five subunits (p22phox, p40phox, p47phox, p67phox and gp91phox)<sup>[12]</sup>. In resting cells, three of these subunits (p22phox, p47phox, and p67phox) form a cytosolic complex. Activation of NOX initiates with the phosphorylation of p47phox, which in turn results in the migration of the cytosolic complex to the membrane and subsequent association with membrane-bound p22phox and gp91 to form the active NADPH oxidase<sup>[13]</sup>. Several homologues of gp91phox-Nox1, Nox3, Nox4 and Nox5 have been identified in non-phagocytic cells<sup>[14]</sup>. NADPH oxidase has been shown to

**Figure 5** Effects of apocynin or allopurinol on serum TNF- $\alpha$  levels. have specific subcellular localizations. The mechanisms by which receptors activate NADPH oxidase and regulate ROS production are poorly understood. One may speculate that ROS may be generated during the early and late phases of the hepatic I/R procedure by xanthine oxidase (XO), mitochondrial respiration, or by Kupffer cell-associated and polymorphonuclear neutrophil (PMN)-associated NADPH oxidase<sup>[5,15]</sup>. Thus, blockage of either XO or NOX with their specific inhibitors decreased the production of superoxide anions, as indicated by less chemiluminescent emission with MCLA, and in turn reduced oxidant stress as reflected by restoration of GSH levels and reversed MDA content in the liver. Consequently, lower levels of serum ALT and TNF- $\alpha$ , improved liver histology, as well as fewer apoptotic cell counts, demonstrating the protective effects of these two inhibitors in the hepatic I/R model system. Our results are consistent with a recent report showing that inhibition of NADPH oxidase prevented alcohol-induced liver injury<sup>[16]</sup>, hemorrhagic shock-induced organ injury<sup>[17]</sup> and hepatic I/R injury<sup>[18]</sup>, likely by inhibiting ROS formation *via* NADPH oxidase. However, in the study by Hasegawa *et al*<sup>[18]</sup>, a less specific NADPH oxidase inhibitor, diphenyleneiodonium chloride (DPI), was used, and superoxide anion levels in the liver were not determined. The cell types which often have high levels of NADPH oxidase include neutrophils, monocytes and Kupffer cells. The former two cell types are recruited during the I/R process and contribute to the damaging process by releasing superoxide anions and proteases<sup>[19]</sup>. Activation of Kupffer cells also participates in the enhanced oxidant stress, and increases the production of TNF- $\alpha$  and other cytotoxic factors because the depletion of Kupffer cells resulted in reduced hepatic I/R-associated injury in rodent models<sup>[20,21]</sup>. Nevertheless, further studies are needed to elucidate the role of each cell type that significantly produces superoxide anions *via* the activation of NADPH oxidase during the hepatic I/R process.

In conclusion, the findings in the present study demonstrate that the pretreatment of both allopurinol and apocynin prevented ischemia/reperfusion-induced acute liver injury and that the protection is associated with the blockage of either xanthine oxidase or NADPH oxidase

activity. The activation of both enzymes contributes to the generation of superoxide anions and related reactive oxygen species during the hepatic ischemia/reperfusion-induced liver injury. This study implies a new pharmacological intervention approach by blocking either xanthine oxidase or NADPH oxidase, or in combination to improve the donor organ quality and survival after the transplantation in recipients.

## COMMENTS

### Background

Ischemia/reperfusion-associated donor liver damage is inevitable during the harvest, preservation, transportation and implantation to a recipient. Enhanced oxidant stress has been linked to the donor organ damage; however, the source of reactive oxygen species (ROS) for enhanced oxidant stress has not been well defined. Superoxide anion generated from the reaction of hypoxanthine to xanthine catalyzed by xanthine oxidase (OX) has been thought to be one source of ROS, but an intrinsic source of ROS, via the activation of NADPH oxidase (NOX), has not been well studied in a hepatic ischemia/reperfusion model system.

### Research frontiers

We employed a sensitive chemiluminescent tracer, MCLA, which reflects tissue levels of superoxide anion, one initial and very active oxygen species, to investigate the importance of superoxide anion via the NADPH oxidase reaction in a model of standard hepatic ischemia/reperfusion procedure in mice.

### Innovations and breakthroughs

We found that there was a marked increase in superoxide anion release during the ischemia/reperfusion procedure, and that the use of apocynin, a specific inhibitor of NADPH oxidase, effectively minimized the superoxide anion release, oxidant stress and liver damage caused by a hepatic ischemia/reperfusion procedure in mice.

### Applications

The study implies a new pharmacological intervention approach by blocking either xanthine oxidase or NADPH oxidase, or in combination to improve the donor organ quality, function and survival after the transplantation in recipients.

### Peer review

This study of the beneficial effects of allopurinol and apocynin on the healing of ischemia/reperfusion-induced liver injury is original. It is a well-designed and well-written paper. Allopurinol and apocynin exerted protective effects on hepatic ischemia/reperfusion injury. The protection is associated with blocking the generation of superoxide anions during the hepatic I/R procedure by inhibiting xanthine oxidase and NADPH oxidase activity.

### Abstract

**AIM:** To compare the efficacy of a 7-d vs 10-d triple therapy regarding *H pylori* eradication, endoscopic findings and histological gastric inflammatory inactivation in the Ecuadorian population.

**METHODS:** 136 patients with dyspepsia and *H pylori* infection were randomized in 2 groups (68 per group): group 1, 7-d therapy; group 2, 10-d therapy. Both groups received the same medication and daily dosage: omeprazole 20 mg bid, clarithromycin 500 mg bid and amoxicillin 1 g bid. Endoscopy was performed for histological assessment and *H pylori* infection status before and 8 wk after treatment.

**RESULTS:** *H pylori* was eradicated in 68% of group 1 vs 83.8% of group 2 for the intention-to-treat analysis (ITT) ( $P = 0.03$ ; OR = 2.48; 95% CI, 1.1-5.8), and 68% in group 1 vs 88% in group 2 for the per-protocol analysis (PP) ( $P = 0.008$ ; OR = 3.66; 95% CI, 1.4-10). Endoscopic gastric mucosa normalization was observed in 56.9% in group 1 vs 61.2% in group 2 for ITT, with similar results for the PP, the difference being statistically not significant. The rate of inflammatory inactivation was 69% in group 1 vs 88.7% in group 2 for ITT ( $P = 0.007$ ; OR = 3.00; 95% CI, 1.2-7.5), and 69% in group 1 vs

### INTRODUCTION

*H pylori* bacterial infection is worldwide in humans. It is the main etiologic factor in chronic gastritis and gastroduodenal ulcer disease<sup>[1]</sup>. It is also closely related to gastric adenocarcinoma and low grade gastric lymphoma of mucosa-associated lymphoid tissue (MALT). Forty percent to 50% of the world population is estimated to be infected, with the highest incidence occurring in older people and in those living in areas with low standards of sanitation<sup>[2]</sup>. In South American countries, the prevalence of *H pylori* infection ranges from 70% to 90%<sup>[3]</sup>, being 89.5% in Ecuador<sup>[4]</sup>.

A proton pump inhibitor (PPI) associated with two antibiotics is considered the standard therapy for *H pylori* eradication<sup>[5]</sup>. Clinical trials show *H pylori* eradication rates varying from 45% to 92.3% using PPI associated with amoxicillin and clarithromycin. However, duration of eradication therapy continues to be controversial<sup>[6]</sup>. In many developed countries, a 7-d therapy is considered enough for bacterial eradication. On the other hand, there is still an argument for increasing the duration of treatment to 10 d or even 14 d<sup>[6]</sup>.

In Europe, a 7-d triple therapy is still recommended because 14-d therapy had an insignificant advantage in terms of treatment success rate<sup>[7]</sup>. On the other hand, guidelines from North America recommend 10-d to 14-d therapy, as some studies have reported superior cure rates with prolonged therapy using triple regimens<sup>[8]</sup>. In Asia, an Indian study reported that prolonged triple therapy with lansoprazole, amoxicillin and tinidazole achieved a significant increase in eradication rates: 47.6% *vs* 80% *vs* 91.3% for 1 wk, 2 wk and 3 wk of therapy, respectively<sup>[9]</sup>.

However, in a recent large multicenter randomized trial based on a Korean population, no differences were observed between 7 d *vs* 14 d of triple therapy with omeprazole associated with amoxicillin and clarithromycin<sup>[10]</sup>.

Two studies from Turkey using PPI-based triple therapy with amoxicillin and clarithromycin have shown low eradication rates<sup>[11,12]</sup>. The first study with a 7-d triple therapy showed an eradication rate of 63.6%<sup>[11]</sup>. The second one using a 14-d therapy showed a 45% eradication rate<sup>[12]</sup>.

In the Mexican population, triple therapy with rabeprazole, amoxicillin and ofloxacin for 14 d achieved significantly superior eradication rates when compared with 7-d therapy (92.3% *vs* 62.2%)<sup>[13]</sup>.

In South America, it is difficult to identify the best regimen, due to the absence of large multicenter controlled trials. Some recommendations have been published based on consensus reports. The last Brazilian consensus, in 2005, recommended a 7-d triple therapy<sup>[14]</sup>.

The aim of *H. pylori* eradication is to stop the chronic inflammatory activity that leads to histological changes in the gastric mucosa. This inflammatory inactivation has also shown to improve patients' symptoms<sup>[15,16]</sup>.

The histopathology associated with *H. pylori* infection includes a specific structural disorganization of the epithelial cells and inflammatory infiltration (neutrophils, lymphocytes)<sup>[17]</sup>. Epithelial nonspecific changes include: presence of microcrypts, reduction of foveolar mucus secretion, atrophy, hyperplasia, metaplasia, atypia, or dysplasia<sup>[17]</sup>.

Many studies have well demonstrated the histological resolution of inflammatory activity after *H. pylori* eradication using PPI associated with two antibiotics (amoxicillin, clarithromycin or metronidazole) for 7 d, 10 d or 14 d<sup>[15,18-20]</sup>. Only two studies, however, correlated bacterial eradication, gastric inflammatory inactivation and duration of treatment, comparing 7-d *vs* 14-d and 10-d *vs* 14-d therapy<sup>[16,21]</sup>.

This is the first study evaluating the best treatment approach for the Ecuadorian population. Our objective was to compare the efficacy of 7-d *vs* 10-d triple therapy regarding *H. pylori* eradication rates, the endoscopic findings and the histological gastric inflammatory inactivation.

## MATERIALS AND METHODS

### Patients

This was a prospective, randomized, open-label study performed at the Ecuadorian Institute of Digestive

Diseases (IECED), in Portoviejo, Ecuador. The study population consisted of patients with dyspepsia who were referred for upper endoscopy. Dyspepsia was defined as pain or discomfort localized in the upper abdomen. Patients were enrolled if they were infected with *H. pylori*.

The exclusion criteria were: (1) Age < 18 years; (2) Use of proton pump inhibitors, antibiotics, H<sub>2</sub>-receptor antagonists or bismuth compounds in the last 4 wk preceding the inclusion of the patient in the study; (3) Chronic use of non-steroidal anti-inflammatory drugs (NSAIDs); (4) Patients with well-known antibiotic allergy; (5) Pregnant women; (6) Patients with chronic hepatic or renal disease; (7) Patients with Zollinger-Ellison syndrome; (8) Previous gastric surgery; (9) Previous failed *H. pylori* therapy.

Written informed consent was obtained from all participants prior to enrollment.

### Endoscopy, histology and assessment of *H. pylori*

During endoscopy, 5 biopsies were obtained for histological assessment in accordance with the updated Sydney System (2 from the antrum, 1 from the incisura angularis and 2 from the corpus)<sup>[22]</sup>. Biopsies were fixed, paraffin embedded and stained with hematoxylin-eosin/Giemsa. A pre-pyloric biopsy was obtained for the rapid urease test. Patients were considered to be infected if histological and rapid urease tests were positive. Eight weeks after treatment, bacterial eradication was checked by using the same endoscopy procedure for histology. At endoscopy, gastritis was defined as the presence of visible alterations of the mucosal appearance, presumably caused by vascular or infiltrative changes (Sydney system definition)<sup>[23]</sup>. Histological diagnosis was coded in two classes according to the Sydney System classification as follows: (1) non-atrophic chronic gastritis, when inflammatory activity of any grade or antral atrophy grade I were present without intestinal metaplasia lesion; and (2) atrophic chronic gastritis, when grade 2 or 3 atrophic mucosa lesions were observed with or without intestinal metaplasia.

The gastric mucosa inflammation activity was also graded in accordance with the updated Sydney System and was considered as the presence of mononuclear cells infiltrate and neutrophilic polymorphonuclear in a background of chronic inflammation<sup>[22]</sup>.

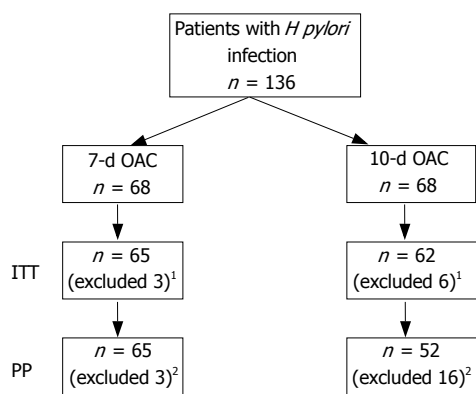

### Treatment

Patients were randomized in a 1:1 ratio to receive omeprazole 20 mg bid, clarithromycin 500 mg bid and amoxicillin 1 g bid for 7 d (group 1) or 10 d (group 2). Treatment compliance was assessed by patient report and pill count at the follow-up visit. Good compliance was defined as consumption of more than 90% of the prescribed drugs. After completing treatment, no patients received PPI or antisecretory drugs during the follow-up period.

### Statistical analysis

Statistical analysis was performed using StatView for Windows (version 5.0). The 95% confidence intervals

**Figure 1** Randomization protocol. <sup>1</sup>Patients were excluded if missing in the follow-up; <sup>2</sup>Patients were excluded if ITT excluded population, non-compliance. ITT: Intention to treat analysis; PP: Per protocol analysis; OAC: Omeprazole, amoxicillin and clarithromycin.

were determined with the chi-square test or Fisher's exact test for small sample sizes, and comparisons were made with Student's test. *P* value of < 0.05 were considered as statistically significant. Per protocol and intention to treat approach was performed for statistical analysis in each group.

### Sample size

As there is no data regarding *H. pylori* eradication rates in the Ecuadorian population, the sample size was calculated a priori, based on available data in the literature. By hypothesizing an 89% eradication rate for the 10-d triple therapy<sup>[30]</sup> and less than 70% (65%) for 7-d triple therapy<sup>[13]</sup>, the estimated sample size was 54 subjects per group, with a power of 0.85 and a significance level of 0.05. Due to the probability of loss from follow-up, the risk of data loss was estimated at around 25%; therefore the final size was considered 68 patients in each group.

## RESULTS

### Baseline demographics

One hundred and thirty-six patients (68 patients by group) were enrolled in the study (Figure 1). At endoscopy, the initial diagnoses were: gastritis in 69/136 (50.7%), duodenal ulcer in 26/136 (19.11%), and gastric ulcer in 22/136 (16.17%). Endoscopy was normal in 19/136 (13.9%).

At histology non-atrophic chronic active gastritis was present in 88.2% of patients for group 1 (60/68) and 82.3% (56/68) for group 2. In group 1, eight patients had atrophic chronic active gastritis (11.7%) in which the presence of intestinal metaplasia was identified in 5/8. In group 2, the presence of atrophic chronic active gastritis was observed in 12 patients (17.6%), all of them with intestinal metaplasia. There were no significant differences between the treatment groups in any of the baseline characteristics. Demographic, endoscopic and histological characteristics are summarized in Table 1.

Three patients (4.4%) in group 1 and six patients (8.8%) in group 2 did not return for follow-up and were excluded from the study. Additionally, ten patients (14.7%) in group 2 were not compliant with the treatment: therapy

**Table 1** Baseline demographic, endoscopic and histological characteristics of patients

	Group 1 (n = 68) OAC 7-d	Group 2 (n = 68) OAC 10-d	P
Age (yr, mean ± SD)	42 ± 11	44 ± 12	NS
Sex (M/F)	23/45	27/41	NS
Endoscopic findings:			
Normal	9	10	NS
Gastritis (IM)	31 (4)	38 (6)	NS
Gastric ulcer (IM)	13 (1)	9 (2)	NS
Duodenal ulcer (IM)	15 (0)	11 (4)	NS
Histological findings:			
Nonatrophic chronic active gastritis (IM)	60	56	NS
Atrophic chronic active gastritis (IM)	8 (5)	12 (12)	

IM: Intestinal metaplasia; M: Male; F: Female; NS: Not significant; OAC: Omeprazole, amoxicillin and clarithromycin.

was stopped at d 8 in 7 patients, at d 3 in 2 patients and at d 4 in 1 patient. In 6 patients (8.8%), the non-compliance was correlated with treatment-adverse events (4 with moderate abdominal pain, 1 with nausea, and 1 with diarrhea).

### Per protocol (PP) analysis

One hundred and seventeen patients underwent a PP analysis (Table 2): 65 patients in group 1 and 52 patients in group 2. Eight weeks after treatment the endoscopy showed a normal gastric mucosa in 56.9% (37/65) of patients in group 1 and in 63.5% (32/52) in group 2. Ulcer healing was observed in 93.7% (45/48) of patients (both groups). In group 1, gastritis was observed in 25 patients (intestinal metaplasia in 5 patients at histology without presence of gastric mucosa inflammation) and an active ulcer in 3 patients (2 with gastric ulcer and 1 with duodenal ulcer). In group 2, gastritis was present in 20 patients (12 patients with intestinal metaplasia at histology and without gastric mucosa inflammation).

*H. pylori* eradication was obtained in 68% (44/65) of patients for group 1 and 88% (46/52) for group 2 (*P* = 0.008; OR = 3.66; 95% CI, 1.4-10).

The total average rate of inflammatory inactivation of gastric mucosa was 80% for both groups. In group 1, 45 patients (69%) showed an inactivation of the inflammation compared with 49 patients (96%) in group 2 (*P* = 0.0002; OR = 7.25; 95% CI, 2-26).

### Intention to treat (ITT) analysis

One hundred and twenty-seven patients underwent an ITT assessment (Table 3): 65 patients in group 1 and 62 patients in group 2. After treatment, the endoscopy showed a normal gastric mucosa in 56.9% (37/65) of patients for group 1 and 61.2% (37/62) in group 2. Gastritis was present in 25 patients in group 2 (12 patients with intestinal metaplasia at histology and without presence of gastric mucosa inflammation).

*H. pylori* eradication was obtained in 68% (44/65) of patients for group 1 and 83.8% (52/62) for group 2 (*P* = 0.03; OR = 2.48; 95% CI, 1.1-5.8).

**Table 2** Per protocol analysis, control results at wk 8 in two groups (%)

	Group 1 (n = 65) OAC 7-d	Group 2 (n = 52) OAC 10-d	P
<i>H. pylori</i> eradication	44/65 (68)	46/52 (88)	0.008
Normal endoscopy	37/65 (56.9)	32/52 (63.5)	NS
Inflammatory inactivation of gastric mucosa	45/65 (69)	49/52 (96)	0.0002

OAC: Omeprazole, amoxicillin and clarithromycin; NS: Not significant.

The total average rate of gastric mucosa inflammatory inactivation was 79.5% for both groups. In group 1, 45/65 patients (69%) showed an inactivation of the inflammation compared with 54/62 patients (88.7%) in group 2 ( $P = 0.007$ ; OR = 3.00; 95% CI, 1.2-7.5).

## DISCUSSION

After the discovery of *H. pylori* many studies were reported for its treatment, including various meta-analyses. Nowadays there is no doubt that triple therapies, that is, PPI & two antibiotics (amoxicillin associated with clarithromycin or metronidazole) are currently the most preferred first-line therapy regimens in clinical practice.

Therapy regimens and their duration could not be standardized because results of clinical data are different between countries. In effect, the results for efficacy of therapy are varied worldwide. This variation of the results could be a consequence of many factors such as bacterial virulence, environmental factors and antibacterial resistance, which are peculiar for each country. In addition, individual factors such as: patient's age less than 60, presence of duodenal ulcer and treatment duration have been also linked to therapy efficacy<sup>[24]</sup>.

Until now, no data or consensus about the duration of treatment for *H. pylori* in Ecuador was available. We therefore evaluated the twice-daily triple therapy of omeprazole 20 mg bid, amoxicillin 1 g bid and clarithromycin 500 mg bid.

Metronidazole resistance in *H. pylori* strains varies geographically, and influences negatively the effectiveness of therapies containing this antibiotic<sup>[25]</sup>. In Latin-American countries, more than 62% of the population is resistant to metronidazole treatment<sup>[3,26]</sup>. This can be explained by the indiscriminate use of these agents for many other diseases (such as parasitosis).

The rates of metronidazole resistance are as high as 81% in Ecuador. In contrast, clarithromycin resistance is still small: < 10%<sup>[27]</sup>. This is the reason for using clarithromycin in our study.

Two clinical trials from South America reported eradication rates of more than 85% with 7-d triple therapy using PPI, amoxicillin and clarithromycin. Coelho *et al.*<sup>[28]</sup>, in the Brazilian population showed 87% of *H. pylori* eradication with a 7-d treatment (using pantoprazole, amoxicillin and clarithromycin) in 71 patients. In Peru, a randomized study with 72 patients showed 86.1% of *H. pylori* eradication with no differences between 7-d *vs* 10-d triple therapy<sup>[29]</sup>.

**Table 3** Intention to treat analysis, control results at wk 8 in two groups (%)

	Group 1 (n = 65) OAC 7-d	Group 2 (n = 62) OAC 10-d	P
<i>H. pylori</i> eradication	44/65 (68)	52/62 (83.8)	0.03
Normal endoscopy	37/65 (56.9)	37/62 (61.2)	NS
Inflammatory inactivation of gastric mucosa	45/65 (69)	54/62 (88.7)	0.007

OAC: Omeprazole, amoxicillin and clarithromycin; NS: Not significant.

In the Ecuadorian population our study showed a 68% and an 86% eradication rate for the 7-d and 10-d triple therapy, respectively, this difference being statistically significant.

Many clinical trials have demonstrated similar eradication rates using 10-d triple therapy with PPI, amoxicillin and clarithromycin<sup>[15,16,30,34]</sup>. A large multicenter double-blind trial in the United States, demonstrated an eradication rate of 84%<sup>[30]</sup>. Fennerty *et al.*, also found comparable results (84% eradication rate) in 284 patients, without difference when compared to 14-d therapy<sup>[16]</sup>. In the Czech Republic, the rate of *H. pylori* eradication obtained was 87%<sup>[15]</sup>.

Moreover, a recent meta-analysis has shown that prolonging triple therapies from 7 to 10 d or 14 d improves treatment cure rates<sup>[31]</sup>. Other meta-analysis suggested that 10-d therapy was associated with less failure than 7-d therapy<sup>[24]</sup>. Our study also indicates that a 10-d regimen was statistically more effective than the 7-d regimen for inactivating the gastric mucosa inflammation.

Acid suppression with PPI in *H. pylori* gastritis only decreases the gastric inflammatory activity, but doesn't produce its inactivation<sup>[32]</sup>. Histological changes after *H. pylori* eradication show a rapid improvement of neutrophils infiltration in the first 2 mo, progressive declination of mononuclear cell infiltration during the first 2 years, and no significant changes in the 12 first mo regarding atrophy or intestinal metaplasia<sup>[17-20,33]</sup>. The presence of an inflammatory activity is seen in fewer cases, even 12 mo after the eradication<sup>[32,33]</sup>.

In our patients, 8 wk after treatment, the endoscopic assessment revealed the persistence of gastric lesions in 43.1% of patients (28/65) in group 1 and 38.5% of patients (20/52) in group 2. However, an inflammatory inactivation was obtained in 69% and 94% of patients in groups 1 and 2 respectively. All cases with intestinal metaplasia had *H. pylori* eradication and gastric inflammatory inactivation. In patients with abnormal control endoscopy, persistence of *H. pylori* was observed in 21/28 patients in group 1 and in 6/20 patients in group 2, being associated with the persistence of an inflammatory activity.

Discordance between endoscopic and histological findings after *H. pylori* eradication with 7-d triple therapy (PPI, amoxicillin, clarithromycin) was previously reported<sup>[16,20]</sup>. Dajani *et al.*, observed a persistence of lesions at the control endoscopy in 46.4% of patients (7.4% of duodenal ulcer and 39% of gastritis lesions), in spite of 93% eradication rates with a remarkable resolution of the

inflammatory activity<sup>[20]</sup>. Another study comparing 10 *vs* 14 d of treatment shows the persistence of an active ulcer in 28% of patients and gastritis in 9% after an eradication rate of 84%<sup>[16]</sup>.

Prolonging therapy duration has been associated with an increased risk of non-compliance due to side-effects<sup>[30,35]</sup>. This was also observed in our study, which shows an increased non-compliance rate in the 10-d therapy group (group 2), being correlated in 6 patients with treatment side-effects.

Finally, although our data points to the superior benefits of the 10-d therapy, we should be careful before establishing definitive recommendations for the Ecuadorian population.

On a day-to-day basis, every medical treatment must consider the cost-benefit analysis, mainly in developing countries, where it is difficult for patients to afford their medications in function of its price. The cost of *H pylori* eradication therapy in South America is very high<sup>[3]</sup>. Some recommended eradication therapies have 7-d duration mainly because of improved compliance and decreased medical cost<sup>[13]</sup>. In our study, 32% of patients in the 7-d *vs* 12% in 10-d therapy did not eradicate *H pylori*. Probably, the re-treatment of this 32% of patients in group 1 with second or third line therapies would be more expensive and less effective than directly treating them for 10 d with the first line approach. This evaluation however was not the objective of our paper, and should be the subject of a future study.

In conclusion, this randomized open study showed that in Ecuador, a 10-d triple therapy using PPI associated with amoxicillin and clarithromycin was significantly more effective than a 7-d triple therapy. The cost-benefit of this treatment in our population should be evaluated in a future study.

## COMMENTS

### Background

The aim of *H pylori* eradication is to stop chronic inflammatory activity that leads to histological changes in the gastric mucosa. A proton pump inhibitor (PPI) associated with two antibiotics is considered the standard therapy for *H pylori* eradication. However, duration of eradication therapy continues to be controversial, due to the variable results from all over the world. There is no data about *H pylori* treatment in the Ecuadorian population and to our knowledge there are no studies correlating the bacterial eradication, gastric inflammatory inactivation and duration of treatment comparing 7-d *vs* 10-d.

### Research frontiers

This study determined the best valid *H pylori* eradication treatment in a population with higher rates of infection correlating the bacterial eradication rate, the endoscopic and histological results with the treatment duration.

### Innovations and breakthroughs

Many studies have well demonstrated the histological resolution of inflammatory activity after *H pylori* eradication using PPI associated with two antibiotics (amoxicillin, clarithromycin or metronidazole) for 7 d, 10 d or 14 d. Only two studies, however, correlated bacterial eradication, gastric inflammatory inactivation and duration of treatment, comparing 7-d *vs* 14-d and 10-d *vs* 14-d therapy. This is the first study evaluating the best treatment approach for the Ecuadorian population. We compared the efficacy of 7-d *vs* 10-d triple therapy regarding *H pylori* eradication rates, the endoscopic findings and the histological gastric inflammatory inactivation.

## Applications

In this Ecuadorian population, 10-d triple therapy using PPI associated with amoxicillin and clarithromycin was significantly more effective than 7-d triple therapy. The cost-benefit of this treatment in our population should be evaluated in a future study.

## Peer review

This is a reasonably well done clinical trial comparing 7-d and 10-d PPI-based triple therapy for *H pylori* infection. Ten-day treatment was significantly superior. The trial is well described.

effectiveness and safety at least comparable to those reported for other options. The endoscopist is very often satisfied with this approach because of the minimization of some steps of the endoscopic procedure and avoidance of relevant iatrogenic risk factors. If the mandatory collaboration between surgeons and endoscopists is guaranteed, this approach can often be preferable for the patient, the surgeon, the endoscopist and the hospital.

### Abstract

**AIM:** To investigate our clinical experience with combined laparo-endoscopic Rendezvous (RV) for the treatment of patients affected by gallstones and common bile duct (CBD) stones and especially to study the never evaluated opinion of the endoscopist concerning the difficulty of the intraoperative endoscopic procedure during the RV in comparison with standard endoscopic retrograde cholangio-pancreatography (ERCP).

**METHODS:** Eighty consecutive patients affected by cholecystolithiasis and diagnosed or suspected CBD stones were treated with a standardized “tailored” RV. The relevant technical features, the feasibility, the effectiveness in stone clearance, the safety but also the simple evaluation of difficulty and agreement of the endoscopist were analyzed with a questionnaire.

**RESULTS:** The feasibility was 97.5% and the effectiveness 100% concerning CBD clearance and solution of coexisting problems at the papilla. Minor morbidity was 3.3%, the operating time was prolonged by a mean of 14 min, the mean hospital stay was 3.8 d and only one stone’s recurrence occurred. The endoscopist evaluated the procedure to be simpler than standard ERCP-ES in 81.2% of the cases.

**CONCLUSION:** Simultaneous RV carries high

La Greca G, Barbagallo F, Di Blasi M, Chisari A, Lombardo R, Bonaccorso R, Latteri S, Di Stefano A, Russello D. Laparo-endoscopic “Rendezvous” to treat cholecysto-choledocolithiasis: Effective, safe and simplifies the endoscopist’s work. *World J Gastroenterol* 2008; 14(18): 2844-2850 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2844.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2844>

### INTRODUCTION

Cholecystolithiasis is one of the most common diseases in which treatment involves general practitioners, gastroenterologists, endoscopists and general surgeons. The management of patients affected by gallstones complicated by common bile duct (CBD) stones and/or problems at the papilla of Vater is anyway a challenge as there are many available options for treatment, all being effective but with the best practice is still unknown. The development of minimally invasive surgery has been associated with development and diffusion of totally laparoscopic exploration of the CBD which is considered the best approach by the pioneers of minimally invasive surgery. This convention contrasts with the fact that the sequential approach, combining the endoscopic retrograde cholangio-pancreatography (ERCP) with endoscopic

sphincterotomy (ES) prior or after cholecystectomy, was for a long time considered to be the preferable choice and also today many gastroenterologists, endoscopists and surgeons still prefer it in clinical practice. The third option, namely the laparo-endoscopic “Rendezvous” (RV) combines in one procedure laparoscopic cholecystectomy (LC), intra-operative cholangiography (IOC) and endoscopic CBD clearance being an actual alternative to the other two. This laparo-endoscopic approach is for the surgeon technically simpler than total laparoscopy, carries interesting advantages but is more complex to organize and is perhaps also considered to reduce the role of the laparoscopic surgeon. Also for the endoscopist this procedure could carry many advantages. Believing in its usefulness we used this approach in 80 consecutive patients affected by gallstones and CBD stones and here we report the results concerning effectiveness, safety and for the first time in the literature we particularly analysed the agreement, evaluation and opinion of the endoscopist normally used to perform ERCP-ES.

## MATERIALS AND METHODS

Eighty patients affected by cholecystolithiasis and CBD stones or suspected stones at IOC were treated simultaneously during the same operation by patient tailored combined laparo-endoscopic “RV”. Our definition of the term “RV” consists of the combined laparo-endoscopic simultaneous approach involving the endoscopist and surgeon in the operating room during one single administration of anesthesia to clear CBD stones or solve associated problems related to sludge or other problems at the papilla of Vater. All the records of the treated patients were analyzed concerning main clinical data, history, diagnosis, surgical or endoscopic technical particularities, duration of the procedures, feasibility, failure, conversion to open surgery, effectiveness in stone clearance, post-operative complications, duration of the hospital stay, late complications and recurrence of stones. At the end of every procedure we submitted a questionnaire to the endoscopist to analyze his satisfaction concerning the intraoperative endoscopic procedure. The questionnaire elicited a simple immediate opinion of the endoscopist concerning his evaluation of the endoscopic difficulty of the procedure graded as: (1) simpler; (2) comparable; (3) more difficult, if compared to a standard ERCP-ES.

## RESULTS

### *Clinical data*

From 2002 to 2006, 80 consecutive patients were submitted to the laparo-endoscopic RV. The mean patient age was 58 years (9-88 years), 29 patients were male and 51 female. The youngest patient was a 9-year-old female patient with a BMI of 27, with gallstones and recurrence of acute biliary pancreatitis due to common bile duct sludge and sphincter of Oddi dysfunction. The oldest patient was a female patient with increasing jaundice, severe cholangitis, and CBD stones impacted in the papilla and coming out of two failed attempts to treat the jaundice and the

stones with ERCP-ES. The diagnosis of CBD stones was given preoperatively in 47 patients (58.7%), in 33 patients (41.2%) the diagnosis was not available preoperatively. 23 patients (28.7%) had a recent history of mild acute pancreatitis or abnormal increase of amylase or lipase levels associated with biliary pain. In 49 patients (61.2%) there was an abnormal increase of bilirubin levels. In 53 patients (66.2%) suspicion or the diagnosis of CBD stones was obtained by ultrasonography. In 46 patients (57.5%) a cholangio-MRI was also performed preoperatively and in 38 of them (82.6%) this confirmed the diagnosis. In 24 patients (30%) with CBD stones a CT scan was also performed during diagnostic work-up but this confirmed the stones in only 9 patients (37.5%). In fact, in 23 of the 33 patients without preoperative diagnosis (69.6%) there was preoperatively a high clinical suspicion of CBD stones but in 10 (31.1%) the diagnosis could be obtained only during surgery by IOC performed because of the surgeon's own decision based on the above mentioned criteria. All 80 patients therefore underwent antretrograde transcystic IOC. The criteria used to perform IOC were the diagnosis of CBD stones or the positiveness of at least one of the following risk factors: history of acute pancreatitis, pre-operative abnormal increase of direct bilirubinemia, ALP or gamma-GT, abnormally dilated CBD at ultrasonography, multiple small stones or sludge in the gallbladder, intraoperative evidence of a large cystic duct or an enlarged CBD. The feasibility of the RV was 97.5%.

### *Technical data*

None of these 80 patients underwent surgical open or laparoscopic CBD exploration. Only in one patient a transcystic biliary drain (Pedinelli) was left at the end of the procedure because the inexperienced endoscopist inflated too much air in the bowel during the endoscopic procedure preventing the surgeon from having a good view of the cystic duct to clip it safely. Conversion to open surgery occurred in 2 cases (2.5%) because of surgical problems related to adhesences due to previous abdominal surgery that rendered the identification of the biliary anatomy difficult. In these two patients the clearance of the CBD was performed by the endoscopist anyway and therefore the procedure remained a RV with open cholecystectomy. Intraoperative cholangiography confirmed CBD stones in 68 patients (85%) and these could be extracted in all cases with stone clearance obtained in 100% of the cases. In 15 patients (18.7%) a delayed contrast medium passage ( $> 30$  min from the injection) was also observed during IOC and resolved by ES. In 12 of the patients (15%) cholangiography did not clearly show stones but ES was performed anyway because of a pre-operative diagnosis of stones, clinical history of recurrent pancreatitis, hyperbilirubinemia or because of CBD dilatation and delay in contrast medium discharge in the duodenum. In 5 of these patients with abnormal delay, the ES could not identify stones in the sudden relevant bile flow after sphincterotomy but in 3, biliary sludge was evident. In 2 of these the ES did not show stones and the images were interpreted as false positives due to air bubbles in the CBD. In only 19 patients (23.7%)

**Table 1** Main differences for the endoscopist between the main steps of endoscopic procedures at the papilla of Vater for CBD exploration comparing RV with standard ERCP-ES

Factors of difference of the endoscopic procedure	RV	ERCP-ES
(1) Position of the patient	Supine Rarely more difficult endoscopy	Lateral Preferred because of habit
(2) Cholangiography	Antegrade transcystic Positive (time reduction)	Retrograde Negative
(3) Wirsung injection (chemical damage)	Absent Positive (risk reduction)	Possible Negative
(4) Ductal hyperpression (physical damage)	Absent Positive (risk reduction)	Frequent Negative
(5) Guide wire help for papilla cannulation	Transcystic Positive (time reduction)	Retrograde Negative
(6) Flushing of the CBD	Antegrade during basket retrieval (synergic) Positive (time reduction)	Retrograde Not synergic
(7) Papilla manipulation causing oedema or Oddi's spasm	Limited or absent Positive (risk reduction)	Frequent Negative
(8) Precut of the Papilla	Absent Positive (risk reduction)	Possible Negative
(9) Reduction of the steps of endoscopic procedure	Possible Positive (time reduction)	Uncommon Negative
Total of positive factors	8/9	1/9

there was the need to pass a guide wire transcystically to help the endoscopist to cannulate the papilla while in the other 61 patients the endoscopist cannulated the papilla without need of surgical help. In the only pediatric case a SOD (sphincter of Oddi dysfunction) was associated with cholecystolithiasis and was successfully managed with pneumatic papilla dilatation. In 5 cases (6.2%) the endoscopist used a mechanical lithotripter to shatter larger stones to facilitate their extraction. In one case with suspected CBD stones at IOC the ES and CBD exploration resulted negative for stones, and this was the only endoscopic procedure considered retrospectively to be an over treatment but unfortunately it was supported by a positive preoperative cholangio-MRI together with multiple risk factors of CBD stones.

### Complications

Only one case of intraoperative complications occurred (1.2%) with self limiting bleeding of the papilla after sphincterotomy. In 7 patients (8.7%) there was an increase of amylase levels after the RV but only in 3 (3.7%) it was a real pathologic increase (3X n.v). Of these 7 patients with an increase of amylase levels 5 (71.4%) had had a retrograde transpapillary injection of the contrast medium. This occurred because they were all patients in the initial group (up to the 19th case) in which the endoscopist was used to injecting in retrograde because of the convention and in one later case the retrograde injection was needed because of accidental intra-operative mobilization of the cholangiography catheter out of the cystic duct. The mean duration of the whole RV was 114 min (49-221 min) whereas the mean duration of the intraoperative endoscopic procedures was 14 min (range 6-33 min). The mean postoperative hospital stay of the patients was 3.8 d, thus 1 d longer than our standard simple LC. All these patients were followed for almost 6 mo and all were symptom free up to the last follow-up. All patients had a bile duct in the normal range at the 6 mo US

control and all without clinical evidence of recurrence of stones or cholangitis. Only in one patient (1.2%) an asymptomatic recurrence of a common bile duct stone was diagnosed 13 mo after RV. This was a patient with a known incomplete ES because of intraoperative bleeding, which led us to suspend the endoscopic procedure. No patient developed jaundice or hyperbilirubinemia (0%) and no patient developed symptoms related to ERCP or acute pancreatitis. Oral feeding started in all patients within 36 h. No patient had to be treated post-operatively for incomplete clearance of the CBD with a post-operative ERCP or ES. We collected the data regarding the endoscopist's opinion concerning the intraoperative endoscopic procedure.

### Endoscopist's opinion

In 65 cases (81.2%) the endoscopist considered the endoscopic procedure simpler, in 12 cases (15%) indifferent if compared to a normal ERCP-ES and in only 3 cases (3.7%) he considered the procedure more difficult, especially because of the problems in papilla cannulation due to the different positions related to the supine position of the patient on the operating table. The main factors that were considered important to facilitate the endoscopic procedure are summarized in Table 1. When considering all the factors, avoidance of some of the steps of standard endoscopic procedures can lead to an overall reduction of time and main risk factors in iatrogenic damage.

## DISCUSSION

In all other papers concerning the laparo-endoscopic RV mostly published by surgeons<sup>[1-8]</sup>, there never was an analysis of the problems related to the main technical factors of the endoscopic procedure, nor were the compliance and explanations from the point of view of the endoscopist considered. This is in our opinion a relevant lacking in the analysis of this particular procedure,

**Table 2** Main indications for the laparo-endoscopic RV with evaluation of the factors that suggest its preferability instead of the other treatment's options

Main indications for the laparo-endoscopic RV	RV preferable vs laparoscopic CBD exploration	RV preferable vs sequential ERCP-ES
(1) Common bile duct stones not easily extractable through the cystic duct Positive factor -> (time reduction)	(A) Need of higher surgical skill (B) Longer operation time (C) Need of biliary drain	(a) Risk of synchronization (b) Risk of unnecessary ERCP (c) Risk of difficult retrograde cannulation
(2) Multiple small CBD stones and large friable stones Positive factor -> (reduction of risk of recurrence)	A, B, C + (D) High risk of residual fragments and recurrence	a, b, c
(3) Any type of CBD stones with delayed passage of the contrast medium during IOC or T-tube-IOC after laparoscopic CBD exploration Positive factor -> (reduction of risk of recurrence)	A, B, C, D + (E) high risk of undertreatment of chronic papillitis and of maintenance of underlying causes	a, b, c
(4) CBD stones with previous cholangitis Positive factor -> (reduction of risk of recurrence)	A, B, C, D + (E) high risk of maintenance of underlying causes at the papilla	a, b, c + (d) Avoidance of contrast medium injection with risk of recurrence of cholangitis
(5) CBD stones after recurrent acute biliary pancreatitis or hyperbilirubinemia Positive factor -> (iatrogenic risk reduction)	A, B, C, D, E	a, b, c, d + (e) risk of recurrence of ERCP related acute pancreatitis
(6) Known or unsuspected Sphincter of Oddi Dysfunction, cholecysto-lithiasis with or without CBD stones Positive factor -> (iatrogenic risk reduction)	A, B, C, D, E	a, b, c, d, e
(7) CBD stones and/or abovementioned problems in patients with Billroth II during open cholecystectomy Positive factor -> (iatrogenic risk reduction)	A, B, C, D, E + (F) Manual drive of the endoscope by the surgeon in the afferent jejunal loop	a, b, c, d, e + (f) more difficult ERCP
(8) CBD stones, SOD, acute pancreatitis in children/CBD stones in patients with normal or thin CBD Positive factor -> (iatrogenic risk reduction)	A, B, C, D, E + (G) difficult laparoscopic CBD exploration and risk of stenosis of the suture	a, b, c, d, e, f + (h) avoidance of sphincterotomy in children
(9) CBD stones and/or SOD after failure of preoperative ERCP-ES or recurrence of acute biliary pancreatitis Positive factor -> (iatrogenic risk reduction)	A, B, C, D, E	a, b, c, d, e, f
(10) Inexperienced surgeon for laparoscopic CBD exploration Positive factor -> (iatrogenic risk reduction)	A, B, C, D, E, G	a, b, c, d, e, f

for which we tried to make aware to both the surgeon and endoscopist concerning its utility as mandatory for its immediate outcome and for its development. On the other hand, it was impossible to plan a prospective randomized study as every case is different and the endoscopist could never treat the same patient with RV and also ERCP-ES so that the evaluation could be based exclusively on the endoscopist's subjective opinion. We would like to underline that our definition is somewhat different because we define a laparo-endoscopic RV also when the guide wire is not passed, in contrast to others that consider a RV only when the surgeon passes a guide wire through the cystic duct to help the endoscopist<sup>[1-3]</sup>. We do not believe that the guide wire has to be passed in every case but, to avoid unnecessary iatrogenic risks, only if needed especially when the endoscopist cannot easily cannulate the papilla. Certainly this combined laparo-endoscopic approach has its main negative factor as the need for synchronized collaboration between surgeon and endoscopist and this is still, not only in our opinion, the main factor that limits its diffusion<sup>[4,5]</sup>. Cholecystolithiasis is worldwide a very common illness that involves general practitioners, gastroenterologists, and surgeons but also frequently the endoscopist particularly if the presence or the simple suspicion of stones in the CBD becomes the main problem. All the cases where the CBD stones are

easily extractable through the cystic duct by the surgeon during LC should be excluded in this discussion but unfortunately this evaluation is never possible prior to surgery so that a rational plan of all treatment options is mandatory. Especially when transcystic extraction of stones is not possible, as happens in about 30%-40% of the patients with CBD stones, the combined laparo-endoscopic approach should be considered often in our opinion, as the preferable option for many simple technical and clinical reasons. These reasons are summarized in Table 2 that shows our main indications explaining the points of preferability of the RV compared to other options. Some other general considerations have to be met as well. First, the treatment of CBD stones in cholecystectomized patients today remains the exclusive work of the endoscopist who often performs a salvage procedure for the patient and helps the surgeon as well<sup>[9-11]</sup>. This endoscopic approach is highly effective<sup>[12]</sup> with sporadic mortality and minimal early and late morbidity, all anyway lower when compared to surgical interventions. The surgical approach is therefore never proposed today as a first option in cholecystectomized patients and moreover the endoscopic treatment with ERCP-ES is never considered wrong or dangerous for these patients. If cholecystectomy still has to be performed, with the combined approach RV, the surgeon can help the

endoscopist or otherwise the endoscopist can help the surgeon to clear the CBD, it only depends on whose point of view is considered. The questionable risk of an “avoidable ERCP-ES” curiously appears only if LC has to be performed. According to our results, the endoscopist’s opinion and literature results, ERCP-ES with help seems to be easier for the endoscopist so that radiologic-endoscopic rendezvous was also used<sup>[13,14]</sup>. On the other hand, CBD clearance during LC with help of the endoscopist also seems easier for the surgeon as all the surgeons using the RV were always satisfied, never reporting results or aspects that lead them to abandon it<sup>[1-8,15,16]</sup>. These patients are all treated in an in-patient hospital setting so normally both surgeon and endoscopist are available and the other mandatory factors to gain the organization of a RV are functioning clocks and telephones to coordinate them. Sometimes the surgeon is also able to perform an endoscopy and in this case he can himself complete the auto-RV. The RV solves both cholecystolithiasis and CBD stones but it can especially avoid the main negative technical aspects of both laparoscopic CBD exploration and of the standard sequential ERCP-ES. Close to the technical reasons shown in our original analysis there are also several clinical reasons and evidences in the literature to use it. The development of minimally invasive surgery with the diffusion of totally laparoscopic exploration of CBD leads many authors to consider it the best option<sup>[17-19]</sup>. This concept is somewhat strained as it is certain that the sequential approach was considered for a long time to be the preferable one<sup>[20]</sup> and even today gastroenterologists, endoscopists and many surgeons still continue to prefer it in the clinical practice<sup>[21]</sup>. In fact, a recent NIH state of the science statement on ERCP showed that both ERCP and laparoscopic CBD clearance are safe and reliable to clear stones<sup>[22,23]</sup>. This statement includes the concept that the simultaneous combination of laparoscopy and ERCP-ES should be considered equally safe and reliable. If this statement concerning ERCP is true, the sequential approach is also reliable and effective so that the RV should theoretically be better, especially for the patient, because for the sequential approach there is the well known old problem of optimal timing between ERCP and LC, to also be considered “The bilateral interface...” between the two procedures<sup>[24]</sup> is eliminated in the simultaneous RV. The RV especially avoids the risks of ineffectiveness of both the pathways of the sequential approach related especially to no synchronization between diagnosis of CBD stones and its treatment. This concept of no synchronization is very important as only during RV the IOC shows the real-time situation of the CBD and moreover other relevant and often unsuspected underlying problems at the papilla. With the sequential approach it could be a renewed passage of stones in the CBD if the ERCP-ES is performed prior to cholecystectomy but moreover ERCP-ES could be unnecessary if performed after LC as stones can often pass spontaneously<sup>[25]</sup>. These risks are confirmed by a recent analysis of management of suspected CBD stones in children<sup>[26]</sup> that clearly shows the poor results and pitfalls of the two common sequential pathways of ERCP-ES. If performed prior to LC a total

of 71% of ERCP were unnecessary and 7% failed. If performed after LC 50% of ERCP were unnecessary because stones were no longer found. Therefore, a large number of unnecessary invasive procedures, all potentially related to morbidity and mortality, are performed but often the majority are ineffective especially because they are out of synch with the evolving pathophysiology of gallstone disease<sup>[25]</sup>. Comparing the RV to totally laparoscopic CBD exploration, it is clear that the RV also solves problems at the papilla of Vater that certainly can not always be solved by laparoscopic CBD exploration and which are the main causes of retained stones and recurrence. Another important problem of the choice of the best option appears in those cases with an unclear IOC with uncertain images of stones or persistence or delayed contrast medium passage in the duodenum. In these unclear situations both transcystic laparoscopic CBD exploration and sequential ERCP-ES are questionable as often related to dense biliary sludge associated with stenosis of the papilla in which ES is certainly the safest solution for the patient. The laparoscopic CBD exploration normally consists of major biliary surgery and needs higher laparoscopic skills and prolongs the duration of the entire operation also increasing the overall risk for the patient<sup>[18,19,27]</sup>. The mean prolongation of the time of RV is normally shorter than those reported for totally laparoscopic CBD exploration<sup>[27,28]</sup>. This difference becomes more evident for those patients with multiple large stones and sludge and problems at the papilla. The laparoscopic CBD exploration in a recent review carries a conversion rate of 2%-8%, a failure of 3.1%. These unlucky patients have to be treated by the endoscopist in a sequential manner with a risk of ineffectiveness<sup>[28]</sup>. Retained stones after laparoscopic CBD exploration in very experienced hands are also up to 8% and a biliary drainage after surgical transverse choledochotomy is needed in up to 94% of the patients so that there is a need for repeated controls, prolonged hospitalization and readmittances<sup>[29]</sup>. The success rate of laparoscopic duct exploration in a review of 28 papers from 1993 to 2000 was between 81% and 98% (mean of 88.4%) with an incidence of retained stones between 0% and 19% and a conversion rate up to 10%. On the contrary in a large review concerning the patients free of biliary symptoms after ERCP-ES this was up to 90% after 14.2 years<sup>[28]</sup>. The randomized multicenter EAES trial showed a therapeutic success of 84% for the ERCP-ES and a success rate of 83% for the laparoscopic exploration<sup>[10]</sup>. The patients matched for simple cholecystectomy reported significantly lower morbidity compared to laparoscopic CBD treatment and biliary complications are up to 16% of the patients, mostly due to the need of biliary drains<sup>[30]</sup>. The reduction and facilitation of the steps of the endoscopic procedure due to the surgeon’s help of the endoscopist finally brings a relevant reduction of the time of the endoscopic procedure. Moreover the post-procedural hyperamylasemia and acute pancreatitis are strongly reduced or absent after RV if compared to standard ERCP<sup>[6,8,16]</sup> and this is principally related to avoidance of the risk factors reported in Table 1. These factors are those clearly related to the incidence and mechanism of post-ERCP pancreatitis in

different analyses<sup>[31-34]</sup>. It is also remarkable that after laparoscopic CBD exploration, acute pancreatitis can be comparably high to sequential ERCP-ES (7.3% *vs* 8.8%)<sup>[12]</sup>. Certainly standard ERCP whenever possible should be limited because, as suggested by experienced endoscopists the only sure way to avoid post-ERCP complications is to avoid ERCP itself<sup>[35]</sup>. The unique prospective randomized comparison of ERCP-ES with laparo-endoscopic RV by Morino<sup>[8]</sup> showed that the risk of incomplete duct clearance with ERCP-ES is 20% and in 77.7% of the cases the cause is the inability to cannulate the papilla. This confirms the main advantage of the RV for the endoscopist, namely the surgeon's help passing the guide wire transcystically. The same study shows that 88% of these ineffective ERCP-ES were brought to an effective intraoperative ERCP-ES during laparoscopic RV, and this happened also in one patient in our series. Simplifying the concept the endoscopist alone was not able to solve the problem but on the contrary, together with the surgeon was effective, confirming the value of the RV.

Our analysis concerning endoscopist's compliance and opinion concerning the RV procedure shows clearly, the very good results concerning feasibility, effectiveness and safety and shows also that in the majority of the cases he was happy and satisfied to perform the endoscopic procedure intra-operatively. This is very simple to understand because the endoscopist is involved only if absolutely needed reducing in this manner both the risk of endoscopic over-treatment and also the risk of failure. Moreover the endoscopist avoids many steps of the procedure that are to his mind the main risk of iatrogenic damage, he is facilitated to easily understand his position inside the CBD, the surgeon can help him with the guide wire or immediately converting to laparoscopic CBD exploration or to open surgery in case of major problems like impacted stone or blockage of the basket inside the CBD. These positive factors for the endoscopist are also positive for the patient, reducing the risk of repeated or unnecessary procedures, the risk of ineffectiveness altogether, and reducing in our opinion the "cumulated iatrogenic risk" if compared to both other options. For all these reasons our positive clinical experience from the point of view of the surgeon and especially of the endoscopist suggests that this combined laparo-endoscopic simultaneous rendezvous approach, despite some, in our opinion questionable, organizational problems can often result in being the preferable treatment option for the patient with cholecystolithiasis and CBD stones.

## COMMENTS

### Background

Cholecystolithiasis is one of the most common diseases in which treatment involves general practitioners, gastroenterologists, endoscopists and general surgeons but the management of patients affected by gallstones complicated by common bile duct (CBD) stones and/or problems at the papilla of Vater is anyway a challenge as there are many available options for treatment, all being effective. A third alternative to the two main treatment's option, sequential or totally laparoscopic, consists of the simultaneous laparoendoscopic "Rendezvous (RV)". This study analyzed the results concerning 80 consecutive patients treated with a laparoendoscopic rendezvous procedure and especially analyzed the previously unanalyzed endoscopist's opinion which is also a very important point for this combined approach.

### Research frontiers

The gold standard for the treatment of cholecystolithiasis combined with CBD stones is still not available. Large prospective randomized studies could help to clarify the issue but the literature shows that the cooperation between surgeons and endoscopists is usually scarce and that each specialist prefers what he believes is better.

### Innovations and breakthroughs

Using the laparoendoscopic rendezvous approach for the treatment of gallstones and CBD stones both feasibility (97.5%) and effectiveness (100%) in stone clearance are very high while morbidity and stone recurrence are low. These results are comparable or even better than those reported for both the other two treatment's options. Moreover the work of the endoscopists results is simpler and safer than standard ERCP-ES in 4/5 of the cases, because of the reduction of the steps of the endoscopic procedure and the avoidance of relevant iatrogenic risk factors.

### Applications

This study shows that the simultaneous laparoendoscopic rendezvous approach is often preferable for the patient, the surgeon, the endoscopist and the hospital. This approach reduces hospital stay and the iatrogenic risk compared to the sequential approach and reduces the need of higher surgical skills and biliary drainage compared to the total laparoscopic treatment. The main problems that still limit the diffusion of this procedure are the problems in organizing the mandatory cooperation between endoscopist and surgeon.

### Terminology

Sequential treatments combine ERCP clearance of the CBD stones with previous or successive laparoscopic cholecystectomy. The laparoendoscopic treatment consists of laparoscopic cholecystectomy (LC) combined with endoscopic treatment of stones or underlying problems at the papilla of Vater during a unique anesthesia. The term "RV" means the meeting of a guide wire (the surgeon passes the guide wire antegradely through the cystic duct) with the endoscope inside the duodenum; the presence of the guide wire and the meeting of the two instruments facilitate the cannulation of the Vater's papilla by the endoscopist himself and so also the clearance of the CBD from the stones. The term RV underlines the concept of "reciprocal implementation" of both surgeon's and endoscopist's work. The laparoendoscopic treatment does not automatically include a rendezvous procedure itself and this brings confusion in the evaluation of the results of the published papers.

### Peer review

The authors described excellent results of the laparoendoscopic rendezvous, without the use of a statistical method.

### Abstract

**AIM:** To evaluate the effectiveness and safety of oral N-acetyl-L-cysteine (NAC) co-administration with mesalamine in ulcerative colitis (UC) patients.

**METHODS:** Thirty seven patients with mild to moderate UC were randomized to receive a four-wk course of oral mesalamine (2.4 g/d) plus N-acetyl-L-cysteine (0.8 g/d) (group A) or mesalamine plus placebo (group B). Patients were monitored using the Modified Truelove-

Witts Severity Index (MTWSI). The primary endpoint was clinical remission ( $MTWSI \leq 2$ ) at 4 wk. Secondary endpoints were clinical response (defined as a reduction from baseline in the MTWSI of  $\geq 2$  points) and drug safety. The serum TNF- $\alpha$ , interleukin-6, interleukin-8 and MCP-1 were evaluated at baseline and at 4 wk of treatment.

**RESULTS:** Analysis per-protocol criteria showed clinical remission rates of 63% and 50% after 4 wk treatment with mesalamine plus N-acetyl-L-cysteine (group A) and mesalamine plus placebo (group B) respectively (OR = 1.71; 95% CI: 0.46 to 6.36;  $P = 0.19$ ; NNT = 7.7). Analysis of variance (ANOVA) of data indicated a significant reduction of MTWSI in group A ( $P = 0.046$ ) with respect to basal condition without significant changes in the group B ( $P = 0.735$ ) during treatment. Clinical responses were 66% (group A) vs 44% (group B) after 4 wk of treatment (OR = 2.5; 95% CI: 0.64 to 9.65;  $P = 0.11$ ; NNT = 4.5). Clinical improvement in group A correlated with a decrease of IL-8 and MCP-1. Rates of adverse events did not differ significantly between both groups.

**CONCLUSION:** In group A (oral NAC combined with mesalamine) contrarily to group B (mesalamine alone), the clinical improvement correlates with a decrease of chemokines such as MCP-1 and IL-8. NAC addition not produced any side effects.

## INTRODUCTION

Ulcerative colitis (UC) is a chronic idiopathic inflammatory disease of the colon characterized by rectal bleeding, diarrhea, abdominal pain, weight loss and fever<sup>[1]</sup>. Histological examination of biopsy specimens reveals the presence of infiltrated white blood cells such as neutrophils, monocytes and lymphocytes in the colonic interstitium<sup>[2]</sup>. In the recruitment and activation of white blood cells, participate cytokines [interleukin (IL)-1 $\beta$ , IL-2, IL-6, IL-12 and tumour necrosis factor- $\alpha$ ]<sup>[3]</sup>, chemokines [IL-8, monocyte chemoattractant protein (MCP)-1 and MCP-3]<sup>[4]</sup>, cell adhesion molecules<sup>[5]</sup> as well as the inducible isoforms of nitric oxide synthase<sup>[6]</sup> and cyclooxygenase<sup>[7]</sup>. Moreover, the infiltration of phagocytes results in the stimulation of the latent plasma membrane associated NADPH oxidase, which release large amounts of superoxide (O<sub>2</sub><sup>-</sup>) and H<sub>2</sub>O<sub>2</sub>, producing hydroxyl radicals<sup>[8]</sup>.

Recently, a new hypothesis termed "Radical Induction Theory" has been proposed to explain the etiology of UC<sup>[9]</sup>. The excess of un-neutralized hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>), produced within colonic epithelial cells as a result of aberrant cellular metabolism, diffuses through cell membranes to the extracellular space, where it is converted to the highly damaging hydroxyl radical (OH) resulting in oxidative damage to structures comprising the colonic epithelial barrier. Once damaged, the barrier is unable to exclude highly immunogenic fecal bacteria invading the normally sterile submucosa. This antigen exposure provokes an initial immune response of white blood cell infiltration into colonic mucosa. The injurious "reactive oxygen species" would be inactivated by protective enzymes (superoxide dismutase, catalase and glutathione peroxidase) and by non-enzymatic antioxidants (glutathione, ascorbate and  $\alpha$ -tocopherol)<sup>[10,11]</sup>. A common feature of patients with inflammatory bowel disease is a depletion of endogenous oxidant defenses such as ascorbate,  $\beta$ -carotene,  $\alpha$ -tocopherol and glutathione<sup>[12,13]</sup>. This last compound is a naturally occurring tripeptide ( $\gamma$ -Glu-Cys-Gly) found in high concentrations within tissues. In experimental acute colitis, cellular glutathione levels decreased significantly and the administration of the antioxidant N-acetyl-L-cysteine (NAC) restored glutathione level and decreased colonic inflammation<sup>[14]</sup>. More recently it has been showed that the combination of NAC and mesalamine accelerates mucosal healing in a rodent model of colitis<sup>[15]</sup>. Taken together, these results suggest an imbalance and inefficient endogenous antioxidant response in the intestinal mucosa of UC patients, which may contribute to the etiology, the pathogenesis and the perpetuation of the inflammatory processes<sup>[10]</sup>. The aim of the present pilot study was to evaluate the possible effectiveness and safety of NAC associated with mesalamine in mild to moderate UC.

## MATERIALS AND METHODS

### Patient's selection criteria and study protocol

Thirty seven patients with mild to moderate UC according to the Modified Truelove and Witts Severity Index (MTWSI)<sup>[16]</sup> were randomized to receive a 4-wk course of oral mesalamine (2.4 g/d) plus N-acetyl-L-cysteine (NAC) (0.8 g/d) (group A) or mesalamine plus placebo (group B). Exclusion criteria were age over 70 or less 18 years, pregnancy, serious underlying systemic diseases and MTWSI > 10. Treatment with oral or topical steroids, topical mesalamine, immunosuppressors (azathioprine, 6-mercaptopurine, *etc.*) or antioxidants was discontinued at least three weeks before commencement of the trial. The protocol was approved by the Ethical Investigation Committee of the corresponding Institutions, and written informed consent was obtained from all the patients. Diagnosis of UC was established by standard clinical, radiological, histological, and endoscopic criteria<sup>[11]</sup>. The patient's characteristics are described in Table 1. Patients were allocated to one of two treatment groups according to a centrally computer-assisted randomization list and received oral mesalamine at a dose of 2.4 g/d combined with NAC at a dose of 0.8 g/d (group A) or oral mesalamine at a dose of 2.4 g/d and placebo (group B) during four wk. NAC was provided as 200 mg sacks of water-soluble powder identical in taste, bulk and appearance to those of placebo. Mesalamine was provided as an 800 mg tablets coated with 1:2 copolymer of metacrylic acid and methylmethacrylate (Eudragit-S) used for colonic delivery of mesalamine<sup>[17]</sup>.

### Measurement of disease activity

Clinical and biochemical findings were assessed by the gastroenterologist at intervals of two and four weeks respectively. All patients were asked to record stool frequency (number of daily stools) and consistency, nocturnal stools, visible blood in stool, fecal incontinence, abdominal pain, abdominal tenderness, need for antidiarrheals and a patient self-rating evaluation based upon the impact of symptoms on normal life activities. For stool frequency and abdominal pain, a scale from 0 (normal) to 4 (markedly abnormal) was used. For use of antidiarrheal medication, a scale from 0 (no) to 1 (yes) was used. For the other parameters, the scale ranged from 0 (normal) to 3 (markedly abnormal). The Modified Truelove-Witts Severity Index, which has been considered useful in therapeutic trials<sup>[16]</sup>, was calculated from these data. The primary endpoint was clinical remission (MTWSI  $\leq$  2) at 4 wk. Secondary endpoints were clinical response (defined as a reduction from baseline in the MTWSI of  $\geq$  2 points) and drug safety.

### Assessment of safety

The hematological and biochemical studies were performed at regular intervals by the analytical laboratory services of the corresponding hospitals: complete blood count, hepatic enzymes, bilirubin, erythrocyte sedimentation rate and C-reactive protein were measured between other biochemical parameters.

Table 1 Basal and demographic data

Data	Group A Mesalamine + NAC (n = 19)	Group B Mesalamine + placebo (n = 18)	Total (n = 37)
Age (mean $\pm$ SD)	51.4 $\pm$ 14	42.2 $\pm$ 13	46.9 $\pm$ 14
White race, n (%)	11 (57.8)	13 (72.2)	24 (64.8)
Smoker, n (%)	2 (10.5)	3 (16.7)	5 (13.5)
Male, n (%)	8 (42.1)	5 (27.8)	13 (35.1)
Basal modified Truelove-Witts severity index (mean $\pm$ SD)	5.95 $\pm$ 2.22	4.61 $\pm$ 2.09	5.30 $\pm$ 2.20

NAC: N-acetyl-L-cysteine.

### Evaluation of reduced glutathione, TNF- $\alpha$ , IL-6, IL-8 and MCP-1 circulating levels

Blood samples were obtained by venipuncture and placed into tubes containing lithium heparin as anticoagulant. For the measurement of GSH in whole-blood samples, 0.5 mL of blood was treated immediately with 0.25 mL of trichloroacetic acid (12%) on ice. After 5 min tubes were centrifuged at 13 000 g during 10 min at 4°C and the acidic supernatants were immediately used for GSH measure. GSH determinations were performed as described previously<sup>[18]</sup> with some modifications. Briefly, the amount of lactoyl-glutathione formed between methylglyoxal (110 mmol/L) and GSH in presence of glyoxalase-I (lactoyl-glutathione lyase) at pH 7.0 buffered with 0.1mmol/L sodium phosphate was measured spectro-photometrically at 240 nm.

The concentration of IL-8, MCP-1, TNF- $\alpha$  and IL-6 present in plasma was determined by using specific sandwich ELISA following manufacturer protocol. Briefly plates (Costar) were coated overnight at 4°C with specific mouse anti-human monoclonal antibody (Becton Dickinson) in 0.1 mol/L Na<sub>2</sub>HPO<sub>4</sub> (pH 9) (dilution 1:200). After washing with PBS containing 0.5% Tween 20 unspecific sites were blocked with PBS containing 3% BSA. Plasma was added to each well and incubated for 12 h at 4°C. Unbound material was discarded and biotinylated mouse anti-human monoclonal antibody (Becton Dickinson) was incubated during 1 h at room temperature. After washing bound antibodies were detected by incubation with avidin-peroxidase (Sigma) for 30 min in presence of the 2,2 azinobis (3-ethybenzthiazolinesulfonic acid) (ABTS of Sigma) as substrate. Absorbance was measured at 405 nm. A Standard curve was constructed for each cytokine or/and chemokines by using recombinant human molecules (Becton Dickinson) in PBS containing 3% BSA.

### Statistical analysis

For quantitative variables, mean and standard deviation were calculated. Statistical analysis was performed with the SAS program. For the comparison of treatment effect on Modified Truelove-Witts Severity Index between both groups of patients, the analysis of covariance (ANCOVA) was used after adjusting for baseline values. To study the evolution of disease score for each group, the analysis of variance (ANOVA) with Bonferroni corrected *post hoc*

Table 2 Changes in disease activity assessed using modified Truelove-Witts Severity Index (mean  $\pm$  SD) in subjects who received the drugs for 2 wk and 4 wk

Week of treatment	0	2	4	ANOVA statistical test (number of patients)
Group A mesalamine plus NAC	5.95 $\pm$ 2.22	4.68 $\pm$ 3.40	3.32 $\pm$ 3.71 <sup>a</sup>	P = 0.046 (n = 19)
Group B mesalamine plus placebo	4.61 $\pm$ 2.09	4.17 $\pm$ 3.85	3.72 $\pm$ 3.91	P = 0.735 (n = 18)

<sup>a</sup>P < 0.05 represents the significance levels compared with the corresponding basal values using the ANOVA statistical test.

comparisons was used to determine significant treatment effects. P < 0.05 was considered statistically significant.

## RESULTS

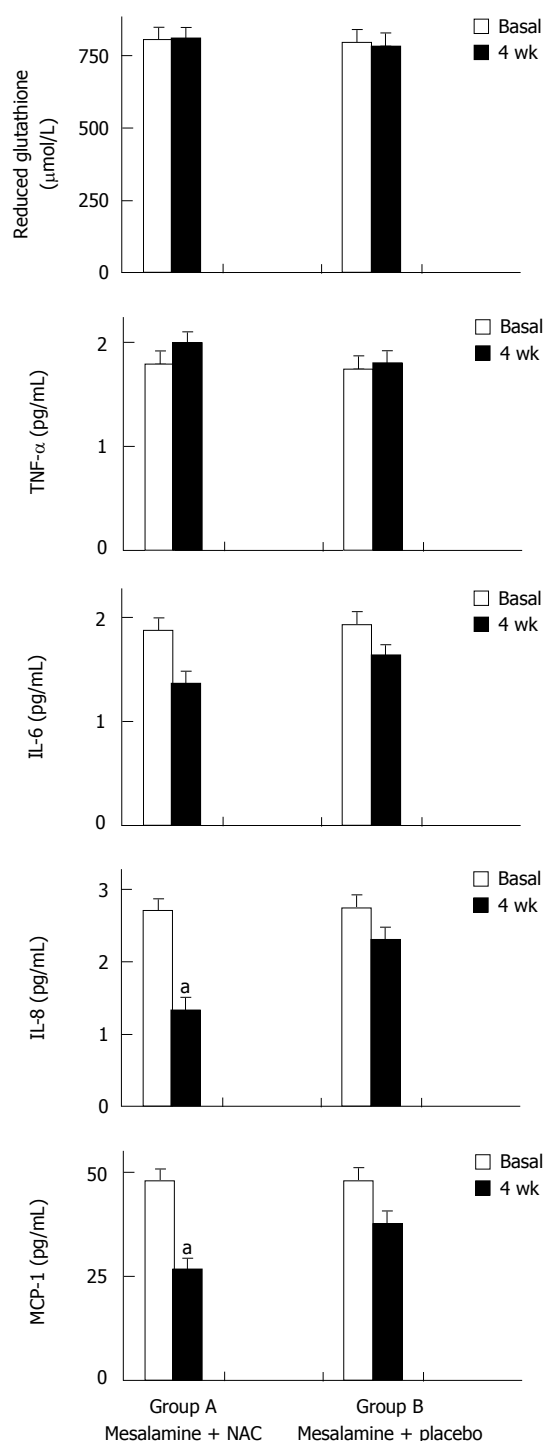

Thirty seven patients were included in the trial. All patients had mild to moderate UC according to the criteria of Modified Truelove-Witts Severity Index<sup>[16]</sup>. Treatment groups were comparable at randomization for baseline demographic characteristics (Table 1). All patients completed the one month study (19 treated with mesalamine plus NAC and 18 treated with mesalamine plus placebo) following the correct protocol.

### Treatment effect on Modified Truelove-Witts Severity Index

The disease score was calculated by “per-protocol” criteria, the data of all randomized patients at 0, 2 and 4 wk of treatment were included. Twelve of 19 patients (63%) in the combination treatment group (A) underwent remission (score  $\leq$  2) at 4 wk of treatment. At the same period of time nine of 18 patients (50%) in the mesalamine plus placebo group (B) underwent clinical remission (score  $\leq$  2). However, statistically not-significant differences were observed between both groups in this clinical parameter (OR = 1.71; 95% CI: 0.46 to 6.36; P = 0.19; NNT = 7.7). During 4 wk of treatment, clinical response measured by MTWSI improved in group A compared with the corresponding baseline values (P = 0.046, ANOVA test) (Table 2). Whereas in the group B no statistical improvement were reached (P = 0.735, ANOVA test) at the same period of time. Although a better favorable trend was observed with the combined therapy (group A) as compared to that observed in the mesalamine plus placebo arm (group B), the significance threshold was not reached (ANCOVA test). The disease score decreased in both groups of patients at 4 wk of treatment with respect to the corresponding baseline values, however, the group B was not statistically significant; the MTWSI change was 2.63  $\pm$  0.82 (P = 0.004) and 0.89  $\pm$  0.9 (P = 0.33) (paired student’ t-test) at 4 wk of treatment for A and B groups, respectively.

### Effect of treatment on reduced glutathione, TNF- $\alpha$ , IL-6, IL-8 and MCP-1 circulating levels

Measurement of biochemical parameters was performed

**Figure 1** Reduced glutathione levels in whole blood and tumor necrosis factor alpha (TNF- $\alpha$ ), interleukin IL-6, IL-8, and monocyte chemoattractant protein (MCP)-1 levels in plasma of subjects after 4 wk of treatment with mesalamine plus NAC (Group A) or mesalamine plus placebo (Group B). mean  $\pm$  SD. <sup>a</sup> $P < 0.05$  represent the significance level compared with basal values using the Student's *t*-test.

at the beginning and at 4 wk of treatment (Figure 1). Blood levels of reduced glutathione (GSH) did not change significantly at 4 wk of treatment in group A (NAC plus mesalamine) with respect to control group (placebo plus mesalamine). TNF- $\alpha$  plasma levels remained constant and did not change along the period studied in either group A or B. IL-6 plasma levels decreased slightly, although

not significantly, in group A, without changes in the group B. By contrast, circulating levels of IL-8 decreased significantly ( $P < 0.05$ ), with respect to baseline values, at 4 wk of treatment in group A, without changes in the group B. The decrease in IL-8 coincided with the induction of remission of the disease in group A. Finally, the profile of MCP-1 circulating levels was similar to that found for IL-8. Thus, at 4 wk of treatment with NAC plus mesalamine (Group A), a significant ( $P < 0.05$ ) decrease in MCP-1 with respect to the corresponding baseline values was demonstrated, while statistically non-significant changes were observed in group B.

### Safety

No serious adverse effects, clinical or analytical, were observed in either treatment group. The hematological and biochemical results at baseline and 4 wk are summarized in Tables 3 and 4 respectively.

### DISCUSSION

The idea that NAC treatment could be useful in UC emerged from previous studies in animal models of that disease<sup>[14]</sup>. Very recently it has been showed that antioxidant therapy with NAC plus mesalamine accelerates mucosal healing in rodent model of colitis<sup>[15]</sup>. Mucosal biopsies taken from active gut inflammation sites from UC patients produced significantly more reactive oxygen species (H<sub>2</sub>O<sub>2</sub> and superoxide) compared to either uninvolved or healthy tissue<sup>[10,19]</sup>. Glutathione and glutathione peroxidase are the most important system for elimination of H<sub>2</sub>O<sub>2</sub>. Consequently, the reduced glutathione levels in the inflamed mucosa from patients with UC could be decreased<sup>[12,13]</sup>. The oral treatment with NAC (a precursor of glutathione) of UC patients could restore the circulating and local levels of reduced glutathione to respond to the excess of reactive oxygen species. Recently, the effectiveness of antioxidant therapy in pediatric Crohn's disease has been reported in an open-label pilot study<sup>[20]</sup>.

Monitoring of standard laboratory data of our patients demonstrated no worsening of the values with respect to baseline data during treatment (with or without NAC). Moreover, no significant differences in standard laboratory data were observed between the values of the two treatment groups (Tables 3 and 4). Finally, no significant adverse events related with the NAC treatment occurred in any of the patients.

Treatment with mesalamine was maintained constant throughout the study for all patients, with improvement of the disease measured by MTWSI. However in the group receiving a supplement of NAC (0.8 g/d), a more favorable trend was seen with respect to mesalamine treatment alone. The mesalamine plus NAC group underwent a significant clinical response with respect to basal state measured by MTWSI at 4 wk of treatment. However, in the control group (mesalamine plus placebo) no significant improvement was observed in the course of the disease at that time. These results suggest that NAC could accelerate the healing process in UC. However, the conclusion could be affected as consequence of non-homogeneity of both

Table 3 Hematological parameters

	Group A		Group B

Monocytes (%)	6.97	7.20	7.14	7.88

Group A: Mesalamine + NAC; Group B: Mesalamine + placebo.

groups according to the age; a definite limitation of this pilot trial is the small size of the groups. This fact must be kept in mind for planning further studies (with higher doses of NAC, route of administration or larger sample size).

The beneficial effect of NAC at 4 wk did not correlate with changes in reduced glutathione in blood, which suggests that the mechanism of action of NAC is local, and not systemic, at that time. Similar pharmacokinetic results were observed in the treatment with 0.6 g/d of NAC of HIV infected patients, resulting in a glutathione increase at 8 wk of treatment<sup>[21]</sup>. Although oral doses of 1.8 g/d of NAC increased the percentage of CD4 lymphocyte counts in HIV infected patients, it did not produce changes in plasma glutathione levels<sup>[22]</sup>, only high oral doses (4-8 g/d of NAC) of this antioxidant could replenished glutathione levels and improved survival rates of HIV infected patients<sup>[23]</sup>. Treatment with comparables doses (100 mg/kg NAC) of acetic acid-induced experimental colitis substantially reduced the degree of colonic injury. Lower doses (20 mg/kg) had no protective effect<sup>[24]</sup>. Moreover, clinical studies suggest liver absorption of NAC when it is administered orally because hepatic clearance of NAC decreased significantly during cirrhosis<sup>[25]</sup> and its metabolism improves hepatosplanchnic flow and liver function in septic shock patients<sup>[26]</sup>. In experimental colitis the beneficial effects of NAC were observed by intrarectal and intraperitoneal administration<sup>[27]</sup>. For all these reasons, clinical trials have used higher doses of NAC bypassing digestive tract without serious adverse events<sup>[28,29]</sup>.

Our study also suggests that the beneficial effect of NAC in UC is related to the down-regulation of chemokines such as MCP-1 and IL-8. At 4 wk of treatment, both molecules decreased in plasma of patients treated with NAC plus mesalamine, whereas in the mesalamine plus placebo group this change was not statistically significant. The induction of the remission in the group A coincided with the decrease in IL-8 and MCP-1 plasma levels, suggesting that the effect of NAC is related to the decrease of molecules that activates the recruitment and activation of neutrophils and monocytes to the inflamed mucosa. Our data are in concordance with previous studies performed in alcoholic hepatitis, where MCP-1 production stimulated by lipopolysaccharides decreased with NAC treatment,

Table 4 Biochemical parameters

	Group A		Group B	
	Basal	4 wk	Basal	4 wk
SGOT (units/L)	16.89	16.47	20.47	25.06
SGPT (units/L)	15.58	17.53	36.94	43.59
Phosphatase alkaline (units/L)	93.56	86.61	93.59	86.71

Iron ( $\mu\text{g}/\text{dL}$ )	70.27	69.00	78.56	84.82
Orosomucoid (mg/100 mL)	85.19	90.98	98.06	89.98
CRP (mg/L)	5.37	4.27	5.20	4.85

Group A: Mesalamine + NAC; Group B: Mesalamine + placebo.

suggesting that the antioxidant act directly on target cells<sup>[30]</sup>. Previously, it was observed that the percentage of cells expressing IL-8 and MCP-1 was significantly enhanced in UC samples as compared to controls<sup>[31]</sup>. Furthermore, the local overexpression of MCP-1 and IL-8 was associated with inflammation in UC<sup>[32]</sup>. A close correlation has been demonstrated between mucosa IL-8 mRNA expression and the colonic inflammation in UC patients, and a decrease of local IL-8 expression has been reported during UC improvement after granulocytapheresis<sup>[33]</sup>. Local changes in IL-8 expression correlates with urinary IL-8, and this chemokine increases around ten fold in the urine during active UC compared with control subjects<sup>[34]</sup>, suggesting that circulating IL-8 is a good indirect marker for the assessment of active inflammation in the colonic mucosa. Other pro-inflammatory cytokines such as TNF- $\alpha$  and IL-6, previously implicated in inflammatory bowel diseases, did not change significantly in plasma with the treatment prescribed in our study. However we can not rule out the hypothesis that down-regulation of TNF- $\alpha$  and IL-6 in the mucosa could explain the improvement observed.

In conclusion, the results of the present pilot study suggest that combined therapy (NAC and mesalamine) produces a clinical improvement of UC patients which correlates with a decrease of MCP-1 and IL8. However, the difference in clinical effect with respect to the control group (mesalamine alone) is not conclusive. NAC is safe and well tolerated.

## COMMENTS

### Background

A new hypothesis termed "Radical Induction Theory" has been proposed to explain the etiology of ulcerative colitis (UC) (J Pravda. *World J Gastroenterol* 2005; 11: 2371). The excess of hydrogen peroxide ( $\text{H}_2\text{O}_2$ ) could damage the colonic epithelial barrier. In experimental acute colitis, cellular glutathione levels decreased and the administration of their precursor (N-acetyl-L-cysteine) (NAC) restore the endogenous level and decreased colonic inflammation. Recently, it has been showed that the combination of NAC and mesalamine accelerates mucosal healing in a rodent model of colitis (Siddiqui *et al*, *Dig Dis Sci* 2006; 51: 698).

## Innovations and breakthroughs

Local overexpression of MCP-1 and IL-8 was associated with inflammation in UC and a decrease of colonic IL-8 has been reported during active UC. Our results show that antioxidant therapy with NAC decreases the levels of IL-8 that activates the recruitment and activation of neutrophils to the inflamed mucosa. It is suggested that higher dose or targeted NAC can alleviate colonic inflammation and hopefully become a novel agent for the treatment of UC.

## Peer review

This is an excellent research paper which highlights the dual role antioxidants play in the pathogenesis of ulcerative colitis. And this is the first paper to cite radical induction theory which logically explains why the addition of NAC to conventional 5-ASA therapy significantly increases the remission rate observed in ulcerative colitis. The findings are potentially important for planning of further studies (e.g. with higher dose of N-acetyl-L-cysteine; more homogenous groups of comparison, larger sample size, et cetera).

### Abstract

**AIM:** To research the etiology, portal vein thrombosis and other features of Budd-Chiari syndrome (BCS) patients prospectively.

**METHODS:** A total of 75 patients (40 female, 35 male) who were diagnosed between January 2002 and July 2004 as having BCS were studied prospectively. Findings from on physical examination, ultrasonography, duplex ultrasonography and venography were analyzed. Hemogram and blood chemistry were studied at the time of diagnosis and on each hospital visit. Bone marrow examination and immune phenotyping were performed by a hematologist when necessary. Protein C, S, antithrombin III, activated protein C resistance, and anticardiolipin antibodies, antinuclear antibodies, and anti ds-DNA were studied twice. The presence of ascite, esophageal varices, and portal thrombosis were evaluated at admission and on every visit.

**RESULTS:** At least one etiological factor was determined in 54 (72%) of the patients. The etiology could not be defined in 21 (28%) patients. One etiological factor was found in 39, 2 factors in 14 and 3 factors in 1 patient. The most common cause was the web (16%), the second was Hydatid disease (11%), the third was Behcet's disease (9%). Portal vein thrombosis was present in 11 patients and at least one etiology was identified in 9 of them (82%).

**CONCLUSION:** Behcet's disease and hydatid disease are more prominent etiological factors in Turkey than in other countries. Patients with web have an excellent response to treatment without signs of portal

### INTRODUCTION

Budd-Chiari syndrome (BCS) is a rare heterogeneous group of disorders characterized by hepatic venous outflow obstruction at the level of hepatic venules, the large hepatic veins, the inferior vena cava, or the right atrium<sup>[1]</sup>. It has been increasingly recognized that a combination of several thrombogenic conditions and triggering factors are necessary for the development of venous thrombosis in general and hepatic vein or cava thrombosis in particular.

The etiology of Budd-Chiari syndrome changes according to geography. In most of the western cases of BCS an etiologic factor has been defined, whereas the causes of BCS in many of patients from India and Japan are not defined<sup>[2-6]</sup>. While thromboses are more prominent in the west, webs are prominent in the east and in Japan<sup>[7-9]</sup>.

Turkey is a country acting as a bridge in between east and west. To date there is insufficient data about the etiology and features of BCS in Turkey. The relation between the etiologic factor and presence of portal vein thrombosis and yet outcome is not well established to date. In this study we prospectively searched the etiology, characteristics and other features of BCS patients in Turkey.

### MATERIALS AND METHODS

#### Patients

Türkiye Yüksek İhtisas Hospital is a tertiary referral center

**Figure 1** A patient with prominent abdominal wall collateral veins as a result of inferior vena cava thrombosis at the hepatic portion.

in gastroenterology in Turkey. A total of 75 patients (40 female, 35 male) who were diagnosed between January 2002 and July 2004 in Türkiye Yüksek İhtisas Hospital as having BCS were studied prospectively.

The diagnosis of BCS was established using ultrasonography, color Doppler ultrasonography (CDU) and venography. A detailed patient history including onset of symptoms, medications, previous disease, pregnancy and use of oral contraceptives for women, oral and genital ulcers, previous surgery, and trauma were especially noted. The onset of symptoms was classified, whether acute, sub acute or chronic. The diagnosis and date of last hospital visit were noted.

Patients were evaluated with a multidisciplinary approach (involving gastroenterology, gastroenterology surgery, hematology, radiology and other clinics when necessary). Findings on physical examination were noted. Ultrasonography was performed by experienced gastroenterologists and CDU and venography were performed by experienced radiologists. The sites of lesions were classified as hepatic vein, inferior vena cava or combined and note was also taken as to whether the obstruction was complete or partial.

Hemogram and blood chemistry were studied at the time of diagnosis and on each visit. All patients were evaluated by a hematologist for myeloproliferative disorders and bone marrow examination and immune phenotyping were performed when necessary. Protein C, S, antithrombin III, factor V Leiden mutation, and anticardiolipin antibodies were studied twice in suitable conditions. Antinuclear antibody and anti ds-DNA were studied when systemic lupus erythematosus was suspected.

The presence of ascite, esophageal varices, and portal vein thrombosis was evaluated at admission and on every visit. Treatments were classified as conservative management, anticoagulation, angioplasty, TIPS and surgery. Complications that occurred during the follow up were recorded.

### Statistical analysis

Variables between groups were compared using the Mann-Whitney *U* test, correlations between parameters were tested by Spearman's correlation analysis and the "Statistical Package for Social Sciences 10.0" program was used for statistical analysis.  $P < 0.05$  was considered as statistically significant.

**Table 1** Etiology

Etiological factors	Patients (%)	Etiological factors	Patients (%)
Web	12 (16)	Anticardiolipin antibodies	3 (4)
Hydatid disease	8 (11)	Oral contraceptive use	3 (4)
Behçet' disease	7 (9)	Tumor	3 (4)
Protein C def.	7 (9)	Anti-thrombin 3 def.	2 (3)
Myeloproliferative disorder	6 (8)	Lupus erythematosus	1 (1)
Protein S def.	5 (7)	Ulcerative colitis	1 (1)
Pregnancy	5 (7)	Paroxysmal nocturnal hemoglobinuria	1 (1)
Activated protein C resistance	3 (4)	Acute pancreatitis	1 (1)

**Table 2** Laboratory parameters

	First			Last		
	min	max	mean	min	max	mean
AST (IU/L)	1300	119700	7520	1000	82900	7044
ALT (IU/L)	700	90700	6118	1700	157200	9477
GGT (IU/L)	1600	78100	13930	2900	64200	14044
Albumin (g/dL)	2100	5100	3460	2400	4800	3781
Bilirubin (mg/dL)	100	1300	286	100	3200	326
Urea (mg/dL)	1300	10600	3478	1100	6100	3078
Prothrombin time (s)	1100	4400	1731	1100	3000	1708

## RESULTS

There were 40 female and 35 male patients. Mean age at first visit was  $33.49 \pm 13.88$  (14-72) years. Most of the patients were diagnosed during the chronic phase of the disease (53.3%). Other patients were diagnosed during acute (26.7%) and sub acute (16%) periods. The site of obstruction was in hepatic veins in 47%, in IVC+ hepatic vein in 30% and IVC in 23% of the patients (Figure 1). A complete obstruction was observed in 54% of the patients. Venography was available for 80% of the patients. Esophageal varices and ascites were observed in 79% and 84% of the patients at admission, and 54% and 35% at last visit, respectively. The patients were followed-up for 1-30 mo (mean, 18 mo). During the follow-up seven patients died (9%).

At least one etiological factor was determined in 54 (72%) of the patients. The etiology could not be defined in 21 (28%) patients. One etiological factor was found in 39, 2 factors in 14 and 3 factors in 1 patient. The most common cause was the web and this was determined in 12 (16%) patients (Table 1). The second most common cause was Hydatid disease and this was found in 8 (11%) of the patients. Behçet's disease was the third most common cause (7 patients, 9%). Etiological factors are presented in Table 1.

Laboratory parameters at admission and at the last hospital visit are presented in Table 2.

Significant positive correlations between first AST-ALT and first prothrombin time ( $P < 0.01$ ), and between last GGT and last urea levels ( $P < 0.05$ ) were found. A significant negative correlation was found between the first prothrombin time and first albumin levels ( $P < 0.01$ ).

No differences were observed when patients were compared according to sex or age over or less than 35 years old.

**Figure 2** A patient with web in the right hepatic vein before angioplasty (A), during angioplasty (B) and after dilatation of the web (C).

Patients who presented with ascites initially had lower albumin and higher Prothrombin times compared to those who did not. Patients who had ascites at their last visit had significantly lower albumin and AST levels than others.

Portal veins were patent in 85% and thrombosed in 15% of the patients. At least one etiology was identified in 9 of the 11 patients (82%) with portal vein thrombosis and BCS. Five patients had 1, 3 patients had 2 and 1 patient had 3 etiological factors. One of the striking results was that none of the patients with web or Behcet's disease as a cause of BCS had portal vein thrombosis. Hydatid disease was observed in 4, protein C deficiency in 3, protein S deficiency in 2, mass lesion in 2, and ulcerative colitis, pregnancy and antithrombin 3 deficiencies in 1 patient. Last bilirubin values were significantly higher ( $16.5/1.7$ ,  $P = 0.002$ ) and last albumin levels were significantly lower ( $32/39$ ,  $P = 0.022$ ) in patients with portal vein thrombosis. Nine patients with portal vein thrombosis were in the chronic, and 2 in a subacute but none in acute phase of BCS.

When compared by means of the extent of the obstruction, patients with complete obstruction had lower initial albumin levels ( $3.2/3.7$ ,  $P = 0.007$ ) and higher prothrombin times ( $19\text{ s}/14\text{ s}$ ,  $P = 0.001$ ). No other significant difference was found between other parameters.

Patients were treated conservatively (53%), with balloon angioplasty (24%, Figure 2), oral anticoagulation (17%), TIPS (4%) or surgery (7%). Three patients experienced warfarin related complications (2 intracranial bleeding, one of whom died, 1 intra abdominal bleeding). Three of the patients who underwent surgery died because of liver failure. The balloon angioplasty procedure was performed in 18 patients and failed in 6 of them. When we examined the patients where it was unsuccessful it was found that none of them were webs but, rather, long segment caval thrombosis or hepatic vein thromboses. Two of the 12 successful web dilatation patients later developed thrombosis and one underwent surgery, the other was treated with TIPS procedure.

## DISCUSSION

The prevalence of underlying thrombophilias is markedly increased in patients with BCS. Factors that confer a predisposition to the development of BCS including hereditary and acquired hypercoagulable states and a variety of other causes can be identified in about 75 percent of patients<sup>[1]</sup>. In our study we identified at least one etiological factor in 54 (72%) patients. The presence of multiple causes in the same patient is increasingly recognized<sup>[3]</sup>. We identified 2 etiological factors in 14 and 3 factors in 1 patient. These results were similar with reports in the literature.

There were slightly more female patients than males ( $40\text{ vs }35$ ) but the imbalance was not as marked as in the literature ( $2/1$ )<sup>[10]</sup>. This may be due to the less frequent use of oral contraceptives in Turkey. Mean age at the time of diagnosis was 33.

The site of the lesion varies according to geography. In our patients hepatic veins were involved in 77% and the inferior vena cava was involved in 53% of the patients. While inferior vena cava involvement is more prominent in Nepal, South Africa, China, India and Japan, hepatic vein involvement is more prominent in the western countries<sup>[7,11-13]</sup>. Our results lay in between these, but were closer to the western countries.

When we look to the etiology, we see that myeloproliferative disorders are found to be the leading cause of BCS in western countries, with a range between 20%-53%<sup>[3,4]</sup>. In this study we identified myeloproliferative disease in 8% of the patients. We confirmed these disorders by bone marrow aspiration and yet only overt forms of disease were diagnosed. We could not look for JAC2 V617f mutation<sup>[14-16]</sup>. So we might have missed some of these patients or myeloproliferative disorders may be less frequent in Turkish population.

Webs were the most common etiology and the most easily treated lesions in our patients (16%). This ratio is not as high as in eastern countries but higher than in western ones. It may be another indicator of Turkey as a bridge

between east and west. These patients rapidly responded to balloon dilatation and ascites dramatically disappeared after successful dilatation. None of these patients had portal vein thrombosis. The chances of a patient with BCS may depend on a web etiology. The etiology of BCS is the most important factor for the prognosis.

The second most frequent etiology in our study was Hydatid disease, at 12%, and this is the highest ratio in the literature. Hydatid disease is a common health problem and deserves more interest in Turkey. Half of the patients with BCS and Hydatid disease also had portal vein thrombosis.

Another frequently observed etiology was Behcet's disease with a ratio of 9%. This ratio is also the highest ratio in the literature. Every patient with BCS must be closely questioned for any history of Behcet's disease. The difficulty in managing these patients was that they usually had long segment thrombosis and thrombosis of other vascular structures. While Bayraktar has reported portal vein thrombosis in these patients, another interesting observation is that none of our patients with Behcet's disease and BCS had portal vein thrombosis<sup>[17]</sup>. This might be due to Bayraktar's long term follow up period. Other etiological factors were similar with the literature.

Portal vein thrombosis in patients with BCS is a poor prognostic factor<sup>[18,19]</sup>. In this study we observed that patients with portal vein thrombosis when compared with those not thrombosed, had lower albumin and higher bilirubin level at their last check. Another difference in patients with portal vein thrombosis was the etiology. Since none of the patients with webs or Behcet's disease had or developed portal vein thrombosis during follow up, this deserves more attention. In our patients one patient had 3 etiological factors and he had also portal vein thrombosis. Since nine patients with portal vein thrombosis were in the chronic, and 2 in a subacute phase of BCS, but none were in an acute phase, we can state that prevention of portal vein thrombosis might be considered in these patients.

Ascites was present in 84% of the patients at admission which means that most of the patients were diagnosed when symptomatic. This ratio lies between the ratio of before and after the 1990 results of Hadengue, indicating that we should diagnose more asymptomatic patients<sup>[10]</sup>. With an increased knowledge about BCS, patients can be diagnosed earlier and further development of new thrombosis and deterioration of liver functions can be prevented. In patients with poor liver functions surgery is unsuccessful, and this may be due to lack of experience as well as to a very enlarged liver that causes difficulty during surgery.

In conclusion, the etiology of BCS changes according to geographic region. Webs, Behcet's disease and Hydatid disease are more prominent etiological factors in Turkey which sets it apart from other countries. Complete obstruction of hepatic veins or inferior vena cava and presence of portal vein thrombosis affects the course of the disease. Presence of more than one prethrombotic factor increases the risk of portal vein thrombosis. Patients with web have excellent treatment response and prognosis.

## COMMENTS

## COMMENTS

The etiology of Budd-Chiari syndrome (BCS) changes according to geography. There is insufficient data about the etiology and portal vein thrombosis relation BCS. The aim of the present study was to evaluate the etiology, presentation, portal vein thrombosis and other features of BCS patients.

### Research frontiers

Several studies have identified that portal vein thrombosis in patients with BCS is a poor prognostic factor. However there are few prospective studies regarding the etiology and portal vein thrombosis relation. We studied the relationship between the etiology, portal vein thrombosis and find that some etiological factors are not associated with portal vein thrombosis.

### Innovations and breakthroughs

The present research studied cases with BCS, but the follow up period was not long enough and some etiological factors such as JAC2 V617f mutation was missing.

### Applications

The results of this study suggest that patients with etiology other than web or Behcet's disease are prone to develop portal vein thrombosis and since portal vein thrombosis mostly were in the chronic, some in a subacute but none in acute phase of BCS, early diagnosis and anticoagulation may be important.

### Peer review

This paper clearly defines that initially the extent of thrombosis and etiology and lately portal vein thrombosis are important factors for BCS. The results are valuable.

## Abstract

**AIM:** To study the efficacy and the safety of laser lithotripsy without direct visual control by using a balloon catheter in patients with bile duct stones that could not be extracted by standard technique.

**METHODS:** The seventeen patients (7 male and 10 female; mean age 67.8 years) with difficult common bile duct (CBD) stones were not amenable for conventional endoscopic maneuvers such as sphincterotomy and mechanical lithotripsy were included in this study. Laser wavelengths of 532 nm and 1064 nm as a double pulse were applied with pulse energy of 120 mJ. The laser fiber was advanced under fluoroscopic control through the ERCP balloon catheter. Laser lithotripsy was continued until the fragment size seemed to be less than 10 mm. Endoscopic extraction of the stones and fragments was performed with the use of the Dormia basket and balloon catheter.

**RESULTS:** Bile duct clearance was achieved in 15 of 17 patients (88%). The mean number of treatment sessions was  $1.7 \pm 0.6$ . Endoscopic stone removal could not be achieved in 2 patients (7%). Adverse effects were noted in three patients (hemobilia, pancreatitis, and cholangitis).

**CONCLUSION:** The Frequency Doubled Double Pulse Nd:YAG (FREDDY) laser may be an effective and safe technique in treatment of difficult bile duct stones.

Clinical usefulness of transpapillary removal of common bile duct stones by frequency doubled double pulsed Nd:YAG laser. *World J Gastroenterol* 2008; 14(18): 2863-2866 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2863.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2863>

## INTRODUCTION

About 90% of all patients with common bile duct stones are currently treated non-surgically using endoscopic sphincterotomy and stone extraction. However, standard endoscopic procedure and mechanical lithotripsy for removal of stones from the bile duct fail in 5% to 10% of patients, because the stones are too large or impacted<sup>[1]</sup>. In such cases, additional methods such as extracorporeal shockwave lithotripsy (ESWL), laser shockwave lithotripsy (LSWL) or electrohydraulic lithotripsy (EHL) are required<sup>[2]</sup>. EHL and LSWL need visual control *via* a mother-baby endoscope system or cholangioscopy for safety because of the potential for accidental damage to the bile duct wall. Moreover, a peroral cholangioscope is expensive, fragile and difficult to use. Laser lithotripsy is expensive due to the cost of the cumbersome endoscopic equipment. Although EHL is inexpensive, it uses high-pulse energy to disintegrate stones<sup>[3-5]</sup>.

The Frequency Doubled Double Pulse Nd:YAG (FREDDY) laser (World of Medicine, Berlin, Germany) is a newly developed economical, short-pulse, double frequency, solid-state laser with wavelengths of 532 nm and 1064 nm that cause less tissue damage. It was specifically designed to fragment urinary and biliary calculi<sup>[6]</sup>. We used a balloon catheter for FREDDY laser lithotripsy (FREDDY LL) in an effort to improve fluoroscopic targeting and to prevent damage to the bile duct. The purpose of this study was to investigate the safety and the effectiveness of using a FREDDY laser to treat bile duct stones that were not amenable to conventional endoscopic therapy.

## MATERIALS AND METHODS

### Patients

Seventeen patients (7 male and 10 female; mean age 67.8 years, range 55-82 years) with extra-hepatic bile duct

stones were included in this study. The inclusion criterion for this study was extrahepatic bile duct stones that were not amenable to standard endoscopic procedure including endoscopic sphincterotomy and mechanical lithotripsy. Stone removal by using conventional methods failed because the stones were not captured in the basket for mechanical lithotripsy or endoscopic sphincterotomy inadequately was done for large perampullary diverticulum with large CBD stones ( $> 1.5$  cm). The main reasons were the following; large stone ( $n = 7$ ), impacted stone ( $n = 3$ ), and large stones with perampullary diverticulum ( $n = 7$ ).

All patients were diagnosed as having bile duct stones by endoscopic retrograde cholangiography and/or MRCP at our hospital. The data regarding stone size, number, and location was based on the endoscopic retrograde cholangiogram (by using the diameter of the distal end of standard duodenoscopy as a reference). The properties of the CBD stones were as follows: 1 stone ( $n = 5$ ), 2 stones ( $n = 7$ ) and more than 2 stones ( $n = 5$ ); diameter of large stone ( $18.5 \pm 3.2$  mm) with 10-20 mm ( $n = 8$ ) and with 21-30 mm ( $n = 9$ ). Large stones with perampullary diverticulum were found in 11 of 17 patients. The study was approved by our institutional review board. Written informed consent was obtained from each patient for laser therapy.

### Methods

We used the FREDDY laser (frequency doubled double pulse Nd:YAG laser, Laser 100, World of Medicine). Laser wavelengths of 532 nm and 1064 nm as a double pulse were applied with pulse energy of 120 mJ. The laser fiber with a 250 nm core diameter was inserted in a 6.8 Fr standard extraction balloon catheter (Wilson-Cook Medical Inc., Winston-Salem, N.C.) with an 18-mm-diameter balloon and this was then passed through the papilla *via* the working channel of a standard duodenoscope (JF-240; Olympus Optical Co., Ltd. Tokyo, Japan).

As the fiber itself is not detectable by fluoroscopy, the radio-opaque tip of the balloon catheter was positioned near the stone, and the balloon was expanded to fix the position of the catheter and the fiber. The tip of the fiber was advanced a few millimeters beyond the radio-opaque tip of the balloon catheter, under fluoroscopic guidance, to ensure that the fiber was positioned on the stone surface. Only one fluoroscopic plane was used to target the stone and to observe fragmentation. The treatment energy level was 120 mJ per pulse at a repetition rate of 8 to 10 Hz. During the laser treatment, we tried to listen to the fragmentation sound of stone by using stethoscope and the fragmentation effect was monitored by fluoroscopy after instillation of contrast media into the bile duct. During laser lithotripsy, the bile duct was continuously irrigated with a mixture of contrast media and saline solution because fluid is required for the generation of shock waves.

After stone disintegration, endoscopic extraction of stones and fragments was done with a Dormia basket and balloon catheter. Laser lithotripsy was limited to a maximum duration of 60 min per session. If, at that time, the ductal clearance was incomplete, then a nasobiliary catheter was inserted. Failure of laser lithotripsy was defined as the inability to achieve complete bile duct

clearance after a maximum of three lithotripsy sessions.

All patients were followed for at least two days after the FREDDY LL. Follow-up included simple radiographs and laboratory tests (hemoglobin, white blood cell count, bilirubin, alanine aminotransferase, aspartate aminotransferase, creatinine, serum urea nitrogen, amylase and lipase levels). The occurrence of any complication within one month of the FREDDY LL procedure was assessed by a patient visit or telephone interview.

## RESULTS

### Lithotripsy

Complete stone fragmentation using FREDDY LL was achieved in 15 of 17 patients without direct visual control (Figure 1). The number of endoscopic retrograde cholangiography sessions per patient that was necessary to totally clear the bile ducts was  $1.7 \pm 0.6$ . After FREDDY LL, 3 patients underwent mechanical lithotripsy to achieve complete clearance of the bile duct.

The stone fragmentation failed in two patients, in whom the positioning of the laser fiber on the stone was inadequate due to a huge impacted stone in the tortuous common bile duct and the biliary stricture. One patient was sent to the surgical department to clear the bile duct by laparoscopic surgery. The other patient was treated by percutaneous cholangioscopy with electro-hydraulic lithotripsy.

### Complications

The side effects and complications of FREDDY LL were mostly mild. Although acute pancreatitis occurred in one patient, it was treated by conservative management, and there was no pseudocyst. Transient hemobilia was observed in two patients. However, the bleeding stopped spontaneously without any change of the hemoglobin level. The hemobilia may have been caused by mucosal damage from insertion of the guiding catheter or the balloon catheter. A patient with acute cholangitis was treated by administration of antibiotics and nasobiliary tube irrigation. This complication may have been caused by transient obstruction of the nasobiliary tube.

## DISCUSSION

Endoscopic retrograde cholangiopancreatography (ERCP) and sphincterotomy have been the standard treatments for choledocholithiasis, yet large stones present a major challenge for the endoscopist. Extending a sphincterotomy increases the risk of bleeding and perforation, and mechanical lithotripters are generally expensive, cumbersome to use, and fragile, and they fail to grasp the stones in a significant number of cases. For treating these patients, the complementary techniques such as extracorporeal shock wave, intracorporeal electrohydraulic, or laser induced lithotripsy are required<sup>[2]</sup>.

Electrohydraulic intracorporeal lithotripsy (EHL) represents an effective treatment option for the endoscopic treatment of difficult bile duct stones. However, EHL requires continuous visual control of the fragmentation procedure because of the high pulse energies that are used.

**Figure 1** Complete stone fragmentation using FREDDY without direct visual control. **A:** Cholangiogram showing stone impacted in the common bile duct; **B:** Cholangiogram made during FREDDY laser lithotripsy, showing multiple stone fragments; **C:** Endoscopic findings showing the fragmented stones from the bile duct.

The probe contacting with the bile duct wall may result in perforation or bleeding. Cholangioscopy with continuous saline solution irrigation is routinely performed during EHL. Transpapillary cholangioscopy with a mother-baby endoscope requires two experienced endoscopists. In addition, this type of endoscope is so fragile, and its cost is high. Also, EHL is associated with a high level of exposure to ionizing radiation for both the patient and the endoscopist<sup>[4,5]</sup>. Data on laser lithotripsy for complicated bile duct stones have been reported by several centers. Stone fragmentation rates of about 80%-90% have been reported for the coumarin green and Nd:YAG laser under direct cholangioscopic control. When performing laser lithotripsy under fluoroscopic guidance, the method failed in up to 80% of patients, because positioning of the glass fiber on the stone was difficult. But in 1993, a flash-lamp pulsed laser with a tissue-stone recognition system was introduced that could identify gallstones by

analyzing the back-scattered light and the energy pulse was interrupted in case of tissue contact. The visual control of placing the tip of the probe to the surface of the stone is facilitated by a helium-aiming beam. This system allows the treatment to be performed under fluoroscopic control with excellent safety and fragmentation success rates of up to 90%. Fluoroscopic control using a rhodamine 6G laser was effective in clearing the bile ducts in about 80% of patients<sup>[2,8]</sup>.

The FREDDY laser has been developed for endoscopic lithotripsy to disintegrate urinary stones. We applied this laser on the biliary stone that was not amenable to standard endoscopic procedure including endoscopic sphincterotomy and mechanical lithotripsy through the transpapillary route. In our study, stone disintegration through the transpapillary route was achieved in 15 of 17 patients (88%). The FREDDY laser is a short pulsed Q-switched frequency-doubled, double pulse Nd:YAG solid-state laser that allows the emission of long pulses. This laser is capable of producing very high pulse intensity because of the partial frequency doubling of the infrared ray into the green range that works synergistically. Laser light at 532 nm (the green spectrum) initiates plasma formation at the stone surface, while light at a wavelength of 1064 nm heats the preformed plasma, to cause expansion and contraction, which fragments calculi, and the pulse duration is 0.5-1.5  $\mu$ s<sup>[9]</sup>. This laser generates very short impulses that are poorly absorbed by soft tissue, and so the tissue is exposed to virtually no thermal effect. *In vitro* experiments show that FREDDY laser is very suitable for performing lithotripsy, and animal model studies have shown little to no effect on normal tissues<sup>[10]</sup>.

Also, in comparison with the holmium laser, the FREDDY laser produces no thermal effect<sup>[11]</sup>. This laser showed a high degree of fragmentation efficiency (95%) on the urinary stone, but yet any studies of its effect on biliary stones are rare. There was an 88% fragmentation rate in our study, although the number of patient was small. The FREDDY laser system combines the advantage of solid-state and pulse-dye lasers such as lower cost, good reliability, and excellent effectiveness.

The number of ERCP sessions necessary for duct clearance was higher in our study than reported for other study groups. When laser therapy was done as the first line method for difficult cases, additional ERCP sessions were necessary to achieve complete bile duct clearance<sup>[12]</sup>. A disadvantage of the FREDDY laser system is the high x-ray exposure to patients and the endoscopist. Also, it is difficult and time consuming to target the stone by fluoroscopy because of the positioning of the laser fiber that is inserted through a balloon catheter<sup>[13]</sup>. A certain level of endoscopic technique is required to contact the balloon catheter with laser fiber on the surface of a stone. Positioning of the balloon may be unsatisfactory in a tortuous angulated bile duct like our cases that laser lithotripsy failed. To ensure that the fiber would target the stone exactly and avoid contact with the bile duct, we monitored stone movement in the bile duct, fragmentation sound by applying stethoscope and hemobilia during this laser treatment.

In conclusion, our results suggest that laser lithotripsy using FREDDY without direct visual control was an effective and safe technique for patients with difficult CBD stones that could not be removed by mechanical lithotripsy. In the future, comparative studies with EHL, ESWL, or other laser systems will be required to assess the utility and efficacy of FREDDY laser.

## COMMENTS

### Background

Endoscopic papillotomy is successful in more than 90% of the cases of choledocholithiasis. For patients with difficult bile duct stones not responding to mechanical lithotripsy, different methods for stone fragmentation such as laser lithotripsy or electrohydraulic lithotripsy (EHL) with direct visual control have been developed. A major problem in using this device is the requirement of cholangioscopic guidance or the "mother and baby" endoscope.

### Research frontiers

Recently, a new laser, the Frequency Doubled Double Pulse Nd:YAG (FREDDY), was developed for endoscopic lithotripsy for urinary stones, and has less tissue damage. The efficacy and safety of laser lithotripsy without cholangioscopy by using the balloon catheter were evaluated in patients with bile duct stones that could not be extracted by standard technique.

### Innovation and breakthroughs

The FREDDY laser is a newly developed economical, short-pulse, double frequency, solid-state laser that results in less tissue damage. Fluoroscopically guided laser lithotripsy with a balloon catheter through a peroral duodenoscope appears to be effective treatment for bile duct stones that cannot be extracted by using conventional techniques such as mechanical lithotripsy.

### Applications

For the fragmentation of the biliary stone, cholangioscopy guidance is expensive due to the cost of the cumbersome endoscopic equipment and the need for two experienced endoscopists operating the "mother and baby" endoscope. When direct visual control is not available or limited, laser lithotripsy with a balloon catheter may be an alternative. To target the laser fiber accurately on the stone in the bile duct, a new and easier method is required.

### Peer review

It is a well-written and interesting paper. The FREDDY laser may be a useful technique in treatment of difficult bile duct stones.

### Abstract

**AIM:** To determine the prevalence and causes of persistently elevated alanine aminotransferase (ALT) levels among the general population in northern Iran.

**METHODS:** A total of 2292 (1376 female, aged 18-75 year), were selected by systematic clustered random sampling from the cities and villages of Gonbad and Kalaleh in Golestan Province and invited to participate in the study. A comprehensive history regarding alcohol drinking and medication was taken. Body mass index (BMI), viral markers and ALT levels were measured. If ALT level was  $\geq 40$  U/L, it was rechecked twice within 6 mo. Those with  $\geq 2$  times elevation of ALT were considered as having persistently elevated ALT level. Non-alcoholic fatty liver disease (NAFLD) was diagnosed based on evidence of fatty liver upon sonography and excluding other etiology.

**RESULTS:** A total of 2049 (1351 female) patients participated in the study, 162 (7.9%) had elevated ALT level at the first measurement. Persistently elevated ALT level was detected in 64 (3.1%) participants, with

51 (79.6%) with no obvious etiology, six (9.3%) with Hepatitis B, four (6.2%) with Hepatitis C virus (HCV) infection and three (4.6%) with alcoholic hepatitis. The prevalence of NAFLD and alcoholic hepatitis was 2.04% (42 patients) and 0.1% (three), respectively. There was correlation between NAFLD and male gender, overweight, diabetes and living in an urban area [odds ratio = 3.03 (95% CI: 1.6-5.72), 4.21 (95% CI: 1.83-9.68), 2.86 (95% CI: 1.05-7.79) and 2.04 (95% CI: 1.00-4.16) respectively].

**CONCLUSION:** NAFLD is the most common cause of persistently elevated serum ALT level among the general population of Iran.

### INTRODUCTION

End-stage liver disease is among the top ten common causes of morbidity and mortality in adults older than 15 years, worldwide<sup>[1]</sup>. The World Health Organization (WHO) estimates that in 2002, cirrhosis caused 382000 deaths worldwide<sup>[1]</sup>. According to the 2002 mortality report of the Ministry of Health of Iran, chronic liver diseases accounted for 1% of mortality of inhabitants aged > 15 years across the whole country<sup>[2]</sup>. Liver cirrhosis was the third and first leading cause of mortality and

hospitalization, respectively, in an Iranian gastrointestinal and hepatology ward<sup>[3]</sup>. Recognition of the relative contribution of various etiologies to a disease burden is important for setting public health priorities and prevention guidelines. Iran, a Middle East developing country, has an average prevalence of Hepatitis B virus (HBV) and Hepatitis C virus (HCV) infection, 3%-5% and 0.5% respectively<sup>[4-9]</sup>. HBV has been reported as the most common cause of chronic liver disease in the last decade in Iran<sup>[10,11]</sup>. The etiology of chronic liver disease changes by health concerns, national prevention programs, and people's lifestyle. The prevalence of HBV infection among healthy Iranian blood donors has declined; this may be due to better donor selection programs and an increasing number of repeat donors<sup>[12]</sup>. Rapidly increasing metabolic syndrome manifestations, including non-alcoholic fatty liver disease (NAFLD), are reported in Iran<sup>[13]</sup>. Information regarding the causes of chronic liver disease in the general population is rare in Middle-east countries. Alanine aminotransferase (ALT) is a sensitive indicator of liver cell injury and has been used to identify patients with liver disease for almost 50 years<sup>[14]</sup>. Currently, determination of serum ALT level constitutes the most frequently applied test for the identification of patients suffering from liver disease. The aim of this study was to determine the causes of chronic liver disease in the general population in Iran, using ALT as a surrogate marker of liver disease.

## MATERIALS AND METHODS

Our study was carried out according to the ethical standards for human experimentation and was approved by the ethics committee of the Digestive Disease Research Center, Tehran University of Medical Sciences. After explaining the aim of the study and the possible need for further blood tests and follow up, written informed consent was obtained.

### Subjects

Golestan province is located in North East Iran and has 1 614 376 inhabitants. Gonbad and Kalaleh are located in the North east of Golestan province. Gonbad has a population of 43 960, Kalaleh has a population of 154 349. In 2006, a total of 2292 (1376 females) 18-79 year old inhabitants of the villages and cities of Gonbad and Kalaleh were selected by systematic clustering random sampling, according to the data from family registry in health care centers, and were invited to take part in this study. Among the invited subjects, 698 of 916 males and 1351 of 1376 females participated in the study (participation rate: 76.2% and 98.1% for men and women, respectively). General parameters including age, gender, weight, height, drug history, especially during the past 3 mo, alcohol consumption (the number and type of drinks per day), hypertension and diabetes mellitus were ascertained and recorded by a trained general physician. An alcohol drinker was defined as a subject with an alcohol intake of > 20 g/d. Diabetes mellitus and hypertension were diagnosed according to previous diagnosis of these diseases by a physician or the use of drugs to control them. BMI of 25-30 kg/m<sup>2</sup> is defined as overweight and

BMI  $\geq$  30 kg/m<sup>2</sup> is obese<sup>[15]</sup>. Morning serum was obtained for measuring ALT and detection of Hepatitis B surface antigen (HBsAg) and HCV antibody (HCV Ab). HCV Ab was detected using ELISA. HCV recombinant immunoblot assay III was carried out on positive samples of HCV by ELISA. Those with a positive test result were considered positive for anti-HCV and exposed to HCV.

The normal range for the kit, as recommended by the manufacturer, for serum ALT level was 0-40 U/L. ALT levels  $\geq$  40 U/L were considered elevated. In step 2 of the study, all participants with serum ALT level  $\geq$  40 U/L in the first blood sampling were invited again and reassessed for alcohol consumption and medication. In step 3 of the study, participants with elevated serum ALT in the second step were considered as having persistently elevated serum ALT level, and were excluded. Those with normal ALT value in the second step were checked again in 3 mo, and if elevated, were considered to have persistently elevated serum ALT. Participants with persistently elevated ALT levels were examined by liver sonography to detect fatty liver. Participants with persistently elevated ALT levels and a negative test result for viral Hepatitis B and C, non-alcohol drinkers, and a negative history of medication intake, along with evidence of fatty infiltration of the liver upon sonography, were presumed to have NAFLD.

### Laboratory assessments

Serum was tested for ALT level using Hitachi autoanalyser 704 (Roche, Switzerland) with Pars Azmoon reagents kit (Tehran, Iran). HBsAg was measured by Enzygnost HBs Ag 5.0 kit (Dade Behring, Germany). HCV Ab was checked by ELISA using the Anti-HCV-EIA-Avicenna kit (Moscow, Russia), and confirmed with recombinant immunoblot assay III using INNOLIA<sup>TM</sup> HCV-Score kit (Innogenetics, Ghent, Belgium). All sonography was carried out by an expert sonographer using a 3.5-MHz probe (Logiq 200 PRO, Tokyo, Japan). Fatty infiltration of the liver was graded from 1 to 3, based on the echogenicity of the liver. In grade 1, echogenicity was slightly increased, with normal visualization of the diaphragm and the intrahepatic vessel borders. In grade 2, echogenicity was moderately increased, with slightly impaired visualization of the diaphragm or intrahepatic vessels. In grade 3, echogenicity was markedly increased, with poor or no visualization of the diaphragm, intrahepatic vessels, and posterior portion of the right lobe. Liver size was also assessed. If the liver was > 15 cm in length in the mid-clavicular line in the sagittal view, a diagnosis of hepatomegaly was made<sup>[16]</sup>.

### Statistical analysis

Statistical analysis was performed using SPSS, version 10.1 (SPSS, Chicago, IL, USA). Continuous variables were analyzed with the *t* test and categorical variables with  $\chi^2$ . *P* < 0.05 was considered statistically significant. Logistic regression analysis (multivariate analysis) was performed to identify factors independently associated with NAFLD.

## RESULTS

A total of 2049 participants (1351 females and 1073

**Table 1** Relative frequency of the participants according to demographic characteristics, laboratory test results, BMI and gender *n* (%)

Characteristic	Male (698)	Female (1351)	<i>P</i> -value	Total (2049)
Mean age $\pm$ SD (yr)	43.91 $\pm$ 15.52	38.88 $\pm$ 13.94	0.000	40.59 $\pm$ 14.69
Mean BMI $\pm$ SD (kg/m <sup>2</sup> )	25.02 $\pm$ 4.29	26.70 $\pm$ 5.34	0.000	26.13 $\pm$ 5.07
Median BMI (kg/m <sup>2</sup> )	24.91	25.94		25.56
BMI (kg/m <sup>2</sup> )				
< 18.5	40 (5.9)	43 (3.3)		83 (4.2)
18.5-24.9	308 (45.3)	509 (38.8)		817 (41)
25-29.9	240 (35.3)	418 (31.8)		650 (33)
30-34.9	82 (12.1)	248 (18.9)		330 (16.6)
35-39.9	9 (1.3)	73 (5.6)		82 (4.1)
$\geq$ 40	1 (0.1)	22 (1.7)		23 (1.2)
Mean ALT $\pm$ SD (U/L)	24.01 $\pm$ 15.67	19.38 $\pm$ 12.56	0.000	20.96 $\pm$ 13.87
HBsAg positive	38 (5.4)	64 (4.7)	0.340	102 (5)
HCV Ab positive	8 (1.1)	12 (0.8)	0.360	20 (1)
Diabetes mellitus	28 (4)	59 (4.3)	0.400	87 (4.2)
Hypertension	64 (9.1)	155 (11.4)	0.060	219 (10.6)

urban) were included in the study. Relative frequency of the participants according to demographic characteristics, laboratory tests, BMI and sex is shown in Table 1.

A total of 162 participants (7.9%) had elevated serum ALT level at the first measurement. Among the 147 of 162 participants who were invited for further evaluation, 64 were considered to have persistently elevated ALT level. In this group 51 (79.6%) had no obvious etiology, six (9.3%) had Hepatitis B, four (6.2%) had Hepatitis C, and three (4.6%) had alcoholic hepatitis. Drug history was unremarkable. Liver sonography was performed for 51 participants with persistently elevated ALT level with no obvious cause, in which 42 (2.04%) showed fatty liver and were presumed to have NAFLD. Demographic characteristics, laboratory test results, and sonography findings in participants with persistently elevated ALT level and fatty liver are shown in Table 2.

The mean BMI of NAFLD participants was  $30.47 \pm 5.07$  kg/m<sup>2</sup> compared with  $26.04 \pm 5.02$  kg/m<sup>2</sup> of those without NAFLD ( $P = 0.001$ ). In participants with NAFLD, there were 34 who were overweight and obese, and seven who were normal weight ( $P = 0.001$ ). In this study, 34/1095 (3.1%) of the overweight and 22/435 (5%) of the obese participants had NAFLD.

The mean BMI in urban participants ( $26.52 \pm 5.32$  kg/m<sup>2</sup>) was greater than that in their rural counterparts ( $25.69 \pm 4.74$  kg/m<sup>2</sup>) ( $P = 0.035$ ). The prevalence of overweight and obese participants was greater in urban (626) than rural (469) participants ( $P = 0.001$ ). NAFLD was more common in urban (31) than rural (11) participants, and also in men (24) than in women (18) ( $P = 0.005$  and  $0.001$ , respectively). There was a correlation between NAFLD and male gender, overweight and obese, diabetes and living in an urban area [odds ratio = 3.03 (95% CI: 1.6-5.72), 4.21 (95% CI: 1.83-9.68), 2.86 (95% CI: 1.05-7.79) and 2.04 (95% CI: 1.00-4.16), respectively].

## DISCUSSION

The prevalence of once-only elevated ALT levels, after excluding individuals with viral hepatitis, alcohol and

Grade 3	0 (0)	0 (0)	0 (0)
Liver span > 15 cm in sonography	0 (0)	0 (0)	0 (0)
Diabetes mellitus	1 (4.1)	4 (22)	5 (11.9)
Hypertension	1 (4.1)	2 (11)	3 (7.1)

drug etiology, was 2.1%, which was nearly half of the previously reported prevalence of 5.7% in healthy blood donors in Iran<sup>[7]</sup>. This may have been due to the greater prevalence of overweight and obese participants and male predominance (70.9% and 74.7%, respectively) in the previous study compared with the present study (54.8% and 34%, respectively). It has already been shown that serum ALT level is associated with male gender and obesity<sup>[17-19]</sup>. This value is near the prevalence reported in the Third National Health and Nutrition study in the United States (2.8%)<sup>[18]</sup>.

The prevalence of persistently elevated serum ALT levels (3.1%) in our study is comparable with that in previous studies from Western countries and the study of healthy blood donors in Iran<sup>[7,20]</sup>. The prevalence of HBsAg positivity was 5% in the present study, which is comparable to previous studies in the general population of Hamadan (2.49%), Nahavand (2.3%) and Golestan (9.7%)<sup>[4-6]</sup>. There are no published data about HCV prevalence in the general population in Iran for comparison. According to previous studies performed in healthy blood donors in Tehran, the prevalence of HBsAg positivity has declined sharply during the past 20 years, which is mainly due to better donor selection and an increasing number of repeat donors<sup>[12]</sup>.

NAFLD is a diagnosis of exclusion when clinical and laboratory examination fail to reveal a cause of liver disease. It is suggested when an imaging study shows fatty liver. Liver sonography is non-invasive, safe, widely available and highly sensitive for the detection of fatty liver. In one study that compared the sensitivity of MRI, CT and liver sonography to detect fatty liver, sonography and CT had sensitivity of 100% and 93%, respectively, in detecting fatty changes that involved > 33% of the liver, with a positive predictive value of 62% and 76%, respectively<sup>[21]</sup>. We did not perform liver biopsy for diagnosis of NAFLD, and we used criteria similar to those

of previous epidemiological studies of NAFLD<sup>[18,22]</sup>. Large epidemiological studies on the prevalence of NAFLD in the general population are lacking, but prevalence of 2.8%-24% has been reported<sup>[18,23,24]</sup>. In the present study, the prevalence of NAFLD was 2.04%, which is comparable to that reported previously in healthy blood donors (2.35%) and autopsies (2.1%) in Iran<sup>[7,25]</sup>. Although the participation rate in men was less than in women, mainly due to work constraints in men, NAFLD was three times more prevalent in men, which accords with previous studies in Asia, including the study of healthy blood donors in Iran<sup>[7,26,27]</sup>. Previously, it was thought NAFLD is more prevalent in women, but recent data suggest there is no significant difference between the sexes. Women are overrepresented in studies of NAFLD, but it is unclear if gender is an independent risk factor for the disease<sup>[22]</sup>. The frequency of overweight (54.9%) and obesity (21.9%) in the present study was close to the frequencies reported previously in northern Iran, which showed 62.2% were overweight and 28% were obese<sup>[28]</sup>. The frequency of NAFLD reaches 80% in obese persons; NASH is reported in 9%-30% of obese adults<sup>[29,30]</sup>. In the present study, 34/1095 (3.1%) overweight and 22/435 (5%) obese participants had NAFLD. There is a correlation between BMI and steatosis in several studies<sup>[22]</sup>. We showed that overweight and obesity were associated with a 4.21-fold increased risk in NAFLD participants, and mean BMI was also greater in NAFLD than non-NAFLD participants.

This study showed that living in an urban area is associated with a 2.04-fold increase in NAFLD, and this may be due to daily physical activity, lifestyle and greater prevalence of overweight and obesity in urban participants. NAFLD is associated with type 2 diabetes mellitus and glucose intolerance with or without superimposed obesity. Type 2 diabetes has been described in 20%-75% of NAFLD patients, and may increase the risk of NAFLD more than two-fold compared with that in non-diabetics. In the present study, prevalence of diabetes was 11.9% in NAFLD, and diabetes was associated with a 2.86-fold increase in NAFLD compared with non-diabetics<sup>[30]</sup>. NAFLD is now recognized as the hepatic manifestation of the metabolic syndrome, which includes hyperlipidemia, hypertension, glucose intolerance and obesity. The risk and severity of NAFLD increase with the number of components of the metabolic syndrome<sup>[31]</sup>. According to previous studies in the general population of Iran, metabolic syndrome has a prevalence of 33%, which is more common than the rate of 22% reported by the Third National Health and Nutrition Examination Survey for the USA<sup>[13,32]</sup>. We did not test for uncommon liver diseases such as Wilson's disease,  $\alpha$ 1-antitrypsin deficiency, primary biliary cirrhosis and primary sclerosing cholangitis, which can also be responsible for elevated ALT levels; as they are too infrequent to have had a major impact on our results. There are two studies that show that self-reported use of alcohol and opium are reliable and valid in this population<sup>[27,33]</sup>.

NAFLD was the most common cause of persistently elevated serum ALT levels in our study. The importance of NAFLD and ALT elevation is their impact on mortality as a component of the metabolic syndrome. NAFLD is

not a western disease, and is the most frequent cause of persistently elevated serum ALT level in the Asia-Pacific region<sup>[26]</sup>. Identifying its risk factors and therapeutic strategies to control this public health problem seems reasonable.

## ACKNOWLEDGMENTS

The authors extend their gratitude to Dr. Afshin Aslani, and Ms Goharshad Googlani from DDRC for their special help and support of this study and Ms. S Raman, B AmooHossein, M Moghtadaie, R Shamriz and M Mirzaie from IBTO for their technical assistance.

## COMMENTS

### Background

End-stage liver disease is among the top ten common causes of mortality in adults worldwide. Recognition of the risk factors for chronic liver disease is important for establishing prevention guidelines.

### Research frontiers

Non-alcoholic fatty liver disease (NAFLD) has been recognized as the main cause of chronic liver injury in both western and developing countries.

### Innovations and breakthroughs

Prevalence of NAFLD in Iranian populations is comparable to that in western countries. Obesity and other manifestations of the metabolic syndrome, in addition to urban lifestyle, are the main risk factors for NAFLD.

### Applications

National planning to increase knowledge regarding NAFLD and control of its risk factors are recommended.

### Terminology

NAFLD is the hepatic manifestation of the metabolic syndrome that includes insulin resistance, obesity, hyperlipidemia and hypertension. NAFLD is recognized by fat infiltration of hepatocytes and inflammatory reaction in the liver.

### Peer review

This is a good and interesting study. It is a very descriptive report about persistently elevated ALT levels in the Iranian population. The authors screened almost 3200 patients in a north eastern part of Iran for elevated ALT.

### Abstract

**AIM:** To develop a simple and convenient method for extracting genomic DNA from intestinal microflora for enterobacterial repetitive intergenic consensus (ERIC)-PCR detection.

**METHODS:** Five methods of extracting bacterial DNA, including Tris-EDTA buffer, chelex-100, ultrapure water, 2% sodium dodecyl sulfate and 10% Triton-100 with and without sonication, were compared with the commercial fecal DNA extraction kit method, which is considered as the gold standard for DNA extraction. The comparison was based on the yield and purity of DNA and the indexes of the structure and property of micro-organisms that were reflected by ERIC-PCR.

**RESULTS:** The yield and purity of DNA obtained by the chelex method was similar to that obtained with the fecal DNA kit. The ERIC-PCR results obtained for the DNA extracted by the chelex method and those obtained for DNA extracted with the fecal DNA kit were basically the same.

**CONCLUSION:** The chelex method is recommended for ERIC-PCR experiments in view of its simplicity and cost-effectiveness; and it is suitable for extracting total DNA from intestinal micro-organisms, particularly for handling a large number of samples.

### INTRODUCTION

The intestinal tract of animals harbors a large, active, and complex community of microbes<sup>[1]</sup>. There are at least 400-500 different microbial species, constituting a complex ecosystem<sup>[2]</sup>. They play significant roles in colonization resistance, i.e., the prevention of colonization of pathogens in the gastrointestinal tract and the growth of autochthonous opportunistic micro-organisms<sup>[3]</sup>. Intestinal bacteria that synthesize or metabolize potential carcinogens and produce anti-tumorigenic products may be related to colorectal cancer, which is the second most common cause of cancer death in the USA<sup>[4]</sup>.

Probiotics are defined as living organisms which, on ingestion in certain numbers, exert health benefits beyond the inherent basic nutrition in the host<sup>[5,6]</sup>. In humans, probiotics are effective in preventing the onset and relapse of pouchitis<sup>[7,8]</sup>, and in mice, they effectively prevent experimental colitis and reduce gut bacterial translocation<sup>[9,10]</sup>.

Commensal intestinal microflora have been monitored by cultivation-based techniques and molecular detections<sup>[11,12]</sup>. Enterobacterial repetitive intergenic consensus (ERIC)-PCR uses oligonucleotides targeting short repetitive sequences that are dispersed throughout various bacterial genomes<sup>[11]</sup>. Commensal intestinal microflora can be identified at the genus, species and strain levels based on the electrophoretic pattern of amplified products<sup>[13-15]</sup>.

The capacity of these assays to monitor bacteria in animal intestines depends on the efficiency of PCR. One of the key factors in obtaining the PCR fingerprinting patterns from the intestinal microflora is the efficiency of the DNA extraction procedure.

Usually, two factors have to be particularly considered during the extraction procedure. The first is to maximize the DNA yield. The second is to ensure that the extracted DNA is amenable to several enzymatic treatments like PCR amplification<sup>[16]</sup>. In other words, the greatest challenge is the extraction of high-quality PCR-compatible DNA from the intestinal microflora. Several methods have been evaluated for bacterial cell wall lysis and DNA extraction using detergents, proteolytic enzymes, lysozyme, mechanical disruption, temperature changes alone or in various combinations, DNA stool mini- kit, *etc.* Although the DNA stool mini-kit method is convenient, rapid and highly efficient, it is not widely applied on account of its high cost<sup>[17-20]</sup>.

In this study, 5 methods of extracting bacterial DNA were compared with that using the fecal DNA kit (FDK). The purpose of this study was to establish an economical, simple, and convenient method for extracting genomic DNA from the intestinal microflora for ERIC-PCR detection.

## MATERIALS AND METHODS

### Collection and preparation of fecal samples

Fresh fecal samples were collected from 20 10-d-old healthy goslings. No subject had received antibiotics, probiotics, or prebiotics. Gosling care and experimental procedures were performed in compliance with the Institutional Animal Care and Use Guidelines provided by the Centers for Disease Control and Prevention. Two goslings were randomly selected and their fecal samples from rectum were collected separately. The samples were collected in sterile bags, refrigerated, and immediately taken to the laboratory.

### Total DNA extraction

Each of the six extraction methods was repeated 3 times. Each sample (20 mg) was first thawed and suspended in 5.0 mL phosphate-buffered saline (PBS; pH 7.2). Centrifugation was carried out at 100 *g* for 15 min at 4°C in order to remove the fecal pellets; and the obtained supernatant was centrifuged at 13000 *g* at 4 °C for 10 min. The pellet was then washed 3 times by suspending it in 1.5 mL acetone. Each preparation was centrifuged at 13000 *g* for 10 min at 4°C in order to remove potential PCR inhibitors in stool<sup>[21]</sup>. The supernatant was discarded, and the pellet was processed for each procedure as follows. (1) The TE boil extraction method (T method): It is a modification of the bacterial DNA extraction protocol described by Li *et al.*<sup>[22]</sup>. The pellet was suspended in 200 µL TE buffer [10 mmol/L Tris-HCl (pH 8.0), 1 mmol/L EDTA]<sup>[23]</sup>, and the mixture was briefly mixed on a vortex mixer. The suspension was placed in a boiling water bath for 1 min, subjected to 3 freeze-thaw cycles alternating between -70°C for 3 min and 100°C for 2 min, and then centrifuged at 10000 *g* for 5 min. A 100 µL aliquot of the

supernatant was transferred to a sterile tube and stored at -20°C until PCR testing. (2) The ultrapure water method (UW method): A 200 µL aliquot of ultrapure water was added to the pellet, and the suspension was treated as described above for the TE buffer. (3) The chelex method (C method): This method is a modification of bacterial DNA extraction protocol described by Emi Suenaga<sup>[24]</sup>. A 200 µL aliquot of Chelex-100 (5%) and 0.2 mg protease K was added to the pellet and the sample was incubated at 56°C for 30 min in a water bath. The mixture was then briefly mixed on a vortex mixer and centrifuged at 10000 *g* for 5 min. A 100 µL aliquot of the supernatant was transferred to a sterile tube and stored at -20°C until PCR testing. (4) SDS method: The pellets were treated as described above for the TE buffer, except that 200 µL of the nonionic detergent mix (2% SDS containing 10% Triton X-100) was substituted for the TE buffer<sup>[18]</sup>. (5) The SDSS method: A 200 µL aliquot of 2% SDS containing 10% Triton X-100 was added to the pellet, and the mixture was briefly agitated on a vortex mixer. The suspension was sonicated for 15 min and then treated as described above for the TE buffer<sup>[18]</sup>. (6) The FDK method: The pellets were processed using the Fecal DNA Kit™ (Tianli, China) and the DNA was purified with a spin column according to the manufacturer's instructions.

### Measurement of DNA concentration and purity

The concentration and purity of DNA were determined spectrophotometrically (BIO-RAD Smart Spec 3000; USA); for this purpose, DNA absorbance was measured at 260 nm (µg DNA/g sample; 1  $A_{260}$  = 50 µg/mL DNA) and protein impurities were checked at 280 nm<sup>[25]</sup>. The concentration and purity of each DNA extraction method was statistically analyzed by Excel 2003 for Windows.

### Genomic DNA detection by different extraction methods

For each method tested, the presence and quality of the extracted genomic DNA from one of the triplicate samples was analyzed using a 0.5% agarose gel containing ethidium bromide at 4°C. Ten microliters of the DNA extracted by each method was added into the gel and electrophoresed for 30 min at 150 V. Gel images were acquired as tagged image file format (TIFF) files with a Gel Imaging System (Bio-Rad). Unless mentioned otherwise, the following molecular procedures were carried out with the extracted genomic DNA obtained from 1 or 2 of the triplicate samples.

### ERIC-PCR and statistical analysis

For fingerprinting the bacterial population in fecal samples, the total fecal DNA was used as a template for ERIC-PCR, and the sequence of the ERIC primers were E1 (ERIC1R): 5'-ATGTAAGCTCCTGGGGATTACAC-3' and E2 (ERIC2): 5'-AAGTAAGTGACTGGGGTGAGCG-3' which was described by Versalovic *et al.*<sup>[11]</sup>. The ERIC-PCRs were performed under the conditions described by Di Giovanni *et al.*<sup>[26]</sup>.

We analyzed the PCR products by agarose gel electrophoresis as described by Melanie W Syrmis<sup>[27]</sup>. We acquired gel images as TIFF files using a Gel Imaging System (Bio-Rad).

**Table 1** DNA yields and purity obtained by six DNA extraction methods ( $\mu\text{g}$  DNA/g sample)

Samples	T-method	C-method	UW-method	SDS-method	SDSS-method	FDK-method
Yield	601.52	1301.52	586.03	1710.95	1820.12	1326.07
Purity ( $A_{260/280}$ )	1.58	1.84	1.6	1.54	1.49	1.82

**Table 2** Cs matrix values of ERIC-PCR fingerprint of the samples extracted by different methods (%)

Samples	T-method	C-method	UW-method	SDS-method	SDSS-method	FDK-method
C-method	25	-	25	0	0	92.1
UW-method	100	25	-	0	0	25
SDS-method	0	0	0	-	100	0
SDSS-method	0	0	0	100	-	0
FDK-method	25	92.1	25	25	25	-

**Figure 1** Electrophoresis results with the samples extracted by different methods. **A:** The genomic DNA; **B:** The ERIC-PCR products. M: marker (TIANYI, China, D-15000); 1: C-method; 2: T-method; 3: UW-method; 4: SDS-method; 5: SDSS-method; 6: FDK-method.

To interpret the ERIC-PCR fingerprint profiles, the Quantity One software package (Applied Bio-Rad) was used with pairwise similarity coefficient ( $C_s$ )<sup>[28]</sup>. Fingerprints were assigned to a different type when any band differences were observed. Variations in band intensity were not considered as band differences. The fingerprints were considered similar when the  $C_s$  was more than 90%, different when the  $C_s$  was 0, and identical when the  $C_s$  was 100%<sup>[28]</sup>.

## RESULTS

### Yield, purity and quality of DNA obtained by different methods

The yield, purity, and quality of genomic DNA obtained from the six extraction methods are shown in Table 1. The quality of the extracted DNA was evaluated by the  $A_{260/280}$  ratio, and values close to 1.8 indicate a good DNA extract with little protein contamination<sup>[25]</sup>. Although high-molecular-weight DNA (approximately 15 kb) was acquired by all the six methods (Figure 1A), discrepancies in the yield and purity of DNA were observed among different methods. For instance, the SDSS and SDS

methods yielded the maximum amount of DNA (mean, 1820.12  $\mu\text{g/g}$  and 1710.95  $\mu\text{g/g}$ , respectively), but the lowest  $A_{260/280}$  ratio (mean, 1.49 and 1.54, respectively), thus implying the lowest purity of DNA. The T and UW methods yielded the least amount of DNA (mean, 601.52  $\mu\text{g/g}$  and 586.03  $\mu\text{g/g}$ , respectively) and lower purity of DNA (mean  $A_{260/280}$  ratio, 1.58 and 1.60, respectively). The C and FDK methods yielded similar amounts of DNA (mean, 1301.52  $\mu\text{g/g}$  and 1326.07  $\mu\text{g/g}$ , respectively) and similar  $A_{260/280}$  ratios (mean, 1.84 and 1.82, respectively). The purity of the DNA obtained by the two methods was the highest.

### Analysis of ERIC-PCR fingerprints

The amplifications of ERIC-PCR were confirmed by agarose gel electrophoresis. Except for the SDSS and SDS methods, the DNA extracted by the remaining methods was effectively amplified (Figure 1B).

The ERIC-PCR fingerprint profiles of the genomic DNA of intestinal bacterium extracted from the same sample by the six methods showed that the results of the C and FDK methods were consistent, and the  $C_s$  value for these methods was 92.1%. However, the  $C_s$  values by other methods were lower than 30%, and the  $C_s$  by SDSS and SDS methods was 0 (Table 2).

The ERIC-PCR fingerprint profiles of the intestinal bacterial genomic DNA extracted from the same sample by the C and FDK methods showed that the C method (1) had a 100%  $C_s$  value when compared with the C method (2), and the FDK method (1) had a 100%  $C_s$  value when compared with FDK method (2) (Figure 2 and Table 3). These results indicated that the stability and reproducibility of the C and FDK methods were equally good.

## DISCUSSION

Although extensive researches with ERIC-PCR have been conducted on the bacterial microflora in the intestine, the effect of the method selected for DNA extraction on the analysis of a bacterial community has barely been considered. This study is important as DNA extraction is one of the most commonly used procedures in genetics, molecular biology, and biochemistry.

Some important factors that should be considered when choosing a DNA extraction method are the time required to complete the extraction, the cost of extraction, and the safety of the chemical reagents employed. Moreover, DNA fragmentation should be avoided during the extraction.

**Figure 2** Electrophoresis for ERIC-PCR fingerprint of the samples extracted by C-method and FDK-method. Lanes: M: marker (TIANYI, China, DL-2000); 1 and 2: C-method; 3 and 4: FDK-method.

From the extraction methods already published for various bacteria, we chose and compared six methods for extracting DNA from the intestinal microflora: the T, C, UW, SDSS, SDS, and commercial FDK methods.

The aim of an extraction procedure is to obtain a high quality and high yield of DNA from the samples. The extracted DNA should contain the least amount of proteins, RNA, or any other PCR inhibitors such as bile salt and cholerythrin, which are present in the feces<sup>[28,29]</sup>. Removing those inhibitors is one of the key factors for a successful PCR. In this study, we used acetone to remove the inhibitors from the stool samples, as reported by Zhong Hua *et al.*<sup>[21]</sup>. Our ERIC-PCR results was found successful in removal of these inhibitors.

DNA absorbance was measured at 260 nm ( $A_{260}$ ) to evaluate the quantity of the extracted DNA, and the ratio of the absorbance at 260 nm to that at 280 nm ( $A_{260/280}$ ) was used to evaluate the DNA quality. This method was employed previously by other researchers to compare different DNA extraction methods<sup>[30,31]</sup>.

In this study, the results of the concentration and the purity for each method were correlated. The SDSS and SDS methods seemed to yield a greater quantity of DNA, but their  $A_{260/280}$  ratio indicated a high protein contamination. On the other hand, the concentrations of the DNA obtained using the C and FDK methods were lower, but the  $A_{260/280}$  ratio showed a high purity of the DNA obtained. When applied to engorged individuals, the C method resulted in 100% successful DNA amplification that was similar to the FDK method. In our study, the C method provided the best results with a Cs close to 92.1% when compared with the FDK method.

Bacterial lysis is the key to obtain bacterial DNA. Although the SDS and SDSS methods can provide the highest DNA yield, the SDS residue inhibits the PCR process. This result is consistent with that reported by Khan<sup>[18]</sup> and Wade<sup>[17]</sup>. The excessive SDS above 0.01% has been shown to inhibit PCR by denaturing the Taq polymerase.

Many reports have described DNA extraction from tissues of other organisms using chelex-100. The results vary by different methods<sup>[32,33]</sup>. The use of chelex-100 has been recommended for DNA extraction in some papers, but other reports have not regarded it as being optimum because of its lowest efficiency for DNA amplification<sup>[32]</sup>. However, we found that the modified chelex-100 protocol was the best method to extract DNA from stool. Although

**Table 3** Cs matrix values of ERIC-PCR fingerprint of the samples extracted by C-method and FDK-methods (%)

Samples	C-method (1)	C-method (2)	FDK-method (1)	FDK-method (2)
C-method (2)	100.0		92.1	92.1
FDK-method (1)	92.1	92.1		100.0
FDK-method (2)	92.1	92.1	100.0	

there are methodological differences between our study and others<sup>[32,33]</sup>, the conclusion is the same that this method is simple and efficient for PCR.

Theoretically, column-purified DNA should be the cleanest, containing the least PCR-inhibitory substances. One purpose of our study was to identify a method for rapid DNA extraction that did not compromise PCR sensitivity. We used the FDK extraction method as the gold standard for PCR purification. Our results showed that for PCR, column purification was unnecessary for DNA extracted from the intestinal microflora. Compared to FDK that requires 2 h, DNA extraction with chelex-100 can be completed within less than 1 h, and it does not involve 3-4 transfers of samples to new tubes.

In conclusion, of the 5 extraction methods evaluated, the chelex method is technically simpler, less expensive, and more rapid than the FDK method; it is the best method for extracting genomic DNA from the intestinal microflora. Although the extraction with TE buffer and ultrapure water is extremely easy and inexpensive, the DNA yield is the lowest. The SDS and SDSS methods consistently inhibit PCR, therefore, they cannot be recommended for DNA extraction from the intestinal microflora.

## COMMENTS

### Background

The term probiotic is a relatively new term that implies "for life". Currently, it is used to refer to intestinal bacteria that have beneficial effects on humans and animals. Probiotics can play an important role in immunological, digestive, and respiratory functions and could have a significant effect in alleviating infectious diseases in children and other high-risk populations. Thus, knowledge about probiotics could contribute to improving human health. It is necessary to understand the bacterial flora in the gastrointestinal tract, particularly at the species level of bacterium. The DNA-based techniques often represent the most appropriate approach in this regard.

### Research frontiers

To date, the chelex method has mainly been used for medicolegal investigations. Since it is a rapid, simple, and inexpensive technique for extracting genomic DNA from intestinal microflora, it will be an ideal method to study the microflora in the gastrointestinal tract.

### Innovations and breakthroughs

In previous studies on DNA extraction from the intestinal microflora, researchers used the traditional DNA extraction process that involved proteinase K digestion by phenol chloroform extraction or the FDK method. However, the chemical products employed in these experiments were either toxic or expensive. Through the present study, we provide a significantly improved method for the rapid, safe, simple and economical extraction of DNA from the intestinal microflora.

### Applications

This study details a new, simple protocol for extracting DNA from the intestinal

bacterial microflora and may ultimately provide new insights in the field of probiotics.

### Peer review

In this study, through the development of new methods for extracting bacterial DNA from the intestinal microflora, the authors found that the chelex method is a simpler, more rapid, and a less expensive method than the FDK method. Moreover, the results presented herein may lead to the development of a novel convenient approach for monitoring the intestinal microflora by molecular detection methods.

### Abstract

**AIM:** To investigate the influence of different quasispecies of hepatitis C virus (HCV) genotype 1b core protein on growth of Chang liver cells.

**METHODS:** Three eukaryotic expression plasmids (pEGFP-N1/core) that contained different quasispecies truncated core proteins of HCV genotype 1b were constructed. These were derived from tumor (T) and non-tumor (NT) tissues of a patient infected with HCV and C191 (HCV-J6). The core protein expression plasmids were transiently transfected into Chang liver cells. At different times, the cell cycle and apoptosis was assayed by flow cytometry, and cell proliferation was assayed by methyl thiazolyl tetrazolium (MTT) assay.

**RESULTS:** The proportion of S-phase Chang liver cells transfected with pEGFP-N1/core was significantly lower than that of cells transfected with blank plasmid at three different times after transfection (all  $P < 0.05$ ). The proliferation ratio of cells transfected with pEGFP-N1/core

was significantly lower than that of cells transfected with blank plasmid. Among three different quasispecies, T, NT and C191 core expression cells, there was no significant difference in the proportion of S- and G<sub>0</sub>/G<sub>1</sub>-phase cells. The percentage of apoptotic cells was highest for T (T > NT > C191), and apoptosis was increased in cells transfected with pEGFP-N1/core as the transfection time increased (72 h > 48 h > 24 h).

**CONCLUSION:** These results suggest that HCV genotype 1b core protein induces apoptosis, and inhibits cell-cycle progression and proliferation of Chang liver cells. Different quasispecies core proteins of HCV genotype 1b might have some differences in the pathogenesis of HCV persistent infection and hepatocellular carcinoma.

### INTRODUCTION

Hepatitis C virus (HCV) infection is prevalent worldwide. HCV infection may lead to the development of chronic hepatitis, cirrhosis and hepatocellular carcinoma (HCC)<sup>[1]</sup>. HCV is a positive-strand RNA virus that belongs to the family Flaviviridae. The HCV RNA genome is 9.6 kb in length and encodes a precursor polyprotein of 3000 amino acids. The precursor polyprotein is cleaved by host and viral proteases and produces a series of structural and non-structural proteins. In addition, HCV genome has the property of variation, and it usually exists as different quasispecies of the same genotype in HCV-infected patients<sup>[2,3]</sup>. The function of different quasispecies of HCV is not fully identical<sup>[4,5]</sup>.

HCV core protein is important as a viral structural component in nucleocapsid formation, and it is highly conserved among different HCV genotypes. Several studies have established that HCV core protein can regulate cell signal transduction, such as MAPK-, JAK-STAT-, NF- $\kappa$ B-, AP-1- and SRE-associated pathways<sup>[6-8]</sup>. Hence, it plays important roles in the pathogenesis of HCV persistent infection, as well as HCC. However, the mechanism of persistent infection and HCC due to HCV core protein infection remains unclear. Although several studies have investigated the influence of the HCV core protein on cell growth and apoptosis, the results of these investigations have been inconsistent and mutually conflicting.

In most studies, HCV core protein has been expressed in single clones of permanently transfected cell lines, while more recently, transiently transfected cells have also been used. These studies have found that core protein affects normal cellular functions, such as proliferation and death, which are involved, directly or indirectly, in HCV hepatocarcinogenesis. Because we have found that different quasispecies core proteins of HCV genotype 1b have some differences in the pathogenesis of HCV persistent infection and HCC. HCV is a hepatotropic virus, it is therefore more appropriate to use a hepatocyte cell line to study the function of HCV core protein.

To further clarify the *in vivo* role of truncated HCV core protein from different genotype 1b quasispecies, we expressed three different truncated forms of HCV core protein derived from tumor tissue (T), non-tumor tissue (NT) and C191 (HCV-J6), which all belong to HCV genotype 1b, in transiently transfected Chang liver cells, an immortalized non-tumor hepatic cell line. Cell cycle and apoptosis were assayed by flow cytometry, and cell proliferation was assayed by methyl thiazolyl tetrazolium (MTT) assay.

## MATERIALS AND METHODS

### Plasmid constructs

Three different truncated HCV core protein eukaryotic expression plasmids, pEGFP-N1/core, were constructed. Truncated core protein nucleotide sequences were amplified from pGEX 4T-1/HCV-core, which contained core sequences from T, NT and C191, respectively. Sequence analysis revealed that T and NT were all HCV genotype 1b. The primers were designed according to the core protein gene sequence of T, NT and C191 (Table 1). PCR reaction system: 50  $\mu$ L: water 40.75  $\mu$ L; PCR reaction buffer (10  $\times$ ), 5  $\mu$ L; template (45 ng), 1  $\mu$ L; primer up 20 pmol/L, 1  $\mu$ L; primer down 20 pmol/L, 1  $\mu$ L; dNTP 20 mmol/L, 1  $\mu$ L, Expand high enzyme 0.25  $\mu$ L, 94°C for 2 min, 94°C for 30 s, 50°C for 30 s, 72°C for 30 s, 10 cycles; 94°C for 30 s, 55°C for 30 s, 72°C for 30 s, 20 cycles; and 72°C for 7 min. PCR products (Figure 1) were purified and cleaved with restriction enzymes *Nhe* I and *Eco*R I, and cloned into pEGFP-N1 to yield GFP-core fusion protein plasmids.

### Cell culture and transfection

Chang liver cells were grown in Dulbecco's modified Eagle's medium (Gibco, USA) supplemented with 10% fetal bovine serum (FBS; Gibco) at 37°C in 5% CO<sub>2</sub>. Cells were incubated for 18 h and then transfected with Lipofectamine

**Table 1** Primers of different quasispecies core proteins of HCV genotype 1b

	Primer up (location)	Primer down (location)
T: 1-172	CGCGCTAGCATGAGG CACGAATCC (1-14)	CCGGAATTCGCAACCGG GCAG (505-516)
NT: 1-172	CGCGCTAGCATGAGG ACGAATCC (1-14)	CCGGAATTCGGCAACCG GGCAGATTC (505-516)
C191: 1-172	CGCGCTAGCATGAGG ACAAATCC (1-14)	CCGGAATTCGGCAACCG GGCAAATTC (505-516)

GCTAGC, *Nhe* I site; GAATTC, *Eco*R I site. Primer designed according to the sequence of different core protein genes.

**Figure 1** PCR product of core protein genes.

2000 (Invitrogen, USA) following the manufacturer's instructions. Two micrograms of plasmids were used to achieve transfection. After 6 h, the medium was changed and cells were collected at different times.

### Flow cytometry analysis

The cell cycle and apoptosis was assayed by flow cytometry at 24, 48 and 72 h after transfection. Ten  $\times 10^5$  cells were trypsinized, pelleted by centrifugation, and resuspended in PBS, and then cells were fixed with 70% ethanol and stored at 4°C overnight. After washing twice, cells were incubated in propidium iodine for 20 min at room temperature. The cell suspension was analyzed by flow cytometry using Cell Quest software (Becton Dickinson, USA).

### Cell growth analysis

Cell proliferation was assayed by MTT assay and a growth curve was created.  $10^4$  cells were seeded per well on a 96-well plate. Zero, 24, 48, 72 and 96 h after transfection, 10  $\mu$ L water-soluble tetrazolium reagent (MTT; Sigma, USA) was added to 100  $\mu$ L culture medium. Cells were then incubated at 37°C in 5% CO<sub>2</sub> for 4 h.  $A_{570}$  was measured. The assay was done in quadruplicate.

### Statistical analysis

The values were expressed as mean  $\pm$  SD. Experimental data were analyzed by SPSS 13.0 software (SPSS Inc, Chicago, IL, USA). Comparison of different groups was analyzed by one-way analysis of variance (ANOVA).  $P < 0.05$  was considered statistically significant.

## RESULTS

### Different HCV genotype 1b quasispecies core proteins inhibited Chang liver cell cycle

As shown in Tables 2-4, three different quasispecies

**Table 2** Core proteins of different quasiespecies of HCV genotype 1b inhibited Chang liver cell cycle by impairing G1 to S transition at 24 h after transfection

truncated core proteins inhibited Chang liver cell cycle progression by impairing G1- to S-phase transition. The proportion of S- and G0/G1-phase Chang liver cells transfected with pEGFP-N1/core was significantly lower than that of cells transfected with blank plasmid at 24, 48 and 72 h after transfection (*P* = 0.002, *P* = 0.001, *P* = 0.001, respectively), but there were no significant differences among cells expressing the three different quasiespecies HCV truncated core proteins.

#### Different HCV genotype 1b quasiespecies core proteins induced Chang liver cell apoptosis

As shown in Figure 2, three different quasiespecies truncated core proteins induced apoptosis at different levels. The apoptotic ratio of Chang liver cells transfected with pEGFP-N1/core was significantly higher than that of cells transfected with blank plasmid. The apoptotic percentage of T was the highest, and C191 was the lowest (T > NT > C191). The apoptosis ratio increased in cells transfected with pEGFP-N1/core as transfection time increased (72 h > 48 h > 24 h).

#### Different HCV genotype 1b quasiespecies core proteins inhibited Chang liver cell proliferation

We found that different HCV genotype 1b quasiespecies

**Figure 2** Core proteins of different quasiespecies of HCV genotype 1b induced Chang liver cell apoptosis at 24, 48 and 72 h after transfection.**Figure 3** Core proteins from different HCV genotype 1b quasiespecies inhibited proliferation of Chang liver cells.

core proteins inhibited the Chang liver cell cycle by impairing G1- to S-phase transition and induced apoptosis at different times after transfection. Chang liver cell proliferation was further analyzed using MTT assay. As shown in Figure 3, different HCV genotype 1b quasiespecies core proteins inhibited Chang liver cell proliferation. Among the three different HCV genotype 1b quasiespecies core proteins, that of T inhibited Chang liver cell proliferation more obviously than NT and C191 (T > NT > C191) at 24, 48, 72 and 96 h.

## DISCUSSION

HCV core protein is a multifunctional protein that can modulate a number of cellular processes, including transcription, inhibition or stimulation of cell cycle and apoptosis, and suppression of host immunity. In this study, using flow cytometry and MTT assay, we investigated the influence of different quasiespecies of truncated HCV genotype 1b core proteins on growth of Chang liver cells, an immortalized non-tumor hepatic cell line. We found that HCV genotype 1b core protein HCV induced apoptosis, and inhibited the cell cycle and cell proliferation. Among

the three different quasispecies core proteins, the rates of inducing apoptosis and inhibiting cell proliferation were different, which suggests that different quasispecies of HCV genotype 1b core proteins might have some differences in their pathogenesis of HCV persistent infection and HCC.

Regulation of cell cycle and apoptosis is essential to maintain normal cell growth. Several studies have reported that HCV core protein can influence cell cycle progression. Two important checkpoints of the cell cycle, G1/S and G2/M, are responsible for accumulation of detrimental mutations that may result in cell transformation. The mechanism of cell cycle regulation is quite complex, and involves a number of proteins, such as p53, p21, PRb, E2F and c-myc<sup>[9,10]</sup>. Ruggieri *et al* have reported that stable expression of core protein in unsynchronized HepG2 cells induces perturbation of the cell cycle by increasing the S-phase fraction. c-myc protein stability is increased, which is one of the regulatory molecules of the cell cycle<sup>[11]</sup>. Honda *et al* have found that core protein promotes cell cycle progression in stable CHO transformation by upregulation of c-myc<sup>[12]</sup>. Ohkawa *et al* have reported that core protein impairs G1 to S transition by using core expression stable CL2 cell, a murine normal liver-derived cell line. E2F-mediated transcription, and PRb, CDK4 and CDK2 activities were suppressed by HCV core protein<sup>[13]</sup>. Different studies have come to different conclusions. We found that transient expression of HCV genotype 1b truncated core proteins could impair G1/S in the Chang liver cell cycle. Different quasispecies core proteins from T, NT and C191 have no significant difference when it comes to impairing G1/S. The above studies suggest that core protein might be a double-function protein, promoting cell cycle progression and inhibiting cell cycle progression. However, the exact mechanisms of how different quasispecies core proteins affect the G1/S checkpoint remain unclear.

Apoptosis is defined as programmed cell death and it is an orderly process. Apoptosis can be induced by a variety of stimuli, including oxidative stress, heat shock, ionizing radiation, cytokines and virus infection. The apoptotic process appears to be a host defense mechanism against viral infections. HCV might lead to viral persistence by inhibiting hepatocyte apoptosis and inducing monocyte apoptosis<sup>[14]</sup>. Although diverse effects of the core protein on apoptosis have been reported, the underlying mechanisms are not fully understood<sup>[15]</sup>. Core protein exhibits both pro- and anti-apoptotic actions. Transient expression of the core protein can inhibit tumor necrosis factor (TNF)- $\alpha$ -mediated apoptosis in MCF7 cells, a cell line derived from breast carcinoma tissue<sup>[16]</sup>. In contrast, several studies have indicated that core protein can promote apoptosis induced by Fas or TNF- $\alpha$  in stable expression systems in HepG2, HeLa and Jurkat T cell lines<sup>[17-19]</sup>. In our study, we found that different quasispecies of HCV genotype 1b truncated core proteins could induce Chang liver cell apoptosis, and the ability to induce apoptosis was different (T > NT > C191). Apoptosis was increased depending on prolongation of transfection time (72 h > 48 h > 24 h). Moreover, the cell proliferation induced by HCV core protein was consistent with our finding that HCV core protein induced cell apoptosis. Nevertheless, the present results allow us to

propose an alternative, and in fact contrasting mechanism for HCV core protein. Our observations imply that the liver cell proliferation observed during liver carcinogenesis is associated with the selection of viral genomes whose core products can resist apoptosis.

This apparently paradoxical finding should be discussed in the light of two important observations. Consistent with previous reports<sup>[20-23]</sup>, in HCV-related HCC, strong arguments exist in favor of the importance of the immune response to HCV proteins in liver cell destruction during acute or chronic HCV infection. Our findings therefore suggest that cell apoptosis may reduce HCV protein expression and the elimination of infected cells, thus favoring viral persistence. A sustained reduction in HCV replication during the later stages of liver cancer development probably depends on other mechanisms, such as a lack in dedifferentiated cancer cells of the tissue-specific cellular factors necessary for HCV polyprotein expression and maturation. This favors the selection of a cell subset that acquires resistance to HCV apoptosis and whose differentiation status maintains down-regulated HCV multiplication.

Cell-cycle progression and apoptosis are balanced processes regulated by a number of cellular factors. Several cell-cycle-regulatory proteins are involved in signal transduction pathways of apoptosis<sup>[24-26]</sup>. Core protein impaired G1/S transition, which might be advantageous to cells that are entering the apoptotic process. The influence of core protein on cell cycle and apoptosis is different, depending on different cell systems and expression systems used<sup>[27-30]</sup>. However, in most studies, human hepatoma-derived cell lines Huh-7 or HepG2 were used, but in our study, Chang liver cell and transient transfection were used. As an immortalized non-tumor cell line, the biological function of Chang liver cells is similar to that of normal human hepatocytes, so it is suitable for studying virus-host interactions *in vitro*.

In summary, we found that HCV genotype 1b core protein could induce apoptosis, and inhibit cell-cycle progression and cell proliferation. Among three different quasispecies core proteins, the capability of inducing apoptosis and inhibiting cell proliferation was different.

## COMMENTS

### Background

It is known that hepatitis C virus (HCV) core protein plays an important role in the pathogenesis of HCV persistent infection and hepatocellular carcinoma (HCC). HCV core protein derived from different quasispecies of the same HCV genotype 1b might have different functions in their pathogenesis.

### Research frontiers

HCV core protein is involved in regulation of host cell growth, including the cell cycle and apoptosis, but the results are conflicting. Recent studies have shown that the influence of HCV core protein on cell growth might be associated with viral persistence and generation of liver carcinogenesis.

### Innovations and breakthroughs

We used Chang liver cells, an immortalized non-tumor hepatic cell line, different from the human hepatoma-derived cell lines in most studies. Moreover, different quasispecies of HCV genotype 1b core proteins are found to have different biological functions.

## Applications

Our findings further show the importance of HCV core proteins on the pathogenesis of HCV persistent infection, as well as HCC. It might provide new ideas for the cure and prevention of HCV infection.

## Peer review

This work investigated the role of the core protein of HCV from different quasispecies on the pathogenesis of Chang liver cells. The findings are potentially interesting and point towards the ability of HCV core protein to induce apoptosis and inhibit cell-cycle progression in Chang liver cells. The intensity of these observed effects seems to be dependent on the quasispecies of the HCV core protein isolated.

## Abstract

**AIM:** To identify the cholecystokinin (CCK)-A receptors (CCK-AR) on the guinea pig gallbladder interstitial cells of cajal (ICC) and to study CCK-8 induced gallbladder muscle strip contractions through the CCK-AR.

**METHODS:** The existence of CCK-AR was examined by immunohistofluorescence on sectioned tissue and cultured cells. *In vitro* contractile response of guinea pig gallbladder muscle strips and the strips with ICC removed were also studied with CCK-8 receptors added.

**RESULTS:** In tissue sections, intensely CCKAR-immunoreactive interstitial cells were found mainly in the muscular layers. In cultured cell sections, distinctive double staining of C-kit and CCK-AR ICCs were found. When we removed the ICC of the gallbladder, CCK-8 induced muscle strip contraction dose response curve significantly shifted to the right.

**CONCLUSION:** We proved that both the existence of CCK-AR on the guinea pig gallbladder ICC and CCK evoked contraction are mediated through direct action on CCK-AR on the gallbladder ICC.

## INTRODUCTION

Cholecystokinin (CCK) is released from mucosal endocrine cells in the proximal small intestine in response to a meal<sup>[1]</sup>, and it is classically known to stimulate the gallbladder contraction. The CCK-induced gallbladder contractions were once believed to be brought about by direct stimulation of gallbladder smooth muscle. The CCK receptors have been identified by using isolated gallbladder muscle membranes and autoradiographical analysis<sup>[2-4]</sup>. Two CCK receptors, CCK-A (CCK-AR) and CCK-B receptors (CCK-BR) have been identified<sup>[5]</sup>. It is well established that CCK-AR and CCK-BR regulate a number of physiological functions, e.g. gallbladder contraction<sup>[6]</sup>, pancreatic enzyme release<sup>[7]</sup>, gastric acid secretion<sup>[8]</sup> and pyloric sphincter closure<sup>[9,10]</sup>. In 1892, a special kind of cell which is now called "interstitial cells of Cajal" (ICC) in the gastrointestinal tract was first described by the famous Spanish neuro-histologist Ramon y Cajal<sup>[11]</sup>. It has been approved that ICC play an important role in gastrointestinal tissues by generating and propagating electrical slow waves to gastrointestinal muscles, and it mediates signals from the enteric nervous system<sup>[12-15]</sup>. ICCs were found in the murine<sup>[16]</sup>, *Homo sapiens*<sup>[17]</sup> and guinea pig gallbladders<sup>[18]</sup>. Both the CCK-AR and CCK-BR mediate the contraction of the guinea pig ileum<sup>[19-21]</sup>, whereas the guinea pig gallbladder contraction is mediated solely by CCK-AR<sup>[22]</sup>. It is considered that CCK-induced gallbladder contractions are controlled through CCK-ARs both on the vagal nerve in stimulating endogenous release of acetylcholine and on the gallbladder to directly stimulate muscle contraction in dogs<sup>[23]</sup>. The recent availability of antibodies directed against the CCK-AR has made it possible to identify the receptor by immunocytochemistry<sup>[24]</sup> and immunohistochemistry<sup>[25]</sup>. It has been reported that some ICCs in the rat pylorus express CCK-ARs<sup>[26]</sup>. Therefore, we used an immunohistochemical approach to localize the CCK-AR in the gallbladder. Surprisingly, we found that the interstitial cells of Cajal express CCKARs to a high degree. We also measured the effect of atropine,

tetrodotoxin and CCK on the gallbladder muscle strips, and the contractions of the muscle strips with ICC removed in the guinea pig. This is the first study in which the CCK-induced gallbladder contraction through CCK-AR on the gallbladder ICC was investigated using the guinea pig as the experimental animal.

## MATERIALS AND METHODS

### Animals

Adult guinea-pigs (250-300 g) were obtained by mail from Animal Experiment Center of Wuhan University. The animal-testing protocol used in the present investigation was approved by the Institutional Animal Care and the Use Committee of the Wuhan University.

### Chemicals

All the chemicals and bovine serum albumin were obtained from Sigma. The rat monoclonal antibodies against C-kit were purchased from R&D. The Rabbit anti-CCK-AR polyclonal antibody was purchased from Chemicon. M199 were purchased from Sigma. All the secondary antibodies were bought from Beijing Zhongshan Biotechnology CO., LTD.

### Experimental procedures

**Demonstration of CCK-AR on the gallbladder tissue by immunohistofluorescence:** The gallbladder was fixed with 4% paraformaldehyde at 4°C for 16 h. Following fixation, the tissues were embedded and cut for immunohistochemistry. Next, they were washed and incubated with normal bovine serum albumin for 10 min. They were subsequently incubated with rat anti-kit monoclonal antibody, with rabbit anti-CCK-AR polyclonal antibody added to the anti-kit solution at 4°C for 24 h. The sections were incubated with the secondary antibody after the first antibody. CCK-AR polyclonal antibody was visualized using the goat anti-rabbit IgG conjugated to Cy3 and the C-kit was visualized using the rabbit anti-rat antibody conjugated to FITC for 2 h at room temperature. A negative control without primary antibody was performed.

**Demonstration of CCK-AR on the gallbladder ICCs by immunohistofluorescence:** The surrounding tissue of guinea pig's gallbladder was cleaned off and cut longitudinally. The tissue was pinned to the base of a dish filled with Sylgard elastomer with the mucosal side facing up. The mucosa was removed by sharp dissection, and the muscular layer tissues were cut out and incubated at 37°C for 23 min in a  $\text{Ca}^{2+}$ -free physiological saline solution (PSS mmol/L: NaCl 135.0, KCl 5.0, glucose 10.0, Hepes 10.0, and  $\text{MgCl}_2$  1.2; pH set to 7.4 with NaOH) containing type II collagenase (1.2 mg/mL), soybean trypsin inhibitor (2.0 mg/mL) and bovine serum albumin (BSA; 2.0 mg/mL). The pieces of tissue were then rinsed five times with  $\text{Ca}^{2+}$ -free PSS and gently triturated with a wide-bore glass pipette to yield the isolated cells. Aliquots of the suspension of the cells were then placed in glass coverslips, and they were left at 4°C for 45-60 min to attach onto the bottom of coverslips for culturing. Cells were washed

four times with Krebs-Ringer buffer (KRB mmol/L: NaCl 118.5, KCl 4.5,  $\text{MgCl}_2$  1.2,  $\text{NaHCO}_3$  23.8,  $\text{KH}_2\text{PO}_4$  1.2, dextrose 11.0 and  $\text{CaCl}_2$  2.4; pH at 7.4) containing penicillin (200 U/mL), streptomycin (200 mg/mL) and amphotericin B (0.5 mg/mL), and they were placed in M199 medium (Sigma) containing similar concentrations of antibiotics and antimycotic. The cells were incubated at 37°C (90% humidity and 95%  $\text{O}_2$ -5%  $\text{CO}_2$ ) for 1 d. Cells were fixed with 4% paraformaldehyde at 4°C for 16 h, and then it was washed and incubated with normal bovine serum albumin for 10 min. Tissues were processed with protocol identical to the cells. The cells and tissues were examined under the TCS SP2 MP laser scanning confocal microscope (Leica, Germany). With an excitation beam (488 nm) produced by argon, the emitted fluorescence was captured using Leica Confocal software running on Windows XP work station.

**Contractile response of the gallbladder muscle strip to CCK-8:** (1) CCK-Induced Contractions on Common Muscle Strips. The adult guinea-pigs sent in were killed by cervical dislocation. The gallbladder was removed and opened, and it was washed several times in Krebs solution to remove bile. Four strips of each gallbladder measuring approximately 0.2 cm  $\times$  0.8 cm were mounted in organ baths containing Krebs solution (30 mL) with the following composition (mmol/L): NaCl 120.35, KCl 5.9,  $\text{MgCl}_2$  2.5,  $\text{NaH}_2\text{PO}_4$  1.2,  $\text{NaHCO}_3$  15.5,  $\text{CaCl}_2$  2.5, and glucose 11.5; pH 7.4. The organ bath was maintained at 37°C and gassed with 95%  $\text{O}_2$  and 5%  $\text{CO}_2$ . A resting 1 g pre-load was applied to each muscle strip and was allowed to equilibrate for 1 h, and during which time the Krebs solution was changed every 20 min. During the equilibration period, the tension was adjusted to 1 g when required. Mechanical activity was recorded using isometric transducers (World Precision Instruments, Stevenage, Herts, U.K.). Tension was continuously monitored and recorded using a MacLab data acquisition system (AD Instruments Ltd., Hastings, U.K.). A dose-response curve for CCK-8 was constructed by adding CCK-8 to the medium in a cumulative way, and the effect of pretreatment with  $10^{-6}$  mol/L atropine,  $3 \times 10^{-7}$  mol/L tetrodotoxin (ITX) on CCK-8 induced gallbladder contraction was also examined. (2) CCK-Induced Contractions on Muscle Strips with ICCs Removed. Methylene blue staining is a nonspecific but effective and time-dependent staining method for ICCs. After the removal of the mucosa, muscle strips were washed with fresh oxygenated Krebs solution (in mmol/L: NaCl 120.35, KCl 5.9,  $\text{MgCl}_2$  2.5,  $\text{NaH}_2\text{PO}_4$  1.2,  $\text{NaHCO}_3$  15.5,  $\text{CaCl}_2$  2.5, and glucose 11.5; pH at 7.4) and then incubated in Krebs solution containing 50  $\mu\text{mol/L}$  methylene blue at 37°C bubbled with 95%  $\text{O}_2$ -5%  $\text{CO}_2$  (v/v) for 40 min in the dark with intermittent visual checking of the staining intensity. After staining, the muscle strips were immediately put under the light (50 mW/cm<sup>2</sup>) for 5 min. Next, CCK-induced contractions on muscle strips with ICCs removed were done as mentioned above for the common muscle strips. Results were expressed as mean  $\pm$  SE. (3) Transmission Electron Microscopy. We used transmission electron microscopy to identify the effect of methylene blue

**Figure 1** Overview of CCKAR-immunoreactive ICC seen on cross section of guinea pig gallbladder. **A:** Low-magnification montage showing C-kit positive cells (arrow) distributed over a band of gallbladder muscle adjacent to the mucosa; **B:** Low-power montage showing CCKAR-immunoreactive cells distribute mainly in the muscular layers of guinea pig gallbladder; **C:** Compound micrographs from (A) and (B). Some, but not all C-kit immunoreactive (green) ICC colocalize CCKAR (red), meanwhile, not all CCKAR-immunoreactive cells are ICC; **D:** Phase-contrast micrographs of the same gallbladders wall at the same magnification.

with light on gallbladder ICC. The muscle strips removed ICC were fixed in 2.5% GA in 0.1 mol/L (PB) for 2 h or overnight. They were then washed in 0.1 mol/L PB ( $2 \times 15$  min) and post-fixed with 2% osmium tetroxide in 0.1 mol/L PB (2 h). After another wash with 0.1 mol/L PB ( $2 \times 15$  min), they were dehydrated through ascending grades of ethanol (50, 75, 95 and  $2 \times 100\%$ , 15-20 min each) and embedded in an epoxy resin, Quetol-812. Ultra-thin sections were cut using a Reichert OMU4 ultramicrotome with a diamond-cutting knife. Sections were picked up on 200 mesh copper grids and stained with 2% uranyl acetate in 30% ethanol, and this was followed by Sato's lead staining. Grids with sections were viewed under the OPTON EM10C transmission electron microscope.

## RESULTS

### *Demonstration of CCK-AR on the gallbladder*

**Tissue sections immunohistochemistry:** In cross sections of the gallbladder, intensely CCK-AR immunoreactive interstitial cells were found mainly in the muscular layers. Labeling in the most intensely stained cells was already optimal at an antibody concentration of 1:8000. At low antibody concentrations, there were very little staining found on smooth muscle cells of the gallbladder muscle, yet, at higher concentrations, the gallbladder muscle showed considerable immunoreactivity, particularly in its inner portions (Figure 1).

**Cultured cells immunohistochemistry:** CCK-AR

**Figure 2** Colocalization of CCKAR immunoreactivity with markers for ICC, kit in guinea pig gallbladder cultured ICC. CCK-AR immunoreactive ICC in the muscle of the gallbladder is distinctive of their labeled processes. ICC possessed several processes (A-D); C-kit immunoreactive (green) ICC colocalize CCKAR (red); **C:** Compound micrographs from (A) and (B); **D:** Phase-contrast micrographs of the same gallbladder ICC at the same magnification; Often two or more labeled ICC were aggregated into a network (E-H), making it difficult to discern the individual cells; C-kit immunoreactive (green) ICCs colocalize CCKAR (red); **G:** Compound micrographs from (E) and (F); **H:** Phase-contrast micrographs of the same gallbladder ICCs at the same magnification; All these ICCs were big and had a large and angular nucleus; Bar (in D) 30  $\mu$ m for (A-D) and (in H) 30  $\mu$ m for (E-H).

immunoreactive ICC in the muscle of the gallbladder differed in the complexity and shape of their labeling processes (Figure 2). In one extreme end, the processes showed multiplicity and the results were frequently subdivided into fine filaments and peaks (Figure 2A-D). In another end, ICCs possessed only three smooth processes and two labeled ICC were aggregated into the network (Figure 2E-H).

### *CCK-8-induced contractions on gallbladder muscle strips*

The contractile responses of muscle strip to CCK-8 was observed at  $10^{-10}$  mol/L, and they reached the maximum at  $10^{-6}$  mol/L as shown in Figures 3 and 4. CCK-8 stimulated tonic contraction in a concentration-dependent manner. The dose response curve for CCK-8 was not affected

**Figure 3** Effect of atropine and TTX on CCK-8 induced contraction of gallbladder muscle strips. The addition of atropine ( $10^{-6}$  mol/L) or TTX ( $3 \times 10^{-7}$  mol/L) to the medium had no effect on the control dose-response curve for CCK-8. Each value is the mean  $\pm$  SE obtained in 5 observations and observed at  $10^{-10}$ ,  $10^{-9}$ ,  $10^{-8}$ ,  $10^{-7}$ ,  $10^{-6}$  mol/L. Series 1: CCK-8+TTX; Series 2: CCK-8+atropine; Series 3: CCK-8 alone.

**Figure 4** Effects of CCK-8 on contraction of gallbladder muscle strips *in vitro*. Removing the ICC of the gallbladder significantly shifted the control dose-response curve to the right. Each value is the mean  $\pm$  SE obtained in 5 observations and observed at  $10^{-10}$ ,  $10^{-9}$ ,  $10^{-8}$ ,  $10^{-7}$ ,  $10^{-6}$  mol/L. Series 1: Common gallbladder muscle strip; Series 2: Gallbladder muscle strip removed ICC.

by pretreatment of the muscle strips with atropine ( $10^{-6}$  mol/L) or TTX ( $3 \times 10^{-7}$  mol/L) (Figure 3). The purpose of using atropine and TTX is to eliminate the effect of nervous system on the contractions of the guinea pig gallbladder. When we removed the ICCs from the gallbladder muscle strip, it significantly shifted the dose response curve to the right (Figure 4).

### Transmission electron microscopy

Methylene blue with light destroyed the structure of the gallbladder ICCs. The ICCs were swollen, and they showed low contrast for the cytoplasm. Cells became smaller and processes diminished. All these changes result in the reduction of contractile function of the gallbladder (Figure 5).

## DISCUSSION

In this study, we demonstrated that: (1) CCK-AR are present on the gallbladder interstitial cells of Cajal; (2) The gallbladder contractions evoked by CCK-8 through the CCK-AR on the gallbladder ICC. This is the first report on on ICC of guinea pig *in vitro* studies on the mechanism of gallbladder contraction evoked by CCK-8 through CCK-AR.

**Figure 5** The effect of methylene blue with light on gallbladder ICC. After incubation with methylene and light, ICC on gallbladder was swollen and had low cytoplasmic, and the nucleolus became smaller and processes diminished.

The study has clearly shown that CCK-AR are present on gallbladder ICCs by *in vitro* study with immunohistochemistry, immunocytochemistry and muscle strip trials. The CCK receptors on the gallbladder have been demonstrated previously by autoradiography in the guinea pig. In this study, we have clearly shown that CCK-AR exists in the gallbladder smooth muscle layer in the guinea pig, and to the best of our knowledge, the CCK-AR has not yet been demonstrated by any other studies. When we initially used high primary antibody concentrations, the entire gallbladder exhibited immunoreactivity. With lower antibody concentration of 1:8000, there were little immunoreactivity associated with the smooth muscle, but intense staining of ICC in the gallbladder sections. CCK may bind to CCK-ARs on both smooth muscle and ICC.

We demonstrate here that a population of guinea pig gallbladder ICC strongly expresses CCK-AR immunoreactivity. Identification of ICC was based on their typical morphological traits such as clusters of mitochondria, well-developed smooth endoplasmic reticulum, dense body, lysosomes, distinctive caveolae and abundant fibers around the lysosomes. In addition, co-localization of C-kit double labeling with CCK-AR showed that only a subpopulation was localized mainly to a contiguous band of circular muscle of the guinea pig.

In the gallbladder, ICCs intimately contact with smooth muscle cells with gap junction, and they are responsible for the generation of smooth muscle rhythmic activity<sup>[18]</sup>. The finding that gallbladder ICCs strongly express CCK-AR suggests a CCK-induced gallbladder activity. ICCs may mediate some of the effect of CCK on gallbladder pressure. It was previously shown that the gallbladder muscle strip contractions evoked by CCK are mediated by a direct myogenic action<sup>[27,28]</sup> and inhibited by a specific CCK-AR antagonist in some species<sup>[29]</sup>. The next question is how CCK action is mediated to the gallbladder through the CCK-AR on the ICC. When we removed the ICCs in the gallbladder, the CCK-8 induced contraction dose response curve shifted significantly to the right. Liu<sup>[30]</sup> showed that intense illumination after incubation with methylene blue resulted in specific lesions of dogs' ICCs, and it was verified by electron microscopy. The ICCs were swollen and had low cytoplasmic contrast. They had barely discernible mitochondria with few caveolae, and the plasma membranes was punctuated so that they were presumably ruptured. All changes in ICCs result in the abolishing of the slow wave. The effects of methylene

blue with light in ICC were specific only to ICCs, but not the associated smooth muscle cells. In our study, the contractile ability of the guinea pig gallbladder muscle strips without the evocation of CCK-8 was sharply weakened. This phenomenon implied that CCK-8 evoked the contraction of the gallbladder through the gallbladder ICC.

Immunohistofluorescence and muscle strip trials proved that CCK acted not only on the CCK-AR on the smooth muscle, but also on the CCK-AR on the gallbladder ICC. This may be the first indication that ICC do not only generate slow-wave pacemaker activity and mediate effect of enteric neurotransmitters, but also mediate the effects of circulating hormones on smooth muscle activity.

In conclusion, we have shown that the CCK-evoked contractions are mediated through direct action on CCK-AR on the gallbladder ICC.

## COMMENTS

### Background

It has been convinced that the interstitial cells of Cajal (ICC) in rat gastric pylorus expresses CCK-ARs to a high degree. The fact that some ICC in the rat pylorus expresses CCK-ARs suggests the possibility that circulating CCK can influence gastrointestinal motility via ICC. It is well known that CCK regulates the guinea pig gallbladder contraction by CCK-AR. The ICC were also found in the murine, human and guinea pig gallbladder. It deserved us to study that if there are CCK-ARs on the guinea pig gallbladder ICC and how CCK regulates gallbladder contraction through CCK-AR on ICC.

### Research frontiers

ICC does not only generate slow-wave pacemaker activity and mediate effects of enteric neurotransmitters, but also mediate effects of circulating hormones such as CCK on smooth muscle activity.

### Innovations and breakthroughs

In the present study, it was demonstrated that: (1) CCK-AR is present on the gallbladder interstitial cells of Cajal; (2) The gallbladder contractions evoked by CCK-8 through the CCK-AR on the gallbladder ICC. This is the first report on guinea pig *in vitro* studies on the mechanism of gallbladder contraction evoked by CCK-8 through CCK-AR on ICC.

### Applications

It has been shown that CCK evoked contraction is mediated through direct action on CCK-AR on the gallbladder ICC. This maybe some use of study in gallbladder motility disorders, such as cholelithiasis.

### Peer review

This manuscript demonstrates CCK-AR receptor immunoreactivity in the gallbladder of the guinea pig. Furthermore, the authors demonstrate that administration of CCK8 to gallbladder muscle strips caused muscle contraction. This study is of important clinical significance and should be of interest to the readers.

### Abstract

**AIM:** To determine the role of leptin system in non-alcoholic fatty liver disease (NAFLD) development by delineating the changes in serum levels of leptin and soluble leptin receptor (sOB-R).

**METHODS:** Blood samples were collected from 30 consecutive patients with liver-biopsy-proven NAFLD and 30 patients with cholecystolithiasis (stationary phase) as controls. Serum leptin levels were determined by radio-immunoassay and concentration of sOB-R was measured by ELISA. Body mass index (BMI) was calculated for all subjects, and serum insulin, C-peptide, and lipoprotein levels were also detected.

**RESULTS:** Mean serum leptin level and BMI in the NAFLD group were significantly higher than in the controls (both  $P < 0.001$ ), but mean sOB-R level was lower in the NAFLD group when compared to the controls. Both men and women in the NAFLD group had higher mean serum leptin levels and lower sOB-R levels than did the men and women in the control group (all  $P < 0.001$ ). There was a significant negative correlation between serum leptin and sOB-R levels ( $r = -0.725$ ,  $P < 0.001$ ). Multivariate analysis showed that the percentage of hepatocyte steatosis, sex, BMI, and homeostasis model assessment of insulin resistance (HOMA IR) were independently related to serum leptin levels.

**CONCLUSION:** Elevated serum leptin seems to be a

### INTRODUCTION

Leptin - the ob gene product - is a circulating 16-kDa peptide hormone secreted mainly by adipocytes of white fat tissue. It regulates food intake, body fat, insulin action, thermogenesis, induction of angiogenesis, and modulation of the immune system. Leptin synthesis in adipocytes is regulated by several hormones<sup>[1]</sup>. Leptin action in peripheral tissues involves interaction with specific transmembrane receptors. The leptin receptor (Ob-R), which is a member of the class-1 cytokine receptor family, may be an important determinant of leptin sensitivity. Ob-R was originally demonstrated in hypothalamic neurons, through which leptin regulates food intake and body weight<sup>[2]</sup>. Alongside several membrane-bound isoforms of Ob-R, with varying cytoplasmic length and with the same extracellular domain, a soluble form of the leptin receptor (sOb-R) can be demonstrated. sOb-R represents the main leptin-binding compound in plasma, which results in fractions of bound and free leptin in plasma<sup>[3]</sup>. The balance between the free form, the rapidly bioavailable compartment, and bound leptin regulates leptin bioavailability<sup>[4]</sup>. However, the precise pathophysiological role of sOb-R has not yet been defined.

Non-alcoholic fatty liver disease (NAFLD) is increasingly recognized as a common and potentially severe condition often associated with obesity, type 2 diabetes and

hyperlipidemia<sup>[5]</sup>. However, the pathogenesis of NAFLD remains unclear. Increased synthesis of fatty acids in the liver, increased delivery of free fatty acids to the liver, and decreased  $\beta$ -oxidation of free fatty acids may cause the accumulation of fat in the liver<sup>[6]</sup>. Therefore, fat in hepatocytes causes cellular dysfunction and may render the liver more vulnerable to any factor that leads to inflammation. Furthermore, hepatic steatosis, the hallmark of NAFLD<sup>[7]</sup>, may damage liver parenchyma.

The close relationship of leptin with adipose tissue and fat stores of the body suggests its involvement in the etiology and pathogenesis of NAFLD. Chitturi *et al.*<sup>[8]</sup> have shown that serum leptin levels are significantly higher in subjects with non-alcoholic steatohepatitis (NASH), when compared to controls. Furthermore, they have shown that serum leptin is independently associated with the degree of hepatic steatosis but not hepatic inflammation or fibrosis. In addition to this study, there have been three other published studies that have yielded conflicting results regarding the role of leptin in the pathogenesis of NASH<sup>[9-11]</sup>. Thus, the role of leptin in NAFLD is not yet clear. Also, the relationship between sOB-R and NAFLD is an unresolved issue. Since concentrations of sOB-R are decreased in obese subjects when compared with lean controls<sup>[12]</sup>, an interaction between sOB-R and NAFLD is suspected. However, currently no data on the association of sOB-R with NAFLD disease are available. Therefore, the objective of this study was to evaluate the association between serum leptin and sOB-R levels and NAFLD.

## MATERIALS AND METHODS

### Patients

A total of 30 consecutive patients with liver-biopsy-proven NAFLD were enrolled in the study from May 2007 to September 2007. NAFLD patients were admitted or referred to our department with incidentally found liver enzyme elevations. For the diagnosis of NAFLD and to rule out other possible liver diseases, all patients underwent liver biopsy. Thirty patients with cholecystolithiasis (stationary phase) were recruited as controls. Liver biopsies were obtained during an examination that preceded laparoscopic cholecystectomy, using a 16-gauge bard core biopsy needle. Informed consent was obtained from all patients.

All subjects underwent a detailed clinical and laboratory evaluation, including liver function tests, hepatitis markers, and autoantibodies, in addition to upper abdominal ultrasonography. Alcohol consumption was absent in all subjects. Subjects with previous or current history of acute or chronic viral hepatitis; malignant disease; acute infections; pituitary, adrenal, thyroid and pancreatic disease, or evidence for any other endocrine disorder; or prolonged use of corticosteroids or sex hormones were excluded. The controls had normal liver enzymes and no clinical, laboratory or imaging evidence of liver disease.

### Clinic and laboratory evaluation

Overnight (12 h) fasting samples of serum obtained after centrifugation were stored in aliquots at -70°C until assayed. Clinical and laboratory data were collected on the

date the liver biopsy was performed. A complete medical history and physical examination was accomplished in all patients and controls. Body mass index (BMI) was calculated. Laboratory evaluation included liver enzymes, glucose, complete blood count, total cholesterol, triglycerides, viral serology for hepatitis B and C, and autoantibodies. C-peptide was measured by a direct, double antibody sequential radioimmunoassay (RIA) (North Bio, Beijing, China). Serum insulin was measured by enzyme immunoassay kits (North Bio). The insulin resistance (IR) index was calculated on the basis of fasting values of plasma glucose and insulin according to the homeostasis model assessment for insulin sensitivity (HOMA) model formula:  $\text{HOMA IR} = \text{fasting insulin (mUI/L)} \times \text{fasting glucose (mmol/L)} / 22.5$ .

Leptin levels were measured by RIA kits (North Bio). The test utilizes <sup>125</sup>I-labelled human leptin and human leptin antiserum to determine the level of total (free of and bound to serum proteins) leptin in serum. The test was 100% specific for human leptin and the sensitivity was 0.45 ng/mL. The coefficient of variation (CV) was < 8.3% and < 6.2%, respectively, for intra- and inter-assay variations ( $n = 5$ ). The total concentration of sOB-R was determined using photometric ELISA kits (BioVendor Laboratory Medicine Inc, Brno, Czech Republic), which utilizes double monoclonal antihuman leptin receptor antibodies labeled with horseradish peroxidase. This test was 100% specific for human leptin receptors and the sensitivity was 0.4 U/mL. The intra-assay (CV < 5.6%) and inter-assay precision was good (CV < 5.5%). Samples were diluted three times according to the manufacturer's recommendation, and results higher than the higher standard were run again at another dilution.

### Liver histology

Liver biopsy specimens were at least 15 mm in length, and had an appropriate number of portal tracts to make a confident evaluation of histological features and diagnosis<sup>[13]</sup>. Slides were routinely stained with hematoxylin-eosin, Masson's trichrome and special stains for iron and copper. Liver biopsies were read by a single liver pathologist who was unaware of the patients' clinical and laboratory data. Degree of steatosis was assessed on a scale of 1-3: 1, mild (5%-33% of hepatocytes affected); 2, moderate (33%-66% of hepatocytes affected); and 3, severe (> 66% of hepatocytes affected). The grades of inflammation and stages of fibrosis were modified to two categories as follows: mild inflammation (Kleiner grades 0 and 1) and moderate-to-severe inflammation (Kleiner grades 2 and 3), mild fibrosis (stages 0-2), and advanced fibrosis (stages 3 and 4). NASH was defined as steatosis plus lobular inflammation, plus either ballooning of hepatocytes or abnormal fibrosis (stages 1-4).

### Statistical analysis

Hepatic steatosis was assessed as categorical (absent or present) or a continuous variable from 0%-100%. Comparisons between the NAFLD group and controls were made using Student's *t* test for continuous variables and the  $\chi^2$  or Fisher's exact probability test for categorical data. All values are presented as mean  $\pm$  SD.  $P < 0.05$  was

**Table 1** Clinical and laboratory data of patients with NAFLD and controls

	NAFLD	Control	P
n	30	30	
Gender (F/M)	15/15	16/14	0.8
Age	41.97 ± 8.36	43.90 ± 8.35	0.374
BMI (kg/m <sup>2</sup> )	26.47 ± 3.11	23.97 ± 1.88	< 0.001
Total cholesterol (mmol/L)	4.11 ± 0.85	3.97 ± 0.63	0.446

Leptin (ng/mL)	10.90 ± 3.39	5.55 ± 1.96	< 0.001
sOB-R (ng/mL)	18.00 ± 3.74	23.51 ± 2.62	< 0.001

considered to be statistically significant. Multiple linear regression has been used in multivariate analysis of factors associated with leptin levels, including age, sex, steatosis, BMI, sOB-R, C-peptide and IR.

## RESULTS

### Comparison of patients and controls

Clinical and biochemical characteristics of the patients with NAFLD and controls are compared in Table 1. Serum leptin levels were found to be significantly higher in patients with NAFLD as compared with the controls ( $P < 0.001$ ), and subjects with NAFLD had significantly lower levels of sOB-R, and higher levels of insulin and HOMA than the controls. There was no significant difference in serum total cholesterol, triglyceride, C-peptide or glucose levels in patients with NAFLD when compared with the controls.

### Gender difference in serum leptin and sOB-R levels

As expected, serum leptin levels were significantly higher in women than in men in the NAFLD group ( $P = 0.002$ ). In contrast, sOB-R levels were significantly lower in women compared with men in the NAFLD group ( $P = 0.018$ ). For this reason, comparisons were made between men and women separately. Both men and women in the NAFLD group had higher mean serum leptin levels and lower sOB-R levels than did the men and women in the control group (all  $P < 0.001$ , Table 2).

### Histological Evaluation

Upon histological staging, steatosis was mild in 17 patients, moderate to severe in 13; inflammation was mild in 16, and moderate to severe in 14; and fibrosis was absent in nine, mild in 21, and advanced in one patient. As summarized in Table 3, patients with moderate to severe steatosis had significantly higher levels of leptin than those with mild steatosis. Similarly, patients with moderate to severe steatosis were more insulin resistant as indicated by higher values of HOMA-IR. sOB-R levels were higher in the mild steatosis group than in the moderate to severe steatosis group, but the difference was not significant ( $P = 0.098$ ).

**Figure 1** Correlation between serum leptin and sOB-R.

### Correlation between serum leptin and sOB-R

There was a significant negative correlation between serum leptin and sOB-R levels ( $r = -0.725$ ,  $P < 0.001$ ; Figure 1).

### Relationship of serum leptin and sOB-R levels with BMI

The proportion of obese patients was rather low in the study population. Therefore, to determine the relationship between obesity and leptin more clearly, the NAFLD patients were divided into two groups according to mean BMI (26.5) as a cut-off point. Thus, patients with a BMI of 26.5 were defined as overweight. There were 12 patients with a BMI  $\geq 26.5$ , and there were 18 patients with a BMI  $< 26.5$ . The serum leptin levels and HOMA IR values were significantly higher in the overweight group than in the normal weight group ( $P < 0.001$  and  $P = 0.01$ , respectively). In addition, the sOB-R levels were significantly lower in the overweight group than in the normal weight group ( $P < 0.001$ , Table 4). Age, sex, BMI, HOMA IR, C-peptide and steatosis were tested in an overall multiple linear regression model, and the percentage of hepatocyte steatosis, sex, and BMI were independently related to serum leptin levels (Table 5).

## DISCUSSION

The findings of the present study show that the adipocyte-derived hormone leptin is involved in metabolic abnormalities that lead to steatosis in NAFLD patients. Significantly high levels of serum leptin in NAFLD patients were found. In contrast to increased leptin level, the concentration of sOB-R significantly decreased in patients with NAFLD as compared to controls. As expected, the serum leptin level was significantly higher in women. Such a gender difference in serum leptin levels has been reported previously<sup>[14]</sup>. Leptin is exclusively expressed in adipose tissue and secreted from white adipose cells<sup>[15]</sup>. The difference is,

Table 2 Leptin and sOB-R results according to gender

HOMA IR	2.98 ± 0.86	4.20 ± 0.83	0.001

Table 4 The results of BMI, leptin and sOB-R tests in NASH patients with normal weight and overweight

	Overweight (BMI ≥ 26.5)	Normal weight (BMI < 26.5)	P
n	12	18	
Female/Male	8/4	9/9	0.5
Leptin (ng/mL)	13.73 ± 2.96	9.02 ± 2.14	< 0.001
sOB-R (ng/mL)	15.16 ± 2.10	19.89 ± 3.40	< 0.001
HOMA IR	4.06 ± 1.06	3.14 ± 0.86	0.01

therefore, in part, due to the higher percentage body fat in women. In addition, our study showed that serum leptin levels were strongly correlated with BMI or fat mass, consistent with a number of previous studies<sup>[16-18]</sup>. Also, the above results suggest a significant difference between normal and overweight NAFLD patients with regard to serum leptin levels.

The antisteatotic effects of leptin, which can curtail intrahepatic lipid accumulation (lipotoxicity), have been demonstrated in rodents. Thus, we considered whether leptin could play a similar role in NAFLD. Steatosis is a feature of clinical states characterized by defective leptin signaling. Steatosis is therefore often present in obese individuals<sup>[19]</sup> who are generally leptin resistant, and also in patients with congenital generalized lipodystrophy, a syndrome of leptin deficiency<sup>[20]</sup>. One of the important results of the study was that higher serum leptin levels were detected in patients with moderate to severe steatosis, compared with mild steatosis. The finding was inconsistent with a simple antisteatotic effect of leptin, which assumes that serum leptin values correlate with leptin biological activity in hepatocytes. There are two most likely explanations for the above finding. Firstly, leptin is inextricably related to IR. It has been suggested that leptin may contribute to hepatic steatosis by promoting IR and by altering insulin signaling in hepatocytes, so as to promote increased intracellular

Table 5 Multiple linear regression analysis ( $R^2 = 0.895$ ) with serum leptin levels as a dependent variable in patients with NAFLD

Variable	Coefficient	SE	t	P
Age	-0.040	-0.099	-1.371	0.183
Sex	2.128	0.319	4.295	< 0.001
BMI (kg/m <sup>2</sup> )	0.529	0.485	5.838	< 0.001
C-peptide (nmol/L)	-0.866	-0.075	-1.072	0.295
HOMA IR	0.744	0.227	2.399	0.025
Steatosis (%)	1.329	0.247	2.675	0.014

fatty acids<sup>[21]</sup>. Moreover, at a later stage, leptin may cause hepatic steatosis to turn into steatohepatitis by amplifying selected proinflammatory responses<sup>[21]</sup>. This explanation is mainly based on the effect of insulin on hepatic fat metabolism. In this study, an elevation of serum insulin level and HOMA IR in NAFLD patients, in comparison to the controls, was detected, which supports the latter suggestion. Secondly, those patients who develop NAFLD differ from obese individuals who do not develop NASH by having a state of peripheral (hepatic) leptin resistance (inadequate leptin signaling or/and decreased levels of sOB-R).

The biological relationship between leptin and its soluble receptor has previously been well established in animal models, as well as in various other clinical conditions, such as obesity, puberty<sup>[22]</sup>, pregnancy<sup>[23]</sup> and inflammation<sup>[24]</sup>. However, to the best of our knowledge, the serum level of sOB-R has not previously been described in NAFLD patients. In this study, a strong negative correlation was found between serum levels of leptin and sOB-R in patients with NAFLD.

The low sOB-R levels in NAFLD patients may be part of a feedback mechanism aimed at reducing the increase in leptin. High free leptin levels were observed in morbidly obese subjects, probably caused by high leptin release by adipocytes due to abundant food intake. Interestingly, during food restriction, circulating leptin levels in lean and obese subjects drop dramatically within 1 d after onset of starvation<sup>[25]</sup>, which indicates that leptin release is strongly reduced. On the other hand, plasma sOB-R might function like the soluble IL-6 receptor for the cytokine IL-6 (also a member of the gp-130 receptor family) and enhance leptin signaling. An increase in the bioavailability of leptin in ob/ob mice by overexpression of sOB-R leads to an improved weight-reducing effect of exogenous leptin<sup>[26]</sup>. It has been suggested that decreased serum levels of sOB-R result in adequate leptin signaling in NAFLD. Furthermore, the origin of sOB-R in plasma is also unclear at present. It may originate from alternative splicing of the OB-R or from

full-length functional OB-Rs released by enzymatic cleavage. In line with this, sOB-R levels in plasma may reflect the amount of OB-R expressed by tissues. The finding of decreased serum levels of sOB-R in NAFLD suggests an increased resistance of peripheral tissues to the action of leptin, due to decreased expression and secretion of the OB-R. This might be in agreement with the proposed leptin resistance in morbidly obese subjects<sup>[27-29]</sup>.

In conclusion, this study shows that increased serum concentrations of leptin are involved in NAFLD. Enhanced release of leptin is accompanied by a decrease in sOB-R concentration, which suggests higher resistance of peripheral tissues towards the action of leptin. However, the precise pathophysiological role of leptin and sOB-R has not yet been defined. We suggest that further studies should focus on local expression of leptin and its receptor in tissues of non-adipose origin, since the expression of leptin has been shown to be non-specific for adipocytes.

## COMMENTS

### Background

The exact pathogenesis in non-alcoholic fatty liver disease (NAFLD) is poorly understood, but some studies have analyzed the role of a variety of soluble peptides and other mediators. The close relationship of leptin with adipose tissue and fat stores of the body suggests its possible involvement in the etiology and pathogenesis of NAFLD.

### Research frontiers

There have been several studies on the association between leptin and NAFLD, which have yielded conflicting results regarding the role of leptin in the pathogenesis of NASH. Since concentrations of the sOB-R are decreased in obese subjects when compared with lean controls, interaction between sOB-R and NAFLD is suspected. However, currently no data on the association of sOB-R with NAFLD disease are available.

### Innovations and breakthroughs

The study showed elevated levels of leptin with a corresponding decrease in the concentration of sOB-R in patients with NAFLD. Although the results of laboratory experiments are not readily applicable to the clinical situation, these findings offer further insight into the role of leptin in the pathogenesis of NAFLD.

### Applications

The results from this study confirm higher resistance of liver towards the action of leptin. This encourages us to study promising new drugs for treating NAFLD to improve leptin resistance in future clinical trials.

### Peer review

This study aimed to investigate the role of leptin system in NAFLD development by delineating the changes in serum levels of leptin and sOB-R. The authors found a higher resistance of peripheral tissues towards the action of leptin. This is an interesting subject.

### Abstract

**AIM:** To investigate the effect of herbal compound 861 (Cpd861) on the transforming growth factor- $\beta$ 1 (TGF $\beta$ 1)/activin receptor-like kinase 1 (ALK1, type I receptor) signaling-pathway-related gene expression in the LX-2 cell line, and the inhibitory mechanism of Cpd861 on the activation of LX-2 cells.

**METHODS:** LX-2 cells were treated with TGF $\beta$ 1 (5 ng/mL) Cpd861 (0.1 mg/mL), TGF $\beta$ 1 (5 ng/mL) plus Cpd861 (5 ng/mL) for 24 h to investigate the effect of Cpd861 on the TGF $\beta$ 1/ALK1 pathway. Real-time PCR was performed to examine the expression of  $\alpha$ -SMA ( $\alpha$ -smooth muscle actin), *ALK1*, *Id1* (inhibitor of differentiation 1). Western blotting was carried out to measure the levels of  $\alpha$ -SMA and phosphorylated Smad1, and immunocytochemical analysis for the expression of  $\alpha$ -SMA.

**RESULTS:** In LX-2 cells, TGF $\beta$ 1/ALK1-pathway-related gene expression could be stimulated by TGF $\beta$ 1, which led to excessive activation of the cells. Cpd861 decreased the activation of LX-2 cells by reducing the expression of  $\alpha$ -SMA mRNA and protein expression. This effect was related to inhibition of the above TGF $\beta$ 1/ALK1-pathway-related expression of genes such as *Id1* and *ALK1*, and phosphorylation of Smad1 in LX-2 cells, even with TGF $\beta$ 1 co-treatment for 24 h.

**CONCLUSION:** Cpd861 can restrain the activation of LX-2 cells by inhibiting the TGF $\beta$ 1/ALK1/Smad1 pathway.

### INTRODUCTION

Hepatic fibrosis is a reversible scarring process that is characterized by increased and altered deposition of extracellular matrix in the liver. During the past 20 years, much research has proved that the activation of hepatic stellate cells (HSCs) triggers fibrogenesis<sup>[1-3]</sup> and TGF $\beta$ 1 has a pivotal regulating role in this process<sup>[1,4,5]</sup>. Currently, TGF $\beta$ 1/ALK1/Smad1 signaling is found in HSCs and is involved in their activation<sup>[6-8]</sup>.

Herbal compound 861 (Cpd861) is a traditional Chinese medicines that is used to treat liver diseases and has been demonstrated to have anti-fibrotic effects and to reverse cirrhosis, especially in the early stage<sup>[9-11]</sup>. Cpd861 is an extract of 10 herbs. A randomized, double-blinded, placebo-controlled clinical trial has demonstrated that Cpd861 can significantly delay and reverse the process of clinical hepatic fibrosis in patients with liver fibrosis and early cirrhosis due to HBV infection, as diagnosed with liver biopsy performed before and after treatment<sup>[11,12]</sup>.

Our previous studies have shown that Cpd861 can inhibit the activation of HSCs to exert its anti-fibrotic effect<sup>[13]</sup>. In this study, we selected the TGF $\beta$ 1/ALK1/Smad1 signaling pathway in an attempt to elucidate the molecular mechanism of Cpd861 in the deactivation of LX-2 cells. The effect of Cpd861 on the expression of

genes in this pathway, such as *ALK1*, *Id1* and the protein level of phosphorylated Smad1 was investigated.

## MATERIALS AND METHODS

### Materials

LX-2 cells were a gift from Dr. Friedman of Mount Sinai School of Medicine, New York, USA. They are activated human HSCs that are generated by spontaneous immortalization in low-serum conditions<sup>[14]</sup>. Cpd861 powder (*Radix Salviae Miltiorrhiae*, *Radix Astragali*, *Suberect Spatholobus*, *Flos Carthami*, *Rhizoma Chuanxiong*, *Radix Paeoniae Rubra*, *Rhizoma Cyperi*, *Pericarpium Citri Reticulatae*, *Radix Angelicae Sinensis*, *Radix bupleuri*, patent No. 99103265.9) was from Jiangyin Pharmaceutical Company, Jiangsu Province, China. Powder (2500 mg) was dissolved in 100 mL PBS, and the final concentration was 0.1 mg/mL in LX-2 cell-culture medium. After centrifugation at 3000 r/min for 10 min, the solution was sterilized at 105°C for 20 min. Dulbecco's modified Eagle's medium (DMEM), L-glutamine, streptomycin and fetal bovine serum (FBS) were purchased from Gibco, NY, USA. Penicillin was from Sigma, St. Louis, USA. Oligo (dT) primers, M-MLV (Moloney murine leukemia virus) reverse transcriptase, recombinant RNasin ribonuclease inhibitor and dNTP were acquired from Promega (Madison, WI, USA). TRIzol reagent was from Invitrogen, Carlsbad, CA, USA. Power SYBR Green PCR Master Mix was purchased from Applied Biosystems, Warrington, UK. The CO<sub>2</sub> incubator was from SANYO, Sakata, Japan. Cell culture wells (6 cm<sup>2</sup>) were from Corning Incorporation, NY, USA. Phospho-Smad1 antibody (60 kDa) was from Cell Signaling Company, Danvers, MA, USA. Mouse anti-human α-SMA (42 kDa) was from Zhongshan Goldenbridge Biotechnology, Beijing, China.

### Cell culture and group design

LX-2 cells were cultivated in DMEM supplemented with 50 mL/L FBS, 200 mmol/L L-glutamine, penicillin G (100 U/mL) and streptomycin (100 U/mL) in a humidified incubator at (37°C, 5% CO<sub>2</sub>). Cells were cultivated in 25 cm<sup>2</sup> culture flasks to 70% confluence or on glass coverslips in six-well culture dishes to 50% confluence. After serum starvation for 16 h, LX-2 cells were treated with Cpd861 0.1 mg/mL<sup>[13]</sup>, TGFβ1 (5 ng/mL)<sup>[13]</sup> and TGFβ1 (5 ng/mL) plus Cpd861 0.1 mg/mL. Untreated cells served as a control group. All four groups were harvested after 24 h treatment to investigate the related gene expression and phosphorylation of Smad1 protein. Cells on glass coverslips in six-well culture dishes were fixed in 4% paraformaldehyde in PBS after 24 h for immunocytochemical analysis. Every group included six samples.

### Immunocytochemistry

Cells were fixed in 4% paraformaldehyde and permeabilized with PBS containing 0.1% Triton X-100 for 15 min. They were incubated with blocking solution (5% Bovine Serum Albumin in PBS) for 30 min. Primary antibodies (mouse anti-human α-SMA, diluted 1:100 in blocking solution) were incubated with the cells overnight.

Table 1 Primers sequence for real time-PCR

Gene	Oligonucleotide primer	Fragment sequence size (bp)
α-SMA (target)		
Sense	CGCATCCTCATCTCCCT	268
Anti-sense	GGCCGTGATCTCCTTCTG

Sense	GGCTCTCCAGAACATCATCC	187
Anti-sense	GCTTACCACCTTCTTGATG	

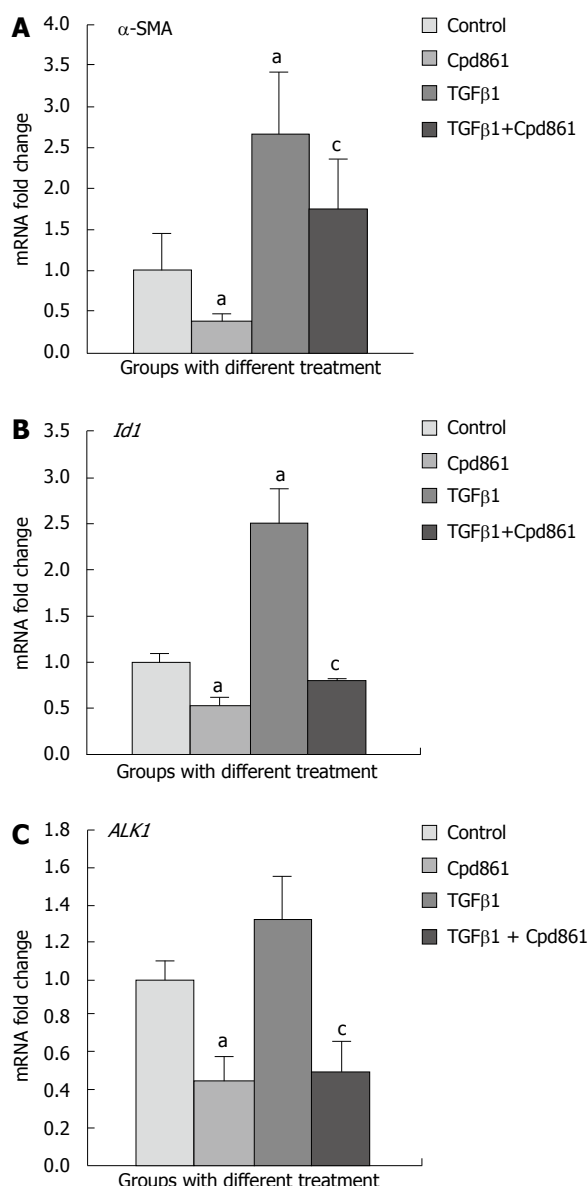

After three washes with PBST (0.2% Tween 20 in PBS) for 15 min, cells were incubated with the secondary antibody (goat anti-mouse IgG labeled with biotin, with streptavidin labeled with horseradish peroxidase), and then with DAB (Diaminobenzidine), Beijing Zhongshan Goldenbridge Co.). PBS (0.01 mol/L) was substituted for primary antibody as a negative control. The α-SMA positive cells presented as brownish yellow. Cells were counterstained with hematoxylin to identify nuclei. Cells were viewed with an Olympus DP71 microscope (Tokyo, Japan) at 20 × magnification.

### RNA isolation and reverse transcription

Total RNA was extracted from LX-2 cells using TRIzol reagent as the lysis buffer. cDNA was synthesized using the Reverse Transcription System (Promega). RNA (1 μg) in 7.7 μL nuclease-free water was added to 2.5 μL 10× transcriptase buffer, 2.5 μL 10 mmol/L dNTP, 0.5 μL RNase inhibitor, and 1 μL M-MLV reverse transcriptase. The reaction was performed for 60 min at 42°C (cDNA synthesis), and 5 min at 95°C (enzyme denaturation).

### Real-time PCR of mRNA

The cDNA samples were analyzed with the Applied Biosystems 7300/7500 real-time PCR system (Applied Biosystems, Foster city, CA, USA) for detecting the gene expression of α-SMA, *ALK1* and *Id1*. Glyceraldehyde-3-phosphate dehydrogenase (GAPDH) was used as the housekeeping gene. The primer sequences were obtained from SaiBaiSheng Biocompany, Beijing, China (Table 1). Each experiment was performed in 20 μL reaction volume. The PCR program consisted of an initial activation step at 50°C for 2 min, followed by 95°C for 10 min, then 40 cycling steps of denaturing for 15 s at 95°C, annealing and extension at 60°C for 1 min (data collected at this stage). The PCR data were analyzed using SDS 2.1 software (Applied Biosystems). mRNA levels were normalized relative to GAPDH values. Fold expression changes and standard errors were calculated using the equation  $2^{-\Delta\Delta C_t}$  (Ct, threshold cycle). Each group had six wells of cells for examining the relative fold change of gene expression. Three replicate reactions per sample and endogenous control were used to ensure statistical significance.

**Figure 1** Effect of different treatment on  $\alpha$ -SMA, *Id1*, *ALK1* expression after 24 h. Cpd861 could decrease the level of all these genes compared with untreated LX-2 cells ( $^aP < 0.05$  vs control LX-2 cell group). Even with TGF $\beta$ 1, Cpd861 could also exert its inhibitory roles in these genes expression ( $^cP < 0.05$  vs TGF $\beta$ 1 treated group). Samples were obtained from 6 wells of cells for examining the relative fold change of  $\alpha$ -SMA (A), *Id1* (B), *ALK1* (C) expression. Three replicate reactions for per sample. Error bars, SD.

### Western blot analysis

Cells were lysed on ice by 80  $\mu$ L lysis buffer for 30 min. The cell lysate was centrifuged at 10000 r/min for 10 min and the supernatant was collected for Western blot analysis. Protein concentration was measured using BCA Protein Assay kit (Pierce Company, Rockford, IL, USA) following the manufacturer's instructions. Protein samples (40  $\mu$ g/lane) were subjected to 10% SDS-PAGE and then transferred onto a PVDF nitrocellulose membrane by electro-blotting. The membrane was incubated in 25 mL blocking buffer for 1 h at room temperature. After blocking, the membrane was incubated in 10 mL blocking buffer containing 1:1000 dilution of rabbit anti-phospho-Smad1 or anti-SMA at 4°C overnight. After gentle washing with blocking buffer, the membrane was incubated in

**Figure 2** The level of  $\alpha$ -SMA protein expression with different treatment after 24 h. Western blot was used as described in Materials and Methods. A: Representative Western blot results of  $\alpha$ -SMA. The positions of protein size markers were given; B: Densitometry of Western blot analyzed by Gel-pro software. The levels of  $\alpha$ -SMA were normalized to the level of  $\beta$ -actin protein. Six independent experiments were performed.  $^aP < 0.05$  vs control LX-2 cell group. Error bars, SD.

rabbit anti- $\beta$ -actin polyclonal antibody (1:200 dilution). After vigorous washing, the membrane was incubated with a 1:5000 dilution of horseradish peroxidase-conjugated anti-rabbit IgG antibody. The intensity of the bands was determined by scanning video densitometry. The levels of phospho-Smad1 and SMA were normalized to the level of  $\beta$ -actin protein. Six independent experiments were performed. The intensity of the bands was determined using Gel-Pro Analyzer Version 3.0 (Media Cybernetics, Silver Spring, MD, USA).

### Statistical analysis

Data were expressed as mean  $\pm$  SD and the statistical significance was assessed by one-way analysis of variance followed by Student-Newman-Keul tests.  $P < 0.05$  was considered to be significant.

## RESULTS

### Effect of TGFβ1 and Cpd861 on $\alpha$ -SMA expression

Changes in gene or protein expression of  $\alpha$ -SMA are often used to study the extent of HSC activation<sup>[16,17]</sup>. In this study, the effect of TGF $\beta$ 1 and Cpd861 on the activation of the LX-2 cell line was investigated by examining changes in gene and protein expression of  $\alpha$ -SMA.

Real-time PCR analysis showed that after exogenous TGF $\beta$ 1 (5 ng/mL) stimulation for 24 h,  $\alpha$ -SMA mRNA expression reached 2.65 fold ( $P < 0.05$ ) compared with that in control LX-2 cells, whereas Cpd861 inhibited the expression to 0.38-fold (24 h,  $P < 0.05$ ) (Figure 1A).  $\alpha$ -SMA mRNA expression in Cpd861 and TGF $\beta$ 1 co-treated cells was 1.73-fold compared to that in the controls.

Western blot analysis confirmed the trend of  $\alpha$ -SMA gene expression changes (Figure 2A and B). In the TGF $\beta$ 1 treatment group,  $\alpha$ -SMA protein expression

**Figure 3** Expression of  $\alpha$ -SMA in different treatment groups. Qualitative expression of  $\alpha$ -SMA in control LX-2 cells (A), treated with TGF $\beta$ 1 (B), Cpd861 (C) and Cpd861 together with TGF $\beta$ 1 (D) for 24 h using immunohistochemical staining.  $\alpha$ -SMA presented brown color in cytoplasm ( $\times 200$ ).

increased significantly compared with that in the controls (photodensity: 0.49 in TGF $\beta$ 1 group and 0.34 in control respectively), whereas its expression was inhibited by Cpd861 (0.19 *vs* 0.49), even in the presence of TGF $\beta$ 1 (0.20 *vs* 0.34) (Figure 2).

Immunocytochemical analysis showed that

$\alpha$ -SMA protein was expressed in the cytoplasm, which was stained brown in low-power fields (Figure 3A). An interesting phenomenon was that after TGF $\beta$ 1 treatment for 24 h, many various-sized, round spaces were present. Cells around the spaces were fusiform in shape, with dark brown cytoplasm. We presumed that it was a result of contraction of adjacent cells, which acquired the contractive property from excessive activation (Figure 3B). Cells treated with Cpd861, however, had a lighter brown cytoplasm (Figure 3C). In the Cpd861 and TGF $\beta$ 1 co-treatment group, the cytoplasm presented lighter brown than in the TGF $\beta$ 1-treated group and no spaces were seen (Figure 3D).

These results confirmed that gene and protein expression and function of  $\alpha$ -SMA in LX-2 cells, markers of activation of LX-2 cells, were enhanced by TGF $\beta$ 1 and inhibited by Cpd861. This is consistent with a previous study, which showed that Cpd861 can inhibit activation of LX-2 cells<sup>[13]</sup>.

#### **Effect of TGF $\beta$ 1 and Cpd861 on TGF $\beta$ 1/ALK1 signaling pathway in LX-2 cell line**

TGF $\beta$ 1/ALK1/Smad1 signaling has been found in HSCs<sup>[18,19]</sup>. In this pathway, ALK1 phosphorylated Smad1 leads to gene expression of *Id1*<sup>[20]</sup>. *Id1* proteins have a helix-loop-helix (HLH) domain but lack ability to bind DNA that acts as an important dominant negative antagonist of the bHLH family of transcription factors<sup>[21,22]</sup>. Recently, the *Id1* gene was identified as a novel target gene that promotes the expression and polymerization of  $\alpha$ -SMA, therefore involving the transdifferentiation of HSCs.

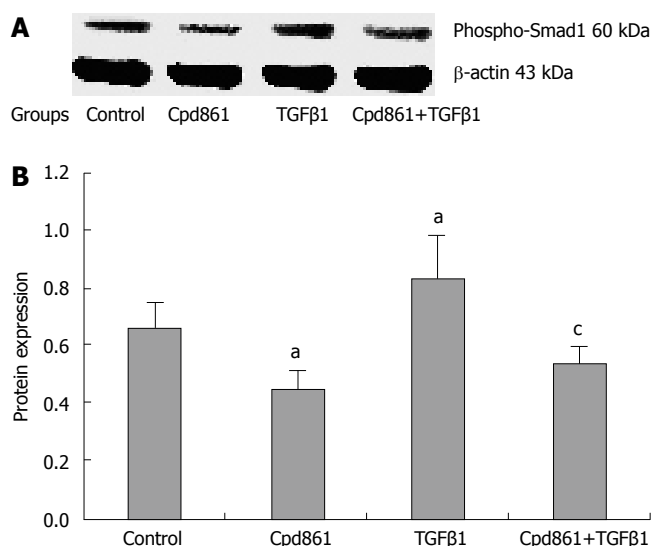

Here, we examined the level of phosphorylated Smad1 (the marker of activation of the pathway) using Western blot analysis. The level of phosphorylated Smad1 increased after TGF $\beta$ 1 treatment and was reduced by Cpd861 or TGF $\beta$ 1 and Cpd861 co-treatment (photodensity was 0.66 in control, 0.45 in Cpd861-treated cells, 0.84 in TGF $\beta$ 1-treated cells, and 0.55 in TGF $\beta$ 1 and Cpd861 co-treated cells, Figure 4).

Stimulation of LX-2 cells with exogenous TGF $\beta$ 1 strongly induced *Id1* gene expression by 2.5-fold, whereas Cpd861 reduced *Id1* expression by 0.53-fold ( $P < 0.05$ ). The fold change of *Id1* expression in Cpd861 and TGF $\beta$ 1 co-treatment was 0.79 compared with that in the controls, but it was significantly lower than that with TGF $\beta$ 1 treatment alone (Figure 1B).

The *ALK1* gene was constitutively expressed in LX-2 cells and TGF $\beta$ 1 did not further increase its expression, but Cpd861 reduced it significantly (Figure 2C). The change in gene expression of the receptor might be an important inhibitory mechanism of Cpd861 in the pathway.

## **DISCUSSION**

Our data indicated that the TGF $\beta$ 1/ALK1/Smad1 pathway could be activated by TGF $\beta$ 1 and abrogated by Cpd861 in LX-2 cells. The TGF $\beta$ 1/ALK1/Smad1 pathway is one of the TGF $\beta$  superfamily signaling branches<sup>[23]</sup>. Several studies have indicated that activation of the

**Figure 4** The level of Phosphorylated Smad1 with different treatment after 24 h. Western blot was used as described. **A:** Representative Western blot results of Phosphorylated Smad1. The positions of protein size markers were given; **B:** Densitometry of Western-blot analyzed by Gel-pro software. The levels of Phospho-Smad1 were normalized to the level of  $\beta$ -actin protein. Six independent experiments were performed.  $^aP < 0.05$  vs untreated LX-2 cell group,  $^cP < 0.05$  vs TGF $\beta$ 1 treated group. Error bars, SD.

pathway might play an important role in development of organ fibrosis<sup>[24-27]</sup>. Recent research has demonstrated that the existence of ALK1 and the TGF $\beta$ 1/ALK1/Smad1 pathway is critical during the transdifferentiation process of primary rat HSCs to myofibroblast (MFB)<sup>[20]</sup>. The present study demonstrated that activation of the TGF $\beta$ 1/ALK1/Smad1 pathway may be enhanced by TGF $\beta$ 1 in LX-2 cells. It was shown that Cpd861 inhibited activation of the TGF $\beta$ 1/ALK1/Smad1 pathway, and this might have been mediated by reducing *ALK1* expression. However, effects of Cpd861 on ALK1 protein expression and on the affinity of TGF $\beta$ 1 for ALK1 need further investigation.

Cpd861 has been demonstrated to be effective for treatment of patients with hepatic fibrosis<sup>[28]</sup>. Previous studies have shown that Cpd861 has multiple anti-fibrotic mechanisms, such as stimulating apoptosis of activated HSCs<sup>[29]</sup>, down-regulating tissue inhibitor of metalloproteinase 1 gene expression<sup>[30]</sup>, reducing expression of collagen and fibrosis-related cytokines. This study presented another possible anti-fibrotic mechanism of Cpd861, and also showed that the TGF $\beta$ 1/ALK1/Smad1 pathway may represent a potential target for antifibrotic therapy. However, which components in the compound play the inhibitory roles needs to be further investigated.

## ACKNOWLEDGMENTS

We thank Dr. Friedman and Mount Sinai, School of Medicine, for their help in providing the LX-2 cell line.

## COMMENTS

### Background

Activation of hepatic stellate cells (HSCs) triggers fibrogenesis and TGF $\beta$ 1/ALK1/

Smad1 signaling has been shown to be involved in the transdifferentiation of HSCs. Herbal compound 861 (Cpd861) can inhibit activation of HSCs to exert its anti-fibrotic effect, but the mechanism is not very clear.

### Research frontiers

The effect of TGF $\beta$ 1/ALK1/Smad1 signaling on the activation of HSCs has recently been reported. This study chose the pathway as a means to establishing the molecular mechanism of Cpd861 in the deactivation of LX-2 cells.

### Innovations and breakthroughs

This is believed to be the first attempt to describe the molecular mechanism of the traditional herbal medicine Cpd861, which has been demonstrated to have anti-fibrotic effects and to reverse liver disease caused by HBV infection. This is believed to be the first time that TGF $\beta$ 1/ALK1/Smad1 has been selected as a pathway to study the effects of deactivation of LX-2 HSCs.

### Applications

This study presents another possible anti-fibrotic mechanism of Cpd861 and shows that the TGF $\beta$ 1/ALK1/Smad1 pathway may represent a potential target for the anti-fibrotic therapy.

### Terminology

ALK1 is activin receptor-like kinase 1, a type I receptor, which is typically activated by the bone morphogenetic proteins, and then phosphorylates Smad1, Smad5 and Smad8 for signal transduction. Id1 is inhibitor of differentiation 1, which has an helix-loop-helix (HLH) domain but lacks a DNA-binding domain. It was first shown to act as a dominant negative antagonist of the basic HLH family of transcription factors, which positively regulate differentiation in many cell lineages. It is an important part of signaling pathways involved in development, cell cycle and tumorigenesis.

### Peer review

This study demonstrates that Cpd861 can down-regulate the TGF $\beta$ 1/ALK1 pathway, which results in the deactivation of HSCs. The study presents novel findings on the anti-fibrotic mechanism of Cpd861 and its possible application in anti-fibrotic therapy.

### Abstract

**AIM:** To investigate the expression level and effects of leptin in human hepatocellular carcinoma cells *in vitro* and to explore the correlation between them.

**METHODS:** Human hepatocellular carcinoma cell line HepG2 was cultured *in vitro*, and (the expression level) mRNA of leptin and leptin receptors in HepG2 were assessed using reverse transcription polymerase chain reaction (RT-PCR). Effects of different concentrations of leptin (50 ng/mL, 100 ng/mL, 200 ng/mL) on HepG2 were detected with colorimetric assay by 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) after incubation periods of 24 h, 48 h, and 72 h. Flow cytometry was performed to assess cell cycle progression of different concentrations of leptin as stated above after each 24 h incubation period.

**RESULTS:** mRNA of leptin and leptin receptors (including short and long isoforms) were expressed in HepG2. The 72 h incubation of leptin at different concentrations (50 ng/mL, 100 ng/mL, 200 ng/mL) promoted proliferation of HepG2 in a concentration- and time-dependent manner. The experimental group shows significant statistical differences when compared to the controlled group which contained 0 ng/mL of leptin. As the concentration of leptin increases, significant fewer cells were detected in G<sub>0</sub>-G<sub>1</sub> phase and more cells in S and G<sub>2</sub>-M phases.

**CONCLUSION:** Leptin and leptin receptor are simultaneously expressed in human hepatocellular carcinoma cell line HepG2. Addition of leptin (0 ng/mL-

200 ng/mL) in 72 h periods indicated there is a concentration- and time-dependent correlation in the stimulation of HepG2 cell proliferation. The effect of proliferation by leptin is due to promotion of DNA synthesis and enhancement of mitotic activity. The relationship between leptin and human hepatocellular carcinoma cells might indicate that adipokine could be associated with the progression of human hepatocellular carcinoma.

### INTRODUCTION

Leptin, a protein product encoded by the obese gene (ob gene)<sup>[1]</sup>, is primarily derived from adipocytes which plays an important role in the regulation of food intake and the control of body weight<sup>[2]</sup>. It takes part in various physical conditions such as lipid metabolism, immune defense, neuroendocrine regulation, pituitary hormone secretion, and pubertal development<sup>[3,4]</sup>. In rodents and humans, leptin is related with many pathological syndromes including obesity, hyperphagia, hyperinsulinemia, reduced fertility, and cholelithiasis (including gallstone and hepatolithiasis)<sup>[5-8]</sup>. Studies have shown that individuals who are obese have increased risk for most cancers compared to individuals who are not obese<sup>[9]</sup>. Since leptin is closely associated with obesity, it may be the bridge conjoining obesity and cancer.

The biological functions of leptin on target cells and tissues are carried out through interaction with its specific receptors (ob-R) which belong to class I cytokine receptor

family<sup>[10]</sup>. In rodents and humans, two leptin receptor isoforms predominate: the short leptin receptor isoform (ob-Ra) and the long leptin receptor isoform (ob-Rb)<sup>[11,12]</sup>. They share the same extracellular domain, but they differ in the length of the transmembrane/cytoplasmic coding regions<sup>[13]</sup>. The physiologic significance of each isoform in relationship to obesity and cancer is still unknown.

Hepatocellular carcinoma (HCC) is one of the most malignant tumors in the world. It causes proximately one hundred and ten thousand deaths annually in China. HCC is extremely difficult to detect in prognosis due to its early metastasis and distant transmission. It has been reported that obesity was related to HCC complicated with cryptogenic cirrhosis and alcoholic liver disease<sup>[14,15]</sup>. Therefore, we presume that leptin might be associated with HCC. In order to investigate the relationship between leptin and HCC, (the expression level) mRNA of leptin and its receptors in human HCC cell line HepG2 were detected by reverse transcription polymerase chain reaction (RT-PCR). In addition, the effects of leptin on HepG2 *in vitro* were also discussed in this study.

## MATERIALS AND METHODS

### Materials

Human hepatocellular carcinoma cell line HepG2 was obtained from Shanghai Cell Biology Institute of Chinese Academy of Sciences. Human recombinant leptin was the product from Sigma (St. Louis, Missouri, USA). Roswell Park Memorial Institute-1640 (RPMI-1640), fetal bovine serum (FBS) and Trizol reagent were the products of Invitrogen (Carlsbad, California, USA). Trypsin, 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT), ethylene diamine tetraacetic acid (EDTA) and dimethyl sulfoxide (DMSO) were purchased from Amresco (Cleveland, Ohio, USA). Revert aid first strand cDNA synthesis kit and TaqDNA polymerase were the products of Fermentas (Burlington, Iowa, USA). All other reagents unless indicated were from Sigma (St. Louis, Missouri, USA).

### Methods

**Cell culture:** HepG2 were grown as a monolayer in RPMI-1640 medium supplemented with 10% heat-inactivated FBS, 100 kU/L penicillin, and 0.1 g/L streptomycin. They were cultured in T-75 cm<sup>2</sup> culture flasks and maintained at 37°C in 5% CO<sub>2</sub> humidified atmosphere. At the beginning of the experiment, cells in the exponential growth phase were detached from the flask with 0.25% trypsin and 0.02% EDTA solution.

**RT-PCR:** mRNA of leptin, ob-Ra and ob-Rb in cell line HepG2 were assessed using RT-PCR as described previously<sup>[16]</sup>. Total RNA was isolated from confluent cells using Trizol reagent according to the manufacture's instructions. The concentration of RNA was quantitated by absorbance change at 260 nm and 280 nm. Total RNA was suspended in DEPC-treated water and stored at -80°C.

Single-stranded cDNA was synthesized from 1 µg of RNA using revert aid first strand cDNA synthesis kit

with random hexamer primer. The housekeeping gene β-actin was amplified to set a control for RNA loading and also to minimize variations in cDNA synthesis to ensure efficiency. Primer sequences for β-actin, leptin, ob-Ra and ob-Rb have been reported in the previous paper<sup>[17]</sup>. Following are the primers for: 1) β-actin: sense strand is 5'-ACCCACACTGTGCCCATCTA-3' and anti-sense strand is 5'-CGGAACCGCTCATTGCC-3' (encodes a 289-bp fragment); 2) leptin: sense strand is 5'-GTGCGGATTCTTGTGGCTTT-3' and anti-sense strand is 5'-GGAATGAAGTCCAAACCGGTG-3' (encodes a 174-bp fragment); 3) ob-Ra: sense strand is 5'-TTGTGCCAGTAATTATTTCTCTT-3' and anti-sense strand is 5'-AGTTGGCACATTGGGTTCAT-3' (encodes a 200-bp fragment); 4) ob-Rb: the sense strand is 5'-TTGTGCCAGTAATTATTTCTCTT-3' and antisense strand is 5'-CTGATCAGCGTGGCGTATTT-3' (encodes a 439-bp fragment).

Amplification of the resulting cDNA sequence was carried out using polymerase chain reaction (PCR). 3 µL cDNA was combined with 25 pmol oligonucleotide primers specific for β-actin, leptin, ob-Ra, ob-Rb and TaqDNA polymerase 1 U, PCR buffer (5 µL), 25 mmol/L MgCl<sub>2</sub> (4 µL), 10 mmol/L dNTP mixture (1 µL), and ddH<sub>2</sub>O (34 µL in a 50 µL solution). PCR was performed in a thermal cycler (Gene Amp PCR system 2400, Perkin-Elmer Corp., Uberlingen, Germany). The condition for the reaction were the following: 1 min at 94°C (predenaturation), followed by 30 cycles of 1 min (denaturation) at 52°C (for β-actin), 55°C (for leptin) or 50°C (for ob-Ra and ob-Rb); 1 min at 72°C (annealing), and then 5 min at 72°C (extension). PCR products were electrophoresed on 2% agarose gels stained with ethidium bromide, and the length were estimated to be 100-bp. Imaging was performed on JS-380 instrument (Peiqing Inc., Shanghai, China).

**MTT for cell proliferation:** MTT colorimetric assay was used to detect the effects of leptin on proliferation of cell line HepG2. Cells were washed extensively with filtered and sterilized phosphate-buffered saline (PBS) to remove the dead cells. HepG2 cells were suspended at a concentration of  $1.0 \times 10^4$ /mL, and then they were seeded into 96-well microplate at 150 µL/well and incubated to adhere overnight. RPMI-1640 medium containing different concentrations of human recombinant leptin were added in 0 ng/mL, 50 ng/mL, 100 ng/mL and 200 ng/mL to HepG2 cells with each concentration account for 6 wells. MTT assay was performed after incubation periods of 24 h, 48 h, and 72 h. MTT 20 µL (5 mg/mL) stock solution in PBS was added to each well. The microplate was incubated for 4 h and 100 µL DMSO was added (to each well). Optical density (A) value was measured by an ELISA plate reader (Digiscan Lab instruments, Austria) at wavelength of 492 nm. Each variant group was performed in triplicate wells for measurement accuracy.

**Flow cytometric analysis:** HepG2 cells in the exponential growth phase were detached by 0.25% trypsin and 0.02% EDTA. The cell suspension was then seeded uniformly

**Figure 1** Expression of  $\beta$ -actin, leptin, ob-Ra and ob-Rb in HepG2. M: DNA marker; A:  $\beta$ -actin 289 bp; B: Leptin 174 bp; C: Ob-Ra 200 bp; D: Ob-Rb 439 bp; E: Negative control.

into four T-75 cm<sup>2</sup> culture flasks and incubated to adhere overnight. RPMI-1640 medium containing different concentrations of human recombinant leptin were added in 0 ng/mL, 50 ng/mL, 100 ng/mL, and 200 ng/mL to HepG2 cells. Flow cytometric analysis was performed after incubated for 24 h. The cells were briefly washed twice with PBS, fixed in ice-cold ethanol (70% vol/vol in ddH<sub>2</sub>O) and stained with propidium iodide (PI) solution (25  $\mu$ g/mL PI, 180 U/ml RNase, 0.15% Triton X-100, and 30 mg/mL polyethylene glycol in 4 mmol/L citrate buffer w/pH = 7.8). DNA contents were detected using a FACScan flow cytometer (Becton Dickinson Co., San Jose, CA). The relative percentages of each phase of the cell cycle were analyzed using Cell Quest Software (Becton Dickinson Co., San Jose, CA). For the measurement accuracy, each variant group was tested in triplicate.

### Statistical analysis

The data were presented as mean  $\pm$  SD. ANOVA was used to analysis the results.  $P < 0.05$  were considered to indicate statistically significant differences. Entire data were analyzed with the statistical software SPSS 11.5.

## RESULTS

### Leptin, ob-Ra and ob-Rb mRNA assay by RT-PCR

Total RNA extracted from HepG2 cells were reversely transcribed to check whether mRNA of leptin, ob-Ra and ob-Rb were expressed. RT-PCR detection with  $\beta$ -actin primers revealed a 289-bp fragment in HepG2. The 174-bp cDNA band indicated that the cells expressed leptin mRNA. PCR products for both the short isoform (ob-Ra, 200-bp) and the long isoform (ob-Rb, 439-bp) of leptin receptor were also detectable. No fragment was detected in the negative control that PCR product without the cDNA (Figure 1).

### Effects of proliferation of leptin on HepG2

MTT assay indicated the cell proliferate conditions of HepG2. As shown in Table 1, leptin significantly stimulated HepG2 cells growth in a concentration- and time-dependent manner. Leptin caused significant growth potency on HepG2 within 72 h. There were significant statistical differences between concentration groups of 0 ng/mL *vs* 50 ng/mL ( $P < 0.01$ ), 0 ng/mL *vs* 100 ng/mL

**Table 1** Effect of leptin on proliferation of HepG2

Concentration (ng/mL)	A		
	24 h	48 h <sup>d</sup>	72 h <sup>d</sup>
0	0.29 $\pm$ 0.01	0.34 $\pm$ 0.01	0.37 $\pm$ 0.01
50 <sup>b</sup>	0.34 $\pm$ 0.02	0.42 $\pm$ 0.01	0.54 $\pm$ 0.02
100 <sup>b</sup>	0.41 $\pm$ 0.03	0.53 $\pm$ 0.05	0.62 $\pm$ 0.02
200 <sup>b</sup>	0.46 $\pm$ 0.04	0.63 $\pm$ 0.01	0.73 $\pm$ 0.03

<sup>b</sup> $P < 0.01$  *vs* group of 0 ng/mL leptin; <sup>d</sup> $P < 0.01$  *vs* group of incubation 24 h.

**Table 2** Effect of leptin on cell cycle of HepG2

Concentration (ng/mL)	Cell phase (%)		
	G <sub>0</sub> -G <sub>1</sub>	S	G <sub>2</sub> -M
0	61.8 $\pm$ 2.5	36.5 $\pm$ 1.0	1.6 $\pm$ 0.3
50	56.9 $\pm$ 2.2	38.5 $\pm$ 0.9	4.7 $\pm$ 1.4
100	50.2 $\pm$ 2.6 <sup>a</sup>	40.3 $\pm$ 1.2	9.4 $\pm$ 2.1 <sup>a</sup>
200	43.6 $\pm$ 2.7 <sup>b</sup>	42.0 $\pm$ 0.3 <sup>a</sup>	14.4 $\pm$ 2.5 <sup>a</sup>

<sup>a</sup> $P < 0.05$ , <sup>b</sup> $P < 0.01$  *vs* group of 0 ng/mL leptin.

( $P < 0.01$ ), 0 ng/mL *vs* 200 ng/mL ( $P < 0.01$ ), 50 ng/mL *vs* 100 ng/mL ( $P < 0.05$ ) and 50 ng/mL *vs* 200 ng/mL ( $P < 0.01$ ). Meanwhile, significant statistical differences also existed between duration groups of 24 h *vs* 48 h ( $P < 0.01$ ) and 24 h *vs* 72 h ( $P < 0.01$ ).

### Effects of leptin on cell cycle progressions of HepG2

The effects of leptin on cell cycle progressions of HepG2 as determined by flow cytometry analysis are shown in Table 2. In the 24 h frame, the results indicate that as the concentration of leptin increases (e.g. 50 ng/mL, 100 ng/mL and 200 ng/mL), the proportion of the HepG2 cells in G<sub>0</sub>-G<sub>1</sub> phase gradually reduces and the number of cells in S and G<sub>2</sub>-M phases gradually increases. In comparison with control group, the data indicates a significant reduction of cells in G<sub>0</sub>-G<sub>1</sub> phase ( $P < 0.01$ ) and a significant increase of cells in S phase ( $P < 0.01$ ) and G<sub>2</sub>-M phase ( $P < 0.01$ ) in response to treatment of leptin.

## DISCUSSION

The relationship between obesity and cancer has been excessively documented for cancers or adenocarcinoma in endometrium, breast, prostate, renal cells, pancreas, colon, and esophagus<sup>[18,19]</sup>. Epidemiological observations revealed that obesity was a risk factor of HCC complicated with cryptogenic cirrhosis and alcoholic liver disease<sup>[14,15]</sup>, and in addition, clinical investigations identified that the leptin level of serum had increased significantly in alcoholic and post-hepatitis liver cirrhosis patients with or without HCC as compared to control subjects w/o the complication<sup>[20-24]</sup>. Still, there were few studies on the involvement of leptin in HCC.

It has been reported that leptin participates in an auto/paracrine manner in the pituitary gland, and it plays regulations roles in the pig<sup>[25]</sup>. One study reported that the proteins of leptin and ob-R had been detected in 72.22% and 30.56% of HCC, respectively<sup>[26]</sup>. Present study

indicated that the mRNA of leptin, and as well as the short and the long leptin receptor isoforms were all expressed in HepG2. These findings suggested that leptin might act as an auto/paracrine growth factor towards hepatocytes, and together with its receptors, they could play role in HCC initiation and progression.

Serum leptin level fluctuations are also detected in some non-physiological conditions. For example, leptin levels up to 400 ng/mL have been reported in children with chronic renal failure<sup>[27]</sup>. When obese, but otherwise healthy subjects treated with leptin (1 mg/kg per day), serum leptin levels rose up to 736 ng/mL<sup>[28]</sup>. However, serum leptin level in normal physiological situation is less than 11.4 ng/mL. Thus, a relatively higher concentration of leptin (200 ng/mL) was used in our study. There are some divericate results among the studies of leptin and cancer. Leptin not only stimulated proliferation of some human cancer cell lines, including breast cancer cell lines (ZR75-1, MCF-7), esophageal cancer cell lines (KYSE 410) and prostate cancer cell lines (PC-3, DU 145), but also it inhibited the growth of other human cancer cell lines, such as pancreatic cancer cell lines (Mia-Paca, PANC-1)<sup>[18]</sup>. Data regarding leptin's effect on HCC cells are rarely reported, and they appear to be contradictory. In one *in vitro* study, leptin was found to have little effect on the proliferation of liver cancer cell line SMMC-7721<sup>[26]</sup>, while in another study, leptin had shown anti-tumor activity<sup>[29]</sup>. In our *in vitro* study, exogenous leptin had effects on the proliferation of HCC cell line HepG2 in a concentration- and time-dependent manner. We might conclude that human cancer cell lines exhibit differential responses to the leptin treatments, depending upon the biological characteristics of the cancer cells and the organ of derivation of the cell lines. Because our study was to interfere HCC cell line with exogenous leptin *in vitro*, results may differ in concentration threshold and activation initiation time with *in vivo* HCC cells in tumor tissues with endogenous leptin. Therefore, it will be necessary to continue the research on leptin's effects on HCC with targeted animal models.

By adopting the techniques of flow cytometry, we were able to significantly expand the analysis of cell cycle progression. With respect to the cell cycle, we were able to accurately determine the relative proportion of cells in each phase of the cycle progression. From our data, it was evident that as the concentration of exogenous leptin increased from 0 to 200 ng/mL, it gradually reduced the relative proportion of the HepG2 cells in G<sub>0</sub>-G<sub>1</sub> phase and gradually increased the number of the cells in S and G<sub>2</sub>-M phases. Since the S phase of the cell cycle is the synthetic phase of DNA, and G<sub>2</sub>-M phase represents a later synthetic phase of DNA and the splitting of the cells through mitotic phase, data from our study demonstrate that leptin increase cell proliferation of HepG2 by promoting of DNA synthesis and enhancing mitotic activity.

It has been reported that leptin replacement is a very promising therapeutic approach for managing the complications of lipodystrophy. In addition, leptin may have therapeutic potential in the treatment of epilepsy<sup>[30,31]</sup>. The primary finding of our study on leptin and HCC cell line indicates that adipokine could be associated with

the progression of human hepatocellular carcinoma. Administration of the leptin antagonists or receptors in the targeted cells may open a new way in HCC prevention and treatment. Further studies are warranted and ongoing.

## COMMENTS

### Background

Leptin is the protein product encoded by obese gene, which plays an important role in the regulation of food intake, and the control of body weight. It is related with many pathological syndrome including obesity, hyperphagia, hyperinsulinemia, reduced fertility, and cholelithiasis. There are considerable researches about the effects of leptin.

### Research frontiers

Recently, the researches of relationships between leptin and tumors are hotspots. But there are few studies on the involvement of leptin in human hepatocellular carcinoma.

### Innovations and breakthroughs

In this study, we found mRNA of leptin and leptin receptors (including short and long isoforms) were expressed in human hepatocellular carcinoma cell line HepG2. Leptin (0 ng/mL-200 ng/mL) in 72 h could stimulate proliferation of HepG2 *in vitro*, and that effect was due to promotion of DNA synthesis and enhancement of mitotic activity.

### Applications

The primary study of leptin and HepG2 may indicate that adipokine could be associated with the progression of human hepatocellular carcinoma, and thus may offer new aim for further understanding of the biological function of leptin and new therapeutic targets.

### Peer review

The manuscript written by Zhou J *et al* describes a possible role of leptin in hepatocarcinogenesis and promotion of the disease. The data are interesting and potentially important. It's recommended the additional experiments using another HCC cell lines which could make this study's conclusions more confidential.

### Abstract

**AIM:** To evaluate the effect of rosiglitazone in a murine model of liver fibrosis induced by *Schistosoma japonicum* infection.

**METHODS:** A total of 50 mice were randomly and averagely divided into groups A, B, C, D and E. The mice in group A served as normal controls, while those in the other four groups were infected with *Schistosoma japonicum* to induce the model of liver fibrosis. Besides, the mice in groups C, D and E were treated with praziquantel, rosiglitazone and praziquantel plus rosiglitazone, respectively. NF- $\kappa$ B binding activity and expression of PPAR $\gamma$ -mRNA were determined by Western blot assay and real-time quantitative PCR. Radioimmunoassay technique was used to detect the serum content changes of TNF- $\alpha$  and IL-6. Histological specimens were stained with HE. Expression of TGF- $\beta$ 1,  $\alpha$ -smooth muscle actin and type I and type III collagen was detected by immunohistochemistry and multimedia color pathographic analysis system.

**RESULTS:** Inflammation and fibrosis in the rosiglitazone plus praziquantel treatment group (group E) were lightest among the mice infected with *Schistosoma* ( $P < 0.05$ ). To further explore the mechanism of rosiglitazone action, we found that rosiglitazone can significantly increase the expression of PPAR $\gamma$  [E:  $-18.212 \pm (-3.909)$  vs B:  $-27.315 \pm (-6.348)$  and C:  $-25.647 \pm (-5.694)$ ,  $P < 0.05$ ],

reduce the NF- $\kappa$ B binding activity (E:  $88.89 \pm 19.34$  vs B:  $141.11 \pm 15.37$ , C:  $112.89 \pm 20.17$  and D:  $108.89 \pm 20.47$ ,  $P < 0.05$ ), and lower the serum level of TNF- $\alpha$  (E:  $1.613 \pm 0.420$  ng/mL vs B:  $2.892 \pm 0.587$  ng/mL, C:  $2.346 \pm 0.371$  ng/mL and D:  $2.160 \pm 0.395$  ng/mL,  $P < 0.05$ ) and IL-6 (E:  $0.106 \pm 0.021$  ng/mL vs B:  $0.140 \pm 0.031$  ng/mL and C:  $0.137 \pm 0.027$  ng/mL,  $P < 0.05$ ) in mice with liver fibrosis. Rosiglitazone can also substantially reduce the hepatic expression of TGF- $\beta$ 1,  $\alpha$ -SMA type I and type III collagen in mice with liver fibrosis.

**CONCLUSION:** The activation of PPAR $\gamma$  by its ligand can retard liver fibrosis and suggest the use of rosiglitazone for the treatment of liver fibrosis due to *Schistosoma japonicum* infection.

### INTRODUCTION

Hepatic schistosomiasis is one of the most prevalent forms of chronic liver diseases in the world, resulting in the morbidity from infection due to its complications of liver fibrosis. However, there are few medicines or means available to control and treat fibrosis in schistosomiasis.

The key pathogenic event in liver fibrosis is the activation of hepatic stellate cells (HSC) and their transformation into myofibroblasts<sup>[1,2]</sup>. The HSC (formally called the Ito cell) is the primary cell-type in the liver responsible for excessive collagen synthesis during hepatic fibrosis<sup>[3,4]</sup>. Following liver injury, the HSC undergoes a complex transformation or activation process in which the cell changes from a quiescent, vitamin A-storing cell to an

activated myofibroblast, resulting in considerable changes such as the appearance of the cytoskeletal protein smooth muscle  $\alpha$ -actin ( $\alpha$ -SMA), the loss in the cellular vitamin A stores<sup>[5,6]</sup>, and the up-regulation of type I and III collagen genes. In addition, transforming growth factor- $\beta$  (TGF- $\beta$ ), as the most potent fibrogenic cytokine described in HSC<sup>[7]</sup>, accompanying its receptors are increased following HSC activation as well. These pathogenic alterations cause excessive depositions of extracellular matrix (ECM) proteins including three large families of protein-glycoproteins, collagens and proteoglycans, and disrupt the balance in ECM integrity to induce hepatic fibrosis<sup>[8]</sup>.

Peroxisome proliferator-activated receptors (PPARs) are a family of ligand-activated nuclear transcription factors, members of the nuclear hormone receptor super-family<sup>[9]</sup>. There are 3 mammalian subtypes identified as PPAR- $\alpha$ , - $\beta$  (or - $\delta$ ), and - $\gamma$ <sup>[10]</sup>; however, current studies demonstrate that only PPAR $\gamma$  is mainly expressed in human HSC, which contributes to the process of liver fibrogenesis, and both its translational and transcriptional levels are significantly decreased in *in vitro* and/or *in vivo* activated human HSC cells. The decreased PPAR $\gamma$  at the early stage of HSC activation and the amelioration of stimulated PPAR $\gamma$  by its ligands to some deterioration resulting from activated HSCs, suggest that PPAR $\gamma$  may be involved in the maintenance of a quiescent phenotype of HSC<sup>[11]</sup>, although the identification of PPAR $\gamma$  as a novel modulator to liver fibrosis remains controversial.

PPAR $\gamma$  ligands, 15-deoxy-triangle up (1214) prostaglandin J (2) (15d-PGJ (2) and rosiglitazone, significantly decreased the expression of  $\alpha$ -SMA and proliferation in activated human HSCs induced by platelet-derived growth factor<sup>[12]</sup>. Oral administration of rosiglitazone is found able to diminish extracellular matrix deposition and HSC activation in liver fibrosis of rat models which are created by bile duct ligation<sup>[13]</sup>. They found PPAR $\gamma$ -specific DNA binding activities in nuclear extracts of HSCs isolated from liver fibrotic rat models are impaired significantly, although they can return, through rosiglitazone administration, to the normal levels as controls. Intriguingly, rosiglitazone induces PPAR $\gamma$  activation to inhibit collagen and fibronectin synthesis in human HSCs initiated by transforming growth factor (TGF)- $\beta$ 1 *in vitro*. These findings implicate that the PPAR $\gamma$  activation in HSC retards fibrosis, suggesting the use of PPAR $\gamma$  ligands for the treatment of fibrosis following liver injury.

To determine amelioration of PPAR $\gamma$  and its ligands to liver fibrosis, we studied several different treatments of ligands, rosiglitazone, with/out the additives and praziquantel in liver fibrosis model mice created by infection of schistosome.

## MATERIALS AND METHODS

### Animal preparation and treatment

Fifty 4-5-wk-old Kunming mice, weighing 16-22 g (obtained from the experimental animal center of Tongji Medical College, Huazhong University of Science and Technology) were used. All animals were housed in a temperature and humidity controlled environment, and all

animal experiments were carried out in accordance with the Chinese Council on Animal Care Guide for the Care and Use of Laboratory Animals.

The mice were randomly divided into five groups (10 per group) as follows: group A, B, C, D and E. The mice in group A served as normal controls, while those in the other four groups were infected with 40 *Schistosoma japonicum cercariae* through skin to create a liver fibrosis model. The mice in groups C, D and E were treated with praziquantel, rosiglitazone, and praziquantel plus rosiglitazone, 4 wk after infection, respectively. Praziquantel (500 mg/kg) was given daily for 2 d by intragastric administration in groups C and E. Rosiglitazone (4 mg/kg) was given daily for 6 wk by intragastric administration in groups D and E. Meanwhile, the mice in the normal control group (group A) and the model control group (group B) were given normal saline daily for 6 wk. All mice were sacrificed at the end of the study period. Vein blood was centrifuged at 1500 r/min for 15 min, and the serum was stored at -20°C for use. Parts of liver tissues were fixed by 40 g/L formaldehyde, and embedded in paraffin. The remaining liver was stored at -70°C.

### Histopathological examination

The sections of the liver were stained with hematoxylin-eosin (HE) staining. Criteria used in histopathological analysis strictly obeyed WHO category and nomenclature for liver fibrosis<sup>[14]</sup>. Mean degrees of liver fibrosis examined from ten randomized scopes under optical microscopy in each slice were used for statistical analysis in current study. Pathological phases are graded as “-”, “+”, “++” and “+++” respectively: “-”, no fibrosis in liver lobules marked phase “0”; “+”, limit fibrosis in lobules, phase “1”; “++”, typical fibrosis spacing around liver lobules, phase “2”; and “+++”, early cirrhosis, fibrosis enveloping liver lobules and spacing into central vein area, phase “3”.

### Serum assay

Serum TNF- $\alpha$  and IL-6 were detected using radioimmunoassay kit (Institute of Radioimmunoassay, Science and Technology Empolder Center, General Hospital of PLA) according to the manufacturer's instructions.

### Immunohistochemistry for TGF- $\beta$ , $\alpha$ -SMA and collagens

TGF- $\beta$ ,  $\alpha$ -SMA and collagens were detected using the three step streptavidin-biotin immunoperoxidase method. Briefly, tissue sections were de-paraffinized and rehydrated, and then were heated in microwave oven for 10 min to enhance antigen retrieval. For minimizing endogenous peroxidase, activity slides were incubated with 3% H<sub>2</sub>O<sub>2</sub>. After blocking with 5% normal goat serum in 0.01% PBS, the primary antibodies (mice raised against  $\alpha$ -SMA, rabbit raised against TGF- $\beta$ , and types I and III collagens, Bosider, Wuhan, China) were applied and incubated at 37°C in a moisture chamber for 1 h. Sections were then washed with PBS 3 times. After reacted with biotinylated hircine anti-mouse (or rabbit) IgG and then avidin at 37°C for 20 min each, sections were washed with PBS 3 times. Then diaminobenzidine solution (1 mg/mL in PBS

containing 0.03% hydrogen peroxide) was applied as the chromogen. Sections were counterstained with hematoxylin for 15 s before checked under microscope. As a negative control, PBS was used instead of primary antibody. The cytoplasm or membrane of the positive cell was stained brown and yellow. The sections were observed under microscope. For quantification, 10 random fields of intralobular and periportal areas were evaluated under microscope at 40 × magnification. The integral light density was determined by multimedia color pathographic analysis system.

### Protein preparation and western blotting

One hundred mg of frozen tissues was homogenized and centrifuged at 5000 r/min at 4°C for 10 min. The sediment was resuspended in 200 µL of ice-cold extraction buffer A (10 mmol/L HEPES pH 7.9, 1.5 mmol/L MgCl<sub>2</sub>, 10 mmol/L KCl, 0.5 mmol/L DTT, 0.5 mmol/L phenylmethylsulfonyl fluoride, 1 µg/mL Aprotinin), and spin down at 5000 r/min at 4°C for 10 min. The sediment was resuspended in 100 µL of extraction buffer C (25% glycerol, 420 mmol/L NaCl, 20 mmol/L HEPES pH 7.9, 1.5 mmol/L MgCl<sub>2</sub>, 1% NP40, 0.2 mmol/L EDTA, 0.5 mmol/L DTT, 0.5 mmol/L phenylmethylsulfonyl fluoride, 1 µg/mL each of aprotinin) and kept on ice for 10 min. Finally, it was transferred to a microdosis centrifuge tube and centrifuged at 15000 r/min at 4°C for 20 min. The supernatant was stored at -70°C for use.

Protein concentration was determined using the Coomassie brilliant blue method with G-250 as a standard. Nuclear or cytoplasmic proteins were electrophoresed through 12% SDS-PAGE in Tris-glycine electrophoresis buffer and transferred onto nitrocellulose membrane. The blot was pre-incubated in blocking buffer [Tris buffered saline (TBS) containing Tween and 7% non-fat dried milk powder] at room temperature for 2 h and probed with a primary antibody [rabbit anti-mouse NF-κB polyclonal antibody (Santa Cruz, CA, USA)] at 4°C overnight. After washed three times with 0.1% Tween-TBS, it was incubated with 1:2000 goat anti-rabbit conjugated with horseradish peroxidase (The Eastman Company, Beijing, China) at room temperature for 2 h. Immunoreactive bands were detected by epiluminescence and quantified in arbitrary units [optical density (A) × band area using Vilber Lourmat image analysis system].

### RNA isolation, reverse transcription and quantitative PCR

Total RNA was extracted from the frozen liver tissue with Trizol reagent (GIBCO, USA). Complementary DNA (cDNA) was synthesized from total RNA using the reverse transcriptase Superscript II (GIBCO, USA) according to the manufacturer's instructions.

Relative quantification of target gene expression was performed using glyceraldehyde-3-phosphate dehydrogenase (GAPDH) as an internal control. The threshold cycle and the standard curve method were used for calculating the relative amount of the target mRNA. For *PPARγ* mRNA detection, the forward and reverse primers were: 5'-TTTCAAGGGTGCCAGTTTCG-3', and 5'-TCTTTATTCATCAGGGAGGC-3'; for GAPDH, the

primers were: 5'-GATGGTGAAGGTCGGTGTG-3', and 5'-GAGGTCAATGAAGGGGTCG-3'. Real-time PCR was carried out in 50 µL of PCR reaction mixture which contained 1.5 µL of the extracted cDNA, 25 mmol/L MgCl<sub>2</sub>, 20 µmol/L each primer, and 1 µL of SYBR Green I (Biotium, USA). A "no template" control was added, which consisted of all the reagents listed above for real-time PCR, except the cDNA template was replaced with water. The following thermal profile was used: 10 min at 94°C, followed by 45 cycles of 94°C for 30 s, 53°C for 30 s, and 72°C for 30 s. Dissociation curve was run to prove the purity of the product.

Data analysis: The relative *PPARγ* mRNA expression levels were calculated by the  $\Delta\Delta C_t$  (threshold cycle) method in relation to *PPARγ* expression in the liver tissues.  $\Delta\Delta C_t = \Delta C_t$  (specimen) -  $\Delta C_t$  (GAPDH),  $\Delta C_t = C_t$  (negative control) -  $C_t$  (specimen).  $\Delta C_t$  is the relative gene expression ( $C_t$ -the number of fractional cycle at which the reporter fluorescence was generated by cleavage of the probe passes a fixed threshold above baseline). The relative difference in expression of the gene of interest and of the internal reference gene is represented by  $\Delta C_t$ . Changes of gene expression in relation to the calibrator are represented by  $2^{\Delta\Delta C_t}$  [relative quantification (RQ)].

### Statistical analysis

Means of triplicates were used for statistical analysis by one-way analysis of variance (ANOVA) with post hoc Tukey test for pairwise group comparisons (SPSS 15, SPSS Inc, Chicago, IL, USA). The level of statistical significance was set at 0.05 (two-sided).

## RESULTS

### Histopathological analysis

Compared with normal mice, slice of the liver from fibrosis model (group B) showed typical damage in the liver lobules: the segregation of liver by collagen fibers, necrosis lesions in the granulomas and inflammatory cells extensively in the periphery of granulomas (Figure 1A). Compared with group B, the decreases were not significant in the fibroplasias, hepatocellular necrosis and inflammatory cell infiltration in the liver slice from groups C and D (fibrosis models treated only with praziquantel or rosiglitazone respectively) (Figure 1B). However, the severity of hepatocellular necrosis and fibroplasias was significantly decreased in the liver of mice treated with praziquantel plus rosiglitazone (group E) compared with group B (Figure 1C). Group E mice also showed thin fibroseptal and decreased inflammatory cell infiltrations in the livers, demonstrating a markedly improved or normal architecture of hepatic lobule.

The pathological phase quantities of groups B, C, D and E were  $2.31 \pm 0.63$ ,  $1.49 \pm 0.77$ ,  $1.38 \pm 0.60$  and  $0.78 \pm 0.53$ , respectively. Fibrosis in the rosiglitazone plus praziquantel treatment group (group E) was lightest among those with *Schistosoma* infection ( $P < 0.05$ ).

### Immunohistochemical findings

TGF-β<sub>1</sub>-positive cells were concentrated in the portal

**Figure 1** Liver histopathology of mice (HE staining,  $\times 10$ ). **A:** Represents the model group; **B:** Represents the group treated with praziquantel; **C:** Represents the group treated with rosiglitazone plus praziquantel.

venule pericytes with perisinusoidal distribution in the normal mouse liver. Similarly distributed and decreased TGF- $\beta_1$ -positive cells were found in group E mice (treated with praziquantel plus rosiglitazone). However, there was a significantly large number of TGF- $\beta_1$ -positive cells in groups B, C and D, which distributed mainly at the fibro-septa band, the area of necrosis and inflammatory cell infiltration, few hepatic cells and lipid-containing vacuoles.

There were few expressions of  $\alpha$ -SMA positive cells in venule pericytes and periphery of granulomas in the mouse livers of normal control and group E. Nevertheless, the positive cells of  $\alpha$ -SMA were substantially distributed at venule pericytes, inflammatory cell infiltration, periphery of granulomas and fibrous proliferation in groups B, C and D.

Moreover, few expressions of type I & III collagen were only found in the central venule pericytes and the linkage region of lobules from the mouse liver of group A (normal control), group D or E. In contrast, there

**Figure 2** NF- $\kappa$ B binding activity in mouse livers with Western blot assay. **A:** Normal group; **B:** Rosiglitazone treatment; **C:** Praziquantel plus rosiglitazone treatment; **D:** Praziquantel treatment; **E:** Model group.

was a significant larger number of positive collagen cells distributed not only in these areas but also in fibrous proliferation and Disec cavities of mouse livers from groups B (fibrosis model) and C treated with praziquantel alone.

TGF- $\beta_1$ ,  $\alpha$ -SMA, type I & III collagen positive cells were quantified with multimedia color pathographic analysis. Quantities of TGF- $\beta_1$  and type I collagen in the mouse livers of praziquantel treatment group (group C) were reduced much more than in group B ( $P < 0.05$ ). No significant difference was found in the volumes of  $\alpha$ -SMA and type III collagen in the mouse livers of groups C and group B ( $P > 0.05$ ). Additionally, volumes of  $\alpha$ -SMA and type III collagen in the mouse livers of rosiglitazone treatment group (group D) decreased dramatically compared with groups B and C ( $P < 0.05$ ). TGF- $\beta_1$  and type I collagen in mouse livers of group D decreased more significantly than in group B ( $P < 0.05$ ). Notably, volumes of TGF- $\beta_1$ ,  $\alpha$ -SMA, type I & III collagen in the mouse livers of group E (praziquantel plus rosiglitazone treatment) decreased substantially compared to groups B and C as well ( $P < 0.05$ ). All data are summarized in Table 1.

### Serum assays

The serum level of TNF- $\alpha$  was markedly lower in group E ( $1.613 \pm 0.420$  ng/mL) than that in groups B ( $2.892 \pm 0.587$  ng/mL), C ( $2.346 \pm 0.371$  ng/mL) and D ( $2.160 \pm 0.395$  ng/mL) ( $P < 0.05$ ). However, the serum level of IL-6 was markedly higher in groups B ( $0.140 \pm 0.031$  ng/mL), and/or C ( $0.137 \pm 0.027$  ng/mL) than that in groups D ( $0.108 \pm 0.021$  ng/mL) and/or E ( $0.106 \pm 0.021$  ng/mL) ( $P < 0.05$ ) as summarized in Table 2.

### NF- $\kappa$ B binding activity

Less NF- $\kappa$ B activity was found in groups A, C, D or E than in group B (without any treatment) ( $P < 0.05$ ). Moreover, the activity of NF- $\kappa$ B decreased much more in group A and E than in either group C or D. The activity of NF- $\kappa$ B in groups C and D ( $112.89 \pm 20.17$  and  $108.89 \pm 20.47$ ) was higher than in groups A and E ( $78.89 \pm 18.12$ ,  $88.89 \pm 19.34$ ,  $P < 0.05$ ), but lower than in group B ( $141.11 \pm 15.37$ ,  $P < 0.05$ ). There was no significant difference between groups C and D ( $P > 0.05$ ) as seen in Table 3 and Figure 2.

### Expression of PPAR- $\gamma$ -mRNA

Levels of PPAR $\gamma$  mRNAs were markedly higher in groups A [-16.557  $\pm$  (-3.022)], D [-18.217  $\pm$  (-4.498)] and E [-18.212  $\pm$  (-3.909)] than that in either group B [-27.315  $\pm$  (-6.348)] or C [-25.647  $\pm$  (-5.694), *P* < 0.05] as summarized in Table 3.

## DISCUSSION

PPAR $\gamma$  is a ligand-activated nuclear transcription factor which belongs to the nuclear hormone receptor superfamily. Normally, PPAR $\gamma$  expresses in quiescent human liver HSC, but significantly lowers both its translational and transcriptional activities after HSC activation in culture<sup>[15,16]</sup>. Some recent findings support a role of PPAR $\gamma$  in the development of liver fibrosis and suggest that PPAR $\gamma$  ligands can be therapeutically used to inhibit HSC activation and the progression to liver fibrosis<sup>[17-19]</sup>.

A mouse model of liver fibrosis through *Japonicum cercariae* infection was generated, and then treated with PPAR $\gamma$  ligand, rosiglitazone and its additive, and praziquantel to diminish liver fibrosis in the current study. Our results demonstrated that the level of hepatic PPAR $\gamma$  mRNA markedly decreased in the model mice and praziquantel treated group as compared with the normal mice. However, rosiglitazone significantly increased the expression of PPAR $\gamma$  and decreased HSC activation and liver fibrosis progression.

Our mouse model successfully showed the key pathogenic events in liver fibrosis: the activation of HSCs and transformation of HSCs into myofibroblasts. Consequently, livers of model mice exhibited cellular changes including the appearance of cytoskeletal protein  $\alpha$ -SMA and substantial expression of TGF- $\beta$ , both fibrogenic cytokines which are activated accompanying

liver HSC activation<sup>[20,21]</sup>.

Based on the results from histopathological and immunohistochemical analyses, current fibrosis model clearly confirmed that an imbalance between the synthesis and degradation of ECM in chronic liver injury is the indispensable process developing into liver fibrosis. Although there are three large families of ECM proteins, glycoproteins, collagens and proteoglycans<sup>[22,23]</sup>, excessive depositions of types I and III collagens are mainly pathologic characteristics of liver fibrosis due to *Schistosoma japonicum* infection. Our results further demonstrated that rosiglitazone alone or plus praziquantel can reduce the inflammation and liver fibrosis with *Schistosoma* infection by reducing the hepatic expression of TGF- $\beta$ 1,  $\alpha$ -SMA, types I & III collagens. These results also suggest that PPAR $\gamma$  ligand, rosiglitazone can impede liver fibrosis after *Schistosoma* infection.

To seek possible regulatory mechanism in liver fibrosis, we further measured some cell factors such as TNF- $\alpha$  and IL-6, and the nuclear factors NF- $\kappa$ B in our model mice with/out treatment. TNF- $\alpha$ , a pro-inflammatory cytokine, plays a key role in a wide variety of physiological processes, including inflammation, proliferation and programmed cell death<sup>[24]</sup> which lead to regeneration of ECM and fibrogenesis<sup>[25]</sup>. Our results showed that the serum level of TNF- $\alpha$  and IL-6 increased in liver tissues. These data also provided a further evidence for the role of these cytokines in inducing hepatic fibrosis. Rosiglitazone alone or rosiglitazone plus praziquantel significantly reduced the serum level of TNF- $\alpha$  and IL-6, suggesting that rosiglitazone could be an alternative treatment for liver fibrosis after liver injury or infection.

NF- $\kappa$ B, a heterodimer, is a functional protein which

is regulated by interaction with a family of regulatory proteins, the inhibitor of nuclear factor  $\kappa$ B (I $\kappa$ B) proteins may be stimulated by many factors, such as TNF- $\alpha$  and lipopolysaccharide, *via* the phosphorylation and degradation of I $\kappa$ B. Activated NF- $\kappa$ B then transports into the cell nucleus and combines with gene promoters to induce the transcription of many cytokines and adhesion molecules<sup>[26,27]</sup>. Physical stress, oxidative stress, and exposure to certain chemicals can also activate NF- $\kappa$ B, suggesting its critical functions in mediating stress responses as well<sup>[28]</sup>. Recent studies show that the activation of NF- $\kappa$ B has a great impact on the pathogenesis of liver fibrosis through regulating hepatocyte, HSC and Kupffer cells<sup>[29,30]</sup>. Some studies demonstrate that NF- $\kappa$ B is also associated with the development of the activated phenotype of HSC and promotes survival of activated HSC<sup>[31]</sup> by protecting activated HSCs against TNF-induced apoptosis<sup>[32]</sup>. Notably, NF- $\kappa$ B binding activity increased in our mouse fibrosis model, while rosiglitazone significantly decreased the activity of, suggesting further that rosiglitazone could partially inhibit liver fibrosis by down-regulating NF- $\kappa$ B as well.

As indicated, our study showed a significant reduction of liver fibrosis following the treatment with rosiglitazone, a PPAR- $\gamma$  ligand, in a murine model of hepatic fibrosis induced by *Schistosoma japonicum*. The effect of this compound on preventing liver fibrosis may be through down-regulation of liver TGF- $\beta$ 1 and collagens, and reduction of inflammatory mediators (IL-6, TNF- $\alpha$ , NF- $\kappa$ B). It suggested the use of rosiglitazone for the treatment of liver fibrosis.

Interestingly, our results showed that praziquantel alone reduced markedly the serum level of TNF- $\alpha$ , NF- $\kappa$ B binding activity, and volumes of TGF- $\beta$ 1 and type I collagen in liver fibrosis due to *Schistosoma* infection. These data may suggest an antifibrotic effect of praziquantel in the early stage of liver fibrosis. Praziquantel might be able to block liver fibrosis through killing parasite to alleviate liver inflammation. Further studies on mechanisms of rosiglitazone and praziquantel during liver injury or infection may shed lights on developing therapeutic methods in clinical practice.

## COMMENTS

### Background

Hepatic schistosomiasis is one of the most prevalent forms of chronic liver diseases in the world, resulting in the morbidity due to its complications of liver fibrosis from infection. However, there are currently few medicines or means available to control and treat fibrosis in schistosomiasis. Many studies demonstrate that PPAR $\gamma$  is mainly expressed in human HSC and contributes to the process of liver fibrogenesis, but the identification of PPAR $\gamma$  as a novel modulator to liver fibrosis remains controversial.

### Research frontiers

Current findings further support the role of PPAR $\gamma$  in the development of liver fibrosis and suggest that PPAR $\gamma$  ligands can be therapeutically used to inhibit HSC activation and the progression of liver fibrosis.

### Innovations and breakthroughs

This is a first report about PPAR $\gamma$  and liver fibrosis due to *Schistosoma* infection. This study evaluates the relationship of PPAR $\gamma$  ligand and hepatic fibrosis due to *Schistosoma* infection.

## Applications

This study provides a perspective for a new therapeutic approach to prevent liver fibrosis following *Schistosoma japonicum* infection.

## Peer review

The study reported a significant reduction of liver fibrosis following the treatment with rosiglitazone, a PPAR- $\gamma$  ligand, in a murine model of hepatic fibrosis induced by *Schistosoma japonicum*. The effect of this compound on preventing liver fibrosis may be through down-regulation of liver TGF- $\beta$ 1 and collagens, and reduction of inflammatory mediators (IL-6, TNF- $\alpha$ , NF- $\kappa$ B). The study is interesting and may herald a new therapeutic approach to prevent liver fibrosis following *Schistosoma japonicum* infection.

## INTRODUCTION

Anti-tumor necrosis factor alpha (TNF- $\alpha$ ) inhibitors are relatively new drugs in the rheumatic arena which are effective in the treatment of various inflammatory rheumatic conditions. Increased risk of infections and possible risk of lymphoma with the use of TNF targeting therapies are the major issues concerning the long-term safety of these agents<sup>[1]</sup>. The association of anti-TNF- $\alpha$  therapy and serious infections has generally been attributed to an increased risk of bacterial (especially microbacteria) and opportunistic fungal microorganisms<sup>[2]</sup>. In recent years, an increasing number of studies, mainly based on case reports, have reported an increased risk of serious viral infections in patients treated with anti-TNF agents.

In this report, we describe a case of severe, biopsy proven cytomegalovirus (CMV) colitis in a patient with Behcet's disease (BD) whose symptoms started 10 d after the third Infliximab (INF; Remicade®, Schering-Plough) infusion.

## CASE REPORT

A 25-year-old man presented with diarrhea and weight loss for two months. He was diagnosed as neuro BD 4 years ago according to recurrent oral and genital ulcerations, uveitis, urinary incontinence and seizures. He was treated with various immunosuppressive drugs including monthly cyclophosphamide infusions, interferon and a combination of cyclosporine and azathioprine. Although these medications were used, his eye involvement could not be controlled and visual acuity decreased to no light perception in the left eye and 10/100 in the right eye. Because of this, INF at a dose of 5 mg/kg was started. Remission of ocular symptoms was observed after two infusions. Ten days after the third dose of INF (52 d after the first infusion), the patient developed abdominal discomfort, anorexia, epigastric pain and diarrhea occurring seven to ten times per day with watery stools, but without any associated blood or mucus. He had no history of chronic diarrhea before INF administration. His symptoms continued to worsen and he lost six kilograms during the past two months. He did not use any medications other than INF, colchicine (1.5 mg/d) and

## Abstract

Anti-tumor necrosis factor alpha (TNF- $\alpha$ ) inhibitors are effective in the treatment of various inflammatory rheumatic conditions. Increased risks of serious infections are the major issues concerning the long-term safety of these agents. We present a case of a young male Behcet's patient whose disease was complicated by cytomegalovirus (CMV) colitis. Colitis started 10 d after the third Infliximab dose and responded to the cessation of TNF blocking treatment and administration of ganciclovir. Tumor necrosis factor alpha and interferon gamma act at several levels in combating viral infections. CMV infections should be kept in mind and included in the differential diagnosis of severe gastrointestinal symptoms in patients receiving anti-TNF agents.

**Figure 1** Colonoscopic appearance of the mucosa before (A) and during the 14 d of anti-viral treatment (B). The presence of edema and redness is seen in both images. Note the ulcers in the sigmoid colon before the treatment as shown in A.

carbamazepine (600 mg/d). Physical examination showed epigastric tenderness on palpation, with hyperactive bowel sounds. Admission laboratory studies were significant for increased C-reactive protein (CRP = 14.4 mg/L). Stool examination was negative for parasites and *Clostridium difficile* toxin. Repeated stool cultures were also negative for enteric pathogens. Colonoscopic examination revealed diffuse redness and edematous mucosa and multiple ulcers throughout the colon including rectum and terminal ileum (Figure 1). Histological examination of the biopsy specimen identified cytomegalovirus (CMV) by specific immunohistochemistry (Figure 2). Serological testing revealed a positive CMV immunoglobulin (Ig) G and a negative IgM antibody. CMV pp65 antigenemia as determined by immunofluorescence was also negative. Infliximab was stopped and the patient was given ganciclovir (600 mg/d IV). On the 14th d of treatment, stool frequency decreased to 4-5 per day and repeated colonoscopy revealed edematous mucosa without ulcers. Immunohistochemical staining for CMV turned negative on histopathological examination of the repeat biopsy specimen. Ganciclovir was continued for an additional 14 d. The patient gained 5 kg and his stool frequency decreased to two per day. In a follow-up period of 30 mo, he did not reveal any recurrence of colitis symptoms. TNF targeting treatments were not considered during this period.

## DISCUSSION

We present a case of a young male Behcet's patient whose disease was complicated by CMV colitis. Colitis started 10 d after the third INF dose and responded to the cessation of TNF blocking treatment and administration of ganciclovir.

CMV is a member of the herpesviridae family which is prevalent among the general population with an overall seroprevalence of 30%-70% in developed countries<sup>[3]</sup>. CMV causes a variety of clinical syndromes in immunocompromised patients. Pneumonitis, retinitis and gastrointestinal (GI) CMV disease are the mostly encountered clinical manifestations<sup>[3]</sup>. GI tract may be affected anywhere from the mouth to the anus. Esophagus

**Figure 2** Colonic endothelial cells showing positive nuclear (A) and cytoplasmic (B) immunostaining of the CMV antigen.

and colon are the frequently involved sites. Ulcerations, erosions, and mucosal hemorrhage are the primary macroscopic findings<sup>[4]</sup>. The clinical signs and symptoms vary depending upon the involved areas. Patients with colonic CMV disease may present with diarrhea with or without blood, abdominal pain, urgency and tenesmus accompanied with systemic symptoms such as fever, malaise anorexia and weight loss<sup>[4]</sup>. Diagnosis of CMV infection is based upon the presence of CMV in clinical specimens demonstrated by conventional tissue culture or rapid culture with confirmation by specific monoclonal antibodies, or by detection of the pp65 CMV antigen in peripheral blood leukocytes<sup>[5]</sup>.

Severe CMV infections during TNF targeting treatments have been reported including retinitis<sup>[6]</sup>, hepatitis<sup>[7]</sup>, duodenitis<sup>[8]</sup>, ileitis<sup>[9]</sup>, colitis<sup>[10]</sup> and disseminated CMV infection<sup>[11]</sup>. All these cases received concomitant immunosuppressive treatment in addition to INF. Except for our patient and patients who developed retinitis, all other reported CMV infections developed in subjects who had primary GI problems, such as inflammatory bowel disease, common variable immunodeficiency sprue and indeterminate colitis.

BD may affect the intestine. Intestinal involvement commonly accompanies ulcerative lesions in the small and large bowel. The lesions are most commonly found in the terminal ileum and the cecum and less frequently in the colon. Rectal and anal involvement is quite rare<sup>[12]</sup>. In our patient, clinical symptomatology mimicked intestinal BD. However, diffuse involvement of the colon including the rectum and development of symptoms after the initiation of TNF inhibitory treatment suggested an infectious etiology. Following histopathological examination of the biopsies, which revealed the causative microorganism, colonic CMV disease was diagnosed. Reactivation of the virus was thought since CMV serology was positive for IgG and negative for IgM.

Tumor necrosis factor alpha and interferon gamma act at several levels in combating viral infections. TNF exhibits its antiviral activities against both DNA and RNA viruses by enhancing the induction of antiviral state in uninfected cells and by selectively killing virus-infected cells<sup>[13]</sup>. CD8+ T cells are the major defense against viruses by direct cytolysis of target cells mediated by perforin release and

Fas, or by secreting cytokines such as TNF and interferon- $\gamma$  and expressing chemokines that attract inflammatory cells to the sites of infection<sup>[14]</sup>. It has been shown that treatment with monoclonal antibodies directing against TNF- $\alpha$  is associated with a progressive loss of CD4+ and CD8+ T cells<sup>[15]</sup>. In addition, Infliximab treatment has been reported to be associated with decreased levels of TNF- $\alpha$  and interferon- $\gamma$ <sup>[16]</sup>. On the other hand, TNF levels are increased during CMV infection and CD4+ T cells specific for the human CMV result in early gene products<sup>[17]</sup>. Up-regulation of TNF gene expression by CMV<sup>[18]</sup> is the major cause for the increased TNF. It has been shown that increased TNF production in response to CMV infection displays anti-CMV activity *in vitro*<sup>[19]</sup>. Furthermore, recombinant TNF- $\alpha$  possesses anti-CMV activity<sup>[17]</sup>.

In conclusion, TNF- $\alpha$  in line with interferon- $\gamma$  acts at several levels in combating viral infections. Blocking the action of TNF- $\alpha$  with novel medications may predispose these patients to serious viral diseases. CMV infections should be kept in mind and included in the differential diagnosis of severe gastrointestinal symptoms in patients receiving Infliximab.

### Abstract

Developmental anomalies of the pancreas have been reported but dorsal pancreatic agenesis is an extremely rare entity. We report an asymptomatic 62-year-old woman with complete agenesis of the dorsal pancreas. Abdominal computed tomography (CT) revealed a normal pancreatic head, but pancreatic body and tail were not visualized. Magnetic resonance imaging (MRI) findings were similar to CT. At magnetic resonance cholangiopancreatography (MRCP), the major pancreatic duct was short and the dorsal pancreatic duct was not visualized. The final diagnosis was dorsal pancreatic agenesis.

### INTRODUCTION

Agenesis of the dorsal pancreas is an extremely rare anomaly which results from defective pancreas formation. A few case reports have been published in the literature about this anomaly. Agenesis of the dorsal pancreas is mostly asymptomatic but abdominal pain, pancreatitis and

diabetes mellitus may be associated<sup>[1]</sup>. We present a case of asymptomatic dorsal pancreatic agenesis.

### CASE REPORT

A 62-year-old female patient was admitted to our hospital with a prediagnosis of gastric lymphoma. The patient has a suspicion of lymphoma with gastroscopy. The biochemical evaluation of the patient revealed mild elevation of fasting plasma glucose (126 mg/dL; reference range: 70-115 mg/dL<sup>[1]</sup>). Pancreatic amylase and lipase levels in serum were within normal limits. On abdominal computed tomography (CT), perigastric lymph nodes were demonstrated ranging between 10 mm and 20 mm. At this examination pancreas body and tail were not seen. Pancreatic head and neck were normal in size and shape (Figure 1A and B). Upper abdominal Magnetic resonance imaging (MRI) and magnetic resonance cholangiopancreatography (MRCP) were carried out with the suspicion of dorsal pancreatic agenesis. At MRCP, the major pancreatic duct was short and the dorsal pancreatic duct was not visualized (Figure 2A and B).

### DISCUSSION

The pancreas develops by ventral and dorsal endodermal buds. The dorsal bud forms the upper part of the head, body and tail of the pancreas which drains through the Santorini duct. The ventral bud gives rise to the major part of the head and uncinate process which drains through Wirsung duct<sup>[1]</sup>. Agenesis of the ventral pancreas and complete agenesis of the pancreas are lethal conditions<sup>[2]</sup>. Dorsal pancreatic agenesis is an extremely rare congenital anomaly. In the literature, about 23 cases of partial agenesis of dorsal pancreas were reported between 1913 and 2007. Pancreas divisum and autodigestion secondary to chronic pancreatitis must be considered in the differential diagnosis of the dorsal pancreatic agenesis. Failure of the ventral and dorsal pancreatic ducts to fuse is called pancreas divisum. In this entity, the ventral duct drains into major papilla, while the dorsal duct drains into separate minor papilla<sup>[1]</sup>. Atrophy of the body and the tail of the pancreas secondary to chronic pancreatitis and sparing of the pancreatic head is called pseudo-agenesis<sup>[3]</sup>. This situation may mimic dorsal pancreatic agenesis. In the differential diagnosis of pseudo-agenesis, histories of previous abdominal pain, pancreatitis, CT scanning and the serum amylase level may be helpful. The complete absence of the dorsal duct and demonstration of short ventral duct is important in the diagnosis of the dorsal bud agenesis. Abdominal CT may not evaluate the pancreatic duct in a

**Figure 1** Axial CT (A) and thick-slice coronal oblique MIP CT (B) images show the pancreatic head (arrow) and the absence of the corpus and tail of the pancreas.

detailed fashion. Therefore ERCP or MRCP is necessary for revealing the major and the accessory duct systems. ERCP is an invasive technique. It might challenge the cannulation of the minor papilla in selected cases. There is also radiation risk to the patient. MRCP can help the diagnosis of the dorsal pancreatic agenesis noninvasively with no radiation risk<sup>[4-6]</sup>.

In our patient, distal pancreas was absent on CT and MRI images. On MRCP, dorsal duct system was not visualized and a short ventral duct was present which supports the diagnosis of dorsal pancreatic agenesis. In summary, this extremely rare congenital anomaly must be kept in mind when the corpus and tail of the pancreas are not seen at routine examinations or as in our case an incidental finding at the examinations for different pathologies.

**Figure 2** Abdominal axial T1-weighted MR image (A) reveals pancreatic head; MRCP demonstrates a short major pancreatic duct (arrow) and dorsal duct is not visualized (B).

### Abstract

Major complications of endoscopic retrograde cholangiopancreatography (ERCP) include pancreatitis, hemorrhage, cholangitis, and duodenal perforation. The occurrence of free air in the peritoneal cavity post-ERCP is a rare event (< 1%), which is usually the result of duodenal or ductal perforation related to therapeutic ERCP with sphincterotomy. We describe for the first time a different aetiology of pneumoperitoneum, in an 84-year-old woman with pancreatic cancer and a large hepatic metastasis, after ERCP with common bile duct stent deployment. Our patient developed pneumoperitoneum due to air leakage from rupture of intrahepatic bile ducts and Glisson's capsule in the area of a peripheral large hepatic metastasis. The potential mechanism underlying this complication might be post-ERCP pneumobilia and increased pressure of intrahepatic bile ducts leading to rupture of intrahepatic bile ducts in the liver metastatic mass owing to neoplastic tissue friability. This case indicates the need for close clinical and radiological observation of patients with hepatic masses (primary or metastatic) subjected to ERCP. In such patients, avoidance of excessive air insufflation during ERCP and/or placement of a nasogastric tube for bowel decompression immediately after ERCP might be a reasonable strategy to prevent such unusual complications.

### INTRODUCTION

Endoscopic retrograde cholangiopancreatography (ERCP) and sphincterotomy are increasingly used in the diagnosis and management of patients with pancreaticobiliary diseases, carrying a lower morbidity and mortality rate than surgery<sup>[1]</sup>. This invasive procedure has been proven to be a safe and effective method for diagnosis and treatment of biliary and pancreatic disorders, with a very low rate of complications even in the very old (> 80 years old) patients despite the higher prevalence of co-morbidities<sup>[2,3]</sup>.

Major complications of ERCP include pancreatitis, hemorrhage, cholangitis, and duodenal perforation<sup>[4,5]</sup>. Pneumoperitoneum occurring after ERCP is usually a sinister sign of bowel or ductal perforation<sup>[6,7]</sup>. We describe for the first time a case of post-ERCP pneumoperitoneum in an 84-year-old woman due to air leakage from rupture of intrahepatic bile ducts and Glisson's capsule in the area of a large hepatic metastasis.

### CASE REPORT

An 84-year-old woman with a past medical history of a carcinoma of the head of the pancreas with hepatic and lung metastases, who underwent an ERCP with stent placement because of obstructive jaundice at the time of diagnosis two months ago, was admitted again to our department because of icterus.

At admission, physical examination was unremarkable except for the presence of skin and conjunctival icterus. Initial laboratory evaluation confirmed the cholestatic

**Figure 1** Contrast-enhanced abdominal CT showing an extensive necrotic air-containing lesion touching Glisson's capsule in the posterior right hepatic lobe within a metastatic hepatic mass (asterisk) and free air (arrow) (A). The metallic stent in the common bile duct is at the proper position and there is pneumobilia of the common bile duct and intrahepatic bile ducts of the metastatic mass in the posterior right hepatic lobe (B).

syndrome [total bilirubin = 8.13 mg/dL (reference range 0.1-1.3 mg/dL), direct bilirubin = 5.6 mg/dL (reference range < 0.4 mg/dL),  $\gamma$ -glutamyl-transaminase = 386 IU/L (reference range 10-50 IU/L), alkaline phosphatase = 541 IU/L (reference range 34-104 IU/L), aspartate aminotransferase = 510 IU/L (reference range 5-40 IU/L) and alanine aminotransferase = 413 IU/L (reference range 5-40 IU/L)]. An upper abdominal ultrasound showed a significant dilatation of the common bile duct and a hypoechoic mass of the right lobe of the liver (known metastasis). The patient underwent a second ERCP to check the stent's patency, function and position. The stent was found to be partially obstructed by tumor ingrowth and reopened by placing a new stent through the previous one. Cholangiography after stent deployment showed that the endoprosthesis was at a correct position and fully expanded, whilst there was a free contrast medium flowing to the common bile duct without any leakage. On the next day, the patient complained of distending abdominal discomfort. Physical examination showed that the patient was afebrile, hemodynamically stable, with abdominal distension but no signs of acute abdomen, such as guarding or rebound tenderness. The peripheral blood cell count showed leukocytosis ( $27\,000/\text{mm}^3$ , with 94% of neutrophils). An urgent contrast-enhanced abdominal computed tomography (CT) scan was performed, demonstrating the presence of free air in the peritoneal cavity, mainly perihepatically (Figure 1). There was no evidence of pneumoretroperitoneum, extraluminal contrast medium leakage or intraperitoneal fluid collection on computed tomography. Beyond the known tumour of the head of the pancreas, the abdominal CT showed that the metallic stent was at the proper position within the common bile duct and that there was pneumobilia of the common bile duct and intrahepatic bile ducts. At the position of the known large metastatic mass of the right hepatic lobe, there was an extensive necrotic air-containing lesion touching Glisson's capsule. The patient was treated conservatively, under close clinical surveillance, with no oral intake of, analgesics and systemic broad-spectrum antibiotics (meropenem, 1 g, three times a day and teicoplanin, 12 mg/kg per day), nasogastric drainage and intravenous fluid replacement. The patient's condition was gradually improved, oral feeding was reinstituted on post-ERCP day 10 without problems and she was discharged in a good condition on post-ERCP d 14.

## DISCUSSION

Major complications of ERCP include pancreatitis, hemorrhage, cholangitis, and duodenal perforation<sup>[4,5]</sup>. The occurrence of free air in the peritoneal cavity post-ERCP is usually the result of duodenal or ductal perforation related to therapeutic ERCP and sphincterotomy<sup>[4,6-8]</sup>. Given that the overall incidence of duodenal and common bile duct perforations is about 1% and most of these cases (80%) have retroperitoneal perforations causing pneumoretroperitoneum, it becomes apparent that post-ERCP pneumoperitoneum is a very rare complication<sup>[4]</sup>.

In our patient, the developed post-ERCP pneumoperitoneum was considered benign in nature as it was not accompanied with peritonitis. The use of contrast-enhanced abdominal CT was helpful in excluding ERCP-related retroperitoneal and bowel perforation, as demonstrated by the absence of pneumoretroperitoneum, extraluminal contrast medium leakage or abnormal intra-abdominal fluid collection. Also the cholangiogram obtained during ERCP after endoprosthesis deployment did not demonstrate any contrast medium leakage secondary to common bile duct injury. Surprisingly, the abdominal CT revealed a large necrotic air-containing lesion in a metastatic mass of the right hepatic lobe, touching Glisson's capsule, suggesting that air from this lesion can pass into the peritoneal cavity through rupture of Glisson's capsule. Analytically, the development of pneumoperitoneum in our patient may result from (1) air insufflation during ERCP leading to bowel distension, (2) retrograde airflow through the widely patent biliary tract after metallic stent deployment, (3) increased pressure of intrahepatic bile ducts and pneumobilia due to ERCP manipulations and retrograde airflow, (4) rupture of intrahepatic bile ducts of the liver metastatic mass owing to neoplastic tissue friability, (5) development of a necrotic air containing cavity in the liver metastatic mass touching Glisson's capsule, and (6) rupture of Glisson's capsule with subsequent air leakage in the peritoneal cavity.

Although there are data on the conservative or surgical management of duodenal perforations complicating ERCP, no previous experience with such an unusual complication is available. There are only scarce reports on benign pneumoperitoneum successfully managed with conservative treatment after endoscopic biliary procedures<sup>[9]</sup>. Regarding the management of ERCP-related duodenal perforations, arguments have been made about

both surgical<sup>[10-12]</sup> and non-surgical management<sup>[13]</sup>. Stapfer and colleagues<sup>[14]</sup> analyzed fourteen cases of ERCP-related perforations and concluded that patients with no peritonitis, sepsis, significant contrast medium leak during ERCP or follow-up upper gastrointestinal study, and retro- or intraperitoneal fluid collections during computed tomography, can be successfully managed conservatively. Based on these criteria, we decided to treat our patient conservatively under frequent clinical re-evaluation for the early recognition of the potential need for surgical treatment. Our patient's rare post-ERCP complication was successfully treated conservatively without need for surgical intervention.

In conclusion, this is the first report of post-ERCP pneumoperitoneum caused by rupture of intrahepatic bile ducts and Glisson's capsule in the area of a large peripheral hepatic metastasis. This case indicates the need for close clinical and radiological observation of patients with hepatic masses (primary or metastatic) subjected to ERCP. In such patients, avoidance of excessive air insufflation during ERCP and/or placement of a nasogastric tube for bowel decompression immediately after ERCP might be a reasonable strategy to prevent such unusual complications.

## Abstract

The paper studies the combined radiologic and endoscopic approach (rendez vous technique) to the treatment of the biliary complications following liver transplant. The "rendez-vous" technique was used with an electrokinetic lithotripter, in the treatment of a biliary anastomotic stricture with multiple biliary stones in a patient who underwent orthotopic liver transplant. In this patient, endoscopic or percutaneous transhepatic management of the biliary complication failed. The combined approach, percutaneous transhepatic and endoscopic treatment (rendez-vous technique) with the use of an electrokinetic lithotritor, was used to solve the biliary stenosis and to remove the stones. Technical success, defined as disappearance of the biliary stenosis and stone removal, was obtained in just one session, which definitively solved the complications. The combined approach of percutaneous transhepatic and endoscopic (rendez-vous technique) treatment, in association with an electrokinetic lithotritor, is a safe and feasible alternative treatment, especially after the failure of endoscopic and/or percutaneous trans-hepatic isolated procedures.

## INTRODUCTION

Biliary complications after liver transplant are a very common and important problem (8%-50%)<sup>[1,2]</sup>. Untreated biliary complications are associated with high morbidity and mortality rates. Magnetic resonance is an effective technique in the diagnosis of the biliary complications<sup>[3]</sup>, whereas Endoscopic retrograde cholangiopancreatography (ERCP)<sup>[4,5]</sup>, and Percutaneous Transhepatic Cholangiography (PTC) remain the gold standard therapeutic options (with successful results in between 70% and 80% of cases)<sup>[6,7]</sup>. Common biliary complications after liver transplant are leaks and strictures, which are divided into anastomotic and non-anastomotic groups. Other less frequent complications include stones, cuts, and oddities<sup>[8,9]</sup>.

We report a case of biliary anastomotic stenosis with multiple biliary stones in a patient after orthotopic liver transplantation, treated with a combined percutaneous radiologic and endoscopic approach (rendez - vous technique) and with the use of an electrokinetic lithotritor.

## CASE REPORT

A 67-year-old man underwent orthotopic liver transplantation for HCV related cirrhosis in 2000, with a choledocho - choledocho anastomosis. The surgical procedure was complicated by renal failure which

**Figure 1** A CT scan showing severe obesity and umbilical laparocoele.

was treated with hemodialysis for 1 mo. No vascular abnormalities were present at the Doppler ultrasound examination. Five years later, after an unsuccessful antiviral treatment for HCV recurrence, medium size esophageal varices were diagnosed. Other co-morbidities present at that time were severe obesity and hypertension.

The patient was recently admitted to our facility because of the onset of severe cholestasis with episodes of cholangitis, and for a general reassessment of the liver disease.

At admission, physical examination showed severe obesity (BMI > 30) and umbilical laparocoele (Figure 1). Laboratory data were the following: AST/ALT 130/187 U/L (normal, 5/65 U/L-40/65 U/L), bilirubin tot/dir 26.46/19.69 mg/dL (0-1.5 mg/dL), alkaline phosphates 357 U/L (40 U/L-134 U/L), gamma-GT 1161 mg/L (5 U/L-85 U/L). A Magnetic Resonance Cholangiography was not performed because of the severe obesity; ERCP was therefore planned. Under general anesthesia, the choledochus was cannulated, showing a mild anastomotic stricture with a very tight angle, just above the stricture, multiple stones above the stenosis and at the confluence, and mild intrahepatic biliary dilation (Figure 2). A guide wire was passed through the stenosis, but because of the stones and the kinking, it was impossible to cross, by the guide wire, either Dormia basket, Fogarty or other catheters. Because of ERCP failure, a PTC was planned. In the angiographic room, under sonographic and fluoroscopic control, a peripheral right biliary duct was punctured with a 20 G needle. A cholangiogram showed a mild biliary dilation and multiple filling defects. It was impossible to put a guide wire into the choledochus, and thus a 6.6 F Ring external catheter (Boston Scientific, MA, USA) was placed for bile drainage. One week later, a second cholangiogram was performed and a 6.6 Fr external - internal biliary catheter (Boston Scientific) was successfully placed (Figure 3).

In the following days, because of worsening jaundice (bilirubin tot/dir 34.22/28.78 mg/dL), a combined radiologic and endoscopic technique (rendez vous technique) was performed. In the angiographic suite under general anesthesia, the patient was monitored continuously with electrocardiography, pulse oximeter and automatic recording of blood pressure and pulse. Intravenous

**Figure 2** A first attempt of ERCP showing multiple stones and anastomotic stricture.

**Figure 3** PTC with external - internal catheter placement.

antibiotic prophylaxis was given before the procedure. After visualizing the biliary tree, and under fluoroscopic control, on an Amplatz guide wire, the biliary drainage was changed with a 7 Fr vascular introducer (St. Jude Medical, Minnetonka, USA).

With an electro - kinetic lithotripter, a ballistic lithotripter which uses high-energy magnetic fields (Electro Medical Supplies, LTD), placed through the introducer, percutaneous lithotripsy was performed (Figure 4A). A percutaneous balloon dilatation of the anastomotic stricture was then performed using an 8 mm balloon catheter (Blumax, Boston Scientific, MA, USA) and, at the same time, under endoscopic control, the stones were completely removed with a Fogarty balloon and a Dormia basket (Figure 4B). A final cholangiogram showed no filling defects or stricture (Figure 4C) and, at the end of the procedure, a 12 Fr external - internal biliary drainage was finally placed (Boston Scientific, MA, USA) (Figure 4D).

Two days later, laboratory data showed: AST/ALT 28/29 U/L (normal, 5/65-40/65 U/L), bilirubin tot/dir 6.5/5.3 mg/dL (0-1.5 mg/dL), alkaline phosphates 104 U/L (40-134 U/L), gamma-GT 107 mg/L (5-85 U/L).

Two months after the procedure, the patient has a biliary catheter in place, is asymptomatic, in good general condition, without signs of cholestasis and in follow up for biliary catheter removal.

## DISCUSSION

Biliary complications after liver transplant are common and biliary stones represent a small part of these<sup>[1,2]</sup>. In

**Figure 4** **A:** With a ballistic lithotripter, placed through the introductory, percutaneous lithotripsy was performed; **B:** Fragmented stones were removed with a Fogarty balloon; **C:** Normal Cholangiography after lithotripsy and stenosis dilation; **D:** An external - internal catheter was placed.

the majority of cases, ERCP alone is not only the best diagnostic and therapeutic treatment with a successful result in 70%-80% of cases<sup>[4,5,10]</sup> but is also considered the least invasive procedure, although with some important complications<sup>[9]</sup>. Western studies showed the efficacy of percutaneous transhepatic cholangioscopy (PTHC) and holmium:yttrium-aluminum-garnet (YAG) laser to remove biliary stones in patients unable or unwilling to undergo endoscopic or surgical removal, but this technique requires much time and prolonged biliary access<sup>[11]</sup>.

In our patient, endoscopic management was attempted first, but we were unable to place a stent in a correct position or to remove the stones, because of the severe biliary stenosis. By a percutaneous transhepatic approach however, we were able to place an external - internal biliary catheter, though not to remove the stones or solve the stenosis.

By a combined technique - radiologic and endoscopic procedure (i.e. the “rendez-vous” technique), associated with the use of a ballistic lithotripter which usually fragments nearly all urinary calculi, we were able to remove the stones and to solve the stenosis.

The rendez-vous technique has been described in the treatment of benign or malignant biliary obstruction, in traumatic bile duct injury repair and in the treatment of large biliary leaks in a liver transplant recipient<sup>[12-15]</sup>. But, to our knowledge, this is the first report of the use of this technique in treatment of biliary stones and anastomotic stenosis, with the use of a ballistic lithotripter in a patient after liver transplantation.

In conclusion, the radiological/endoscopic rendez-vous technique, associated with an electrokinetic lithotritor, is a feasible alternative for stone removal and biliary stricture treatment, especially after the failure of endoscopic

and/or percutaneous trans-hepatic isolated procedures. Also, this combined approach improve costs, timing and effectiveness in the therapy of biliary complications.

## Abstract

A 79-year-old man was referred to this department due to the presence of extrahepatic bile duct carcinoma with a tumor at the left chest wall. The lesion was suspected to be a metastasis of bile duct carcinoma to the left wall, however, computed tomography (CT) revealed no regional lymph node or liver metastases. In addition, cytological and pathological examinations did not show malignancy. At the time of admission, the white blood cell count was 21 460 cells/ $\mu$ L (neutrophils, 18 240 cells/ $\mu$ L) and this elevated to 106 040 before death. In addition, serum granulocyte colony-stimulating factor (G-CSF) was elevated. At 28 d after admission, the patient died. An autopsy showed a poorly differentiated adenocarcinoma with sarcomatous change, which had slightly invaded into the pancreas around the bile duct, and was found in the distal bile duct with multiple metastases to the chest wall, lung, kidney, adrenal body, liver, mesentery, vertebra and mediastinal and para-aortic lymph nodes, without locoregional lymph node and liver metastasis. The cancer cells showed positive immunohistochemical staining for anti-G-CSF antibody. This is believed to be the first report of an extrahepatic bile duct carcinoma that produces G-CSF. Since G-CSF-producing carcinoma and sarcomatous change of the biliary tract leads to poor prognosis, early diagnosis and treatment are needed. When infection is ruled out, the G-CSF in serum should be examined. In addition, examinations such as bone

## INTRODUCTION

Granulocyte colony-stimulating factor (G-CSF) produced in some cancers is thought to be an autocrine growth factor<sup>[1,2]</sup>. Therefore, patients with G-CSF-producing cancer generally have a poor prognosis, and early diagnosis and treatment are required. Biliary cancer, such as cholangiocellular and gallbladder carcinoma are reported to produce G-CSF in some cases<sup>[3-10]</sup>, however, extrahepatic bile duct cancer that produces G-CSF has not yet been reported.

This report describes a case of extrahepatic bile duct cancer that produced G-CSF, in which neither regional lymph node metastasis nor massive progression was observed by radiological examination, but autopsy showed multiple organ metastasis.

## CASE REPORT

A 79-year-old man who suffered from left lateral chest pain for one month was referred to our department for treatment of a tumor on the left chest wall and extrahepatic bile duct cancer found during an annual medical examination. His body temperature was 36.9°C. From the left axillar to anterior axillary line of the left chest wall, many nodules, 5-10 mm in diameter, were palpated, without tenderness. He had no history of chest trauma. Chest radiography showed massive pleural effusion

**Figure 1** Chest radiography revealed massive pleural effusion and a tumor elevating smoothly from the left chest wall (arrowheads), near which the fifth rib could not be traced.

**Figure 3** Bone scintigraphy showed an abnormal opaque uptake in the left third to fifth ribs (arrows).

**Figure 2** Chest CCT depicted a mass with necrosis inside the tumor (arrows) and enhancement of its border (arrowheads), and extrapleural tumor and pleural effusion.

**Figure 4** Abdominal CT revealed a gradually enhanced tumor in the distal bile duct (arrows), without any regional lymph node or liver metastasis.

and a tumor that elevated smoothly from the left chest wall, near which the fifth rib could not be traced (Figure 1). Enhanced chest computed tomography (CT) depicted a mass with necrosis inside the tumor and enhancement on its border, as well as two osteolytic lesions on the seventh thoracic vertebra, swelling of many anterior mediastinal and left axillary lymph nodes, and pleural effusion around extrapleural fluid collection (Figure 2). Enhanced magnetic resonance imaging (MRI) of the chest showed extensive enhancement of the muscle and connective tissue around the ribs, as well as a cavity within the muscle. Bone scintigraphy showed an abnormal opaque uptake in the left third to fifth ribs and vertebrae (Figure 3). Cytopathology of the pleural and extrapleural effusion showed solitary atypical cells, regarded as histiocytes, scattered in numerous inflammatory cells. Those atypical cells had swelling nuclei and a distinct eosinophilic nucleolus; however, it was difficult to diagnose the lesion as an adenocarcinoma from the chromatin pattern. Abdominal CT demonstrated a gradually enhanced tumor in the distal bile duct, without any regional lymph node and liver metastasis (Figure 4), and magnetic resonance cholangiopancreatography (MRCP) revealed stenosis of the distal common bile duct (Figure 5). Laboratory data showed an increase in the following: white blood cell count (WBC) 21 460 cells/ $\mu$ L (neutrophils, 18 240 cells/ $\mu$ L), ALP 536 IU/L,  $\gamma$ -GTP 300 IU/L, LDH 251 IU/L, CRP 4.33 mg/dL, but carcinoembryonic antigen (CEA), carbohydrate antigen 19-9 (CA19-9) and DU-PAN-2, a tumor marker which is especially elevated in

**Figure 5** MRCP revealed stenosis (arrow heads) of the distal common bile duct.

pancreato-biliary cancer patients, were within the normal limit. The neutrophil alkaline phosphatase (NAP) score was elevated to 381 to exclude chronic myeloblastoid leukemia.

Histological examination of the nodule on the chest wall that was partially resected for diagnosis revealed scattered atypical cells among numerous fibroblasts, macrophages and neutrophils in the skeletal muscle and adipose tissue. These atypical cells showed positive immunohistochemical staining for pan-cytokeratin and vimentin, but not for desmin, which excluded leiomyosarcoma (Figure 6). Since such atypical cells had no epithelial connection or basement membrane, they

**Figure 6** Histological examination of the resected chest wall showed scattered atypical cells among numerous inflammatory cells (A). Immunohistochemistry for pan-cytokeratin as an epithelial cell marker (B) and vimentin as a mesenchymal cell marker (C) both showed positivity in these atypical cells.

were thought to be reactive mesothelial and not carcinoma cells. Therefore, the pathological diagnosis was considered to be either proliferative myositis or nodular fasciitis-like granuloma.

Eighteen days after admission the patient's appetite, consciousness and daily activity deteriorated, and WBC was elevated to 86 050 cells/ $\mu$ L (neutrophils, 80 880 cells/ $\mu$ L) without pyrexia. Until then, no bacterium was seen in the sputum, pleural effusion and fluid in the chest wall cavity. Expecting an improvement of his general condition and inflammation of myositis on the left chest wall, we drained pleural effusion fluid and the patient received an injection of dexamethasone. However, his general condition and laboratory data did not improve. WBC increased to 106 040 cells/ $\mu$ L (neutrophils, 91 900 cells/ $\mu$ L) before death. Twenty-seven days after admission, a multiple cerebral infarction was found, which had not been observed 7 d earlier. The patient died the following day and

**Figure 7** Histological examination revealed a poorly differentiated adenocarcinoma with sarcomatous change in the distal bile duct, which slightly invaded into the pancreas (A), and cancer cells showed positive immunohistochemical staining for G-CSF (B).

underwent an autopsy.

The autopsy revealed a poorly differentiated adenocarcinoma with sarcomatous change, which had slightly invaded into the pancreas in the distal bile duct (Figure 7A). In addition, no other primary cancer was observed macroscopically in the chest and abdomen. The cancer cells showed positive immunohistochemical staining for G-CSF (Figure 7B). The G-CSF concentration in serum samples archived by the hospital was 53, 38 and 134 pg/mL on 21, 23 and 26 d after admission, respectively (normal < 18 pg/mL). This result was obtained 9 d after death. In a specimen of the left chest wall, solitary cancer cells, numerous surrounding inflammatory cells such as neutrophils and macrophages, had invaded into the skeletal muscles, similar to the biopsy tissue. Therefore, the pathological diagnosis of the left chest wall was a metastasis of the bile duct carcinoma with sarcomatous change, and the anterior mediastinal lymph nodes showed the same histological findings. Moreover, under the serosa of the mesentery and liver, some white nodules, measuring 5 mm in diameter, were macroscopically discovered and their histology showed them to be metastases. In addition, histological examination of all the organs in the chest and abdomen demonstrated multiple metastases in the lung, kidney, adrenal gland, mesentery, vertebral bone marrow and mediastinal and para-aortic lymph nodes. In contrast, no metastasis was found in the regional lymph nodes. These findings proved the presence of extensive systemic dissemination of cancer cells.

## DISCUSSION

This is believed to be the first report of an extrahepatic bile duct carcinoma that produces G-CSF. A search of PubMed by the key words CSF and biliary cancer, revealed three and five reports, respectively, of intrahepatic cholangiocarcinoma and gallbladder carcinoma<sup>[3-10]</sup>, but there have so far been no reports of extrahepatic bile duct malignancy. While two of these patients underwent curative surgery and survived without recurrence for 18 mo and 27 mo, respectively<sup>[6,8]</sup>, three patients died within 6 mo after palliative or exploratory surgery<sup>[3,5,9]</sup>. In one case, the details of the surgery were unknown<sup>[4]</sup>, and the other was a report of archival histological examination<sup>[7]</sup>. In a case of rapid progression, the patient died 5 d after admission<sup>[10]</sup>. As with other organs such as the lung, thyroid and kidney, the prognosis of G-CSF-producing carcinoma in the biliary tract is considered to be poor, and early diagnosis and surgical treatment are needed. In the present case, surgery could not have been performed, even if the diagnosis had been done correctly and rapidly. However, an early examination of G-CSF in the serum would have identified the lesions as multiple metastasis of a common bile duct cancer, thereby leading to more appropriate treatment, such as chemotherapy. To avoid wasting time with additional radiological examination and inefficient treatment such as antibiotics for leukocytosis, G-CSF in serum should be examined when bacterial infection is ruled out for leukocytosis by a routine preoperative examination.

In this case, it was not possible to diagnose the correct extent of the carcinoma, in spite of various radiological and pathological data. This was because the accumulation of inflammatory cells induced by G-CSF produced by the cancer cells in the metastatic lesions mimicked inflammation of the chest wall and vertebra in the radiological and pathological examinations. Furthermore, the lack of loco-regional lymph node and liver metastases in the radiological examination led us to consider other lesions in the differential diagnosis, such as mediastinal lymphadenopathy and chest wall nodules, as an inflammatory reaction from the left chest wall lesion. Although endoscopic ultrasonography was not performed in this case, the loco-regional stage of cancer was diagnosed as stage I a or I b. This type of dissociation between the loco-regional and whole body extent of carcinoma has occasionally been reported with gastric cancer<sup>[11-13]</sup>, however, no report has been found regarding extrahepatic bile duct carcinoma. Scattered carcinoma cells in many inflammatory cells, thus indicating sarcomatous change, could not be correctly diagnosed due to these changes, such as the loss of basal membrane and intercellular connection between cancer cells. Shimada *et al.*<sup>[14]</sup> have reported cholangiocarcinomas with two types of sarcomatous change, spindle and pleomorphic type, which have very poor prognosis, especially the latter type. Moreover, Nakajima *et al.*<sup>[15]</sup> have shown aggressive intrahepatic spreading and widespread metastasis of the sarcomatous cells of an intrahepatic cholangiocarcinoma.

In the present case, dissociation between the findings of the loco-regional and whole body examination might have been due to sarcomatous change and G-CSF, which is thought to be a growth factor. For a case of extrahepatic bile duct carcinoma that produces G-CSF, an examination for distant metastasis, such as bone scintigraphy and chest CT, should be considered.

ileal gastrointestinal stromal tumor causing hemoperitoneum. *World J Gastroenterol* 2008; 14(18): 2928-2931 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2928.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2928>

## INTRODUCTION

Gastrointestinal stromal tumor (GIST) is the designation for a major subset of mesenchymal tumors of the gastrointestinal (GI) tract<sup>[1-5]</sup>. GIST arising in the digestive tract is most commonly located in the stomach and small intestine<sup>[6,7]</sup>. GIST originating from the small intestine rarely causes hemoperitoneum<sup>[8]</sup>. Herein, we describe a relatively rare case of extraluminal ileal GIST causing hemoperitoneum.

## Abstract

We describe an 87-year-old woman with a large ileal gastrointestinal stromal tumor (GIST) causing hemoperitoneum. A CT scan demonstrated a large heterogeneous mass measuring about 13 cm × 11 cm in the pelvis and hemoperitoneum, with a non-uniform enhancement pattern. The mass was diagnosed as a GIST originating from the gastrointestinal tract. She underwent an urgent laparotomy and an ileal GIST with a rupture was found 130 cm from the anal to the Treitz's ligament. Hemoperitoneum caused by ileal GIST rupture is a rare condition. Bleeding in the large tumor leading to rupture of the capsule might cause hemoperitoneum in the present case.

## CASE REPORT

An 87-year-old woman presented with the symptom of a short loss of consciousness. She was in good health with no specific family or past medical history. Her body temperature was 36.7°C, blood pressure was 148/82 mmHg, radial pulse rate was 72 beats/min and regular. She had slight anemia, but no jaundice. Neurological examination revealed no abnormal findings and lymphadenopathy. Abdominal palpation revealed tenderness in the right lower quadrant. Laboratory tests showed a red blood cell count of  $315 \times 10^4/\mu\text{L}$  [normal range (NR),  $380-500 \times 10^4/\mu\text{L}$ ], a white blood cell count of  $10\,500/\mu\text{L}$  (NR,  $4000-9000/\mu\text{L}$ ), a platelet count of  $29.8 \times 10^4/\mu\text{L}$ , and a hemoglobin concentration of 10.1 g/dL (NR, 12-16 g/dL). The levels of hepatic and biliary enzymes, such as aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase (ALP), leucin aminopeptidase (LAP), and  $\gamma$ -glutamyltranspeptidase ( $\gamma$ -GTP) were normal except for lactate dehydrogenase (LDH) which was 336 IU/L (NR, 106-211 IU/L). A test for C reactive protein revealed a level of 30.3 mg/dL (NR, < 0.5 mg/dL). Renal function tests showed that the blood urea nitrogen level was 38.0 mg/dL (NR, 8-20 mg/dL) and the creatinine level was normal. Serological studies for hepatitis B and C viruses were negative. Urinary protein and sugar were negative. A computed tomography (CT) scan demonstrated a large heterogeneous mass measuring about 13 cm × 11 cm in the pelvis and hemoperitoneum, with a non-

**Figure 1** CT scan demonstrating a large heterogeneous mass with a non-uniform enhancement pattern (white arrow) in the pelvis and hemoperitoneum (black arrows).

**Figure 2** Macroscopic finding of the tumor. **A:** A large tumor (measuring 13 cm × 11 cm) arising from the ileum with extraluminal growth; **B:** The cut surface showing bleeding blood clots in the tumor.

**Figure 3** Microscopic findings of the tumor. **A:** Histological examination demonstrating interlaced bundles of large Bizarre spindle cells without mitotic figures (HE, × 100); **B:** Tumor cells present in the subserosa (black arrow) (HE, × 20).

uniform enhancement pattern (Figure 1). Based on the imaging examination, this tumor was diagnosed as a GIST originating from the GI tract or omentum, although it should be distinguished from an ovarian tumor or an adenocarcinoma of the small bowel. The patient underwent an urgent laparotomy.

At laparotomy, a 13 cm × 11 cm semipedunculated solid tumor that was 130 cm from the anal to the Treitz's ligament, showed extraluminal growth (Figure 2A). The tumor was ruptured with no peritoneal metastasis, and partial resection of the ileum was carried out. The resected tumor was brown-red in color, and had bleeding blood clots (Figure 2B). Histological examination of the resected specimen revealed interlaced bundles of large Bizarre spindle-like tumor cells without mitotic figures (Figure 3A). No fission images were evident. Tumor cells were present in the subserosa (Figure 3B). Immunohistological findings

were negative for CD34,  $\alpha$ -smooth muscle actin (SMA), desmin and S-100 protein, but positive for CD117. Based on the above findings, this tumor was diagnosed as a malignant GIST. The postoperative course was uneventful. The patient has been followed up for 16 mo with no evidence of recurrence.

## DISCUSSION

GIST is the most common mesenchymal tumor of the GI tract and expresses c-kit protein, also known as CD117, which is considered a highly specific marker differentiating GIST from other mesenchymal tumors, such as leiomyomas<sup>[9-11]</sup>. The majority of GISTs occur in the stomach (60%-70%) and small intestine (20%-30%)<sup>[10]</sup>. Approximately, 10%-30% of patients with GIST may be asymptomatic<sup>[11]</sup>. Gastric and small intestinal stromal tumors

Table 1 Summary of 10 cases of small bowel GIST causing hemoperitoneum in Japan (since 2000)

	Author <sup>Ref</sup>	Age	Sex	Year	Tumor location	Tumor size (cm)	Symptoms
1	Ri	45	Male	2000	Ileum	5	Abdominal pain
2	Yanaginuma	58	Male	2001	Ileum	13 × 10 × 8	Abdominal pain
3	Sugawara <sup>[8]</sup>	37	Male	2001	Ileum	4 × 4 × 3	Abdominal pain
4	Okita	79	Male	2003	Ileum	18.5 × 15.7 × 6.5	Abdominal pain
5	Hirose	71	Female	2003	Ileum	7	Vomiting
6	Kinoshita	70	Male	2005	Jejunum	11 × 7	Abdominal pain
7	Saito	62	Male	2006	Ileum	5.0 × 4.5 × 3	Abdominal pain
8	Goto	71	Female	2006	Ileum	9 × 4 × 5	Consciousness loss, vomiting
9	Hisaoka <sup>[13]</sup>	73	Female	2007	Ileum	1	Abdominal pain
10	Present case	87	Female	2007	Ileum	13 × 11	Consciousness loss, abdominal pain

are usually associated with abdominal pain, GI bleeding or palpable mass<sup>[12]</sup>. However, GIST in the small intestine rarely causes hemoperitoneum. A MEDLINE search of the literature has revealed only 10 cases of GIST in the small intestine with hemoperitoneum since 2000, including the present case in Japan<sup>[8,13]</sup> (Table 1). The tumor size was over 5 cm in 9 of the 10 cases. However, Hisaoka *et al*<sup>[13]</sup> have reported a case of small intestinal GIST, measuring about 1 cm in size, with intraperitoneal hemorrhage. Thus, a small GIST does not necessarily have a low risk of bleeding. We found that 7 of the 10 patients were in their sixties or over and GIST was predominant in older patients. The male to female ratio was 6:4. The major symptom was abdominal pain. Two patients had consciousness loss, including our case, which might be related to bleeding.

The mechanism underlying hemoperitoneum might be due to bleeding in the tumor leading to hematoma and rupture of the capsule, or transudation of blood components from the tumor. In the present case, bleeding in the tumor leading to rupture of the capsule might have caused hemoperitoneum. Currently, there is no single prognostic factor that can be used alone to predict tumor behavior. The biological behavior of tumors depends on the location (GIST arising from the small bowel is generally associated with a less favorable outcome than that arising in the stomach)<sup>[14]</sup>. Radiological and surgical factors that have been used to determine malignancy include invasion to adjacent organs, omental or peritoneal seeding, tumor recurrence after surgical resection, and distant metastasis<sup>[9,15]</sup>. Pathological factors that determine malignancy are tumor size, mitotic activity, pleomorphism of nuclei, degree of cellularity, nucleus/cytoplasm ratio, and mucosal invasion<sup>[16]</sup>. The present patient was diagnosed with malignant GIST because of the tumor size and rupture. Although peritoneal metastasis was not seen in the present patient, we should pay attention to tumor recurrence because the tumor was ruptured. This patient remains alive without disease 16 mo after surgery. We should carefully follow up with CT or MRI images and this patient is going to undergo imatinib mesilate therapy if tumor recurrence is identified.

Computed tomography (CT) and MR imaging are useful for the diagnosis of GIST and demonstration of the tumor extent<sup>[17-19]</sup>. Because of the high soft-tissue contrast, MR imaging shows a tendency of GIST toward necrosis and hemorrhage<sup>[20]</sup>. In particular, hemorrhage observed in large tumors is associated with large necrosis.

Because GIST can rupture and result in hemoperitoneum, as in the present case, the presence of hemorrhage inside and outside the tumor should be detected. It is impossible to differentiate benign from malignant GIST confidently based on imaging findings alone. It was recently reported that a markedly enhanced GIST on MRI might demonstrate a higher mitosis index even if it is relatively small<sup>[20]</sup>. To clarify the relationship between MRI and pathological findings, we should accumulate and analyze many cases of GIST. Because of hemoperitoneum, our patient underwent urgent laparotomy but not MRI. In addition, previous reports of contrast-enhanced CT indicate that tumor density and heterogeneity after contrast enhancement may reflect the poor prognosis and tumor response to chemotherapy, respectively<sup>[21,22]</sup>. Further studies on the correlation between imaging diagnosis and pathological findings of GIST are certainly required.

In conclusion, we reported the case of a woman with a large ileal GIST causing hemoperitoneum. It is necessary to know that a large GIST may cause hemoperitoneum, although GIST in the small intestine rarely causes hemoperitoneum.

## Abstract

Hemolymphangioma of the pancreas is a very rare benign tumor. There were only five reports of this disease until March 2008. Herein, we report a case of hemolymphangioma of the pancreas with gastrointestinal bleeding due to duodenal invasion. A 53-year-old man had been admitted a referral hospital because of severe anemia due to gastrointestinal bleeding in December 2005. He was then transferred to our institute with a diagnosis of a tumor of the head of the pancreas with duodenal invasion in January 2006. No abnormalities were revealed except for anemia in laboratory data including CEA and CA19-9. Gastrointestinal endoscopy revealed bleeding at the duodenum. Computed tomography also demonstrated a heterogenous mass at the pancreatic head and suspected invasion to the duodenal wall. Ultrasonography showed a huge mass at the pancreatic head with a mixture of high and low echoic areas. Pylorus-preserving pancreatoduodenectomy was performed. The pancreatic tumor was soft and had invaded to the duodenum. The pathological diagnosis was a hemolymphangioma of the pancreas invaded to the duodenum. His postoperative course was uneventful and he was discharged on the 26th d after surgery. Hemolymphangioma of the pancreas is a very rare benign tumor. In a literature review until March 2008, we found five case reports. Major symptoms are abdominal pain and distension due to the enlarged tumor. However, we experienced a case of hemolymphangioma of the pancreas with gastrointestinal bleeding due to invasion to the duodenum. This disease is a very rare entity, but should be considered when patients have gastrointestinal bleeding.

## INTRODUCTION

Hemolymphangioma of the pancreas is an uncommon disease and basically benign tumor. There were only five reports of this tumor of the pancreas until March 2008<sup>[1-5]</sup>. Vascular tumors of the pancreas are cystic tumors accounting for 0.1% of all pancreatic tumors<sup>[6]</sup>. The most frequent of these pancreatic tumors is lymphangioma.

Major symptoms in this hemolymphangioma are abdominal pain and distension associated with the enlarged tumor. This tumor is commonly a benign disease and has no invasion ability. Herein, we report a case of hemolymphangioma of the pancreas with gastrointestinal bleeding due to invasion to the duodenum.

## CASE REPORT

A 53-year-old man was admitted to a referral hospital because of severe anemia due to gastrointestinal bleeding in December 2005. He was then transferred to our institute with a diagnosis of a tumor of the head of the pancreas with duodenal invasion in January 2006. No abnormalities were revealed except for anemia in laboratory data including tumor markers such as CEA and CA19-9. Gastrointestinal endoscopy revealed bleeding at the duodenum from a flat elevated lesion (Figure 1A). Computed tomography also demonstrated a heterogenous mass at the pancreatic head and suspected invasion to the duodenal wall (Figure 1B). Ultrasonography showed a huge mass at the pancreatic head with a mixture of high and low echoic areas. Endoscopic retrograde cholangio-pancreatography showed no abnormal findings in the bile duct and pancreatic duct. Pylorus-preserving pancreatoduodenectomy was

**Figure 1** A: Gastrointestinal endoscopy revealed bleeding at the duodenum; B: Computed tomography demonstrating a heterogenous mass (arrow) at the pancreatic head and suspected invasion to the duodenal wall (arrowhead).

**Figure 2** Histology consists of a benign soft tissue mass with lymphatic and blood vessels. Arrows show invasion to the duodenal wall.

performed. The pancreatic head tumor was soft and had invaded to the duodenum. Final pathological diagnosis of this tumor was a hemolymphangioma of the pancreas with invasion to the duodenum (Figure 2). His postoperative course was uneventful and he was discharged 26 d after surgery. He is currently enjoying normal life without signs of recurrence.

## DISCUSSION

Hemolymphangioma of the pancreas is an uncommon and benign tumor. In a literature review until March 2008 (PubMed), there were only five reports of this tumor occurring in the pancreas<sup>[1-5]</sup>. The first report by a French group, Couinaud *et al* reported a giant hemolymphangioma

of the pancreas in 1966<sup>[5]</sup>. Banchini *et al* considered this tumor a congenital malformation of the vascular system<sup>[2]</sup>. However, there are no reports that describe invasive features of this tumor.

Most frequent symptoms of this disease in these 5 case reports were abdominal pain and distension associated with enlarged tumor. Other symptoms such as vomiting and nausea are caused by occupied tumor<sup>[5]</sup>. This tumor is commonly a benign disease and has no invasion ability. In this case, the chief complaint was severe anemia caused by duodenal bleeding because of hemolymphangioma of the pancreas which invaded to the duodenum. This symptom is extremely rare. In generally, this disease is benign, but it is possible that this tumor invaded other organs like our case.

Despite its low frequency, this disease should be considered when gastrointestinal bleeding is seen. Surgery including local resection is a definitive modality. All cases in the literature had good postoperative courses as did our case. The risk of recurrence or metastasis seems very low, but careful follow-up is necessary. Herein, we reported a

case of hemolymphangioma of the pancreas head with gastrointestinal bleeding due to duodenal invasion.

## Abstract

Angiosarcoma is a rare tumor that account for less than 1% of all sarcomas. Although hepatic angiosarcoma usually presents with unspecific symptoms, it rapidly progresses and has a high mortality. We report a rare case of primary hepatic angiosarcoma manifested as recurrent hemoperitoneum.

## INTRODUCTION

Angiosarcoma is a rare tumor that account for less than 1% of all sarcomas<sup>[1]</sup>, and only 2% of all primary tumors of liver<sup>[2]</sup>. Although it is rarely observed, it is the third most common primary malignant liver tumor<sup>[3]</sup>. Clinical diagnosis

is usually difficult because the symptoms and signs are unspecific, and tumors are difficult to differentiate from other hepatic tumors radiologically<sup>[4]</sup>. Moreover, although tissue is required for diagnosis, the rate of diagnosis by needle biopsy is not high<sup>[5]</sup>. Angiosarcoma progresses rapidly and has a poor prognosis<sup>[6]</sup>. Treatment guidelines have not been issued as yet, however, we think it important to diagnose angiosarcoma as early as possible. Herein, we report a case of primary hepatic angiosarcoma, which was manifested as recurrent hemoperitoneum.

## CASE REPORT

A 73-year-old woman presented with epigastric pain and right shoulder pain. She had suffered from hypertension for several years, but no other past medical histories. On physical examination, the patient appeared with acutely ill and had right upper quadrant pain and tenderness. A complete blood count and blood chemistry were: hemoglobin 11.3 g/dL, hematocrit 34.2%, white blood count 18400/mm<sup>3</sup> (segmented neutrophil 86.6%), platelet 284000/mm<sup>3</sup>, total protein/albumin 5.7/3.8 g/dL, total bilirubin 0.7 mg/dL, direct bilirubin 0.1 mg/dL, AST 24 IU/L, ALT 36 U/L, ALP 49 IU/L, G-GTP 59 IU/L, PT 13.2 s, and amylase 60. Tumor markers such as alpha fetoprotein, CEA, CA19-9 and CA125 were all within normal limit.

Computed tomography (CT) of the abdomen showed multiple hypervascular masses in the liver and a large amount of hematoma in lesser sac. We thought that a mass in the caudate lobe had ruptured into the abdominal cavity and had caused hemoperitoneum (Figure 1A and B). Transarterial embolization was performed. Her condition then stabilized and she was discharged. However, one month later she revisited the emergency room with identical symptoms. Abdominal CT revealed rupture of two hypervascular mass in the right hepatic lobe. After the 2nd transarterial embolization, she became destabilized. A sono-guided needle biopsy was performed but we failed to confirm a specific diagnosis. Five days after discharge, she visited the emergency room again with the same symptoms. Abdominal CT showed interval increased size of low attenuated lesions with peripheral nodular enhancement in the left lateral and right lobe. One of them shows septum-like and peripheral enhancement within the mass (Figure 1C and D). Transarterial embolization was performed repeatedly (Figure 2) but her vital signs were unstable and bleeding of the hepatic mass continued. On the 8th d after the 3rd embolization, we decided to resect

**Figure 1** Initial abdominal computed tomography images. **A** and **B**: A large amount of hematoma in lesser sac and a lowly attenuated nodular lesion with peripheral globular enhancement in the left lobe. Abdominal CT images after 1 mo; **C** and **D**: increased size of lowly attenuated lesions in the right lobe and the left lateral lobe. One showing septum-like appearance and peripheral enhancement within the mass (black arrow).

**Figure 2** Transarterial embolization images. **A**: A large tumor stain in the lateral segment of left lobe (arrows); **B**: Post-embolization angiogram showing no remained tumor stain.

the left hepatic lobe, which showed active bleeding on abdominal CT scan. In operation, there was much blood in the abdominal cavity. The rupture of hepatic mass at segment 2 and 3 was noted. So we decided to resect the left lateral segment which contained the bleeding mass. However, the intra-abdominal bleeding continued and she finally died of disseminated intravascular coagulation. The postoperative surgical specimen showed a great amount of atypical cells forming solid sheets filled with red blood cells (RBCs), which is suggestive of hepatic angiosarcoma. Immunohistochemical staining for CD31 and CD34 showed diffuse strong positive expression (Figure 3).

## DISCUSSION

Angiosarcoma (AS) can originate from the endothelia of lymphatics or blood vessels and is a rarely encountered type of soft tissue sarcoma<sup>[7]</sup>. Angiosarcoma has a predilection for cutaneous sites in the head and neck region of elderly male patients<sup>[8]</sup>. Moreover, despite its

rarity, hepatic angiosarcoma is the third most common primary malignant tumor of the liver<sup>[3]</sup>. Environmental toxins are suggested to be the etiology of AS, for example, the industrial intermediates thorotrast and vinyl chloride and agricultural insecticides are associated with AS<sup>[9,10]</sup>, as do the anabolic steroids and synthetic estrogens<sup>[11,12]</sup>. However, the majority of hepatic angiosarcomas are not related to the above agents.

Angiosarcoma usually presents with nonspecific symptoms, such as abdominal pain, weight loss and general weakness<sup>[2]</sup>. Its physical findings are ascites, hepatomegaly and jaundice. In this case, the main symptoms were abdominal and right shoulder pain.

Primary hepatic angiosarcoma is difficult to differentiate from other vascular tumors of the liver using radiographic techniques. On ultrasound, single or multiple masses are demonstrated with different echotextures due to different levels of necrosis and hemorrhage<sup>[13]</sup>. On nonenhanced helical CT, tumors present as multiple hypodense masses or as a large solitary hypodense mass. In enhanced view,

**Figure 3** Pathologic findings. **A** and **B**: Atypical cells forming solid sheets filled with RBCs (HE stain,  $\times 200$ ,  $\times 400$ , respectively); **C** and **D**: Immunohistochemical staining for CD31 and CD34 showing diffuse strong positive expression ( $\times 200$ ,  $\times 400$ , respectively).

some of the masses are hyperattenuated while others remain hypoattenuated<sup>[14]</sup>. Within hyperattenuated mass areas, an area of hypoattenuation may be seen, which reflect areas of necrosis and/or old hemorrhage. The delayed scans of some lesions show progressive enhancement over minutes due to the vascular nature of the tumor<sup>[15]</sup>. In this case, multiple heterogeneous and lowly attenuated lesions with septum like structures were observed on CT scans. Arteriportal shunting is not seen in hemangiomas, and if it is present, it favors a diagnosis of angiosarcoma<sup>[16]</sup>. The magnetic resonance imaging findings of angiosarcomas and hemangiomas are also similar. Liver biopsies in angiosarcoma patients are accompanied by risks of morbidity and mortality, because the vascular nature of the tumor and its tendency to hemorrhage make the percutaneous biopsy dangerous<sup>[2]</sup>. Microscopic features include sinusoidal and solid patterns. The sinusoidal pattern is characterized by the proliferation of single or multilayered tumor cell along sinusoids which show sinusoidal dilation, atrophy of liver cell cords. The solid pattern is composed of spindle and polyhedral cells, which form a solid tumor nest without significant vascular spaces<sup>[17]</sup>. The immunohistochemical staining for CD31 and factor VIII related antigen can aid diagnosis<sup>[18]</sup>.

The treatment of hepatic angiosarcoma has not been defined because of its rarity and associated mortality. The median survival is 6 mo if not treated and only 3% of patients live longer than 2 years<sup>[2]</sup>. Hepatic resection is indicated when the tumor is localized to one lobe and the remainder of the liver is relatively normal<sup>[19]</sup>. However, patients meeting these criteria are extremely rare. Timaran *et al.*<sup>[20]</sup> reported a case of hepatic angiosarcoma with a long postoperative survival after complete surgical resection of the tumor.

Radiation therapy to the liver has been used to palliate liver metastases<sup>[21]</sup>, but soft tissue sarcoma is relatively radioresistant and the dosage required to treat sarcoma is higher than the tolerable dose<sup>[22]</sup>.

Chemotherapy plays a role in the treatment of soft tissue sarcomas. The drugs that show some activity are: alkylating agents, vincristine, actinomycin, adriamycin, and DTIC (Dimethyl triazeno imidazole carboxamide)<sup>[23]</sup>. Gershon *et al.*<sup>[2]</sup> reported that adriamycin produced two definite responses, as documented by angiography. Dannaer *et al.*<sup>[24]</sup> reported that chemotherapy produced an objective improvement in three of four patients and stabilized the disease in one patient. Transarterial chemoembolization is useful for preventing acute arterial bleeding from the liver. Catheter directed embolization allows planning and well structured surgery without the need of emergency liver surgery, which carries high risks of morbidity and lethality<sup>[25]</sup>. In this case, the patient underwent hepatic resection after transarterial chemoembolization due to acute arterial bleeding in the liver. Liver transplantation has been described in a patient with an unresectable primary hepatic tumor. However, no patient has been reported to survive for longer than 28 mo because of the high recurrence rate of hepatic angiosarcoma<sup>[26]</sup>.

When a ruptured mass causes the spillage of tumor cells into the peritoneal cavity and diffuse sarcomatosis in the peritoneum, the angiosarcomatous lesions subsequently formed induce diffuse and severe hemorrhage, thus appearing to be a leading cause of death<sup>[25]</sup>.

The prognosis of patients with hepatic angiosarcoma is dismal<sup>[6]</sup>. Although hepatic angiosarcoma is usually found to be unresectable at the time of diagnosis, early diagnosis and complete resection of the tumor may reduce the mortality associated with this disease. In conclusion,

we advise that the possibility of angiosarcoma should be considered when a bleeding hepatic mass is encountered.

## INTRODUCTION

Hermansky-Pudlak syndrome (HPS) is a rare form of congenital platelet disorder, affecting 1 in 500 000-1 000 000 populations of different ethnicity<sup>[1]</sup>. A high prevalence is seen in northern Puerto Rico where 1 per 1800 people is affected. It is inherited as an autosomal recessive disorder of intracytoplasmic organelle-specific protein biosynthesis and trafficking<sup>[2]</sup>. Eight subtypes with known genetic mutations have been described<sup>[1,3-7]</sup>. The disease is characterized by oculocutaneous albinism and bleeding diathesis due to platelet storage pool deficiency. Colitis is an important bowel complication in patients with HPS<sup>[8]</sup>. Involvement of the upper gastrointestinal tract has not been reported and can be potentially confused with thrombocytopathic bleeding. Our successful diagnosis and management under such circumstances is reported below.

## CASE REPORT

The patient first presented at 5 years of age with a longstanding history of easy bruising and recurrent epistaxis. Both parents were of Chinese origin and unrelated. There was no history of bleeding into muscles, joints or the gastrointestinal tract. He had occasional mild eczema but no recurrent infections. Initial physical examination was remarkable only for multiple bruises of varying ages on his legs. The first laboratory investigations revealed mild thrombocytopenia (platelet counts, 118 and  $84 \times 10^9/L$  on two occasions) with normal platelet volume and morphology under light microscopy. A microcytic, hypochromic anemia (Hb, 10.4 g/dL) due to  $\beta$ -thalassaemia trait was also found. The coagulation screen was normal.

Four months later, he had a scalp laceration after a minor fall at home. The wound was sutured but he was re-admitted a few hours later because of progressive wound swelling. An excessive scalp hematoma was found but intracranial bleeding was excluded on computer tomography (CT) scan. The total blood counts were remarkable with Hb 9.3 g/dL and platelets  $91 \times 10^9/L$ . A prolonged bleeding time of 13 min was then documented. Platelet function studies showed a diminished response

## Abstract

A 10-year-old Chinese boy who had a history of congenital thrombocytopathy presented with severe iron deficiency anemia secondary to chronic gastric inflammation and duodenal ulcerations. Subtle oculocutaneous albinism led to the finding of diminished dense bodies in the platelets under electron microscopy, hence the diagnosis of Hermansky-Pudlak syndrome (HPS). Biopsies from the stomach and duodenum revealed a lymphocytic infiltration in the submucosa, but *H. pylori* infection was absent. The gastroduodenitis responded to the treatment with omeprazole while iron deficiency anemia was corrected by oral iron therapy. HPS is a rare cause of congenital bleeding disorder with multisystemic manifestations. Upper gastrointestinal involvement is rare and should be distinguished from a mere manifestation of the bleeding diathesis.

Lee ACW, Poon KH, Lo WH, Wong LG. Chronic ulcerative gastroduodenitis as a first gastrointestinal manifestation of Hermansky-Pudlak syndrome in a 10-year-old child. *World J Gastroenterol* 2008; 14(18): 2939-2941 Available from: URL:

**Figure 1** Electron photomicrograph of the patient's platelets, showing a diminished number (normal, 4-8) of dense bodies (DB) in one, and absence of dense bodies in the adjacent platelets.

**Figure 3** Histologic section of duodenal mucosa showing intact villous architecture with a moderate inflammatory infiltrate of lymphocytes, plasma cells and eosinophils in lamina propria.

**Figure 2** Pictures obtained at esophagogastroduodenoscopy. **A:** Esophagus appeared normal except for mild nodularis near gastroesophageal junction; **B:** Stomach was covered with a coffee-ground substance and a patch of mucosal irregularity at proximal lesser curve was seen; **C:** A solitary ulcer of 2 cm in diameter with a rolled margin was found at anterior wall of the first part of duodenum; **D:** Multiple small, flat and oval aphthoid ulcers were found in the second part of duodenum.

to collagen and no response to arachidonic acid while response to adenosine diphosphate (ADP), adrenaline, ristocetin and calcium ionophore was normal. The findings were suggestive, but not typical, of storage pool deficiency.

The child has had only mild bleeding manifestations since then with cutaneous bruises and epistaxis. None of them required any hemostatic control other than local pressure. His skin color was paler compared with other children but the color of his hair and iris was not noticeably different. His mother recalled that he had once developed severe sunburn with skin blistering after having fun on the beach and he would never tan under the sun.

He presented at 10 years of age again because of a 3-mo history of recurrent severe epigastric pain, nausea and vomiting. There was no diarrhea, overt gastrointestinal bleeding or joint pain. He had lost 2.2 kg over the course of the illness. The blood counts showed Hb 5.9 g/dL and platelet  $237 \times 10^9/L$ . Serum biochemistries including hepatic transaminases and amylase were normal except

for diminished ferritin level (30 pmol/L, normal 67-896). Tests for C-reactive protein, erythrocyte sedimentation rate (ESR), anti-nuclear antibody, serum IgE, C3 and C4 were all normal. Bacterial, viral and parasitic studies of the stool were negative, while occult blood was found.  $C^{13}$ -urea breath test was negative. An ophthalmological consultation revealed diminished pigmentations in the iris and retina. Electron microscopy showed that dense bodies were diminished in some platelets and were absent in other platelets (Figure 1). The diagnosis of HPS was therefore made.

On esophagogastroduodenoscopy, scattered areas of inflammatory changes were noted in the esophagus and stomach. Mucosal ulcerations were noted in the first and second parts of the duodenum (Figure 2A-D). Biopsies taken from the stomach and the duodenum showed a mixed chronic infiltration with lymphocytes, plasma cells and some eosinophils in the lamina propria consistent with inactive chronic gastritis and non-specific duodenitis, respectively (Figure 3). *H. pylori*-like organism and intracellular ceroid-lipofuscin inclusions were not found.

The child was treated with omeprazole 20 mg (0.8 mg/kg) daily and iron (elemental iron 6 mg/kg per day) orally. He also received counseling on protection from solar damage with respect to his visual and dermatological vulnerabilities. Reassessment 5 wk later showed complete remission of epigastric pain, near total correction of anemia, complete ulcer healing and marked improvement in the gastric and duodenal inflammation on endoscopic and histologic examination. Omeprazole was given for 4 mo until his premorbid body weight and hemoglobin levels were restored. A normal fasting serum level of gastrin (16 pmol/L, normal < 55) obtained after cessation of omeprazole excluded hypergastrinemia.

However, two weeks after stopping omeprazole, the clinical symptoms and endoscopic signs of gastroduodenitis recurred. Although a full gastrointestinal workup was declined, the child responded again to omeprazole treatment, which would be given for long term acid suppression.

## DISCUSSION

Although the combination of oculocutaneous albinism

and platelet function disorder has only been described in HPS<sup>[9,10]</sup>, the definitive diagnosis was delayed in this patient. This was in part due to the subtleness of the hypopigmentation and the fact that the condition has not been previously reported in Hong Kong. Nevertheless, the emergence of an unusual complication during the course of the child's illness prompted to a re-evaluation, thus establishing the diagnosis of HPS. It is interesting that our case experienced marked upper gastrointestinal inflammation in association with his rare inherited disorder.

In addition to bleeding tendency, visual and cutaneous problems, patients with HPS may be complicated by diseases of the lungs, the gastrointestinal tract, the heart, and the kidneys<sup>[1,11]</sup>. Chronic neutropenia with recurrent infections have been reported in a few children with type 2 HPS<sup>[12]</sup>. Progressive pulmonary fibrosis, appearing during the fourth decade of life, is the most important cause of early mortality among patients with HPS<sup>[1,13]</sup>. It primarily affects individuals with types 1 and 4 HPS.

Gastrointestinal complications are an important manifestation in patients with HPS. Granulomatous colitis is the most frequently reported feature and may affect 10%-20% of patients with HPS<sup>[1,14]</sup>. The mean age at presentation is 15 years and about 15% of patients may present with severe inflammatory lesions. Granulomatous colitis may resemble Crohn's disease both clinically and histologically. The clinical features include signs and symptoms of inflammatory bowel disease like abdominal pain, bloody diarrhea, symptoms of bowel constriction, and perianal fistula<sup>[15]</sup>. Microscopically, the bowel shows areas of hyperemia and denuded epithelium with non-necrotizing granulomas. Ceroid deposits may be identified in the intestinal lesions but they may be absent even with severe disease<sup>[8]</sup>. Management of granulomatous colitis in HPS is also similar to Crohn's disease and consists of immunomodulatory therapy. Total colectomy has been required in a few patients with severe illness<sup>[1,8,14]</sup>.

Extra-colonic involvement of the gastrointestinal tract in HPS is unusual<sup>[8]</sup> and the clinical features and specific management have not been characterized. In the present case, the patient's clinical manifestations were similar to peptic ulceration except that *H pylori* infection was absent and rapid relapse followed cessation of therapy with proton-pump inhibitor. Treatment with a proton-pump inhibitor was found to be satisfactory, but the optimal duration of treatment was not known.

In summary, HPS is an unusual cause but an important differential diagnosis of upper gastrointestinal inflammatory disease in children. Endoscopic evaluation

is a safe and helpful adjunct in the diagnosis, but the optimal long-term management and outcomes of the gastrointestinal disease are unknown.

## Abstract

Primary malignant fibrous histiocytoma (MFH) of the pancreas is rare and a distinct clinical entity. We report a case of recurrence of pancreatic MFH with computed tomography (CT) and magnetic resonance imaging (MRI) findings. A 67-year-old man presented with a history of decreased body weight over the past 6 mo. Abdominal CT revealed a large, multilocular cystic mass in the head of the pancreas with obvious atrophy in the body and tail of the pancreas. After 6 mo postoperatively, MRI demonstrated a recurrent large mass in the primary area of the head of the pancreas. The lesion was heterogeneous, hypointense to the liver on T1-weighted imaging, and heterogeneously hyperintense to the liver with a hypointense area in the central part of the tumor on fat-saturated T2-weighted imaging. Contrast-enhanced T1-weighted imaging demonstrated a large multilocular cystic mass with a cystic wall, fibrous septa and enhancement of solid components. To the best of our knowledge, this is the first report on recurrence of primary MFH of the pancreas, and the first with MRI findings.

## INTRODUCTION

Malignant fibrous histiocytoma (MFH) is the most common type of soft tissue sarcoma of middle and late adulthood<sup>[1-4]</sup>, but it originates only infrequently in the pancreas<sup>[5-8]</sup>. Since the first MFH of the pancreas was described in 1976 by Margules *et al*<sup>[9]</sup>, only 20 cases have been documented in the world literature, including the present case<sup>[10-13]</sup>. Some of these cases have exhibited the characteristic radiological findings<sup>[10-12]</sup>, and no case with recurrence has been reported. Herein, we present a patient with primary MFH of the pancreas, which recurred 6 mo after surgery, and its computed tomography (CT) and magnetic resonance imaging (MRI) appearance. To the best of our knowledge, this is the first report on recurrence of primary MFH of the pancreas and the first with MRI findings.

## CASE REPORT

A 67-year-old man was referred to the hospital because of abnormal ultrasonographic findings in the pancreas, found by chance at medical checkup. He was asymptomatic apart from a 3-kg decrease in body weight over the past 6 mo. The patient had no history of alcohol consumption or smoking. Physical examination on admission was unremarkable except for a 9 cm × 10 cm hard mass located in the middle abdomen. No lymph nodes were detected at the body surface. Hepatitis B and C serology was negative, and blood cell counts, liver function tests and serum amylase were normal. Serum levels of carcinoembryonic antigen (CEA) and carbohydrate antigen 19-9 (CA19-9) were not elevated.

Abdominal ultrasound showed a huge soft-tissue mass with cystic and solid components in the head of the pancreas. Abdominal CT revealed a large (8.2 cm × 9.5 cm), non-homogeneous, dense mass in the head of the pancreas, with obvious atrophy in the body and tail of the pancreas on pre-contrast CT (Figure 1A). The lesion showed a well-defined, multilocular cystic

**Figure 1** A: Pre-contrast CT shows a large, non-homogeneous, density mass in the head of the pancreas, with obvious atrophy in the body and tail of the pancreas; B: Lesion illustrates a well-defined, multilocular cystic mass with a cystic wall, fibrous septa and enhancement of solid components on post-contrast CT.

**Figure 2** Pathology of the pancreatic mass shows spindle cells arranged in a storiform pattern, with varying numbers of polymorphic neoplastic and multinucleated cells (HE,  $\times 200$ ).

mass with a cystic wall, fibrous septa and enhancement of solid components on post-contrast CT (Figure 1B). None of the imaging examinations showed abnormal findings in the liver, spleen or retroperitoneum. There was no evidence of metastatic disease, and the patient underwent pancreaticoduodenectomy. Intraoperative findings demonstrated a large mass in the head of the pancreas and no adhesion to the liver or retroperitoneum. Macroscopically, the tumor specimen measured 10 cm  $\times$  11 cm  $\times$  8 cm in size, and was partially encapsulated by the normal pancreas. The cut surface of the tumor was gray-white in color, with a large area of hemorrhage and necrosis. Microscopically, the tumor was composed of spindle cells arranged in a storiform pattern with varying numbers of polymorphic neoplastic and multinucleated cells (Figure 2). To clarify the diagnosis of the tumor further, immunoperoxidase staining was performed on the tumor specimen. The tumor cells were negative for desmin, CEA and S-100; positive for CD68 (Figure 3A), vimentin (Figure 3B), lysozyme and  $\alpha$ -1-ACT; and no evidence of epithelial differentiation was found. In summary, the diagnosis of storiform-pleomorphic MFH of the pancreas was made.

The patient enjoyed a smooth recovery and was discharged on postoperative d 10. The patient was followed at 2-mo intervals by abdominal ultrasound. There was no evidence of recurrence or metastasis until 6 mo postoperatively. MRI demonstrated that a new mass had developed at the location of the MFH. T1-

**Figure 3** Immunohistochemical staining shows that the tumor cells are positive for CD68 (A) and vimentin (B) ( $\times 250$ ).

weighted imaging showed a large (7 cm  $\times$  8.5 cm), non-heterogeneous, hypointense lesion of the liver. Fat-saturated T2-weighted imaging showed non-heterogeneous hyperintensity in the liver, with a hypointense area in the central part of the tumor (Figure 4A). Contrast-enhanced T1-weighted imaging demonstrated a large multilocular cystic mass with a cystic wall, fibrous septa and enhancement of solid components (Figure 4B). A diagnosis of recurrence was made. The patient died from the recurrence at 11 mo after operation.

## DISCUSSION

MFH accounts for > 30% of all soft tissue sarcomas<sup>[14]</sup>, and occurs most frequently in the extremities, trunk and retroperitoneum<sup>[15-18]</sup>. Men are affected twice as frequently as women<sup>[15,19]</sup>. Primary MFH of the pancreas is exceedingly

**Figure 4** A: MR fat-saturated T2-weighted image shows a large, non-heterogeneous, hyperintense lesion in the liver, with a hypointense area in the central part of the tumor; B: Contrast-enhanced T1-weighted image shows a large multilocular cystic mass with a cystic wall, fibrous septa and enhancement of solid components.

rare<sup>[5-8]</sup>. Akatsu *et al* have reviewed 16 cases and reported that the tumor has a male predominance with a median age at onset of 55 years. It is usually a large mass (mean tumor diameter is 13 cm, with a range of 4-35 cm)<sup>[11]</sup>. Of the documented cases, only three survived for > 48 mo<sup>[10-13]</sup>, which suggests a poor prognosis for long-term survival. Only one case had lymph node metastases<sup>[12]</sup>. Our case was the only one with recurrence.

MFH consists of histiocyte-like and fibroblast-like cells arranged in a storiform pattern, with other pleomorphic cells and multinucleated giant cells<sup>[20-23]</sup>. There are five subtypes of MFH according to histology<sup>[10,24]</sup>: storiform-pleomorphic, myxoid, giant cell, inflammatory, and angiomatoid. The storiform-pleomorphic pattern is the most common variant<sup>[25]</sup>. Three histological subtypes have been observed among the 20 cases previously reported in the literature: 13 (65%) storiform-pleomorphic, four (20%) giant cell, and three (15%) myxoid<sup>[2-5]</sup>. Our case belonged to the storiform-pleomorphic type.

Only a few radiological findings of primary MFH of the pancreas have been described<sup>[10-12]</sup>. The CT findings of the tumor include the following: a large, heterogeneous, low-attenuation density or multinodular mass, with intratumoral calcification on pre-contrast CT; non-homogeneously enhancing pancreatic mass with a large amount of necrosis<sup>[11,12]</sup>; and single enhancing peripheral pseudo-capsular mass on post-contrast CT<sup>[10]</sup>. To the best of our knowledge, we describe the first case of primary MFH of the pancreas, with CT showing a large multilocular cystic mass with a cystic wall, fibrous septa and enhancement of solid components. It is not clear whether or not the pathological features of pancreatic MFH correlate with the CT findings. Liu *et al* have described a predominant cystic MFH of the pancreas of the myxoid variety<sup>[10]</sup>, but other reports and our case suggest that not all cystic degeneration of the tumor belongs to the myxoid pattern<sup>[11,12]</sup>. Ko *et al* have considered that abdominal MFH, especially the storiform-pleomorphic subtype, exhibits metaplastic calcifications on CT, and they showed a heterogeneously enhanced mass with a large necrotic area in the pancreatic body and tail, and eccentrically located ring calcification<sup>[26]</sup>. Akatsu *et al* did not, however, support this sign and concluded that calcification is not always helpful in differentiating pancreatic MFH from other pancreatic tumors<sup>[11]</sup>. Therefore, we think that more cases need to be studied to prove the relationship between the CT findings

and the subtypes of primary MFH.

Mahajan and colleagues have retrospectively reviewed the MRI changes in 39 patients with MFH, however, none of these originated from the pancreas<sup>[27]</sup>. This study concluded that MRI sensitivity and specificity for detecting a neoplasm were 96% and 83%, respectively, but the signal changes were non-specific for MFH. When compared to CT in 14 patients, MRI better defined the extent of the MFH, its relationship to surrounding tissues and vessels, and best differentiated residual or recurrent disease from postoperative changes when examined at least 3 mo after surgery. There was no significant difference in signal intensity of 12 preoperative and 13 recurrent neoplasms<sup>[27]</sup>.

Tateishi *et al* have described the manner in which that primary MFH has a high signal intensity on T2-weighted MR images and non-homogeneous isosignal intensity compared with the surrounding muscle<sup>[28]</sup>. Miller *et al* have reported that a correlation between MRI appearance and histopathology may not be established, but concluded that MRI exhibits general features suggestive of malignant soft tissue neoplasm, namely, internal low signal septation, and heterogeneous high signal intensity on T2-weighted images<sup>[29]</sup>. Kitajima *et al*<sup>[30]</sup> have considered that MRI is helpful in the differential diagnosis between MFH of the renal capsule and other renal tumors, and that a hypointense area identified on T2-weighted images is an important characteristic of renal MFH. In our case, MRI showed a large multilocular cystic mass, which was similar to that on preoperative CT, and it could reveal the exact location and extent of the tumor recurrence. An obviously hypointense area on T2-weighted images that reflected the fibrous component was also seen in our pancreatic MFH.

In conclusion, primary MFH of the pancreas is rare and a distinct clinical entity. It may recur and the prognosis is poor. Although there are no unique findings of pancreatic MFH, a large, massive liquescent necrotic mass or multilocular cystic lesion, with calcification on CT or a hypointense area within the mass on T2-weighted imaging in an older male patient, should lead to consideration of a differential diagnosis of pancreatic MFH.

## Abstract

Spanish investigators described recently the so-called occult hepatitis C virus (HCV) infection, emphasizing the detection of genomic and antigenomic HCV RNA strands in liver and peripheral blood mononuclear cells. Therefore, the persistence of viral replication in occult HCV infection should be considered as a putative source of infection among family members and patients undergoing invasive procedures, transfusion or transplantation. Additionally, the most worrisome finding is that an occult HCV infection may persist in patients with sustained virological response.

Moreno-Otero R. Desperately seeking hepatitis C virus. *World J Gastroenterol* 2008; 14(18): 2946-2947 Available from: URL: <http://www.wjgnet.com/1007-9327/14/2946.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.2946>

response (SVR) in approximately 45% of patients with genotype 1 and in 80% of those with genotypes 2 or 3. SVR is associated with HCV eradication and liver damage reduction. Enormous scientific and economic efforts have dramatically changed the medical focus on HCV, and the prior condition of shipwrecked hepatologists has evolved into skilful navigators trained to cure chronic hepatitis C (CHC), adapting treatment to each patient instead of adapting the patient to an established therapy<sup>[1,2]</sup>.

Spanish investigators described recently the so-called occult hepatitis C virus (HCV) infection<sup>[3]</sup> summarizing its successive studies in a comprehensive review<sup>[4]</sup> that emphasizes the detection of genomic and antigenomic HCV RNA strands in liver and peripheral blood mononuclear cells (PBMCs). Therefore, the persistence of viral replication in occult HCV infection should be considered as a putative source of infection among family members and patients undergoing invasive procedures, transfusion or transplantation. Additionally, the most worrisome finding is that an occult HVC infection may persist in SVR patients, with HCV RNA presence in liver and PBMCs<sup>[4,5]</sup>. The hope of treated patients, who consider themselves having got rid of the virus, and of physicians, struggling for control and cure CHC, is most probably devastated.

These authors also found that HCV RNA is detected in the sera of patients with occult HCV infection after ultracentrifugation<sup>[6]</sup>. What is the significance of this new entity? Answers are a challenge for the scientific community in order to dissect the epidemiological aspects and pathological consequences of occult HCV infection, not to mention the design of therapeutic strategies. The social and medical costs can be astronomic, including work incapacity, absenteeism and intangible costs able to ruin the private life of some patients. Concerns and doubtful questions enunciated by frightened persons and medical doctors have been raised after an extensive report on occult hepatitis C was published, alluding the aforementioned study<sup>[6]</sup>, on a newspaper from Madrid (LA RAZÓN, July 10-2007, page 31). Whether all the information has any alarming relevance remains to be seen.

## TO THE EDITOR

Research into hepatitis C virus infection has progressed substantially over the past 15 years. Treatment with peginterferon plus ribavirin yields a sustained virological

### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (WJG, ISSN 1007-9327 CN 14-1219/R) is a weekly open access peer-reviewed journal supported by an editorial board consisting of 1208 experts in gastroenterology and hepatology from 60 countries. The aim of the journal is to deliver the most clinically relevant original and commentary articles to readers, and to make the full text publicly available to all clinicians, scientists, patients and biomedical students on an unrestricted platform, so that they can access and learn about the most recent key advances in the field.

In addition to the open access nature, another key characteristic of WJG is its reading guidance for each article which includes background, research frontier, related reports, breakthroughs, applications, terminology, and comments of peer reviewers for the general readers.

WJG publishes articles on esophageal, gastrointestinal, hepatobiliary and pancreatic tumors, and other esophageal, gastrointestinal, hepatic-biliary and pancreatic diseases in relation to epidermiology, immunology, microbiology, motility & nerve-gut interaction, endocrinology, nutrition & obesity, endoscopy, imaging and advanced hi-technology.

The main goal of WJG is to publish high quality commentary articles contributed by leading experts in gastroenterology and hepatology and original articles that combine the clinical practice and advanced basic research, to provide an interactive platform for clinicians and researchers in internal medicine, surgery, infectious diseases, traditional Chinese medicine, oncology, integrated Chinese and Western medicine, imaging, endoscopy, interventional therapy, pathology and other basic medical specialties, and thus eventually improving the clinical practice and healthcare for patients.

### Indexed and abstracted in

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, Index Medicus, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology and Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

### Published by

The WJG Press

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297 mm × 210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or

damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjgnet.com>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjgnet.com](mailto:submission@wjgnet.com), or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. font with ample margins. The preferred font is Book Antiqua. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was carried out; author contributions; disclosure of any financial support for the research; and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (remove all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s), and full family name.

**Author contributions:** The format of this section should be like this: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed research; Wang CL, Zou CC, Hong F and Wu XM performed research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed data; and Wang CL, Liang L and Fu JF wrote the paper.

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in WJG, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

#### Abstract

An informative, structured abstract of no more than 350 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipment, and the experimental procedures should be included. RESULTS: The observed and experimental results, including data, effects, outcome, *etc.* should be included. Authors should present *P* value where necessary, and also include any significant data. CONCLUSION: Accurate view and the value of the results should be included.

The format for structured abstracts can be found at: <http://www.wjgnet.com/wjg/help/11.doc>.

**Key words**

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

**Text**

For articles of these sections, original articles, rapid communication and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, should be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

**Illustrations**

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

**Tables**

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

**Notes in tables and illustrations**

Data that are not statistically significant should not be noted. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P* < 0.05 and <sup>d</sup>*P* < 0.01 are used. A third series of *P* values can be expressed as <sup>e</sup>*P* < 0.05 and <sup>f</sup>*P* < 0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

**Acknowledgments**

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

**REFERENCES****Coding system**

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

**PMID requirement**

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information for journal citations is very important. Using the reference testing system, the authors and editor should check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in an ASP file so that the readers can immediately access the abstract of the citations online.

**DOI requirement**

A CrossRef DOI® (Digital Object Identifier) name is a unique string created to identify a piece of scholarly content in the online environment. The author should supply the DOIs for journal citation (doi:10.3748/wjg.13.6458). This link (<http://www.crossref.org/SimpleTextQuery/>) allows you to retrieve Digital Object Identifiers (DOIs) for journal articles, books, and chapters by simply cutting and pasting the reference list into the box. You may use the form with any reference style, although the tool works most reliably if references are formatted in a standard style such as shown in this example: Assimakopoulos SF, Scopa CD, Vagianos CE. Pathophysiology of increased intestinal permeability in obstructive jaundice. *World J Gastroenterol* 2007; 13(48): 6458-6464

The accuracy of the information of journal citations is very important. We will interlink all references with DOI in ASP file so that readers can access the abstracts of cited articles online immediately.

**Style for journal references**

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

**Style for book references**

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

### Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those linked with a hyphen when the difference between the two numbers is greater than five. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered inappropriate references. Authors should not cite their own unrelated published articles.

### Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

### Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as *v* (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

### Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5  $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: <http://www.wjgnet.com/wjg/help/15.doc>.

### Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless

they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

### Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, *etc.*

Restriction enzymes: *EcoRI*, *HindIII*, *BamHI*, *Kho I*, *Kpn I*, *etc.*

Biology: *H pylori*, *E coli*, *etc.*

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

### Editorial Office

#### World Journal of Gastroenterology

Editorial Department: Room 903

Ocean International Center, Building D

No. 62 Dongsihuan Zhonglu

Chaoyang District, Beijing 100025, China

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

Telephone: +86-10-59080039

Fax: +86-10-85381893

### Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

### Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/9.doc>.

### Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/10.doc>.

### Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

### Links to documents related to the manuscript

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

### Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

### Publication fee

Authors of accepted articles must pay a publication fee.

EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

## Contents

### EDITORIAL

- 2953** Chronic intestinal pseudo-obstruction  
*Antonucci A, Fronzoni L, Cogliandro L, Cogliandro RF, Caputo C, De Giorgio R, Pallotti F, Barbara G, Corinaldesi R, Stanghellini V*
- 2962** Endoscopic submucosal dissection for gastrointestinal neoplasms  
*Kakushima N, Fujishiro M*

### CLINICAL PRACTICE GUIDELINES

- 2968** Pharmacological approach to acute pancreatitis  
*Bang UC, Semb S, Nøjgaard C, Bendtsen F*

### OBSERVER

- 2977** Intraductal papillary mucinous neoplasms and other pancreatic cystic lesions  
*Freeman HJ*

### REVIEW

- 2980** Proton pump inhibitors in cirrhosis: Tradition or evidence based practice?  
*Lodato F, Azzaroli F, Di Girolamo M, Feletti V, Cecinato P, Lisotti A, Festi D, Roda E, Mazzella G*

### TOPIC HIGHLIGHTS

- 2986** Mechanisms of biliary carcinogenesis and growth  
*Wise C, Piliathananon M, Perry BF, Alpini G, McNeal M, Glaser SS*
- 2990** c-Met targeted therapy of cholangiocarcinoma  
*Socoteanu MP, Mott F, Alpini G, Frankel AE*
- 2995** Review of endoscopic techniques in the diagnosis and management of cholangiocarcinoma  
*Nguyen K, Sing JT Jr*
- 3000** Diagnosis and initial management of cholangiocarcinoma with obstructive jaundice  
*Tajiri T, Yoshida H, Mamada Y, Taniai N, Yokomuro S, Mizuguchi Y*

### GASTRIC CANCER

- 3006** Investigation of transcriptional gene silencing and mechanism induced by shRNAs targeted to *RUNX3* *in vitro*  
*Feng XZ, He XS, Zhuang YZ, Luo Q, Jiang JH, Yang S, Tang XF, Liu JL, Chen T*

### LIVER CANCER

- 3015** Transplanted bone marrow stromal cells are not cellular origin of hepatocellular carcinomas in a mouse model of carcinogenesis  
*Zheng JF, Liang LJ*

### Abstract

Chronic intestinal pseudo-obstruction (CIPO) is a severe digestive syndrome characterized by derangement of gut propulsive motility which resembles mechanical obstruction, in the absence of any obstructive process. Although uncommon in clinical practice, this syndrome represents one of the main causes of intestinal failure and is characterized by high morbidity and mortality. It may be idiopathic or secondary to a variety of diseases. Most cases are sporadic, even though familial forms with either dominant or recessive autosomal inheritance have been described. Based on histological features intestinal pseudo-obstruction can be classified into three main categories: neuropathies, mesenchymopathies, and myopathies, according on the predominant involvement of enteric neurones, interstitial cells of Cajal or smooth muscle cells, respectively. Treatment of intestinal pseudo-obstruction involves nutritional, pharmacological and surgical therapies, but it is often unsatisfactory and the long-term outcome is generally poor in the majority of cases.

### INTRODUCTION

Chronic intestinal pseudo-obstruction (CIPO) is a rare, severe disease characterized by the failure of the intestinal tract to propel its contents which results in a clinical picture mimicking mechanical obstruction in the absence of any lesion occluding the gut. CIPO is one of the most important causes of chronic intestinal failure both in pediatric (15%) and adult cases (20%)<sup>[1-5]</sup>, since affected individuals are often unable to maintain normal body weight and/or normal oral nutrition. The severity of clinical picture, generally characterized by disabling digestive symptoms even between sub-occlusive episodes, contributes to deterioration of quality of life of the patients. Furthermore, CIPO often passes unrecognized for long time, so that patients almost invariably undergo repeated, useless and potentially dangerous surgical procedures.

This article is aimed at reviewing the current knowledge on pathophysiology, clinical features and management of patients affected by CIPO.

### ETIOLOGY AND PATHOPHYSIOLOGY

CIPO is idiopathic in the majority of cases. In our experience organic, systemic or metabolic causes of the disease were identified in only 4 patients of 77 CIPO patients consecutively referred in our laboratory (5%)<sup>[2]</sup>. Nevertheless, it is mandatory to investigate affected individuals by traditional diagnostic procedures (radiology, endoscopy, lab tests, etc) in order to exclude every possible cause of secondary CIPO. The main secondary causes of CIPO are specified in Table 1.

In fact, every disease that affects one of the control mechanisms of intestinal functioning, including intrinsic and extrinsic neural supplies as well as muscle cells, can be responsible for secondary and potentially curable forms of CIPO. The extrinsic autonomic nervous system can be affected both centrally (i.e. Parkinson syndrome, Shy-Drager syndrome, stroke, encephalitis, neoplasm and any

Table 1 Main causes of secondary chronic idiopathic pseudo-obstruction and relative gut tissue that is predominantly involved

Underlying disease	Main causes
Diseases of central autonomic and enteric nervous systems	Stroke, encephalitis, calcification of basal ganglia, orthostatic hypotension, Von Recklinghausen, Hirschsprung
Immune-mediated and collagen diseases	Paraneoplastic (CNS neoplasms, lung microstoma, bronchial carcinoid, leiomyosarcomas), scleroderma, dermatomyositis, amyloidosis, Ehlers-Danlos, LES
Endocrine and metabolic diseases	Diabetes, hypothyroidism, hypoparathyroidism, pheochromocytoma
Other	Iatrogenic (radiation enteritis, clonidine, phenothiazines, antidepressants, antiparkinsonians, antineoplastics, bronchodilators, anthraquinones) jejunal diverticulosis, chagas

other disease that could affect the encephalic autonomous centres), and peripherally (i.e. diabetic neuropathy, or other neuropathies potentially involving the enteric nervous system including Hirschsprung, Chagas, Von Recklinghausen, as well as non-specific diseases, like paraneoplastic syndromes, autoimmune diseases, viral infections). Enteric smooth muscle cells can be markedly damaged in patients affected by myotonic dystrophy or progressive systemic sclerosis. Collagenosis, Ehlers-Danlos syndrome, jejunal diverticulosis and radiation enteritis can be responsible for both a neuronal and myogenic impairment.

Nonetheless, diseases like hypothyroidism, hypoparathyroidism, and celiac disease have been described to be responsible for some cases of secondary CIPO, even if the underlying mechanism remains undetermined<sup>[1,4]</sup>.

CIPO is generally sporadic, but familial forms have also been described both with autosomal dominant, autosomal recessive and X-linked transmission<sup>[1,6,7]</sup>. Some genes and loci have been identified in syndromic forms of CIPO, including the transcription factor *SOX10* on chromosome 22 (22p12), the DNA polymerase gamma gene (*POLG*) on chromosome 21 (21q17) and a locus on chromosome 8<sup>[7-9]</sup>. In terms of X-linked transmission, recently Gargiulo *et al* have identified a 2-base pair deletion in exon 2 of the *filamin A* gene (encoding for a large cytoskeletal protein involved in the modulation of the cellular response to chemical and mechanical environmental factors) that is present at the heterozygous state in the carrier females of a family with syndromic CIPO<sup>[10]</sup>. Familial cases are more frequent in mitochondrial neurogastrointestinal encephalomyopathy (MNGIE), which is characterized by subocclusive episodes and lactic acidosis, skeletal muscle abnormalities (i.e. “ragged red fiber”) and specific mitochondrial changes at the ultrastructural level<sup>[11,12]</sup>. Mutations of the gene encoding the thymidine phosphorylase gene (*TP* or endothelial cell growth factor-1, *ECGF1*), mapped to locus 22q13.32qter have a pathogenic role and are responsible for MNGIE<sup>[11-15]</sup>. The biochemical dysfunctions underlying MNGIE consists of decreased TP activity leading to accumulation of thymidine (dThd) and deoxyuridine (dUrd) in blood and tissues<sup>[16,17]</sup>.

Toxic levels of dThd and dUrd induce nucleotide pool imbalance that, in turn, leads to mitochondrial DNA abnormalities including point mutations, multiple deletions and depletion<sup>[16,18]</sup>.

### Histopathology and putative pathogenic mechanisms

Examination of full-thickness biopsies of the intestinal

wall may help in establishing a correct diagnosis, revealing pathological abnormalities underlying the neuromuscular impairment. Histopathologic features of CIPO include neuropathic, mesenchymopathic and myopathic forms based on abnormalities affecting the integrity of nerve pathways supplying the gut (either intrinsic or extrinsic), interstitial cells of Cajal (ICC) and smooth muscle cells, respectively. Neuropathic, mesenchymopathic and myopathic changes may contribute to gut dysmotility either individually or in combination (e.g. neuro-myopathies or neuro-ICC alterations) (Table 2)<sup>[1,6,7]</sup>.

### Enteric neuropathies and enteroglia cell abnormalities

Enteric neurodegenerative abnormalities and immune-mediated changes may occur in gut specimens of patients with neuropathic CIPO. Inflammatory neuropathies are characterized by a dense inflammatory infiltrate characterized by CD3 positive (composed of both CD4 and CD8) lymphocytes almost invariably confined to the myenteric plexus (hence the term of *lymphocytic myenteric ganglionitis*)<sup>[7-9,19]</sup>. The close apposition of CD3 lymphocytes to myenteric neurons provides the basis to neuro-immune interactions targeting and affecting ganglion cell structure and survival<sup>[20,21]</sup>. Indeed, experimental evidence indicates that inflammation/immune activation in the gastrointestinal tract can profoundly affect both morphology and function of the enteric nervous system (ENS).

The evidence that patients with inflammatory neuropathy have circulating anti-neuronal auto-antibodies (e.g. anti-Hu anti-neuronal antibodies) also suggests the role of the immune system in neuronal dysfunction<sup>[19]</sup>. Previous results indicated that these autoantibodies alter ascending reflex pathway of peristalsis in *in vitro* preparations<sup>[22]</sup> and elicit neuronal hyperexcitability as demonstrated by Ca<sup>2+</sup>-imaging technique<sup>[23]</sup>. In addition, anti-HuD neuronal antibodies evoked activation of caspase-3 and apaf-1 along with apoptosis when incubated with primary culture of myenteric neurons<sup>[24]</sup>. Taken together, these experimental data suggest that anti-Hu antibodies may exert either a direct pathogenic role or contribute in association with the lymphocytic infiltrate in ENS dysfunction in patients with CIPO related to an inflammatory neuropathy. Although the etiology of inflammatory neuropathies remains undetermined, the demonstration showing herpes virus DNA in the myenteric plexus of patients with CIPO<sup>[25]</sup> raises the exciting possibility that infectious agents can be involved in the pathogenic cascade leading to inflammatory damage of the ENS.

Table 2 Immunohistochemical markers to analyze full thickness biopsy of patients with CIPO

Markers	Cell targets and sites	Description
PGP9.5, NSE, MAP-2, NFs, tubulins, Hu C/D	Neurons: Membrane/Cytoplasmic	Identification of the general structure of the ENS
$\beta$ -S-100, GFAP	Glial cells: Cytoplasmic	Detection of enteroglia cells
Kit	Interstitial cells of Cajal: Membrane/Cytoplasmic	Different ICC networks
SP, VIP, PACAP, CGRP, NPY, Galanin, 5-HT, NOS, ChAT, somatostatin, Calbindin, NeuN, NK1, NK2 and NK3	Subclasses of enteric neurons; interstitial cells of Cajal: Membrane/Cytoplasmic	Characterization of neurochemical coding and enteric neuron subclasses; subsets of interstitial cells of Cajal
Bcl-2, TUNEL, Caspase-3, Caspase-8, Apaf-1	Apoptosis and related mechanisms: Nuclear/Cytoplasmic	Assessment of apoptosis and related pathways
Actin, myosin, desmin, smoothelin	Smooth muscle cells: Cytoplasmic	Assessment of smooth muscle integrity
CD3, CD4, CD8, CD79 $\alpha$ , CD68; MIP-1 $\alpha$ , TNF- $\alpha$ , IFN- $\gamma$	Immune cells, chemokines and cytokines: Membrane/Cytoplasmic	Evaluation of B (CD79 $\alpha$ ) and T-lymphocytes (CD3), T-helper (CD4), T-suppressor (CD8), macrophages (CD68) in enteric ganglionitis; MIP-1 $\alpha$ is a chemokine; TNF- $\alpha$ and IFN- $\gamma$ are inflammatory cytokines

Bcl-2: B cell lymphoma-2 protein; ChAT: Choline acetyltransferase; CGRP: Calcitonin gene-related peptide; ENS: Enteric nervous system; GFAP: Glial fibrillary acidic protein; Hu C/D: Hu C/D molecular antigen; IFN- $\gamma$ : Interferon  $\gamma$ ; MAP-2: Microtubule associated protein-2; MIP-1 $\alpha$ : Macrophage inflammatory protein-1 $\alpha$ ; NeuN: Neuronal-specific nuclear protein; NFs: Neurofilaments; NK1, NK2, NK3: Neurokinin1, neurokinin2, neurokinin3; NOS: Nitric oxide synthase; NPY: Neuropeptide Y; NSE: Neuron-specific enolase; PACAP: Pituitary adenylate cyclase activating polypeptide; PGP9.5: Protein gene product 9.5; 5-HT: 5-hydroxytryptamine (serotonin); SP: Substance P; TNF- $\alpha$ : Tumor necrosis factor  $\alpha$ ; Tubulins: Cytoskeletal proteins; TUNEL: Terminal deoxynucleotidyl transferase-mediated deoxyuridine triphosphate nick-end labeling; VIP: Vasoactive intestinal polypeptide.

Further to lymphocytic ganglionitis, Schappi *et al* have reported on eosinophilic ganglionitis characterized by eosinophils infiltrating the myenteric plexus of pediatric patients with CIPO<sup>[26]</sup>. In contrast to lymphocytic, the eosinophilic ganglionitis does not appear to evoke neuronal degeneration and loss and, therefore, gut dysmotility may be interpreted as a functional impairment of the ENS due to the infiltrate *per se* or humoral messengers released by eosinophils. Recently, mast cell predominant ganglionitis has been described in patients with severe gut dysmotility (including CIPO)<sup>[27]</sup>. The mast cells detected within myenteric ganglia in these patients were associated with markedly reduced neuronal nitric oxide synthase expression identified at molecular and immunohistochemical level. These findings suggest an impaired enteric inhibitory innervation in these peculiar subsets of CIPO.

Degenerative (or non inflammatory) neuropathies may be regarded as the end result of several putative pathogenic mechanisms, such as altered calcium signaling, mitochondrial dysfunction and production of free radicals, leading to degeneration and loss of the intrinsic neurons of the gut<sup>[28]</sup>. Degenerative neuropathies can be familial (related to a genetic background-see above) or sporadic and classified into primary (idiopathic) or secondary forms to a variety of causes, such as radiations, vinka alkaloids, myxedema, diabetes mellitus, muscular dystrophy and amyloidosis. Typical neuropathological findings reported in neurodegenerative CIPO include various qualitative (neuronal swelling, intranuclear inclusions, axonal degeneration and other lesions) and quantitative (especially hypoganglionosis) abnormalities of the ENS. Sporadic cases of visceral neuropathies are associated with two major patterns of alterations: (1) A marked reduction of intramural (especially myenteric) neural cells mainly associated with swollen neural cell bodies and processes, fragmentation and loss of axons and proliferation of glial cells; (2) A loss of the normal staining in subsets of enteric neurons, in the absence of

dendritic swelling or glial proliferation<sup>[6,20,21]</sup>. Since no reliable models of degenerative neuropathies exist, the mechanisms through which exogenous noxae or other triggering factors initiate degenerative processes in enteric neurons remain obscure. Enteric neurons of patients with severe forms of idiopathic intrinsic neuropathy display a decreased expression of the protein encoded by *Bcl-2*, a gene related to one of the intracellular pathways leading to programmed cell death<sup>[4,29,30]</sup>. Indeed, this finding has been associated with an increased number of neurons displaying TUNEL, a marker of apoptosis<sup>[31]</sup>.

Abnormalities of enteric glia may also contribute to intrinsic neuropathy either attracting immune cells to the ENS or resulting in insufficient support/trophism to enteric neurons and thus eliciting neurodegenerative events in the absence of inflammation<sup>[32]</sup>.

### Enteric mesenchymopathies

Abnormalities to ICCs have been detected in gut tissues of patients with CIPO. These include decreased ICC density, loss of processes and damaged intracellular cytoskeleton and organelles as revealed by immunohistochemical analysis and electron microscopy<sup>[33-37]</sup>. As a result, it has been proposed that the impairment of the major functional subclasses of ICC (i.e. those involved in pacemaker activity and neurotransmission to smooth muscle) may contribute to enteric motility abnormalities detectable in patients with CIPO.

### Enteric myopathies

Histopathological analysis of the enteric muscle layer may reveal the existence of muscular abnormalities (i.e. smooth muscle fibrosis and vacuolization) of the circular and longitudinal layers in patients with primary visceral myopathy<sup>[38,39]</sup>. A controlled multinational study conducted by Knowles *et al* has proposed that a selective decrease or even absence of  $\alpha$ -actin in the circular muscle of the small bowel wall can be regarded as biological markers of

CIPO<sup>[40]</sup>. Although exciting, the possibility that a defective expression/localization of  $\alpha$ -actin may be a biomarker of a heterogeneous disease such as CIPO awaits solid confirmatory evidence.

The histopathological details concerning other segments of the gut as well as extra-digestive systems (i.e. urinary tract, gall-bladder) is poorly characterized and further studies are awaited to elucidate this important aspect.

## CLINICAL FEATURES

Subocclusive episodes can strike in apparently healthy people, but the onset of CIPO is generally insidious, with gastrointestinal symptoms which precede the first acute episode.

The typical clinical manifestation of CIPO is characterized by recurrent episodes of abdominal pain, abdominal distension and inability to defecate (flatus may not be completely suppressed), with or without vomiting, mimicking a mechanical sub-occlusion. During acute episodes radiological evidence of distended bowel loops and air-fluid levels in the upright position is an important diagnostic marker of this pathological condition. Acute episodes can last only a few hours, but in the most severe cases intestinal loops are chronically distended and air-fluid levels are invariably detected. Due to this misleading clinical manifestation, a history of multiple, useless surgeries are typical of the syndrome. Thus, many patients have abdominal adhesions and the concomitant presence of functional and mechanical (secondary to adhesions) obstruction is often impossible to rule out despite extensive investigations.

Between subocclusive episodes patients are very rarely asymptomatic, and almost invariably complain of severe digestive symptoms<sup>[1,2]</sup> suggestive of delayed transit in the proximal and/or distal portions of the alimentary canal. Nausea, vomiting and weight loss are predominant symptoms when the functional derangement primarily affects the upper gastrointestinal tract, while diffuse abdominal pain, abdominal distension and constipation are suggestive of a more distal involvement of the gut. Dysphagia is present in a low proportion of CIPO patients although it is relatively frequent in forms secondary to progressive systemic sclerosis.

Diarrhea and steatorrhea often occur as a consequence to small bowel bacterial overgrowth.

This pathologically accelerated transit is often well accepted by patients since it is associated with partial relief of other digestive symptoms, but it contributes to determine intestinal malabsorption and deteriorate nutritional conditions. Indeed, many patients are afflicted by inability to maintain a normal body weight, despite dietary manipulations, both because of the deranged digestive functions and because food ingestion often exacerbates digestive symptoms and consequently patients tend to avoid a normal oral nutrition.

Urinary symptoms, generally associated with evidence of urinary tract distension, are also frequent.

Depression or other psychological disturbances are often secondary to the disabling digestive problems and the disappointing quality of healthcare received.

## DIAGNOSTIC PROCEDURES

The diagnosis of CIPO is mainly clinical, supported by radiographic documentation of dilated bowel with air-fluid level, after exclusion of organic lesions occluding the gut lumen, as detected by radiologic and/or endoscopic investigations. Thus, diagnostic tests in patients with suspected CIPO are necessary to exclude mechanical occlusion, identify possible causes of secondary forms, explore underlying pathophysiological mechanisms and disclose possible complications.

### Radiology

Radiology is one of the most important examinations in the diagnosis of CIPO. Plain abdominal films identify typical signs of intestinal occlusion such as distended bowel loops with air-fluid levels, the latter obtained with the patients in the upright position (as specified above). Contrast studies are necessary to exclude the presence of organic lesions responsible for the occlusion. Entero-CT scan allows simultaneous internal and external views of the gut wall, abdominal CT and MR scans are important in investigating possible causes of gut compression, while MR angiography may non-invasively identify congenital or acquired vascular abnormalities. Excretory urograms should be performed in patients with urinary symptoms.

Symptoms suggestive of a subocclusive state in the absence of dilated bowel with air fluid levels at radiology have been defined by some authors as a "mild forms of CIPO"<sup>[41]</sup>. Nonetheless, this definition has been criticized<sup>[4]</sup>. In fact, preliminary studies suggest that patients with extremely severe digestive symptoms and malnutrition, but no radiological evidence of intestinal occlusion, have a significantly reduced probability of undergoing abdominal surgery and present less severe motility disorders<sup>[42]</sup>.

### Endoscopy

The main indication of upper gastrointestinal endoscopy is exclusion of mechanical occlusions in the gastro-jejunal and ileo-colonic regions. It allows to exclusion of false positive radiologic diagnoses of mechanical occlusion in the duodenum and proximal small bowel, as in many cases of the so-called "aorto-mesenteric compression syndrome"<sup>[43]</sup>. Mucosal biopsies of the small bowel should be taken to rule out celiac disease. Colonoscopy also has a therapeutic potential, since it can be used to try to decompress the large bowel<sup>[44]</sup>.

### Laboratory tests

Laboratory tests are useful to identify the presence of potentially curable diseases responsible for secondary forms, but also to monitor hydro-electrolyte balance and circulating levels of essential elements in patients on parenteral nutrition or, in general, with a severe malnutrition.

### Manometry

Small bowel manometry is invariably abnormal in CIPO patients<sup>[2,3,45]</sup>; however, the test is not of diagnostic value due to its low specificity. At best, it can play a supportive role in defining the diagnosis, since it can contribute to differentiate mechanical from functional obstruction and

to recognize the underlying pathophysiological mechanism<sup>[2,3,45]</sup>.

Describing in detail small bowel manometric abnormalities of CIPO goes beyond the scope of the present review. They can be summarized as follows: uncoordinated bursts of powerful contractions with variable duration are suggestive of an underlying intrinsic neuropathy<sup>[1-4,45-48]</sup> conversely, normally coordinated motor patterns with low amplitude have been reported in patients with a myogenic disorder<sup>[1-4,45-48]</sup>. Nonetheless, low amplitude contractions may merely reflect the inability of the manometric technique to record non-occlusive contractions, such as in the case of dilated bowel loops<sup>[1-4,45-48]</sup>.

Unlike what is observed in pseudo-obstruction, the manometric pattern of mechanical occlusion is characterized by giant contractions (prolonged contractions lasting at least 10 s and can be either propagated or non propagated) or clustered contractions (3-10 regular contractions, occurring 1 per 5 s preceded and followed by  $\geq 1$  min of absent motor activity lasting at least 20 min and can be either propagated or non propagated)<sup>[1-4,45-49]</sup>.

Esophageal manometry generally adds very little to the diagnostic work-up of CIPO, but it plays an important diagnostic and prognostic role if the disease is secondary to scleroderma. Ano-rectal manometry is important to rule out Hirschsprung's disease, particularly in patients with intractable constipation and a marked distension of the large intestine.

### **Biopsy and pathologic examination**

Full thickness biopsies should be obtained from dilated and nor dilated tracts of the alimentary canal in all patients with suspected CIPO who undergo surgery for unexplained occlusive episodes. Biopsies should be processed for in depth pathological evaluation by both traditional staining and immunohistochemistry techniques in dedicated laboratories with a specific interest in this area, as specified above.

## **NATURAL HISTORY**

Even if clinical experience shows that CIPO is a progressive disease that often leads to death, only few studies have precisely described the natural history of this pathology and its symptoms prognostic values, especially in the adult age. Children generally present the first manifestations of CIPO at birth or during the first years of age<sup>[50-53]</sup>. The pediatric expression of the disease is often characterized by a particularly severe course, with mortality rates extremely high within the first year of age, mainly due to surgical and parenteral nutrition complications<sup>[52,53]</sup>. Several predictors of poor outcome have been identified in children including myopathic forms, malrotation, short bowel syndrome, and urinary tract involvement<sup>[50,51]</sup>.

In the adult population, the first sub-occlusive episode is often preceded by a long history of non-specific, progressively more severe digestive symptoms. An acute onset of the disease occurs in only one-fourth of the cases<sup>[2]</sup>.

After diagnosis is established the frequency of sub-

occlusive episodes and, consequently, also of surgical procedures tend to decrease. Nevertheless, the clinical course of CIPO is almost invariably severe<sup>[1,2,52-54]</sup> with progressive deterioration of bowel function and digestive symptoms. In order to control both the body weight and the abdominal pain most patients progressively limit oral nutrition and end up on long-term parenteral nutrition.

The main causes of death are TPN-related complications, surgery-related complications, and post-transplantation complication, together with septic shock of GI origin. A variety of clinical, histological and manometric parameters have been found to be predictive of a poor clinical outcome in adult patients, including myopathy and decreased contractile activity<sup>[2,50,52,53,55-60]</sup>. MNGIE has a particularly poor prognosis with slowly progressive evolution and death around 40 years of age<sup>[11]</sup>.

## **THERAPY**

The treatment of CIPO is difficult and often provides unsatisfactory results. Of course, treatment of the underlying disease is mandatory in secondary forms whenever available<sup>[57]</sup>.

### **Treatment of the acute phase**

During acute phases patients should be treated as those with acute mechanical obstruction. Fluid and electrolytes balance should be maintained *via IV* infusions; abdominal decompression should be attempted by positioning of nasogastric and rectal tubes. The former generally prevents vomiting and *ab ingestis* while the latter is generally ineffective and colonic decompression can be attempted by colonoscopy or cecostomy (see below). In case of prolonged subocclusive episodes systemic or poorly absorbable antibiotics are necessary to prevent bacterial overgrowth. Appropriate caloric support must be provided by *IV* infusion. Erythromycin, somatostatin and neostigmine can be used to promote transit and decrease the duration of acute episodes<sup>[61-63]</sup>.

### **Nutritional support**

The nutritional status of patients with CIPO is generally poor. Frequent small meals with liquid or homogenized foods, with or without oral nutritional supplements, may help patients with sufficient residual digestive functions. Enteral nutrition is an option for patients whose motility disorder is mainly localized in the stomach and duodenum. It presents fewer complications than parenteral nutrition, but clinical experience suggests that enteral feeding is rarely tolerated by patients. In the most severe cases, when small bowel function is diffusely affected, parenteral nutrition is necessary to satisfy nutritional requirements. The main limitations of this nutritional support include liver insufficiency, pancreatitis, glomerulonephritis and catheter-related complications (i.e. thrombosis and septicemia)<sup>[58,59]</sup>.

### **Pharmacological therapy**

The pharmacological treatment of CIPO is aimed at controlling symptoms and avoiding complications. Co-

prescription of antiemetics, antisecretory, antispasmodics, laxatives or antidiarrheal and analgesic drugs is often necessary. Prokinetics are often prescribed, with the intention to improve gastrointestinal motility and to control visceral sensitivity<sup>[2,54]</sup>.

Some prokinetics seem to be more effective than others: metoclopramide, domperidone, bethanechol or neostigmine are often used, but with only limited success, while cisapride, that is currently available only in some parts of the world, has been reported to exert positive effects<sup>[60,64-67]</sup>. Two controlled trials including CIPO patients described positive effects of cisapride in accelerating gastric emptying<sup>[60]</sup> and improving symptoms<sup>[66]</sup>. Erythromycin is a macrolide antibiotic with a specific agonist action on the motilin receptors of the proximal gastrointestinal tract. It increases antral contraction and promotes gastric emptying, while its effects on colonic motility are controversial: at low doses it stimulates intestinal contractions, but doses normally used to enhance gastric emptying decrease motility of the small intestine<sup>[61]</sup>. Octreotide is a long-acting somatostatin analog which increases intestinal motor activity and decreases bacterial overgrowth<sup>[62]</sup>. Co-prescription of erythromycin and octreotide can be useful to control both the gastric emptying and the intestinal motility<sup>[68]</sup>. Anticholinesterase drugs have been described as effective in autoimmune gastrointestinal motor disorders<sup>[69]</sup>. Tegaserod, a more recent 5-HT<sub>4</sub> agonist, was also recommended for the treatment of subocclusive episodes in CIPO, but the drug has been withdrawn from the market<sup>[70]</sup>. A preliminary open study describes encouraging results exerted gastric electrical stimulation on nausea and vomiting in a small number of CIPO patients<sup>[71]</sup>.

Opioids are required in patients with intractable pain, but their constipating effect can further deteriorate digestive functions<sup>[72,73]</sup>.

Antibiotics are often useful to contrast bacterial overgrowth. Poorly absorbable antibiotics such as paramomycin and rifaximine should be preferred, but alternating cycles with metronidazole and tetracycline are necessary to limit resistances<sup>[74]</sup>.

Steroids or other immunosuppressive treatments are recommended when CIPO is related to an underlying inflammatory neuropathy. These cases have to be selected through tissue analysis or at least suspected by the identification of circulating anti-neuronal antibodies<sup>[6]</sup>. Treatment of MNGIE is largely supportive, being based on parenteral nutrition and/or supplementation with coenzyme Q, riboflavin and other vitamins (vitamin C, vitamin K3, carnitine). Prompt treatment of fever and infections and avoidance of extremes in temperature, over exercise, drugs known to interfere with mitochondrial functions (phenytoin, chloramphenicol, tetracycline, macrolides, and aminoglycosides), are also recommended. Infusion platelets to reduce thymidine level have been reported to exert some positive effect in preliminary study in MNGIE patients<sup>[75]</sup>.

### **Surgical therapy**

Even if CIPO patients often undergo surgical procedures, this kind of approach has only a limited role in the

management of the disease and has to be considered only in some carefully selected patients. Specifically, since CIPO generally involves the whole alimentary canal, only rare cases can benefit from surgical resections. Indeed surgery can precipitate deterioration of the clinical conditions and should be performed only if strictly necessary. Full thickness biopsies should be obtained whenever possible for pathological examination as stated above. In particular, surgery can be considered in patients having what appears to be localized involvement of the gastrointestinal tract, but CIPO is often a progressive disease and the benefit is likely temporary<sup>[41,76]</sup>.

Gastrostomies and enterostomies can effectively decrease retching, vomiting and abdominal distension and represent a possible option in patients who can be fed by enteral nutrition. Furthermore, decompression of distended bowel loops can exert a positive effect on the transport capacities of the alimentary canal which, in turn, results in a decreased frequency of further hospital admissions and surgeries.

Small bowel or, when needed, multivisceral transplantation is available only in a few highly specialized centers. The general outcome of this surgical procedure has markedly improved with the use of the immunosuppressive agent tacrolimus associated with steroid and together a number of induction agents such as alemtuzumab, antithymocyte globulins and daclizumab<sup>[77]</sup>. However, the need for long-term parenteral nutrition, re-laparotomies, organ rejection and, especially, bacterial infections are frequent complications and the procedure still have mortality rates approaching 50% at 5 years. Predictors of post-transplant complications are: concomitant neuromuscular disorders of the urinary tract, chronic use of opioids and technical problems determined by previous multiple laparotomies and/or the need of gastrectomy for gastroparesis. Nonetheless, transplantation should be considered when all other therapeutic options have failed according to the following indications: chronic intestinal failure with a high risk of mortality, life-threatening complications of parenteral nutrition, lack of venous access, disease-related poor quality of life despite optimal parenteral nutrition<sup>[58]</sup>.

## **CONCLUSION**

CIPO is a rare and often misdiagnosed pathological condition. Even if the acute phases can be hardly differentiated by mechanical occlusions and the inter-crisis digestive symptoms can mimic other severe functional digestive syndromes, the syndrome should be recognized based on the typical combination of clinical features, natural course and radiological signs. The diagnostic suspicion should be then confirmed by more accurate examinations, in order to identify possible causes of secondary forms and underlying pathophysiological mechanisms.

Management of CIPO remains extremely challenging and often disappointing.

A greater awareness of the clinical features of CIPO would help to limit surgical procedures to a minimum and, even more importantly, to collect full-thickness biopsies

for analysis of the gut neuromuscular layer at an early and potentially curable stage of the disease.

### Abstract

Endoscopic submucosal dissection (ESD) is an advanced technique of therapeutic endoscopy for superficial gastrointestinal neoplasms. Three steps characterize it: injecting fluid into the submucosa to elevate the lesion, cutting the surrounding mucosa of the lesion, and dissecting the submucosa beneath the lesion. The ESD technique has rapidly permeated in Japan for treatment of early gastric cancer, due to its excellent results of en-bloc resection compared to endoscopic mucosal resection (EMR). Although there is still room for improvement to lessen its technical difficulty, ESD has recently been applied to esophageal and colorectal neoplasms. Favorable short-term results have been reported, but the application of ESD should be well considered by three aspects: (1) the possibility of nodal metastases of the lesion, (2) technical difficulty such as location, ulceration and operator's skill, and (3) organ characteristics.

### INTRODUCTION

Application of endoscopic resection (ER) to gastrointestinal (GI) neoplasms is limited to lesions with no risk of nodal metastasis. Either polypectomy or endoscopic mucosal resection (EMR) is beneficial for patients because of its low level of invasiveness. However, to ensure the curative potential of these treatment modalities, accurate histopathologic assessment of the resected specimens is essential because the depth of invasion and lymphovascular infiltration of the tumor is associated with considerable risk for lymph node metastasis. For accurate assessment of the appropriateness of the therapy, en bloc resection is more desirable than piecemeal resection. For a reliable en bloc resection of GI neoplasms, a new method of ER called endoscopic submucosal dissection (ESD) has been developed. In this article, an outline of the current status of ESD will be discussed.

### DEVELOPMENT OF ESD

The ESD technique has developed from one of the EMR techniques, namely endoscopic resection after local injection of a solution of hypertonic saline-epinephrine (ERHSE)<sup>[1]</sup>. Initially, the ESD technique was called by various names such as cutting EMR, exfoliating EMR, EMR with circumferential incision *etc.* However, a new name was proposed to this technique in 2003, as a treatment positioned between EMR and laparoscopic surgery, since this technique is innovative and enables complete resection of neoplasms that were impossible to resect en bloc by EMR.

At present, numerous electrosurgical knives such as insulation-tipped diathermic knife (IT-knife)<sup>[2-6]</sup>, needle knife<sup>[7]</sup>, hook knife<sup>[8]</sup>, flex knife<sup>[9-11]</sup>, triangle-tipped knife<sup>[12]</sup>, flush knife<sup>[13]</sup>, mucosectomy<sup>[14]</sup>, splash needle<sup>[15]</sup> and a special device called a small-caliber tip transparent (ST) hood<sup>[7]</sup> are available for this technique. One or two of these electrosurgical knives are used in combination with a high frequency electrosurgical current (HFEC) generator with an automatically controlled system (Endocut mode, Erbotom ICC200, ICC350, VIO300D, ERBE, Tubingen, Germany) (PSD-60, Olympus, Tokyo, Japan). New types of endoscopes are available for ESD, such as an endoscope with a water jet system (EG-2931, Pentax, Tokyo, Japan, GIF-Q260J, Olympus, Tokyo, Japan), an endoscope with a multi-bending system (M-scope: XGIF-Q240M, R-scope: XGIF-2TQ240R, Olympus, Tokyo, Japan) to facilitate the ESD procedure<sup>[16-19]</sup>. As another approach to successful

ESD, investigations of submucosal injection solutions have been actively done. It was reported that a hyaluronic acid solution makes a better long-lasting submucosal cushion without tissue damage than other available solutions<sup>[7,20-23]</sup>. As a further improvement of hyaluronic acid solution, usefulness of a mixture of high-molecular-weight hyaluronic acid, glycerin, and sugar has also been reported<sup>[24,25]</sup>.

ESD is characterized by three steps: injecting fluid into the submucosa to elevate the lesion from the muscle layer, circumferential cutting of the surrounding mucosa of the lesion, and subsequent dissection of the connective tissue of the submucosa beneath the lesion. Major advantages of this technique in comparison with polypectomy or EMR are as follows. The resected size and shape can be controlled, en bloc resection is possible even in a large neoplasm, and neoplasms with submucosal fibrosis are also resectable. So this technique can be applied to the resection of complex neoplasms such as large neoplasms, ulcerative non-lifting neoplasms, and recurrent neoplasms. The disadvantages of this technique are the requirement of two or more assistants, it is time-consuming, there is a higher risk of bleeding and perforation than EMR. In Japan, ESD is now gaining acceptance as the standard endoscopic resection technique for stomach neoplasms in an early stage, especially for large or ulcerative neoplasms. Recently, the ESD technique is applied to esophageal or colorectal neoplasms in some institutions, although it is still controversial considering the technical difficulty, associated risks, and favorable outcomes by EMR.

## INDICATION FOR ENDOSCOPIC RESECTION

### *Gastric cancer*

Early gastric cancer (EGC) is defined to a mucosal or submucosal invasive cancer (T1 cancer) irrespective of the presence of lymph node metastasis. Lesions indicated for ER should be EGC with no risk of nodal metastasis and that can be resected in a single fragment. Using a large database of more than 5000 EGC patients who underwent gastrectomy with D2 lymph node dissection, a criteria of node negative cancer has been defined<sup>[26]</sup>. At present, lesions with preoperative endoscopic diagnosis of differentiated type intramucosal cancer without ulcer findings, differentiated type intramucosal cancer no larger than 3 cm in diameter with ulcer findings, differentiated type minute invasive submucosal (less than 500 micrometers below muscularis mucosa) cancer no larger than 3 cm in diameter are considered as expanding indication for ER<sup>[27]</sup>. Undifferentiated type cancer lesions, and preoperative diagnosis of ulcerative findings is difficult, so that ER for these lesions should be carefully considered.

### *Esophageal cancer*

Early esophageal cancer (EEC) involving the epithelium (m1: carcinoma in situ) or the lamina propria (m2) are candidates for ER because no lymph node metastasis have been reported in cancers limited to these two layers<sup>[28]</sup>. For EEC invading the muscularis mucosa (m3), the lymph

node metastasis rate is reported as 9%, and for cancer with minute submucosal invasion (< 200 micrometers below the muscularis mucosa; sm1) the rate is 19%<sup>[29]</sup>. The lymph node metastasis rate of m3 or sm1 cancer without lymphovascular infiltration of the tumor is reported as 4.7%<sup>[29]</sup>. Therefore, for patients unwilling for esophagectomy or patients with comorbid diseases not suited for surgery, ER may be a relative indication for m3 or sm1 cancer. Also, for lesions spreading more than three-quarter of circumference of the esophagus are considered as relative indication for ER because post-operative stricture occurs in a high rate.

### *Colorectal cancer*

Early colorectal cancer (ECC) limited to the mucosa or with slight submucosal invasion (< 1000 micrometers below the muscularis mucosa; sm1) are candidates for ER<sup>[30]</sup>. However, even for lesions that meet the criteria above, laparoscopic or open surgery may be selected in some institutions considering the location and size of the lesion. In institutions actively performing ESD for colorectal lesions, depressed lesions and laterally spreading tumors of non-granular type (LST-NG) are considered as good candidates for ESD because these lesions have a high possibility of submucosal invasion which may be difficult to diagnose preoperatively, and a thorough histopathological assessment of the resected specimen is essential.

### *Preoperative evaluation for candidates of ER*

Endoscopy with chromoendoscopy is essential to define the lesion. To evaluate the depth of the lesion, size, redness, presence or absence of ulceration, superficial structure of the lesion, and deformity of the wall of the organ in compliance with air-flow rate are carefully observed by endoscopy and chromoendoscopy. Magnification endoscopy with narrow band imaging technique (NBI) has been reported as a promising new modality to evaluate the depth of ECC. Magnification endoscopy with NBI is also useful to distinguish the border of EGC in case of lack of utility of chromoendoscopy with indigocarmine. Magnification endoscopy with crystal violet staining or NBI is useful in estimating the depth of colorectal lesions. Endoscopic ultrasonography is often performed to evaluate the depth of invasion, and computed tomography may be performed to detect lymph node metastasis if any, if the diagnosis of node negative cancer is difficult to judge even with multiple diagnostic modalities.

### *Pathological evaluation of the removed specimen*

Whether a lesion may be included into the criteria of node-negative neoplasms is considered before treatment. However, at present, it is impossible to make a definite diagnosis of a neoplasm regarding depth, histological type and lymphatic vessel invasion before treatment. It is often experienced that although a biopsy specimen shows adenoma/dysplasia of a lesion, a diagnosis of cancer is made after total resection of the lesion. Therefore, a precise pathological evaluation of the resected specimen is essential, and an en bloc resection of the lesion is desirable in this respect.

After removal, the specimen should be oriented immediately before it is immersed in formalin. Orientation of the specimen is accomplished by fixing the periphery with thin needles on a plate of rubber or wood. The submucosal side of the specimen is faced to the plate. After fixation, the specimen is sectioned serially at 2 mm intervals parallel to a line that includes the closest part between the margin of the specimen and of the neoplasm, so that both lateral and vertical margins are assessed. The depth of invasion is then evaluated microscopically along with the degree of differentiation and lymphovascular infiltration, if any.

In result of thorough pathological assessment, if the lesion is resected en bloc with negative margins of neoplasm and fulfills the criteria of node-negative neoplasms with no lymphovascular infiltration, the treatment is judged as curative resection. For lesions with piecemeal resection but being judged as node-negative neoplasms, or lesions with histologically non-evaluable areas due to artifact or tissue burning, a periodical endoscopic follow-up should be performed to detect residual neoplasm or local recurrence. On the other hand, for lesions that do not fulfill the criteria of node-negative neoplasms, additional surgery with nodal dissection should be strongly recommended.

## OUTCOMES OF ESD

### En bloc resection rate

Recent results of en bloc resection rate and local recurrence of ESD for neoplasms in the stomach, esophagus and colorectum are described in Table 1. For gastric neoplasms larger than 20 mm, en bloc resection rate is extremely low among conventional EMR methods, and local recurrence rates are around 10%<sup>[44]</sup>. Although ESD was considered as a difficult and complicated technique when it was first described in the stomach, after maturity of the techniques of ESD, en bloc resection rates became greater than 90%, regardless of size, and local recurrence rates became almost zero. Technical feasibility and favorable results of ESD have also been reported in recurrent neoplasms<sup>[45-47]</sup>, neoplasms of the esophago-gastric junction<sup>[48]</sup>, and duodenal neoplasms although the number of cases is small. Few reports of ESD for resection of subepithelial tumors have also been published<sup>[49]</sup>.

### Complication

Complications of ESD include pain, bleeding, perforation, and stricture. Pain after ESD is often mild and lasts one or two days after the procedure although the frequency is low. Patients of esophageal ESD are more likely to develop pain than gastric or colorectal ESD.

Complications of post-operative bleeding and perforation among various ESD methods in the stomach, esophagus and colorectum are described in Table 2. Bleeding is more frequent in the stomach cases, whereas perforation is more frequent in the colorectal cases. To prevent post-procedural bleeding, hemostasis of appearing vessels on the artificial ulcer after removing the specimen is essential. Hemostasis is performed by hemostatic forceps (HDB2422/HDB2418, Pentax), coagrasper (FD-410LR,

<sup>1</sup>En bloc resection + R0 resection rate.

Olympus), hot biopsy forceps, argon plasma coagulation or endoclips. According to perforation, recent case series suggest that small perforation immediately recognized can be successfully sealed with endoclips and treated conservatively by nasogastric suction, fasting and antibiotics without emergency laparotomy<sup>[51,52]</sup>. However, there are rare cases of delayed perforation, which requires surgical rescue. Delayed perforation may occur in the esophagus, stomach, duodenum and colorectum<sup>[31,53-56]</sup>, mostly at two or more days after a successful ESD. The reason for delayed perforation is unknown, however patients with uncontrolled diabetes mellitus, patients on permanent hemodialysis, lesions located on surgical anastomosis, and too much coagulation are considered as possible risk factors.

Stricture after ESD may occur in esophageal ESD when the ESD ulcer is larger than two-third of circumference of the esophageal lumen, or in gastric ESD when the ESD ulcer involves more than three quarter of the pylorus or pre-pylorus area. In these cases, early intervention to avoid passage obstruction is required. Dilation using bougie or balloon are often applied one week after ESD and repeated several times until healing of the ESD ulcer<sup>[8,11,57]</sup>.

## MANAGEMENTS AFTER ESD

In Japan, ESD is performed on hospitalized patients. After ESD, eating is usually started on the next or 2 d after ESD if there is no complication, and the patient

	Hurlstone <sup>[50]</sup>	2007	ESD-Flex knife	42	12	2.4
	Onozato <sup>[43]</sup>	2007	ESD-Flex knife	35	0	2.9

may be discharged within a few days. Antacids are usually administered to gastric and esophageal ESD patients to relieve pain, prevent postoperative bleeding and promote ulcer healing. A recent study showed that proton pump inhibitors more effectively prevented bleeding from the gastric ulcer created after ESD than did H<sub>2</sub>-receptor antagonists<sup>[58]</sup>. Ulcers after ESD are reported to heal within 6 to 8 wk in the esophagus, stomach and colorectum<sup>[59-63]</sup>.

Endoscopic surveillance should be carried out in patients after ESD not only to detect local recurrence but also metachronous cancer especially in the esophagus and stomach. A recent study showed that the average time to detect a first metachronous gastric cancer (MGC) was 3.1  $\pm$  1.7 years after EMR/ESD, and the cumulative 3-year incidence was 5.9%<sup>[64]</sup>. In order to detect MGC at an early stage to perform a successful ER, annual endoscopic surveillance program may be practical for post-ER patients.

## LONG-TERM OUTCOMES AFTER ESD

Long-term outcomes after ESD for gastric cancers within the expanded indication are currently under investigation. Survival data is still lacking in the literature, however in the 2007 annual meeting of Japanese gastroenterological endoscopy society (JGES), a symposium was held upon long-term outcomes after gastric and esophageal ESD. For gastric ESD, 3-year disease free survival rate was reported as 90%-92%, local recurrence rate was reported as 0.8%-12%. For lesions within the criteria of node negative cancers, there were no reports of distant metastasis. Metachronous gastric cancer detection rate during follow-up was reported as 3.4%-10.2%. In comparison, long-term outcomes after EMR for small differentiated mucosal EGC less than 20 mm in diameter have been reported as comparable to those after gastrectomy. The disease-specific 5- and 10-year survival rates were 99% and 99%<sup>[65]</sup>. For esophageal ESD, in the 2007 JGES meeting, 3-year survival rate for m1-2 cancer and m3-sm1 cancer were 95.1% and 86.7%, respectively. According to colorectal ESD, there is still no long-term data at present.

## FUTURE PERSPECTIVES

With the development of ESD, more than half of GI cancers in the early stage are removed by ER in advanced institutions in Japan. En bloc retrieval of lesions is essential for detailed histopathologic studies, which form the basis for stratification of treatment outcomes and patient's prognosis. ESD theoretically offers greater histopathological accuracy than conventional EMR methods or piecemeal resection. However, ESD requires highly skilled endoscopists, and a suitable training program is demanded for permeation of this technique. For trainees starting ESD, skills of routine endoscopy and colonoscopy, target biopsy, endoscopic hemostasis techniques and simple EMR techniques should be required. A trainee would gain early proficiency of ESD after 30 cases under supervision of a mentor<sup>[32,66]</sup>. On the other hand, serious complications such as delayed perforation have been reported, and a thorough patient care before and after ESD is essential. At present, selection of a lesion within the criteria for ER, selection of the patient with adequate general function should be well considered. It is important to share the information and experience among endoscopists to skill up and avoid serious complications. The ESD technique is still not a treatment at ease, and further refinements of the technique is required to popularize ESD as a safe and reliable, less invasive treatment for patients with GI neoplasms.

## Abstract

The aim of the present review is to summarize the current knowledge regarding pharmacological prevention and treatment of acute pancreatitis (AP) based on experimental animal models and clinical trials. Somatostatin (SS) and octreotide inhibit the exocrine production of pancreatic enzymes and may be useful as prophylaxis against Post Endoscopic retrograde cholangiopancreatography Pancreatitis (PEP). The protease inhibitor Gabexate mesilate (GM) is used routinely as treatment to AP in some countries, but randomized clinical trials and a meta-analysis do not support this practice. Nitroglycerin (NGL) is a nitrogen oxide (NO) donor, which relaxes the sphincter of Oddi. Studies show conflicting results when applied prior to ERCP and a large multicenter randomized study is warranted. Steroids administered as prophylaxis against PEP has been validated without effect in several randomized trials. The non-steroidal anti-inflammatory drugs (NSAID) indomethacin and diclofenac have in randomized studies showed potential as prophylaxis against PEP. Interleukin 10 (IL-10) is a cytokine with anti-inflammatory properties but two trials testing IL-10 as prophylaxis to PEP have returned conflicting results. Antibodies against tumor necrosis factor-alpha (TNF- $\alpha$ ) have a potential as rescue therapy but no clinical trials are currently being conducted. The antibiotics beta-lactams and quinolones reduce mortality when necrosis is present in pancreas and may also reduce incidence of infected necrosis. Evidence based pharmacological treatment of AP is limited and studies on the effect of potent anti-inflammatory drugs are warranted.

## INTRODUCTION

Acute pancreatitis (AP) is a localized inflammatory condition, which may extent to other organs. The etiology is usually excessive consumption of alcohol or gallstone disease, but is in some cases iatrogenic following medication or endoscopic retrograde cholangiopancreatography (ERCP).

Only a few reviews summarizing the available pharmacological options for treating AP have been published despite various experimental and clinical testing of potential drugs<sup>[1]</sup>. The aim of the present review is to validate the current literature covering the pharmacological treatment of AP. The main focus is on human clinical trials but some animal experimental models have been included as well (Table 1). AP after ERCP [post-ERCP pancreatitis (PEP)] can be regarded as a clinical "experimental" model of AP and hence is subject to preventive measures. The studies of potentially prophylactic drugs to PEP are therefore included (Table 2).

## PATHOPHYSIOLOGY

The pathobiological processes have primarily been investigated in experimental animal models and it is widely accepted that the acinar cells play a central role in the development of AP. The secretory acinar cells (SAC) contain zymogen precursors and the intra-acinar activation of digestive enzymes is a key event in the pathogenesis of AP. The molecular mechanism by which zymogen in AP fails to leave the SAC is unknown. Studies suggest a loss of the terminal actin web or a displacement of one of the SNARE membrane proteins, which regulate exocytosis<sup>[2]</sup>.

The inflammatory response is partly caused by the release of chemokines from SAC, which is followed by recruitment of helper T lymphocytes and macrophages leading to pancreatic edema and accumulation of neutrophils. The systemic release of cytokines including major pro-inflammatory cytokines causes a systemic

**Table 1** Pharmacological treatment of acute pancreatitis: Overview of drugs tested in animal experimental models and clinical trials

Name	Mechanism	Effect in animal models	Result in human trials
Somatostatin	Inhibition of pancreatic secretion	No reduced mortality	No reduced mortality
Octreotid	Inhibition of pancreatic secretion	No effect (divergent results)	No reduced mortality
Gabexate mesilate	Protease inhibitor	Reduced histology score	Maybe reduced mortality
N-acetyl-cysteine	Reduction of oxidative stress	Reduced severity	No reduced mortality
Nitrogen oxide	Improvement of micro-circulation	Reduced edema	No published trials
Steroids	Non-specific anti-inflammatory	Reduced mortality	No published trials
Interleukin-10	Anti-inflammatory	Reduced mortality	No published trials
TNF-alpha antibody	Specific anti-inflammatory	Reduced mortality	No published trials
PAF inhibitor	Specific anti-inflammatory	No reduced mortality	No reduced mortality
Antibiotics	Antibacterial	-	Reduced mortality
Probiotics	Prevention of colonization of the gut	-	No reduced mortality

**Table 2** Pharmacological prevention of PEP: Overview of drugs tested in clinical trials

Name	Mechanism	Incidence of PEP
Somatostatin	Inhibition of pancreatic secretion	No effect
Octreotid	Inhibition of pancreatic secretion	Probably reduced
Gabexate mesilate	Protease inhibitor	No effect
N-acetylcysteine	Reduction of oxidative stress	No effect
Nitrogen oxide	Improvement of micro-circulation	No effect
Steroids	Non-specific anti-inflammatory	No effect
Interleukin-10	Anti-inflammatory	Probably no effect
TNF-alpha	Specific anti-inflammatory	No published trials
Antibiotics	Antibacterial	Reduced

response, which may include remote organs<sup>[3]</sup>. The inflammatory process is followed by interstitial edema and the disease will in 10%-15% of the cases progress to necrosis in parts of the pancreas and possible bacterial infection. During an attack of AP the microvascular circulation is affected, which compromises oxygenation of the tissue<sup>[2]</sup>.

The clinical manifestations of AP include upper abdominal pain and symptoms related to the systemic inflammatory response. In complicated cases with involvement of remote organ systems mortality is increased to 5% with ranges from 0% to 47% depending on the severity of the disease. The current treatment of AP is mainly supportive care using analgesics and relevant measures when other organs are involved. Enteral nutrition must be initiated as soon as possible and whenever patients are unable to eat, feeding tubes should be used. Supplementary treatment often involves antibiotics when an infection is suspected and surgery or endoscopic ultrasonic (EUS)-guided drainage in case of infected necrotizing pancreatitis<sup>[4]</sup>.

AP after ERCP is a common complication and reported incidences vary from 5% to 15% in larger series. The majority of the cases are mild self-limiting conditions but up to 1% may develop a severe and potentially fatal pancreatitis. Although the pathophysiological mechanism remains to be elucidated several risk factors are identified: known sphincter Oddi dysfunction, sphincterotomy, injection of contrast more than one time and experience of the endoscopists<sup>[5-7]</sup>.

## METHODS

Published trials were identified on PubMed using the MeSH term "AP" in combination with the following MeSH terms: steroids, cortisone, hydrocortisone, corticosteroids, nitroglycerin (NGL), non-steroidal anti-inflammatory drugs (NSAID), celecoxib, COX- II, diclofenac, indomethacin, interleukin 10 (IL-10), tumor necrosis factor-alpha (TNF- $\alpha$ ), infliximab, Remicade<sup>®</sup>, etanercept, adalimumab, Humira<sup>®</sup>, platelet activating-factor (PAF), lexipafant, antibiotics, somatostatin (SS), octreotide, Sandostatin<sup>®</sup>, probiotics, gabexate, nutrition. Only articles in English were included. Earlier published reviews were manually examined for other relevant studies.

### SS/octreotide

SS is a peptide hormone mainly produced in the gastrointestinal tract, where it has an inhibitory effect on gastric emptying, intestinal motility and intestinal blood flow. Furthermore, SS strongly inhibits the production of pancreatic enzymes, which has been the basis for using SS or its analogue octreotide as treatment for AP<sup>[8]</sup>.

Both experimental and clinical trials have been conducted with SS and octreotide, but no effect on the course of the disease has hitherto been demonstrated. Most of the clinical trials comprised only few patients and often patients with interstitial pancreatitis were included although this condition is self-limiting and does not require specific therapy<sup>[9]</sup>. The largest and best conducted study is a German prospective multicenter study with 302 patients from 32 hospitals with moderate to severe AP randomized to either octreotide or placebo. This study revealed no significant differences between the treatment groups with respect to mortality, rate of complications, surgical interventions or length of hospital stay<sup>[10]</sup>.

Several studies have examined SS or octreotide as prophylaxis to PEP. Various regimes have demonstrated a reduced incidence of PEP compared to placebo: SS administered as a bolus immediately after ERCP (4.4% *vs* 13.3%,  $P = 0.01$ )<sup>[11]</sup>, SS given as a 12-h continuous infusion starting 30 min before ERCP (1.7% *vs* 9.8%,  $P < 0.05$ )<sup>[12]</sup> and octreotide in repeated injections starting 24 h prior to ERCP (2% *vs* 8.9%,  $P = 0.03$ )<sup>[13]</sup>. It should be noted that these studies have a fairly high incidence of PEP in the placebo groups. Andriulli *et al* have performed two similar

large, double blind, multicenter, placebo-controlled trials using SS. They used a dosage of 750 micrograms SS as an infusion starting 30 min prior to ERCP, ending 2 h (SS = 183, placebo = 199) or 6 h (SS = 351, placebo = 395) after ERCP. The incidences of PEP in the placebo groups were 6.5% and 4.8% respectively and no advantageous effect of SS was observed<sup>[14,15]</sup>.

The reports published during the years 2002 to 2006 have been summarized in a meta-analysis, which concluded that SS or octreotide have no effect as prophylaxis prior to ERCP<sup>[16]</sup>. However, this meta-analysis did not include the most recent trial from China with 832 patients. In this study, octreotide was administered as a combination of intravenous infusion and subcutaneous injections and the incidence of PEP in the treatment group ( $n = 414$ ) and the placebo group ( $n = 418$ ) was 2.42% and 5.26% respectively ( $P = 0.046$ )<sup>[17]</sup>.

Octreotide and SS have thus been investigated in several clinical studies and may have an advantageous effect as prophylaxis prior to ERCP. Optimal dosage and cost-effectiveness still need to be elucidated.

### Protease inhibitor-Gabexate mesilate (GM)

The intracellular activation of proteases is a mandatory step in the development of AP and the protease inhibitors could theoretically have an effect in the treatment of AP or as prophylaxis prior to ERCP. The first protease inhibitor, Aprotinin, was widely used in the 1960's but randomized trials could not demonstrate any beneficial effect<sup>[18,19]</sup>. GM is a synthetic protease inhibitor, which improve histology score in animal models of AP<sup>[20]</sup>.

In the 1980's several reports with a varying number of patients with AP ( $n = 42$  to 223) have been published but none showed any advantage of GM<sup>[21-26]</sup>. Conversely Chen *et al* observed a significant improved survival in a randomized trial including 52 patients with severe AP who received GM (mortality 33% *vs* 8%)<sup>[27]</sup>. A meta-analysis later concluded that GM may reduce the mortality in patients with moderate to severe pancreatitis, but the authors also noted that poor quality of the included randomized trials limits the power of this meta-analysis<sup>[28]</sup>.

Several papers from Japan report a reduced mortality rate in patients with necrotizing AP receiving GM as continuous regional arterial infusion (CRAI). However this conclusion is based merely on clinical observations and not placebo-controlled randomized trials<sup>[29,30]</sup>.

Looking at the effect on PEP two large studies by Andriulli *et al* with in total 1172 patients did not reveal any beneficial effect of GM. These results are in conflict with an earlier study by Cavallini *et al*, who in a study of 418 patients observed a PEP incidence of 6% in the GM group and 14% in the placebo group ( $P = 0.009$ )<sup>[31]</sup>. However, a recent meta-analysis concludes that GM does not have an advantageous effect as prophylaxis to PEP<sup>[32]</sup>.
