**CONCLUSION:** Our findings suggest that NVP-LBH589 and NVP-LAQ824 are active against human pancreatic cancer, although the precise mechanism of *in vivo* drug action is not yet completely understood. Therefore, further preclinical and clinical studies for the treatment of pancreatic cancer are recommended.

### Abstract

**AIM:** To investigate *in vitro* and *in vivo* treatment with histone deacetylase inhibitors NVP-LAQ824 and NVP-LBH589 in pancreatic cancer.

**METHODS:** Cell-growth inhibition by NVP-LAQ824 and NVP-LBH589 was studied *in vitro* in 8 human pancreatic cancer cell lines using the 3-(4,5-dimethylthiazole-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay. In addition, the anti-tumoral effect of NVP-LBH589 was studied in a chimeric mouse model. Anti-tumoral activity of the drugs was assessed by immunoblotting for p21<sup>WAF-1</sup>, acH4, cell cycle analysis, TUNEL assay, and immunohistochemistry for MIB-1.

**RESULTS:** *In vitro* treatment with both compounds significantly suppressed the growth of all cancer cell lines and was associated with hyperacetylation of nucleosomal histone H4, increased expression of p21<sup>WAF-1</sup>, cell cycle arrest at G2/M-checkpoint, and increased apoptosis. *In vivo*, NVP-LBH589 alone significantly reduced tumor mass and potentiated the efficacy of gemcitabine. Further analysis of the tumor specimens revealed slightly increased apoptosis and no significant reduction of cell proliferation.

### INTRODUCTION

Pancreatic cancer is the fifth to sixth leading cause of cancer death in Europe and the fourth leading cause of cancer death in the USA<sup>[1]</sup>. The lethality of this malignancy is demonstrated by the fact that the annual incidence is approximately equal to the annual deaths. Unfortunately, carcinoma of the pancreas is increasing in incidence, and its risk factors are poorly understood. Although surgical resection remains the only chance for cure, less than 10% of patients diagnosed with pancreatic cancer are eligible for curative (R0) resection, since up to 90% of patients will present with locally advanced or metastatic disease. In addition, there is a high rate of relapse, even in patients who receive adjuvant therapy<sup>[2]</sup>. A recent evaluation of the Finnish Cancer Registry, which recorded 4922 pancreatic cancer patients between 1990 and 1996, detected only 89 five year survivors (1.8%)<sup>[3]</sup>. Metastatic cancer tends to be a rapidly progressing disease, often accompanied by significant weight loss, abdominal pain, nausea, and/or depression. For decades, 5-fluorouracil (5-FU) was the most widely used chemotherapeutic agent in

metastatic pancreatic cancer. Today gemcitabine, a nucleoside analogue that is incorporated into replicating DNA resulting in premature chain termination and apoptosis, is the current standard of care<sup>[4]</sup>. In a phase III approval study 126 patients with metastatic disease who had not received prior chemotherapy were randomized to weekly gemcitabine ( $n = 63$ ) or weekly bolus 5-FU ( $n = 63$ )<sup>[5]</sup>. Overall survival in patients treated with gemcitabine was significantly improved compared with patients treated with 5-FU; However, there was no convincing gain in median survival time (median survival 5.7 mo *vs* 4.4 mo,  $P = 0.0025$ ). The primary efficacy measure in this study was clinical benefit response, a composite of patient-oriented parameters including pain, Karnofsky performance status, daily analgesic usage, and body weight. Clinical benefit was experienced in 23.8% of patients treated with gemcitabine compared with only 4.5% of the patients treated with 5-FU ( $P = 0.022$ ). Fixed-dose-rate (FDR) gemcitabine (1500 mg/m<sup>2</sup> at 10 mg/m<sup>2</sup> per minute) has also been investigated by Tempero *et al* in comparison to 2200 mg/m<sup>2</sup> gemcitabine over 30 min<sup>[6]</sup>. Although median survival time improved from 5.0 mo in the standard arm to 8.0 mo in the FDR arm ( $P = 0.013$ ), grade 3 and 4 toxicity increased significantly. Many combination regimens with gemcitabine have been tested in open-label phase II or III studies with higher response and progression-free survival rates, but no definitive benefit in overall survival, with the only exception being a combination with capecitabine<sup>[4,7]</sup>. As little progress has been made in the past decade, new strategies should focus on targeting cancer cells at the molecular level. Recently, in a randomized phase III placebo-controlled trial, Moore *et al* demonstrated that combining gemcitabine with EGFR inhibitor erlotinib was associated with a modest, but statistically significant survival benefit of 15 d<sup>[8]</sup>. In contrast, a recent phase III trial (SWOG S0205 study) failed to demonstrate a clinically significant advantage of the addition of cetuximab, an anti-EGFR monoclonal antibody, to gemcitabine for overall survival, progression free survival and response<sup>[9]</sup>. Another approach is targeting VEGF as a key player in tumor growth and resistance to therapy. In a phase II trial with 52 patients, a combination of VEGF inhibitor bevacizumab and gemcitabine yielded a 21% response rate and a median survival of 8.8 mo<sup>[10]</sup>. These data led CALGB to conduct a randomized, double-blind, placebo-controlled, phase III trial (CALGB 80303). However, the addition of bevacizumab to gemcitabine did not improve survival<sup>[11]</sup>. Inhibiting histone deacetylases (HDACs), which regulate interactions between histones and DNA together with histone acetylases (HATs) as counter-players, may be another promising molecular target. Clinical studies published so far have shown that HDAC inhibitors (HDACIs) can be administered safely in humans and that treatment of some cancers with such agents seems to be beneficial<sup>[12,13]</sup>. NVP-LAQ824 and NVP-LBH589 are new chemical entities belonging to a structurally novel class of cinnamic hydroxamic

acid compounds<sup>[14-17]</sup>, which are currently in phase I clinical evaluation in advanced refractory solid tumors and hematologic malignancies<sup>[18-22]</sup>. However, little is known about their potential efficacy in pancreatic cancer. Therefore, the objectives of the current study were to investigate the efficacy of *in vitro* and *in vivo* treatment with the novel pan-HDAC inhibitors NVP-LAQ824 and NVP-LBH589 and to evaluate effects of combination with gemcitabine.

## MATERIALS AND METHODS

### Materials

Eight human pancreatic cancer cell lines (Hs766T, As-PC-1, CFPAC-1, Capan-2, Panc-1, MiaPaca-2, HPAF-2 and L3.6pl) were examined<sup>[23-27]</sup>. All cell lines were cultured in a 37°C incubator with 50-100 mL/L CO<sub>2</sub> in appropriate media. The HDACIs NVP-LAQ824 and NVP-LBH589 were provided by Novartis (Basel, Switzerland) and dissolved in dimethyl sulfoxide (DMSO) (10 mmol/L stock). Hoechst dye, sodium butyrate and monoclonal (mc)  $\beta$ -actin antibody were purchased from Sigma (Sigma-Aldrich Chemie GmbH Munich, Germany), mc p21<sup>WAF-1/Cip-1</sup> from Cell Signaling (Cell Signaling Technology, Beverly, USA), mc acH4 antibody from Upstate (Upstate Biotechnology, Lake Placid, USA), mc MIB-1 antibody from Dako (Glostrup, Denmark), and gemcitabine (diluted in D5W and 50 mL/L DMSO) from our hospital pharmacy. Six to eight-wk-old female athymic NMRI nude mice were supplied by Taconic (Taconic Europe, Ry, Denmark) and held under pathogen-free conditions. Humane care was administered, and study protocols complied with the institutional guidelines.

### Inhibition of cell growth

Cytotoxic effects of both drugs were determined by the 3-(4,5-dimethylthiazole-2-yl)-2,5-diphenyltetrazolium bromide (MTT, Sigma-Aldrich Chemie GmbH Munich, Germany) assay.  $1-5 \times 10^3$  cells were seeded in triplicate in 96-well plates (100  $\mu$ L/well) and allowed to attach overnight. The medium was then replaced with media (100  $\mu$ L) containing the designated drug or vehicle control (50 mL/L DMSO in D5W) followed by an incubation for 3 or 6 d. For the 6 d experiment, medium was changed after 3 d. Three hours before the end of the incubation period, 10  $\mu$ L of PBS containing MTT (5 g/L) was added to each well. Following this, the medium was removed. The precipitate was then resuspended in 100  $\mu$ L of lysis buffer (DMSO, 100 g/L SDS). Absorbance was measured on a plate reader at 590 nm using a reference wavelength of 630 nm. Each experiment was performed in triplicate.

### Immunoblotting

Cell culture monolayers were washed twice with ice-cold PBS and lysed with RIPA-buffer containing Tris-HCl (50 mmol/L, pH 7.4), NP-40 (10 g/L), sodium-desoxycholate (2.5 g/L), NaCl (150 mmol/L), EDTA (1 mmol/L), sodium-orthovanadate (1 mmol/L), and

one tablet of complete mini-EDTA-free protease inhibitor cocktail (Boehringer, Mannheim, Germany, in 10 mL buffer). Histones for anti-acH4 immunoblotting were isolated by acid extraction [cells were lysed in ice-cold lysis buffer (HEPES 10 mmol/L; pH 7.9), MgCl<sub>2</sub> (1.5 mmol/L), KCl (10 mmol/L), DTT (0.5 mmol/L), PMSF (1.5 mmol/L), and additional protease inhibitor]. One molar HCl was added to a final concentration of 0.2 mol/L, followed by an incubation on ice for 30 min and centrifugation at 13000 r/min for 10 min. The supernatant was retained and dialysed against 200 mL of 0.2 mol/L acetic acid twice for 1 h and against 200 mL H<sub>2</sub>O overnight). Proteins were quantified by Bradford protein assay (Bio-Rad, Munich, Germany) and stored at -80°C. 50 µg of cell or tissue lysates were separated on SDS-polyacrylamide gels and electroblotted onto polyvinylidene difluoride membranes (Amersham Pharmacia Biotech, Freiburg, Germany). Membranes were then incubated in blocking solution [50 g/L dry milk in 10 mmol/L Tris-HCl, 140 mmol/L NaCl, 1 g/L Tween-20 (TBS-T)], followed by incubation with the primary antibody at 4°C overnight (50 g/L BSA in TBS-T). The membranes were then washed in TBS-T and incubated with horseradish peroxidase (HRPO)-conjugated secondary antibodies for 1 h at room temperature. Antibody detection was performed with an enhanced chemoluminescence reaction (SuperSignal West Dura, Pierce, Rockford, USA).

### Cell cycle analysis

Cells were seeded in T-25 flasks ( $2 \times 10^5$ ), treated with various concentrations of NVP-LAQ824 or NVP-LBH589 or vehicle control (50 mL/L DMSO in D5W) for 72 h, washed with PBS, trypsinized, centrifuged, and fixed in 750 mL/L ice-cold ethanol-phosphate-buffered saline containing 10 g/L EDTA. DNA was labeled with 100 mL/L propidium iodide. Cells were sorted by FACSscan analysis, and cell cycle profiles were determined using ModFitLT V2.0 software (Becton Dickinson, San Diego, USA). Each experiment was performed in triplicate.

### Animal studies

Tumors were induced by injecting  $5 \times 10^6$  HPAF-2 or L3.6pl cells in 200 µL PBS sc into the flank region of NMRI nude mice. Treatment was started when an average tumor volume of 150 mm<sup>3</sup> was reached (usually after 2 wk). The verum groups received either NVP-LBH589 (25 mg/kg, 5 × weekly) or gemcitabine (5 mg/kg, 1 × weekly) or a combination of both (NVP-LBH589 at 25 mg/kg, 5 × weekly plus gemcitabine at 5 mg/kg, 1 × weekly) ip, whereas the control group received placebo (carrier solution 50 mL/L DMSO in D5W) only. Treatment was continued for 28 consecutive days, tumors were measured daily with a Vernier caliper and tumor volumes were calculated using the formula tumor volume =  $0.5 \times L \times W^2$ , where *L* represents the length and *W* the width of the tumor. When treatment was finished, animals were sacrificed and tumors excised and weighed.

### TUNEL POD test

Terminal deoxynucleotidyl transferase-mediated dUTP nick end labeling (*in situ* cell death detection kit, POD) was used to detect apoptosis in paraffin sections from mouse tumor tissue. TUNEL was carried out following the manufacturer's instructions (Roche, Penzberg, Germany) as previously described<sup>[28]</sup>. Apoptotic cells (red) were counted under a light microscope after fluorescence signal conversion using peroxidase-conjugated antibody and peroxidase substrate (DAB, Roche, Penzberg, Germany). The number of positive cells was counted by an experienced pathologist (M.N.) in a total of 8 high power fields (HPFs) and expressed as mean percentage of total cells in these fields of the tumor. Necrotic tumor cells were excluded from the cell count.

### Immunohistochemical staining

For MIB-1 staining, we used paraffin sections following a protocol that has been described elsewhere<sup>[29]</sup>. The number of positive cells was counted by an experienced pathologist (M.N.) in a total of 4 HPFs and expressed as mean percentage of total cells in these fields of the tumor.

### Statistical analysis

Statistical calculations were performed using SPSS, version 10.0 (SPSS Inc., Chicago, USA). Numeric data were presented as mean value with SD or SEM. Inter-group comparisons were performed with the Student *t*-test and ANOVA. *P* < 0.05 was considered significant.

## RESULTS

### Inhibition of cell growth

After 3 d of incubation, 7 of 8 tested cell lines were sensitive to NVP-LAQ824 (mean IC<sub>50</sub> (3 d) =  $0.18 \pm 0.24$  µmol/L) and even more to NVP-LBH589 (mean IC<sub>50</sub> (3 d) =  $0.09 \pm 0.14$  µmol/L). Only cell line Capan-2 demonstrated an IC<sub>50</sub> (3 d) value > 1 µmol/L for both compounds. Inhibition of cell growth was more pronounced if incubation time was extended to 6 d with a mean IC<sub>50</sub> value of  $0.06 \pm 0.07$  µmol/L for NVP-LAQ824 and  $0.03 \pm 0.02$  µmol/L for NVP-LBH589. After 6 d of incubation, cell line Capan-2 also became responsive (Figure 1 and Table 1). In addition, DMSO alone (the solvent for NVP-LAQ824 and NVP-LBH589) had no influence on cell growth (data not shown).

### Immunoblotting

Treatment of cell lines HPAF-2 and L3.6pl with 0.1 µmol/L NVP-LAQ824 or 0.1 µmol/L NVP-LBH589 for 24 h resulted in acetylation of histone H4 (Figure 2A and B). The same treatment caused an induction of p21<sup>WAF-1/CIP-1</sup> expression (Figure 2C and D). A dose increase to 0.2 µmol/L NVP-LAQ824 or NVP-LBH589 corresponded with an increase in histone H4 acetylation and p21<sup>WAF-1/CIP-1</sup> levels. Histone H4 acetylation was higher in treated HPAF-2 than L3.6pl cells, whereas p21<sup>WAF-1/CIP-1</sup> expression was slightly higher in treated L3.6pl cells.

**Figure 1** *In vitro* treatment of pancreatic cancer with NVP-LAQ824 and NVP-LBH589 (MTT assay). **A:** 3-d incubation with NVP-LAQ824 ( $n = 3$ ); **B:** 6-d incubation with NVP-LAQ824 ( $n = 3$ ); **C:** 3-d incubation with NVP-LBH589 ( $n = 3$ ); **D:** 6-d incubation with NVP-LBH589 ( $n = 3$ ).

Capan-2	> 1	0.19	> 1	0.05

### Cell cycle analysis

Treatment of cell lines HPAF-2 and L3.6pl with 0.1 μmol/L NVP-LAQ824 or NVP-LBH589 for 72 h resulted in G2/M arrest. This arrest was, in general, more pronounced if the dose of NVP-LAQ824 or NVP-LBH589 was increased to 0.2 μmol/L. Percentual G2/M arrest was lower for 0.2 μmol/L than 0.1 μmol/L only for the treatment of HPAF-2 cells with NVP-LBH589. This phenomenon may derive from the fact, that at

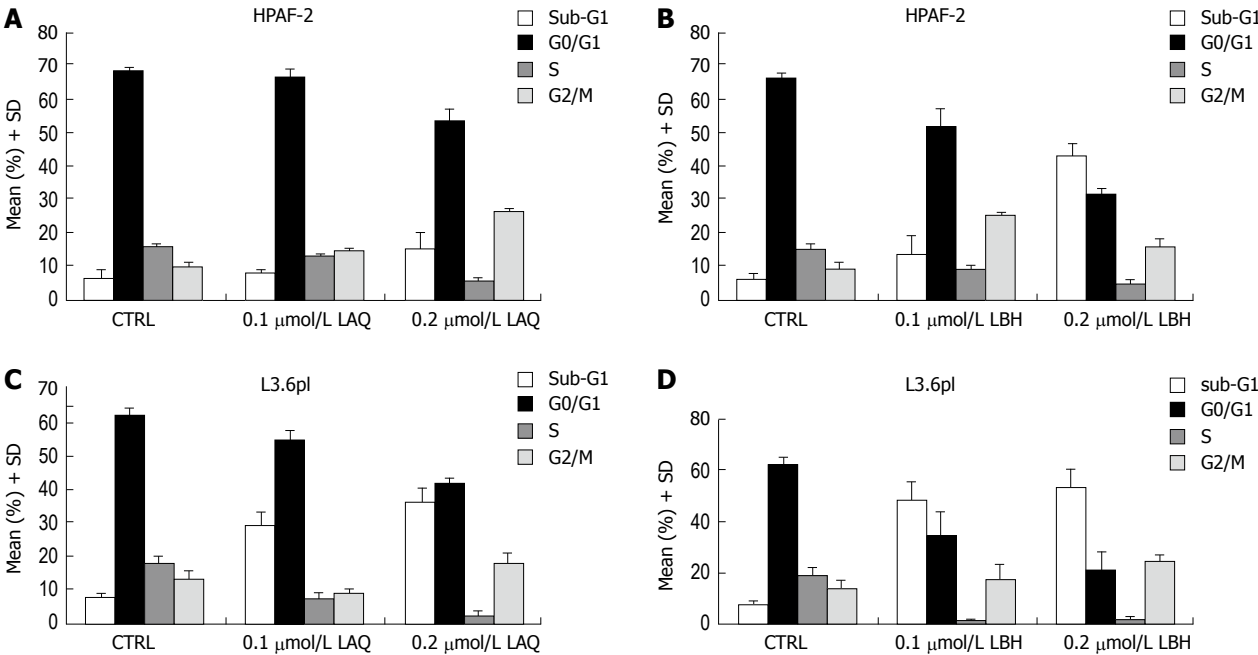

the same time the sub-G1-peak was much higher for 0.2 μmol/L. For both concentrations, the effect of NVP-LBH589 was stronger than the effect of NVP-LAQ824 with the aforementioned exception of 0.2 μmol/L NVP-LBH589 in HPAF-2 cells (Figure 3). In addition, incubation with NVP-LAQ824 or NVP-LBH589 for 72 h resulted in a dose-dependent significant increase in the sub-G1-peak, which was higher for NVP-LBH589 than NVP-LAQ824 and higher in L3.6pl than in HPAF-2 cells. This result correlated well with the fact that IC<sub>50</sub> values in the cell growth inhibition experiment (Figure 1) were lower for L3.6pl in comparison to HPAF-2 cells.

### Chimeric mouse model

Tumors were induced in nude mice by subcutaneous injection of HPAF-2 and L3.6pl cells. These cell lines were selected because they had the best growth capability in our nude mice in a pilot study. Treatment of mice consisted of ip injections with NVP-LBH589, gemcitabine, NVP-LBH589 plus gemcitabine (COMBO) or placebo (50 mL/L DMSO in D5W). Three days after commencement of NVP-LBH589 or COMBO treatment, HPAF-2 cell tumors showed a signifi-

**Figure 2** Mechanism of drug action after *in vitro* treatment with NVP-LAQ824 and NVP-LBH589 for 24 h. **A** and **B**: Acetylation of histone H4. Protein extracts from HELA cells that were treated with 5 mmol/L sodium butyrate served as positive controls; **C** and **D**: p21<sup>waf-1/cip-1</sup> expression. Cell lysate from HCT 116 colon cancer cells served as positive control; **A-D**: Staining with  $\beta$ -actin antibody confirmed equal protein loading.

**Figure 3** Cell cycle analysis. **A**: Treatment of cell line HPAF-2 with 0.1 or 0.2  $\mu\text{mol/L}$  NVP-LAQ824 for 72 h ( $n = 3$ ); **B**: Treatment of cell line HPAF-2 with 0.1 or 0.2  $\mu\text{mol/L}$  NVP-LBH589 for 72 h ( $n = 3$ ); **C**: Treatment of cell line L3.6pl with 0.1 or 0.2  $\mu\text{mol/L}$  NVP-LAQ824 for 72 h ( $n = 3$ ); **D**: Treatment of cell line L3.6pl with 0.1 or 0.2  $\mu\text{mol/L}$  NVP-LBH589 for 72 h ( $n = 3$ ).

cantly reduced volume in comparison to control ( $n = 7$  for each group,  $P < 0.05$ ). Treatment of mice with gemcitabine alone resulted in a significant reduction of tumor volume compared to control after 4 d from commencement of treatment. These differences were maintained until the end of the experiment. COMBO therapy was significantly more efficient than gemcitabine treatment alone on treatment day 7, 8, 13, 14, 15, and 16 and was significantly more efficient than NVP-LBH589 therapy alone on treatment day 7 and 14 ( $P < 0.05$ ,

Figure 4A). Treatment of L3.6pl tumors with NVP-LBH589 or COMBO resulted in a significantly reduced volume in comparison to control after 4 d ( $P < 0.05$ ) and 3 d ( $P < 0.05$ ) from commencement of therapy, respectively ( $n = 7$  for each group). These differences were also maintained until the end of the experiment. Treatment of mice with gemcitabine alone resulted in a significant reduction of tumor volume compared to control at treatment day 12, 13, 16, 17, and 18 ( $P < 0.05$ ). COMBO therapy was significantly more

**Figure 4** *In vivo* treatment with NVP-LBH589 + gemcitabine in chimeric mice. **A:** Effect on tumor volume of HPAF-2 cells; **B:** Effect on tumor volume of L3.6pl cells; **C:** Effect on tumor mass (<sup>a</sup> $P < 0.05$ , COMBO vs control; <sup>b</sup> $P < 0.01$ , NVP-LBH589 or COMBO vs control).

efficient than gemcitabine treatment alone on treatment day 3-20 and was significantly more efficient than NVP-LBH589 therapy alone on treatment day 3 ( $P < 0.05$ ). NVP-LBH589 therapy was significantly more efficient than gemcitabine treatment alone on treatment day 5-20 ( $P < 0.05$ , Figure 4B). At the end of the experiment after 30 d, tumor mass in HPAF-2 cells bearing mice

was significantly diminished as compared to placebo after treatment with COMBO (-63%,  $P < 0.05$ ). In contrast, treatment of mice with gemcitabine (-24%,  $P = 0.45$ ) or NVP-LBH589 alone (-58%,  $P = 0.056$ ) did not result in any significant reduction of tumor mass as compared to control (Figure 4C). L3.6pl cell tumor mass in mice was significantly diminished after treatment

**Figure 5** Hematoxylin-eosin (HE), MIB-1 (proliferation marker) and TUNEL (apoptosis marker) staining of mouse tumors (SABC, x 40). **A:** Cell line HPAF-2; **B:** Cell line L3.6pl.

with either NVP-LBH589 (-70%,  $P < 0.01$ ) or COMBO (-81%,  $P < 0.01$ ), but not with gemcitabine (-24%,  $P = 0.28$ ),

**Table 2** MIB-1- and TUNEL-staining of mouse tumor specimens

Mean in %	HPAF-2		L3.6pl	
	MIB-1	Apoptosis	MIB-1	Apoptosis
CTRL	67.5	1.3	61.3	0
GEM	66.3	2.5	70	0
LBH	51.3	3.8	76.3	6.3
COMBO	55.0	3.8	78.8	3.8

respectively. In addition, the combination of NVP-LBH589 with gemcitabine was more effective at tumor mass reduction in comparison to gemcitabine alone ( $P < 0.05$ ). The L3.6pl animal experiment was stopped at day 21 for ethical reasons, since animals suffered from tumor burden. Regarding side effects of the different drugs used in HPAF-2 cell tumor bearing mice, weight loss was 2%, 0%, 13%, and 6%, in the control, gemcitabine, NVP-LBH589, and COMBO groups. There was a statistically significant difference between the control and NVP-LBH589 group ( $P < 0.05$ ) and between the gemcitabine and NVP-LBH589 group ( $P < 0.01$ ). Concerning side effects of the different drugs used in L3.6pl cell tumor bearing mice, weight loss was 23%, 17%, 12%, and 25%, in the control, gemcitabine, NVP-LBH589, and COMBO groups. There was a statistically significant difference between the control and NVP-LBH589 group ( $P < 0.05$ ).

In order to assess the anti-tumoral drug mechanism, paraffin sections of mouse tumors were stained with hematoxylin-eosin (H&E), MIB-1 (proliferation marker) and TUNEL (apoptosis marker) (Figure 5). Treatment with NVP-LBH589 and COMBO slightly reduced proliferation (reduced MIB-1 staining) and slightly induced apoptosis (increased TUNEL-staining) in HPAF-2 cell bearing mice, whereas proliferation was not decreased and apoptosis only slightly increased in L3.6pl cell bearing mice (Table 2).

## DISCUSSION

Analyzing palliative treatment data, a novel approach for patients with metastatic pancreatic cancer is urgently required. Targeting HDACs may be a new option for this tumor entity. Preliminary studies have demonstrated *in vitro* activity of HDACIs in pancreatic cancer cell lines. Natoni *et al*<sup>[30]</sup> showed that treatment with sodium butyrate, a carboxyl acid class inhibitor of HDACs, resulted in marked down-regulation of anti-apoptotic Bcl-xL protein expression, mitochondrial membrane depolarization, cytochrome c release from mitochondria, activation of caspase-9 and -3, and apoptosis induction. Garcia-Morales *et al*<sup>[31]</sup> reported HDACIs induced apoptosis in the pancreatic cancer cell lines IMIM-PC-1, IMIM-PC-2, and RWP-1 that are normally resistant to other antineoplastic drugs. This finding was previously observed by Sato *et al*<sup>[32]</sup> for five normally chemotherapy-resistant cell lines when treated with FR901228, a cyclic peptide HDACI belonging to the depsipeptides class. Recently, another class of HDACIs, the hydroxamic

acids, with representatives such as trichostatin A (TSA), suberoylanilide hydroxamic acid (vorinostat, SAHA), azelaic bis-hydroxamic acid (ABHA), scriptaid, oxamflatin, pyroxamide, m-carboxycinnamic acid bis-hydroxamide (CBHA), and the recently developed NVP-LAQ824, NVP-LBH589, and PXD101 have become the focus for further research, including pancreatic cancer. Gahr *et al*<sup>[33]</sup> used HDACI trichostatin A for *in vitro* treatment of pancreatic carcinoma cell lines YAP C and DAN G. They described an apoptosis rate of 71% and 66% after 72 h using a drug concentration of 1  $\mu\text{mol/L}$ . Moore *et al*<sup>[34]</sup> tested trichostatin A in PaCa44 cells using microarrays containing 22283 probe sets. One prominent feature was the increased ratio between the levels of expression of pro-apoptotic (BIM) and anti-apoptotic (Bcl-xL and Bcl-W) genes. In addition, Cecconi *et al*<sup>[35]</sup> reported for the same cell line PaCa44 that trichostatin A caused cell cycle arrest at the G2 phase and induced apoptotic cell death. Another hydroxamic acid, SAHA, induced growth inhibition in three pancreatic cell lines BxPC3, COLO-357, and PANC-1 by upregulating p21 and sequestering it in the cytoplasm<sup>[36]</sup>. In our current study, we investigated the two novel cinnamic hydroxamic acid compounds NVP-LAQ824 and NVP-LBH589 for *in vitro* treatment of 8 different human pancreatic cancer cell lines. Cell-growth inhibition by NVP-LAQ824 and NVP-LBH589 was studied by MTT assay. Treatment with both compounds significantly suppressed the growth of 7 cancer cell lines after 3 d of incubation and all cancer cell lines after 6 d of incubation. We hypothesize that the lack of response of Capan-2 cells after 3 d of treatment may be based on the status of the tumor suppressor p53. A genetic profile of 10 different human pancreatic cancer cell lines (6 of the 8 cell lines used in our experiment being amongst them) created by a group from John Hopkins University (<http://pathology2.jhu.edu/pancreas/geneticsweb/profiles.htm>) discovered p53 mutations in almost all cell lines, but not in Capan-2 cells. On the other hand, it has been shown that acetylation and deacetylation of p53 is likely to be part of the mechanism that controls its physiological activity. Whereas HDACs are capable of downregulating p53 function, HDAC inhibition can cause the opposite effect<sup>[37]</sup>. Interestingly, it has also been shown that HDAC inhibitors, such as FR901228 and trichostatin A, completely deplete mutant p53 in cancer cell lines and restore p53-like functions, which is highly toxic to cell lines with mutant p53<sup>[38]</sup>. Donadelli *et al* confirmed this finding in p53 gene mutated pancreatic cancer cell lines which were treated with trichostatin A. The compound induced G2 phase arrest and apoptotic cell death by activation of p21<sup>waf1</sup>, which is normally induced by p53<sup>[39]</sup>.

In previous *in vitro* studies, NVP-LAQ824 exhibited potent anti-proliferative activity against colon carcinoma ( $\text{IC}_{50} = 0.01 \mu\text{mol/L}$ ), and biliary tract cancer ( $\text{IC}_{50} = 0.11 \mu\text{mol/L}$ ) as well as against non-small cell lung carcinoma ( $\text{IC}_{50} = 0.15 \mu\text{mol/L}$ ), prostate cancer ( $\text{IC}_{50} = 0.018\text{--}0.023 \mu\text{mol/L}$ ), head and neck squamous

carcinoma ( $IC_{50} = 0.04\text{--}0.34\ \mu\text{mol/L}$ ), and human breast adenocarcinoma cells ( $IC_{50} = 0.03\text{--}0.039\ \mu\text{mol/L}$ ) after 72 h of exposure<sup>[16,40-42]</sup>. The *in vitro* effects of NVP-LAQ824 on hematologic malignancies have been examined in several human cell lines with a death rate of more than 90% following 48 h of drug incubation, with exposures as low as  $0.1\ \mu\text{mol/L}$ <sup>[43-45]</sup>. Our second compound NVP-LBH589, was even more effective *in vitro* for the treatment of human chronic myeloid leukemia blast crisis K562 and LAMA-84, multiple myeloma, and acute leukemia MV4-11 cells<sup>[15,46-48]</sup>.

The *in vitro* anti-tumoral drug mechanism in our study was assessed by immunoblotting for acH4 (surrogate marker for histone acetylation) p21<sup>WAF-1/CIP-1</sup>, and cell cycle analysis. Treatment with both compounds was associated with hyperacetylation of nucleosomal histone H4, increased expression of p21<sup>WAF-1/CIP-1</sup>, cell cycle arrest at G2/M-checkpoint, and significant induction of apoptosis (increased sub-G1-peak). Therefore, our results are very consistent with the *in vitro* results of the aforementioned studies by Natoni *et al.*<sup>[30]</sup>, Garcia-Morales *et al.*<sup>[31]</sup>, Sato *et al.*<sup>[32]</sup>, Gahr *et al.*<sup>[33]</sup>, Donadelli *et al.*<sup>[39]</sup>, Cecconi *et al.*<sup>[35]</sup>, and Arnold *et al.*<sup>[36]</sup>.

Encouraged by our *in vitro* results, we decided to test the most effective drug NVP-LBH589 *in vivo* in comparison to placebo using the chimeric mouse model. The NVP-LBH589 dose of 25 mg/kg (5 d/wk) was selected according to a study testing different iv doses of NVP-LAQ824 between 5 and 100 mg/kg (5 d/wk) in a similar chimeric mouse model using the human colon cancer cell line HCT 116<sup>[16]</sup>. *In vivo* data for NVP-LBH589 using human prostate carcinoma cell PC-3 xenografts became available only after completion of our study, and showed tumor reduction at a dose of 10 mg/kg per day<sup>[49]</sup>. In our experiments, NVP-LBH589 significantly reduced tumor mass in comparison to placebo and potentiated the efficacy of gemcitabine. In accordance with our observations, Gahr *et al.*<sup>[33]</sup> and Piacentini *et al.*<sup>[50]</sup> showed that a combination with gemcitabine potentiated the *in vitro* effects of trichostatin A in pancreatic cancer cells, demonstrating a synergistic effect between both agents. This phenomenon has been shown for *in vitro* cotreatment with SAHA, too, where the compound rendered pancreatic cancer cells sensitive to the inhibitory and proapoptotic effects of gemcitabine<sup>[36]</sup>. In human breast cancer cell lines SKBR-3 and BT-474, NVP-LAQ824 also enhanced gemcitabine-induced apoptosis *in vitro*<sup>[41]</sup>. For head and neck squamous carcinoma cells, the combination of NVP-LAQ824 with gemcitabine was more effective *in vitro* than a combination with docetaxel, paclitaxel, or cisplatin, especially when the cytotoxic agent was used first for 24 h followed by 48 h of NVP-LAQ824<sup>[40]</sup>. Unfortunately, in the first recently published randomized, double-blind, placebo-controlled multicenter-phase II trial, gemcitabine plus benzamide HDACI CI-994 (N-acetyldinaline) showed no advantage over gemcitabine alone in patients with advanced pancreatic cancer<sup>[51]</sup>. In this study, a total of 174 patients received combination therapy (CI-994, 6 mg/m<sup>2</sup> per day, day 1-21

plus gemcitabine, 1000 mg/m<sup>2</sup>, day 1, 8 and 15 each 28-d cycle) or placebo plus gemcitabine (1000 mg/m<sup>2</sup>, day 1, 8 and 15 each 28-d cycle). Median survival was 194 d (combination therapy) *vs* 214 d (gemcitabine) ( $P = 0.908$ ). The objective response rate was 12% *vs* 14% when investigator-assessed and 1% *vs* 6%, respectively, when assessed centrally. Time to treatment failure did not differ between the two arms ( $P = 0.304$ ). Quality of life scores at 2 mo were worse with the combination than with gemcitabine alone. Pain response rates were similar between the two groups. There was an increased incidence of neutropenia and thrombocytopenia with combination therapy. However, it is currently unknown whether these clinical observations are also true for the hydroxamic acids class of HDACIs. In addition, recent *in vitro* and *in vivo* data have shown synergistic effects of trichostatin A in combination with DNA methyltransferase inhibitors azacytidine<sup>[52,53]</sup> and zebularine<sup>[54]</sup> and proteasome inhibitor PS-341<sup>[55]</sup>, suggesting alternative combination partners for HDACIs. Whereas upregulation of tumor suppressors DUSP6<sup>[52]</sup> and MUC 2<sup>[53]</sup> is the proposed mechanism for the additional effect of DNA methyltransferase inhibitors, it is inactivation of NFkappaB signalling, downregulation of anti-apoptotic Bcl-xL and disruption of MAP kinase pathway for combination with the proteasome inhibitor PS-341<sup>[55]</sup>.

Regarding side effects of the different drugs used in our studies, there was no significant additional weight loss in the COMBO group as compared to placebo. Moreover, NVP-LBH589 alone only induced additional weight loss in the HPAF-2 cell experiment. Weight loss in general was apparently more pronounced in the L3.6pl than in the HPAF-2 cell experiment. This may be due to the fact that L3.6pl cells are a selected variant of COLO-357 cells with increased metastatic potential<sup>[24,56,57]</sup>. Regarding other studies, weight loss of animals was not previously reported for NVP-LAQ824<sup>[16]</sup>, but for NVP-LBH589<sup>[42]</sup>.

In order to assess *in vivo* anti-tumoral drug mechanisms, paraffin sections of mouse tumors were stained with hematoxylin-eosin (H&E), MIB-1 (proliferation marker) and TUNEL (apoptosis marker). Treatment with NVP-LBH589 and COMBO slightly reduced proliferation (reduced MIB-1 staining) and slightly induced apoptosis (increased TUNEL-staining) in HPAF-2 cell bearing mice, whereas proliferation was not decreased and apoptosis only slightly increased in L3.6pl cell bearing mice. Surprisingly, the calculated numbers were much smaller than expected from the *in vitro* experiments. This might be derived from the fact that other pathways, like inhibition of angiogenesis, which we were unable to study in our model due to insufficient tissue quality, may be more important for NVP-LBH589 action in the *in vivo* setting.

Our findings suggest that NVP-LBH589 and NVP-LAQ824 are active against human pancreatic cancer cells *in vitro*, mainly by inhibition of proliferation and induction of apoptosis. NVP-LBH589 is also active in the *in vivo* setting, although the precise mechanism of

drug action is not yet completely understood. Therefore, a clinical study testing NVP-LBH589 for the treatment of pancreaticobiliary cancer has just been initiated at our department.

## ACKNOWLEDGMENTS

The authors thank A Kluge for technical assistance, Professor CJ Bruns (Department of Surgery, Klinikum Grosshadern, Ludwig-Maximilian-University, Munich, Germany) for provision of L3.6pl cells and Novartis Pharma for financial support and provision of NVP-LAQ824 and NVP-LBH589.

## COMMENTS

### Background

Pancreatic adenocarcinoma is essentially an incurable disease, with mortality closely approaching incidence. Single agent gemcitabine is currently considered the standard of care for the treatment of inoperable pancreatic cancer, providing a small but sizable benefit in survival and palliation of symptoms.

### Research frontiers

In the past ten years, several molecular-targeting agents have been introduced in the clinical setting. Despite promising results in phase II studies, randomized clinical trials exploring the new compounds, such as matrix-metalloprotease-inhibitors (MMPi), farnesyl transferase inhibitors (FTI), signal transduction inhibitors, and angiogenesis inhibitors, either alone or in combination with gemcitabine have been largely disappointing. Polo-like kinase 1 (PLK-1), death receptor 5 (DR5), and histone deacetylase (HDAC) inhibitors are currently under clinical evaluation as new treatment options.

### Innovations and breakthroughs

In 2003, fixed-dose-rate (FDR) gemcitabine (1500 mg/m<sup>2</sup> at 10 mg/m<sup>2</sup> per minute) improved median survival time from 5.0 mo in the standard arm to 8.0 mo in a randomized study; However, grade 3 and 4 toxicity increased significantly. In 2005, investigators of a phase III study found that the gemcitabine-capecitabine combination significantly improved overall survival over gemcitabine alone (hazard ratio 0.80; 95% CI 0.65-0.98; *P* = 0.026). Recently, a randomized phase III placebo-controlled trial demonstrated that combining gemcitabine with EGFR inhibitor erlotinib was associated with a modest, but statistically significant survival benefit of 15 d.

### Applications

The aim of our study was to investigate *in vitro* and *in vivo* treatment with the histone deacetylase inhibitors NVP-LAQ824 and NVP-LBH589 in pancreatic cancer. Our findings suggested that NVP-LBH589 and NVP-LAQ824 are active against human pancreatic cancer *in vitro*. In addition, NVP-LBH589 demonstrated significant *in vivo* activity and potentiated the efficacy of gemcitabine.

### Terminology

Histones (positively charged proteins) are the major components of chromatin. Histone acetylation and deacetylation modulate chromosome structure and regulate gene transcription. Two families of enzymes, histone acetyltransferases (HATs) and histone deacetylases (HDACs), activate and repress gene expression, respectively. Aberrant HAT or HDAC activity is associated with various epithelial and hematologic cancers. HDACs may play an important role in human oncogenesis through HDAC-mediated gene silencing and interaction of HDACs with proteins involved in tumorigenesis. HDAC inhibition could potentially restore normal processes in transformed cells without affecting normal cells.

### Peer review

This paper addresses the use of histone deacetylase inhibitors in the treatment of pancreatic cancer *in vitro* and *in vivo*. It represents an important experimental assessment of novel agents in the treatment of a cancer for which effective therapy is currently lacking. It's a very interesting paper.

### Abstract

**AIM:** To evaluate the protective effect of 2'-p-hydroxy benzoylmussaenosidic acid [negundoside (NG)], against carbon tetrachloride (CCl<sub>4</sub>)-induced toxicity in HuH-7 cells.

**METHODS:** CCl<sub>4</sub> is a well characterized hepatotoxin, and inducer of cytochrome P450 2E1 (CYP2E1)-mediated oxidative stress. In addition, lipid peroxidation and accumulation of intracellular calcium are important steps in the pathway involved in CCl<sub>4</sub> toxicity. Liver cells (HuH-7) were treated with CCl<sub>4</sub>, and the mechanism of the cytoprotective effect of NG was assessed. Silymarin, a known hepatoprotective drug, was used as control.

**RESULTS:** NG protected HuH-7 cells against CCl<sub>4</sub> toxicity and loss of viability without modulating CYP2E1 activity. Prevention of CCl<sub>4</sub> toxicity was associated with a reduction in oxidative damage as reflected by decreased generation of reactive oxygen species (ROS), a decrease in lipid peroxidation and accumulation of intracellular Ca<sup>2+</sup> levels and maintenance of intracellular glutathione homeostasis. Decreased mitochondrial membrane

potential (MMP), induction of caspases mediated DNA fragmentation and cell cycle arrest, as a result of CCl<sub>4</sub> treatment, were also blocked by NG. The protection afforded by NG seemed to be mediated by activation of cyclic adenosine monophosphate (cAMP) synthesis and inhibition of phospholipases (cPLA2).

**CONCLUSION:** NG exerts a protective effect on CYP2E1-dependent CCl<sub>4</sub> toxicity *via* inhibition of lipid peroxidation, followed by an improved intracellular calcium homeostasis and inhibition of Ca<sup>2+</sup>-dependent proteases.

### INTRODUCTION

Natural products from plant sources have extensive past and present use in treatment of diverse diseases and serve as compounds of interest both in their natural form and as templates for synthetic modification. The importance of natural products in modern medicine has been well recognized. More than 20 new drugs, launched world over between 2000 and 2005, originate from natural products. Scrutiny of medical indications by source of compounds has demonstrated that natural products and related drugs are used to treat 87% of all categorized human diseases (infectious and non-

infectious)<sup>[1]</sup>.

*Vitex negundo* (verbenaceae) is an important source of such natural drugs. It is a reputed medicinal herb and its parts have been employed as a traditional cure in Asian systems of medicine (Indian, Chinese, Malaysian) for a variety of disease conditions. A number of pharmacological activities have been attributed to *V. negundo*, such as: analgesic and anti-inflammatory activity<sup>[2]</sup>, enzymes inhibition<sup>[3]</sup>, nitric oxide scavenging activity<sup>[4]</sup>, snake venom neutralization activity<sup>[5]</sup>, antifeeding activity<sup>[6]</sup>, antiradical and antilipoperoxidative<sup>[7]</sup>, CNS activity<sup>[8]</sup>, hepatoprotective activity<sup>[9]</sup>, anti-bacterial activity<sup>[10]</sup>, anti-fungal<sup>[11]</sup>, larvicidal activity<sup>[12]</sup>, antiandrogenic effects<sup>[13]</sup>, mosquito repellent activity<sup>[14]</sup>.

In the recent past, some of our work and work as reported by others on botanical products from *V. negundo* have shown a promising hepatoprotective activity<sup>[9,15]</sup>. This activity has been evaluated against various hepatotoxic agents including carbon tetrachloride (CCl<sub>4</sub>). CCl<sub>4</sub> is a well established and widely used hepatotoxin and the principle cause of CCl<sub>4</sub>-induced liver injury is proposed to be lipid peroxidation by free radical derivatives of CCl<sub>4</sub>. CCl<sub>4</sub> is activated by NADH-CYP 450 2E1 system of the liver endoplasmic reticulum and converted into trimethyl CCl<sub>3</sub> radicals (*via* reductive dehalogenation) and, under aerobic conditions, in the more reactive trichloromethyl peroxy radical CCl<sub>3</sub>OO<sup>\*</sup>. Formation of the radicals CCl<sub>3</sub><sup>\*</sup> and CCl<sub>3</sub>OO<sup>\*</sup> causes oxidative stress. The CYP 2E1-mediated metabolism results in generation of reactive oxygen species, which further contributes to the development of cellular injury<sup>[16]</sup>. Also, considerable evidence suggests that CCl<sub>4</sub> modifies the expression levels of several pro-apoptotic and anti-apoptotic growth factors and receptors<sup>[17]</sup> especially during chronic administration. CCl<sub>4</sub> has been shown to be a carcinogen and has been classified as a group 2B carcinogen by inducing gene conversion, homozygosity and intra-chromosomal recombinations<sup>[18]</sup>.

It was, therefore, our interest to investigate, in-depth, the mechanism of modulation of CCl<sub>4</sub>-induced toxic manifestations with 2'-p-hydroxybenzoylmussaenosidic acid [negundoside (NG)] (a purified irridoid glycoside from leaves of *Vitex negundo*), particularly inhibition of downstream CYP 2E1 cascade of pro-apoptotic events with reference to the following: (1) role of CYP 450 2E1 activation on calcium-mediated oxidative stress; (2) involvement of calcium in phospholipase A2 (PLA2) and cyclic adenosine monophosphate (cAMP) regulation; (3) effect of activated cPLA2 on mitochondrial depolarization, inducing cytochrome C release resulting in caspase mediated apoptosis.

## MATERIALS AND METHODS

### Chemicals

DMEM F12 medium, Fetal calf serum, trypsin-EDTA solution, 2', 7'-dichlorofluoresceine diacetate (DCF-DA), rhodamine-123 (Rh-123), propidium iodide (PI), DNase-free RNase, proteinase K, 3-(4,5-dimethylthiazole-2-yl)-2,5-diphenyltetrazolium bromide (MTT), Hoechst 33258,

cyclosporine A, penicillin, streptomycin, L-glutamine, pyruvic acid, camptothecin, malondialdehyde (MDA) and other biochemicals were purchased from Sigma Chemicals Co. (St. Louis, Mo). Caspase-3 (ApoAlert caspases assay kits) were from B.D. Clontech, USA. Phospholipase A2 (PLA2) and cyclic adenosine triphosphatase (cAMP) were measured by commercially available kits from Cyman company, USA, and R&D systems, USA respectively. Protein concentration was measured using the BCA Protein Assay Kit from Pierce (Rockford, IL, USA).

### Collection and identification of test material

Aerial parts of the plant *Vitex negundo* Linn were collected locally during August to October. Plant material was identified and authenticated by examination of the morphological characteristics by taxonomist of the Institute. A voucher specimen has been deposited in Indian Institute of Integrative Medicine (I.I.I.M.) Jammu Herbarium under collection No. 17814.

### Extraction procedure for preparation of NG

The shade dried and powdered leaves (1 kg) of *V. negundo* were soaked in ethanol (5 L) and kept overnight. The percolate was filtered and concentrated under reduced pressure at below 50°C. The extraction procedure was repeated three times more using 3 L of ethanol each time. The combined ethanol extract was stirred with water (300 mL) for 1 h and filtered through Celite. The aqueous extract was concentrated at 50°C and finally dried in vacuum desiccators.

### Isolation of NG

The ethanol extract (50 g) of *V. negundo* was adsorbed over silica gel (100 g) to make slurry which was packed over a column of silica gel (1 kg) packed in chloroform. Elution was done with chloroform followed by mixture of chloroform and methanol. Elution with 10% methanol in chloroform gave agnuside followed by mixture of agnuside and negundoside and then negundoside. The compounds were characterized on the basis of <sup>1</sup>HNMR, <sup>13</sup>CNMR mass spectral data (data not shown) and standardized by HPLC (Figure 1).

### Cell culture

The study was carried out using as a model a human hepatoma HuH-7 cells line (ATCC-USA), a generous gift from Dr. Vijai Kumar, International Centre for Genetic Engineering and Biotechnology (ICGEB), New Delhi, India. Cells were grown in Dulbecco's Modified Eagle's Medium (DMEM) containing 10% fetal calf serum (FCS), supplemented with 100 Units/mL penicillin, 100 mg/L streptomycin in a humidified atmosphere in 5% CO<sub>2</sub> at 37°C, and were sub-cultured at 1:5 ratio once a week.

### Cell treatment

FCS was reduced to 3% for the experiments. Cells were plated at a density of 3 × 10<sup>4</sup> cells/cm<sup>2</sup> and maintained in culture medium for 12 h. Stock solutions of CCl<sub>4</sub>, NG and silymarin were prepared fresh to avoid

**Figure 1** Finger print profile and chemical structure of NG. The HPLC profile of NG was performed by employing Shimadzu HPLC system consisting of a diode array detector and C18 column (5  $\mu$ m, 250 mm x 4.0 mm I.D.) by UV detection at 254 nm. NG was resolved on a mobile phase consisting of methanol: 2% acetonitrile (30:70) and delivered at a flow rate of 0.6 mL/min. The chromatogram is representative of one of three independent analyses.

oxidation. For  $\text{CCl}_4$  toxicity experiments, test substances, were added to the cell cultures an hour prior to  $\text{CCl}_4$  treatment. Cells or supernatant were then collected for determination of various parameters.

### Cytotoxicity assays

Cells were seeded onto 24-well plates, and after the corresponding treatment, the medium was removed and cell viability was evaluated by assaying for the ability of functional mitochondria to catalyze the reduction of MTT to form formazan salt by mitochondrial dehydrogenases, as described<sup>[19]</sup> and determined by ELISA reader at 565 nm (Multiskan Spectrum; Thermo Electron Corporation, USA).

### Cellular and nuclear morphology

The cellular and nuclear morphology was observed under the light microscope (Nikon Eclipse TE2000U), at 40  $\times$  magnification, or under fluorescent microscopy, using Hoechst 33258 staining method as described<sup>[20]</sup> with certain modifications. Briefly, untreated and treated HuH-7 cells in 6 well plates were harvested by trypsinization, centrifuged at 100  $\times g$  for 5 min and washed twice with PBS. Cells were gently suspended in 100  $\mu$ L PBS and fixed in 400  $\mu$ L cold acetic acid: methanol (v/v = 1:3) overnight at 4°C. Cells were washed again in 1 mL of fixing solution, suspended in the residual volume of about 50  $\mu$ L, spread on a clean slide and dried overnight at room temperature. One milliliter of staining solution (Hoechst 33258, 10 mg/L in 0.01 mol/L citric acid and 0.45 mol/L disodium phosphate containing 0.05% Tween 20) was poured on each slide and stained for 30 min under subdued light at room temperature. Slides were washed under gentle flow of tap water, rinsed in distilled water followed by in PBS. While wet, 50  $\mu$ L of mounting fluid (PBS:glycerol, 1:1) was poured over the center of slide and covered with glass cover slip. The

slides were sealed with nail polish and observed for any nuclear morphological alterations and apoptotic bodies under inverted fluorescence microscope (Nikon Eclipse TE2000U, magnification 40X) using UV excitation.

### Anti-hemolytic activity

Anti-hemolytic activity of NG and silymarin was studied as described<sup>[21]</sup>. Briefly, blood was collected from healthy volunteers and centrifuged (3000 r/min) with an equal volume of sterilized Alsever solution (2% dextrose, 0.8% sodium citrate, 0.05% citric acid, and 0.42% sodium chloride in water) to obtain the packed cells. The cells were washed with isosaline (0.85%, pH 7.4) and diluted with phosphate buffer (0.15 mol/L, pH 7.4). RBCs ( $10^8$  cells/mL) were incubated with triton  $\times$  100 (1 g/L) to induce 100% cell lysis, in absence and presence of test materials at 37°C for 1 h. The  $A$  of the supernatant was determined at 540 nm.

### CYP2E1 catalytic activity assay

CYP2E1 activity was determined by assaying *p*-nitrophenol hydroxylation in rat liver microsomes prepared by calcium precipitation method as described earlier<sup>[22]</sup>. In brief, 1 mg microsomes in presence and absence of test material caused hydroxylation of 100 mmol/L aniline hydrochloride in presence of 30 mmol/L cumene hydroperoxide in 0.1 mol/L Tris buffer, pH 7.5. Liberated *p*-aminophenol was treated with 1 mL of 1 mol/L  $\text{Na}_2\text{CO}_3$  and 1 mL of 2% phenol solution in 0.5 mol/L NaOH. The samples were allowed to stand at room temperature for 30 min and read at 630 nm.

### Lipid peroxidation analysis

Cells were plated onto 60 mm Petri dishes, and at the end of the treatment they were washed twice in cold PBS and harvested using rubber policeman in 1 mL PBS. To the resulting cell suspension, we added 2 mL

of TCA-TBA reagent (15% TCA + 0.375% TBA in 5 mol/L HCl) in glass tubes. Tubes were kept in a boiling water bath (100°C) for 1 h, and then cooled to room temp. The contents were centrifuged at  $1500 \times g$  for 10 min. Absorbance of the supernatants was read at 535 nm against blank. Malonyldialdehyde (MDA) was used to draw the standard curve. The results were expressed as nmoles MDA/mg protein.

In other set of experiments, 1 g/L of rat liver microsomes in 0.15 mol/L NaCl were incubated with 0.1 mmol/L  $\text{FeSO}_4$  and 35 mmol/L  $\text{H}_2\text{O}_2$  in the presence and absence of test materials to stimulate lipid peroxidation. Generation of MDA was determined by assaying for thiobarbituric acid-reactive substances (TBARS) as described<sup>[22]</sup>.

### Determination of glutathione levels

Cells were seeded onto 60 mm Petri dishes and collected after the corresponding treatments. The total GSH content (reduced form) of samples was assayed as described<sup>[23]</sup>. Briefly, after treatments, cells were washed with ice cold PBS containing 10 mmol/L EDTA and centrifuged at  $1500 \times g$ . The cell pellets were resuspended in PBS/EDTA solution with 35% perchloric acid. The cell suspensions were kept on ice for 10 min and vortexed in between 5 times. Cell suspension was centrifuged at 13000 r/min for 10 min at 4°C. The supernatant was transferred to fresh tubes and the pH adjusted to 7 with triethanolamine, 1 mol/L,  $\text{K}_2\text{CO}_3$  1.65 mol/L and EDTA 30 mmol/L. The contents were centrifuged at 13000 r/min for 10 min. To the 50  $\mu\text{L}$  of the supernatant, we added 1850  $\mu\text{L}$  of PBS/EDTA solution and 100  $\mu\text{L}$  of o-phthalaldehyde (1 g/L in methanol). The samples were incubated in the dark for 20 min and read at 350 nm (excitation) and 420 nm (emission) with a fluorescent spectrofluorometer (Perkin Elmer; LS-55).

### Determination of cytochrome C by HPLC

Cytochrome C was determined as described<sup>[24]</sup>. Briefly, the reaction medium (2.5 mL) containing mitochondria (1 mg protein/mL) was 0.2 mol/L sucrose, 1 mmol/L  $\text{KH}_2\text{PO}_4$ , 5 mmol/L succinate, 2  $\mu\text{mol/L}$  rotenone, 10 mmol/L Tris-MOPS, pH 7.3 at 25°C. Mitochondria were preincubated with test materials [NG, silymarin and cyclosporin A (CsA; 0.2  $\mu\text{mol/L}$ )] for 10 min, and then in presence of  $\text{CCl}_4$  (2 mmol/L) for 30 min. After incubation, aliquots of mitochondrial suspensions were centrifuged at  $11000 \times g$  for 8 min to obtain the supernatant. Finally, the supernatant (50  $\mu\text{L}$ ) was introduced into an HPLC system equipped with a reverse-phase C4 Cosmosil column (150 mm  $\times$  4.6 mm, 5- $\mu\text{m}$  particle size, equipped with a UV-visible detector (393 nm). The column (Spelco; Supercosil LC-304; 24  $\mu\text{m} \times 4.6 \mu\text{m} \times 5 \mu\text{m}$ ) was eluted with a linear gradient of acetonitrile-water (solvents modified with 0.1 mL/L trifluoroacetic acid); the gradient started at 20% acetonitrile and changed to 60% during 12 min and the flow rate was 1.0 mL/min. The column was then

washed with the 60% acetonitrile for 5 min followed by reequilibration for 5 min in the 20% acetonitrile.

### Preparation of rat liver mitochondria

Mitochondria from livers of rats (Wistar) were prepared as described<sup>[25]</sup>. In brief, rat livers were washed once with physiological saline, dissected and washed twice in cold isolation solution (200 mmol/L D-mannitol, 70 mmol/L sucrose, 2 mmol/L HEPES, 0.5 g/L BSA). Dissected livers were minced with two volumes of isolation solution and homogenized (IKA homogenizer-WERK, Ultra Turrax, T 25 B). The homogenate was diluted with 7 volumes of isolation buffer and centrifuged for 10 min at  $560 \times g$ . The supernatant collected was again centrifuged for 15 min at  $7000 \times g$ . The mitochondrial pellet was collected and resuspended in 2.5 volumes of isolation solution and stored at -80°C until use.

### Measurement of intracellular calcium

Intracellular calcium levels were determined with the fluorescent calcium indicator fura2-AM by ratiometric fluorimetry as described<sup>[26]</sup>. HuH-7 cells were detached from the plate using HBSS buffer (118 mmol/L NaCl, 4.6 mmol/L KCl, 10 mmol/L glucose, 20 mmol/L Hepes, pH 7.2) containing 0.02% EDTA, resuspended in HBSS with 1 mmol/L  $\text{CaCl}_2$ , and incubated with 1  $\mu\text{mol/L}$  fura2-AM in the dark for 1 h at 37°C. Cells were washed with HBSS/ $\text{CaCl}_2$ , and resuspended in HBSS/ $\text{CaCl}_2$  at a density of  $1 \times 10^6$  cells/mL. EGTA (10 mmol/L) was added at the beginning of the experiment, followed by a 60 s-equilibration period<sup>[27]</sup>. Intracellular free calcium measurements were performed at 37°C using a ratiometric fluorescence spectrophotometer (Perkin-Elmer LS 50B). Intracellular  $\text{Ca}^{2+}$  concentration was estimated as described<sup>[28]</sup> based on the equation:  $[\text{Ca}^{2+}]_i = K_d[(R - R_{\min})/(R_{\max} - R)]F_{\min(380)}/F_{\max(380)}$ , where  $R$  is  $F_{340}/F_{380}$  ratio,  $R_{\min}$  and  $R_{\max}$  are the ratios with 50 mmol/L digitonin, and 50 mmol/L digitonin + 11 mmol/L  $\text{CaCl}_2$ , respectively.  $K_d$  represents the apparent dissociation constant of Fura-2 (224 nmol/L) and  $F_{\min(380)}/F_{\max(380)}$  are the fluorescence values of digitonized cells without or with 11 mmol/L  $\text{CaCl}_2$ , respectively.

### Flow cytometric analysis of mitochondrial membrane potential ( $\Delta\psi_m$ )

Changes in the mitochondrial membrane potential ( $\Delta\psi_m$ ) were examined by monitoring the cell fluorescence after staining with rhodamine 123 (Rh123) as described<sup>[29]</sup>. Rh123 is a membrane permeable fluorescent cationic dye that is selectively taken up by mitochondria directly proportional to the MMP<sup>[30]</sup>. The intensities from Rh123 and PI were determined using a BD-LSR flow cytometer equipped with electronic doublet discriminating capability.

### Intracellular measurement of reactive oxygen species (ROS)

The production of ROS was monitored with DCF-DA as the probe<sup>[31]</sup>. DCF-DA diffuses through the cell membrane and is enzymatically hydrolyzed by

intracellular esterases to nonfluorescent DCF-H, which is then rapidly oxidized to the highly fluorescent DCF in presence of ROS. Treated and non-treated HuH-7 cells were incubated for 1 h with DCF-DA (2  $\mu\text{mol/L}$ ) and, after the washing of cells, the production of free radicals were assessed *in situ* as the enhancement of fluorescence at excitation wavelength of 500 nm and emission wavelength of 520 nm and was measured in a fluorescent plate reader (Perkin Elmer LS 55, USA).

#### Measurement of intracellular $\text{H}_2\text{O}_2$

Intracellular  $\text{H}_2\text{O}_2$  levels were analyzed using 123 dihydorhodamine (123-DHR) as specific fluorescent dye probe as described by Katiyar *et al* with modifications for HuH-7 cells<sup>[32]</sup>. Briefly, non-treated and treated HuH-7 were washed twice with PBS and incubated in the culture medium without FCS and loaded with 123-DHR (5  $\mu\text{mol/L}$ ). Cells were further incubated for 45 min to irreversibly oxidize and convert DHR to fluorescent compound rhodamine 123 and fluorescence was read with aid of spectrofluorometer (Perkin Elmer LS 55, USA) with excitation wavelength 485 nm and emission wavelength of 530 nm. The cells for fluorescent-based assays were grown onto sterile black fluorescent plates (96 well format; Nunc, Denmark).

#### Cell cycle analysis (apoptosis)

Cell cycle was analysed as described by Yang *et al*<sup>[33]</sup>. Briefly, non-treated and treated HuH-7 cells were harvested by trypsinization, centrifuged at  $1500 \times g$  for 5 min, washed with PBS, and fixed in 70% ethanol at 4°C overnight. Fixed cells were washed twice with PBS and incubated in PBS containing 1.5 mg/L RNase A for 1 h at 37°C, followed by staining with 5  $\mu\text{L}$  PI (1 mmol/L stock) for 20 min on ice. The cells were analyzed for DNA content using BD-LSR flow cytometer equipped with electronic doublet discrimination capability using blue (488 nm) excitation from argon laser. Data were collected in list mode on 10 000 events for FL2-A vs FL2-W.

#### DNA laddering

DNA fragmentation was analysed as described by Yang *et al*<sup>[33]</sup>. Briefly, HuH-7 cells treated or untreated were harvested and centrifuged at  $1500 \times g$  for 5 min. After washing twice with PBS/ethylenediamine-N, N, N', N'-tetraacetic acid (EDTA). Cells were incubated in a lysis buffer [0.5 mL/L Triton X-100, 10 mmol/L EDTA, 0.4 g/L proteinase K, and 10 mmol/L Tris-HCl, pH 7.4] at 56°C for 1 h. Cell lysate was treated with 0.4 g/L RNase at 37°C for 30 min. The genomic DNAs were purified by phenol/chloroform extraction and ethanol precipitation, and resuspended in a Tris-EDTA buffer, DNA fragments were stained with ethidium bromide and visualized by 2.5% agarose electrophoresis.

#### Enzymic assay of caspase 3-activity

Caspase activation was measured using a caspase 3 fluorometric assay kit (BD Apoalert caspase 3 fluorescent assay kit). HuH-7 cells, treated or untreated were harvested, and centrifuged (approximately 1 mg protein)

at  $400 \times g$  for 5 min. The cell pellets were re-suspended in 50  $\mu\text{L}$  of chilled cell lysis buffer and incubated on ice for 10 min, and the lysates were centrifuged at  $15000 \times g$  for 10 min at 4°C to precipitate cellular debris. A total of 50  $\mu\text{L}$  of cell lysates was incubated with 50  $\mu\text{L}$  of reaction buffer/DTT mix. DEVD-CHO was used as an inhibitor of caspase 3 in an induced sample. Five  $\mu\text{L}$  of 1 mmol/L caspase-3 substrate (DEVD-AFC at a final concentration of 50  $\mu\text{mol/L}$ ) was added to each sample. The samples were incubated at 37°C for 1 h and read on a spectrofluorometer (Perkin Elmer LS 55) with excitation wavelength 400 nm and emission wavelength of 505 nm.

#### Cytosolic phospholipase $\text{A}_2$ assay

cPLA<sub>2</sub> activity was measured in cell lysates, using cPLA<sub>2</sub> assay kit (Cayman Chemical Company cPLA<sub>2</sub> assay kit) as per the instructions of the supplier. The kit involves the principle that cPLA<sub>2</sub> exhibits specificity towards arachidonic acid. Arachidonoyl thio-PC is used as a synthetic substrate to detect the phospholipase activity. Hydrolysis of the arachidonoyl thioester bond at the *sn*-2 position by cPLA<sub>2</sub> releases free thiol which are detected by DTNB (5, 5'-dithiobis-2-dinitrobenzoic acid).

#### Adenosine 3', 5'-cyclic monophosphate (cAMP) assay

cAMP activity was measured in the cell lysates, using cAMP assay kit (R&D Systems, Inc, cAMP assay kit) as per the instructions of the supplier. The kit is based on the competitive binding technique in which cAMP present in a sample competes with a fixed amount of horseradish peroxidase (HRP)-labeled cAMP for sites on a mouse monoclonal antibody. During the incubation, the monoclonal antibody becomes bound to the goat anti-mouse antibody coated onto the microplate. Following a wash to remove excess conjugate and unbound sample, a substrate solution is added to the wells to determine the bound activity. The colour developed was stopped and the absorbance read at 450 nm. The intensity of the colour is inversely proportional to the concentration of cAMP in the sample.

#### 2, 2'-azino-di-[3-ethylbenzthiazoline sulphate] oxidation inhibition assay (ABTS assay)

The assay was performed using antioxidant assay kit from Cayman Chemical Company, as per the instructions by the manufacturer. The assay was used to access the ability of the test materials (NG, Silymarin *etc*) to inhibit the oxidation of ABTS to ABTS<sup>+</sup> by metmyoglobin. The amount of ABTS<sup>+</sup> produced in absence and presence of test material was monitored by reading absorbance at 750 nm. Suppression of the absorbance at 750 nm in presence of test material is proportional to their antioxidant activity. The capacity of the antioxidant activity (inhibition of ABTS<sup>+</sup> formation) in the test sample was compared with that of Trolox, a water-soluble tocopherol analogue.

#### 1,1-diphenyl-2-picrylhydrazyl (DPPH) discolouration assay

This assay was performed as described by Gonzalez

*et al*<sup>[34]</sup>. In brief, for the assay, various concentrations of test compound were added to 3 mL of DPPH solution (20 mg/L methanol) and incubated for 5 min at 25°C. The absorbance was measured at 517 nm. A 100% decoloration was established using methanol-water 2:1 and the percentage of DPPH decoloration was calculated.

### Superoxide anion scavenging activity

*In vitro* effect of NG on superoxide anion radical generation was studied as described previously<sup>[35]</sup>. Two reaction systems used were: (a) enzymic; (b) non-enzymic. System (a) comprised of 100  $\mu$ mol/L xanthine, 600  $\mu$ mol/L nitroblue tetrazolium (NBT) and 0.07 U/mL xanthine oxidase in 50 mmol/L sodium carbonate pH 9.2, incubated for 10 min in presence and absence of test materials and *A* read at 560 nm. System (b) comprised of 10  $\mu$ mol/L phenazine methosulphate, 78  $\mu$ mol/L NADH, 25  $\mu$ mol/L NBT, incubated for 2 min in presence and absence of test materials and *A* read at 560 nm.

### Protein estimation

Protein concentration was measured with BCA Protein Assay Kit from Pierce (Rockford, IL, USA) as per the instructions of the manufacturer.

### Statistical analysis

Results are expressed as mean  $\pm$  SD. Comparisons were made between control and treated groups unless otherwise indicated using unpaired Student's *t*-test and *P* values < 0.05 were considered statistically significant.

## RESULTS

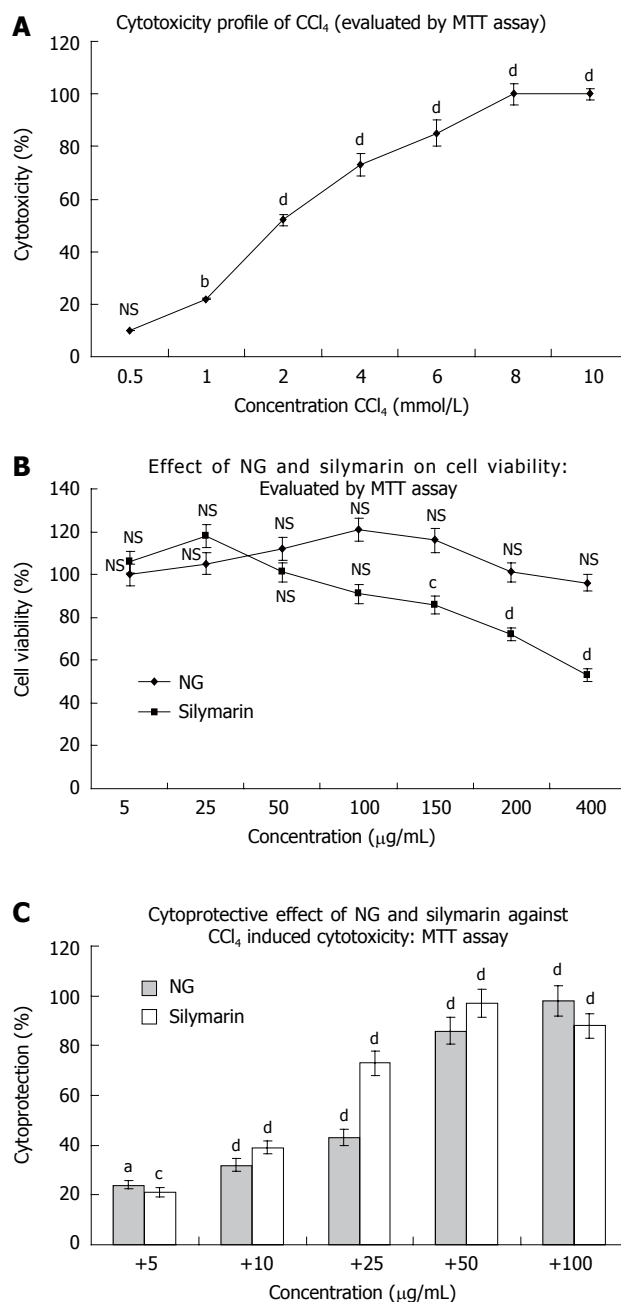

### Standardization of NG

For better scientific and clinical acceptability and proper global positioning of plant based products, it has become implicit to determine their chemical profile data on the basis of purity of compound. In this respect we have developed the HPLC protocol for NG (Figure 1). HPLC profile confirmed that NG was isolated as < 95% pure.

### Cytoprotective and membrane stabilizing effect of NG and silymarin against CCl<sub>4</sub>-induced cytotoxicity in HuH-7 cells

CCl<sub>4</sub> produced a concentration dependent loss of viability in HuH-7 cells as evaluated by MTT assay. At 24 h of incubation, the IC<sub>50</sub> value of CCl<sub>4</sub> was found to be 2 mmol/L approximately (1.958 mmol/L; Figure 2A). This concentration was used to generate oxidative stress to study the cytoprotective effect of NG and silymarin in further experimentations. NG alone was not toxic under the assay conditions up to a concentration of 400 mg/L. However, silymarin at concentrations above 50 mg/L produced loss of cell viability, with an estimated IC<sub>50</sub> value of 413.38 mg/L (Figure 2B).

To characterize the protective effect of NG and silymarin on CCl<sub>4</sub> induced cytotoxicity in HuH-7 cells,

**Figure 2** Cytotoxicity profile of CCl<sub>4</sub> and protective effect of NG and silymarin on CCl<sub>4</sub>-induced inhibition of cellular proliferation in HuH-7 cells. For cell proliferation assay, HuH-7 cells grown in 24-well culture plate were incubated with indicated concentrations of test materials. Cell proliferation was assessed by MTT reduction assay. **A, B:** Represents inhibition of cell proliferation by CCl<sub>4</sub> and test materials (NG and silymarin); **C:** Represents protection of NG and silymarin, against CCl<sub>4</sub> induced inhibition of cell proliferation. HuH-7 cells were treated with various concentrations of NG and silymarin (5 to 100 mg/L) 1 h before treatment with CCl<sub>4</sub> for 24 h and the cell proliferation was determined by MTT reduction assay. Control wells received medium containing DMSO (< 0.2 mL/L). The % cell cytotoxicity, % viability and % cytoprotection was calculated as, % Cytotoxicity = (Control - Test)/Control  $\times$  100, % Cell viability = % Cytotoxicity - 100, % Cytoprotection = 100 - (Treated - Control)/(CCl<sub>4</sub> - Control)  $\times$  100. Data are mean  $\pm$  SD (*n* = 8) and representative of one of three similar experiments and statistically significant *P* values: <sup>a</sup>*P* < 0.01; <sup>b</sup>*P* < 0.001; <sup>c</sup>*P* < 0.02; <sup>d</sup>*P* < 0.05; NS: Non-significant, CCl<sub>4</sub> treated vs control cells; CCl<sub>4</sub> + LIV-1/silymarin vs CCl<sub>4</sub> treated cells.

dose-response experiments were conducted using various concentrations of NG and silymarin. NG showed a significant dose dependent protective effect

against  $\text{CCl}_4$  induced loss of cell viability. The PC50 (50% protective concentration) for NG was estimated to be 24.46 mg/L and 15.30 mg/L for silymarin (Figure 2C).

Results obtained from MTT assay were in total correlation with the extent of cell death as confirmed by morphological changes observed under light microscope and Hoechst 33258 staining under fluorescence microscopy (Figure 3). Treatment with  $\text{CCl}_4$  caused HuH-7 cells to lose their normal structure with signs of cell swelling, most of the cells were detached and monolayer was disturbed (Figure 3 I A compared with Figure 3 I B). These structural changes were prevented to a large extent by 30 and 100  $\mu\text{g/mL}$  of NG and were comparable with the protection offered by silymarin at 50 mg/L (Figure 3 I C-F).

Nuclei of untreated HuH-7 cells appeared prominently round in shape (Figure 3 II A). After exposure with  $\text{CCl}_4$ , cells showed morphological alterations and condensation of nuclei (Figure 3 II B). The prominent changes were accompanied by an increase in apoptotic bodies and increase in cellular debris. All these alterations were prevented by co-exposure with NG and silymarin in a dose dependent manner (Figure 3 II C-E).

The above mentioned cytoprotective results were further correlated with the membrane stabilizing effect of NG and silymarin against Triton X 100 (1 g/L)-induced membrane disruption in human RBCs. NG showed an effect in the range of 4% to 91% in a concentration dependent manner (5 mg/L to 100 mg/L) against a protective effect of 6% to 88% at the same concentration, shown by silymarin (Figure 4).

#### **Effect of NG and silymarin on CYP2E1 catalytic activity**

To study the mechanism by which NG was preventing  $\text{CCl}_4$ -induced toxicity in HuH-7 cells, the possible interference of NG and silymarin on CYP2E1 activity (aniline hydroxylation) was studied. Hepatic microsomes from Wistar rats were used as a source to assay *in vitro* effect of NG and silymarin on CYP2E1 levels (Figure 5A). In another set of experiments, the CYP2E1 protein levels were analyzed to assay the protective effect of NG and silymarin against oxidation of 2.5 mmol/L ethanol (Figure 5B).

NG alone showed no significant effect on aniline hydroxylation levels at any concentrations used (5 to 100 mg/L), whereas silymarin produced an inhibitory effect in the range of 2.6% to 26.2% at the same concentrations (Figure 5A). Isoniazid (used as a positive control for inhibition of CYP2E1) showed a dose dependent inhibition, with IC<sub>50</sub> at 500  $\mu\text{mol/L}$  (data not shown).

Treatment of microsomes with 2.5 mmol/L ethanol caused an increase of 63% in aniline hydroxylation levels. Co-treatment of NG with ethanol showed no inhibitory effect on aniline hydroxylation levels induced by ethanol. However, silymarin caused inhibitions of 8.4%, 41%, 76% and 149% at 10 mg/L, 25 mg/L, 50 mg/L and 100 mg/L, respectively in aniline hydroxylation levels compared to microsomes treated with ethanol alone (Figure 5B).

The results (Figure 5 A and B) show that NG did not

inhibit CYP2E1 activity, suggesting that NG is most probably acting as an antioxidant, and not as a CYP2E1 inhibitor and silymarin acts both as an antioxidant, and an inhibitor of CYP2E1.

#### **Effect of NG and silymarin on $\text{FeSO}_4 + \text{H}_2\text{O}_2$ stimulated lipid peroxidation (LPO) in rat liver microsomes and on $\text{CCl}_4$ induced LPO in HuH-7 cells**

$\text{FeSO}_4 + \text{H}_2\text{O}_2$  increased LPO in rat liver microsomes by 6.8-fold. Incubation with NG (10 to 100 mg/L) decreased in a range of 3% to 69%, this increase in LPO levels (Figure 6A). Silymarin at the equivalent concentrations showed an enhanced inhibitory effect of 21% to 111%. Treatment of HuH-7 cells with  $\text{CCl}_4$ , increased LPO levels up to 4.6-fold. NG offered a protective effect against this increase by 10.4%, 21%, 39%, 54% and 131% at 5 mg/L, 10 mg/L, 25 mg/L, 50 mg/L and 100 mg/L, respectively. At similar concentrations, silymarin produced respective inhibitory effects of 17%, 32%, 64%, 146% and 164% (Figure 6B).

#### **Effect of NG and silymarin on the ROS generation induced by $\text{CCl}_4$**

Oxidative stress was studied by fluorescence spectrophotometrical analysis of the levels of ROS, using DCF-DA and DHR as the probes. Figure 7 shows the mean values of DCF and DHR fluorescence for cell populations with various treatments. Treatment with  $\text{CCl}_4$ , increased by 2.1 (DCF) and 2.2-fold (DHR) the production of ROS in HuH-7 cells in comparison with no addition control. NG and silymarin (10 to 100 mg/L) reduced the increase in the ROS levels produced by  $\text{CCl}_4$  in a significant and dose dependent manner. NG at 10 mg/L decreased DCF fluorescence intensity by 32% and DHR by 52%. At 50 mg/L, DCF and DHR intensities were decreased by 76% and 105%, respectively. At 100 mg/L, both the fluorescence intensities were down by 104% and 143%.  $\text{H}_2\text{O}_2$  (500  $\mu\text{mol/L}$ ) was used as positive control for ROS generation.

#### **Effect of NG and silymarin on intracellular $\text{Ca}^{2+}$ and caspase 3 levels induced by $\text{CCl}_4$**

Intracellular  $\text{Ca}^{2+}$  and caspase 3 levels were increased significantly by  $\text{CCl}_4$  treatment, which reflects the requirement of  $\text{Ca}^{2+}$  and caspase 3 in the overall toxicity pathway of  $\text{CCl}_4$  (Figures 8 and 9).  $\text{CCl}_4$  caused an increase of 4.8-fold in  $\text{Ca}^{2+}$  and 2.3-fold in caspase 3 levels in HuH-7 cells. This abnormal rise in  $\text{Ca}^{2+}$  levels were decreased by NG by 15%, 72% and 106% and caspase 3 levels were decreased by 16%, 92% and 139% at 10 mg/L, 50 mg/L and 100 mg/L, respectively. Silymarin also showed a dose dependent inhibitory effect on  $\text{Ca}^{2+}$  and caspase 3 levels increased by  $\text{CCl}_4$ . The effect was 28%, 114% and 207% in  $\text{Ca}^{2+}$  levels at 10 mg/L, 50 mg/L and 100 mg/L, and 34% and 160% in caspase 3 levels at 10 mg/L and 50 mg/L, respectively. However at 100 mg/L, silymarin showed a less significant effect (28% decrease). Thus, silymarin showed a higher  $\text{Ca}^{2+}$  inhibitory effect compared to NG, but less caspase 3 inhibition at concentrations

**Figure 3** Effect of NG and silymarin against  $\text{CCl}_4$ -induced altered cellular and nuclear morphology of HuH-7 cells. NG and silymarin rescued  $\text{CCl}_4$ -induced cellular (I) and nuclear morphological (II) changes. Cellular morphology was observed by normal phase contrast microscopy, while as nuclear morphology was evaluated by Hoechst 33258 staining of HuH-7 cells and observed under fluorescence microscopy as described in Materials and Methods. These methods detected influences of  $\text{CCl}_4$  on cellular and nuclear changes. **A:** Untreated control cells show normal cellular characteristics and rounded nuclei; **B:** Cells treated with  $\text{CCl}_4$  (2 mmol/L) for 24 h show altered membrane structure and condensed chromatin/nuclei, apoptotic (arrows) and scattered apoptotic bodies; **C:** Cells incubated with NG (30 mg/L); **D:** Cells incubated with NG (100 mg/L); **E:** Cells incubated with silymarin (50 mg/L), 1 h before the treatment with  $\text{CCl}_4$  showed protection against  $\text{CCl}_4$ -mediated cellular and nuclear alterations.

above 50 mg/L. Cyclosporine (10  $\mu\text{mol/L}$ ) was used as positive control for  $\text{Ca}^{2+}$  inhibition and camptothecin

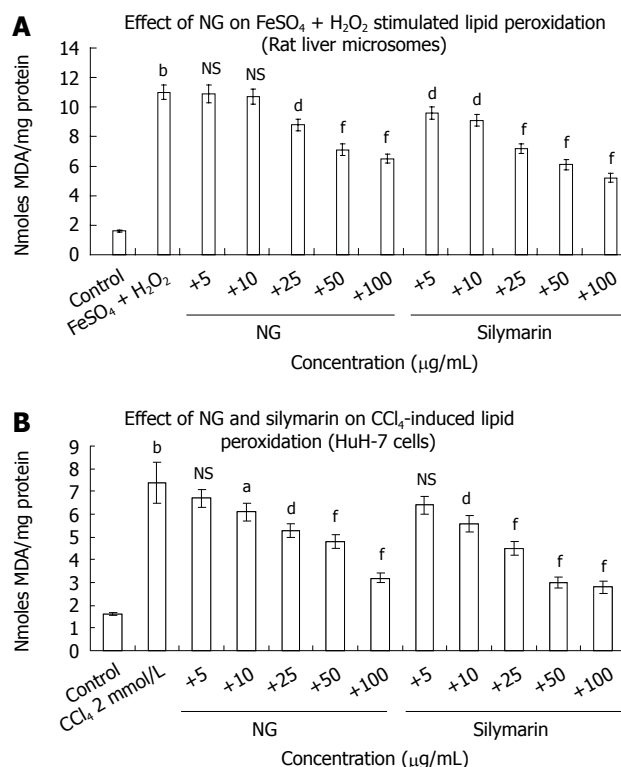

(inducer, 4  $\mu\text{mol/L}$ ) and DEVD-CHO (inhibitor, 20  $\mu\text{mol/L}$ ) were used as positive controls.

**Figure 4** Membrane stabilizing effect of NG and silymarin on human RBCs. RBC suspensions were pre-incubated with or without (control) test materials and triton (1 g/L) in phosphate buffered saline as described in Materials and Methods section. Data are mean  $\pm$  SD ( $n = 3$ ) and representative of one of three similar experiments and statistically significant  $P$  values: <sup>b</sup> $P < 0.01$ ; <sup>a</sup> $P < 0.05$ ; <sup>d</sup> $P < 0.001$ ; NS = Non-significant. Triton treated vs control cells; triton + NG/silymarin vs triton treated cells.

**Figure 5** Effect of NG and silymarin *in vitro* on CYP2E1 catalytic activity. **A:** Rat liver microsomes were incubated in the absence or presence of different concentrations (5 to 100 mg/L) of test materials. CYP2E1 activity was assayed by following the hydroxylation of aniline hydrochloride in presence of cumene hydroperoxide as described in Materials and Methods section; **B:** Concentration dependent protection by NG and silymarin against alcohol (2.5 mmol/L)-induced aniline hydroxylase levels in rat liver microsomes. The microsomes were pre-incubated with medium containing various concentrations (5 to 100 mg/L) of test materials for 5 min before addition of alcohol and aniline hydroxylase levels were determined. Data are expressed as mean  $\pm$  SEM and are from a representative experiments repeated twice and conducted in triplicate.  $P$  values: <sup>b</sup> $P < 0.001$  vs the corresponding alcohol-treated microsomes; <sup>d</sup> $P < 0.001$  and <sup>f</sup> $P < 0.001$  vs alcohol-treated cells in presence of test materials; NS: Non-significant.

**Figure 6** Protective effect of NG and silymarin against stimulated lipid peroxidation. **A:** Anti-lipid peroxidative effect of NG and silymarin *in vitro*. Liver microsomes (1 mg protein/mL, 0.15 mol/L NaCl, pH 7.0) were incubated for 20 min at 37°C in the absence (control) and presence of 100 mmol/L FeSO<sub>4</sub> + 50 mmol/L H<sub>2</sub>O<sub>2</sub> (stimulated). In identically set-up Fe<sup>2+</sup>/H<sub>2</sub>O<sub>2</sub>-stimulated incubations, NG and silymarin (20 mg/L to 100 mg/L, in 30% DMSO) were added (test C). Control incubations received vehicle only; **B:** HuH-7 cells were pre-incubated for 1 h with medium containing test materials (NG and silymarin) at different concentrations (5 mg/L to 100 mg/L). The cells were further incubated in absence or presence of 2 mmol/L CCl<sub>4</sub> (stimulated) for further 24 h. The cells were harvested by scraping and assayed for the production of MDA using TBARS assay, as described under materials and methods section. Reaction was terminated by the addition of 2.0 mL TCA-TBA reagent (15% TCA, 0.375% TBA in 5mol/L HCl) and LPO content determined as nmol MDA formed/mg protein. Data are expressed as mean  $\pm$  SD and are from representative experiments repeated twice and conducted in triplicate. Statistical significance, <sup>b</sup> $P < 0.01$  vs the untreated control. <sup>d</sup> $P < 0.01$ ; <sup>a</sup> $P < 0.05$ ; <sup>f</sup> $P < 0.001$  and NS: Non-significant vs stimulated (FeSO<sub>4</sub> + H<sub>2</sub>O<sub>2</sub> and CCl<sub>4</sub> treatments).

#### Effect of NG and silymarin on cytochrome C release from isolated rat liver mitochondria induced by CCl<sub>4</sub>

Isolated rat liver mitochondria were used to study the effect of NG and silymarin on cytochrome C release induced by CCl<sub>4</sub> (Figure 10). CCl<sub>4</sub> caused an increase of 2.1-fold in cytochrome C levels, which was inhibited by 75% and 105% at 50 mg/L and 100 mg/L of NG treatment, respectively. Silymarin showed an effect in the range of 27% at 10 mg/L, 135% at 50 mg/L. However at a higher concentration (100 mg/L), silymarin showed a biphasic effect, with a slight increase in cytochrome C levels compared to 50 mg/L (36% increase). Cyclosporine 5 µmol/L was used as a positive control for cytochrome C inhibition.

#### Effect of NG and silymarin on mitochondrial membrane permeability transition onset by CCl<sub>4</sub> in HuH-7 cells

Oxidative damage to mitochondria and the onset of MMP transition seems to play an important role in CCl<sub>4</sub>-

**Figure 7** Effect of NG and silymarin on CCl<sub>4</sub>-induced ROS production. HuH-7 cells were pre-incubated for 1 h with medium containing test materials (NG and silymarin) at different concentrations (10 to 100 mg/L). The cells were kept for further incubation in absence or presence of 2 mmol/L CCl<sub>4</sub> (stimulated). After 24 h of incubation maintaining the specific treatments, the cells were incubated with serum-free medium containing DCF-DA and 123-DHR and ROS levels were studied as mentioned in material and methods section. H<sub>2</sub>O<sub>2</sub> (100 μmol/L) was used as positive control for ROS generation. Data are expressed as mean ± SD and are from representative experiments repeated twice and conducted in triplicate. Statistical significance: <sup>b</sup>*P* < 0.001 vs the untreated control; <sup>d</sup>*P* < 0.001, <sup>a</sup>*P* < 0.05; <sup>i</sup>*P* < 0.01 vs CCl<sub>4</sub>-treated cells.

**Figure 8** Effect of NG and silymarin against CCl<sub>4</sub>-induced cytosolic free Ca<sup>2+</sup> concentrations. HuH-7 cells pre-incubated for 1 h with medium containing test materials (NG and silymarin) at different concentrations (10 to 100 mg/L) were exposed to CCl<sub>4</sub> (2 mmol/L) for indicated time period, washed and loaded with Fura-2 AM as described in materials and methods section. Cyclosporine (10 μmol/L) was used as positive control. Data are expressed as mean ± SD, and are from a representative experiments repeated twice and conducted in triplicate. Statistical significance: <sup>b</sup>*P* < 0.001 vs the untreated control, <sup>d</sup>*P* < 0.001 vs CCl<sub>4</sub> treated cells.

induced toxicity in HuH-7 cells. MMP transitions were analyzed by flow cytometry after staining with Rh123 (Figure 11). Untreated HuH-7 cells were strong in Rh123 fluorescence intensity, suggestive of intact viable cells. A very small percentage of cells (8%) were showing low Rh123 fluorescence, reflective of damaged cells. CCl<sub>4</sub> caused a 6-fold increase in percentage of cells with low Rh123 fluorescence. Incubation in the presence of 50 mg/L and 100 mg/L of NG and silymarin, respectively significantly protected HuH-7 cells from decline in MMP produced by CCl<sub>4</sub>.

#### Effect of NG and silymarin on CCl<sub>4</sub>-induced apoptosis in HuH-7 cells

Apoptosis was studied by internucleosomal DNA fragmentation analysis and cell cycle analysis by flow

**Figure 9** Effect of NG and silymarin against caspase 3-mediated apoptosis. CCl<sub>4</sub> treatment increases caspase 3 activity in HuH-7 cells. HuH-7 cells were treated with CCl<sub>4</sub> in presence or absence of test materials (NG and silymarin) and caspase 3 activity was measured as described in Materials and Methods section. Data are expressed as mean ± SD and are from representative experiments repeated twice and conducted in triplicate. Statistical significance: <sup>b</sup>*P* < 0.001 vs the untreated control; <sup>d</sup>*P* < 0.01; <sup>i</sup>*P* < 0.001 vs CCl<sub>4</sub>-treated cells.

**Figure 10** Effect of NG and silymarin against CCl<sub>4</sub>-induced cytochrome C release from isolated rat liver mitochondria. CCl<sub>4</sub> treatment causes cytochrome C release from rat liver mitochondria. Mitochondria were treated with CCl<sub>4</sub> in presence or absence of test materials (NG and silymarin) and cytochrome C levels were measured as described in Materials and Methods section. Data are expressed as mean ± SD and are from a representative experiments repeated twice and conducted in triplicate. Statistical significance: <sup>b</sup>*P* < 0.001 vs the untreated control; <sup>a</sup>*P* < 0.02; <sup>d</sup>*P* < 0.001 and NS = non-significant vs CCl<sub>4</sub> treated mitochondria.

cytometry. A DNA ladder formation was found with cells treated with CCl<sub>4</sub> (Figure 12). Treatment with NG and silymarin protected HuH-7 cells against CCl<sub>4</sub> induced DNA fragmentation.

In cell cycle analysis, treatment with CCl<sub>4</sub> markedly increased proportion of apoptotic cells significantly (49%). NG and silymarin had an obvious anti-apoptosis effect. As shown in Figure 13, the co-treatment with 25 mg/L, 50 mg/L and 100 mg/L of NG markedly reduced the percentage of the apoptotic cells to 27%, 14% and 11%, respectively. Silymarin showed a reduction in apoptotic cells by 21% and 9% at 25 mg/L and 50 mg/L, respectively. At 100 mg/L, however, silymarin had an effect of 18% (Figure 13).

#### Effect of NG and silymarin on CCl<sub>4</sub>-induced alterations in cAMP and cPLA<sub>2</sub> levels in HuH-7 cells

To test the effect of CCl<sub>4</sub>-induced oxidative stress on cAMP levels in HuH-7 cells, we evaluated cAMP with

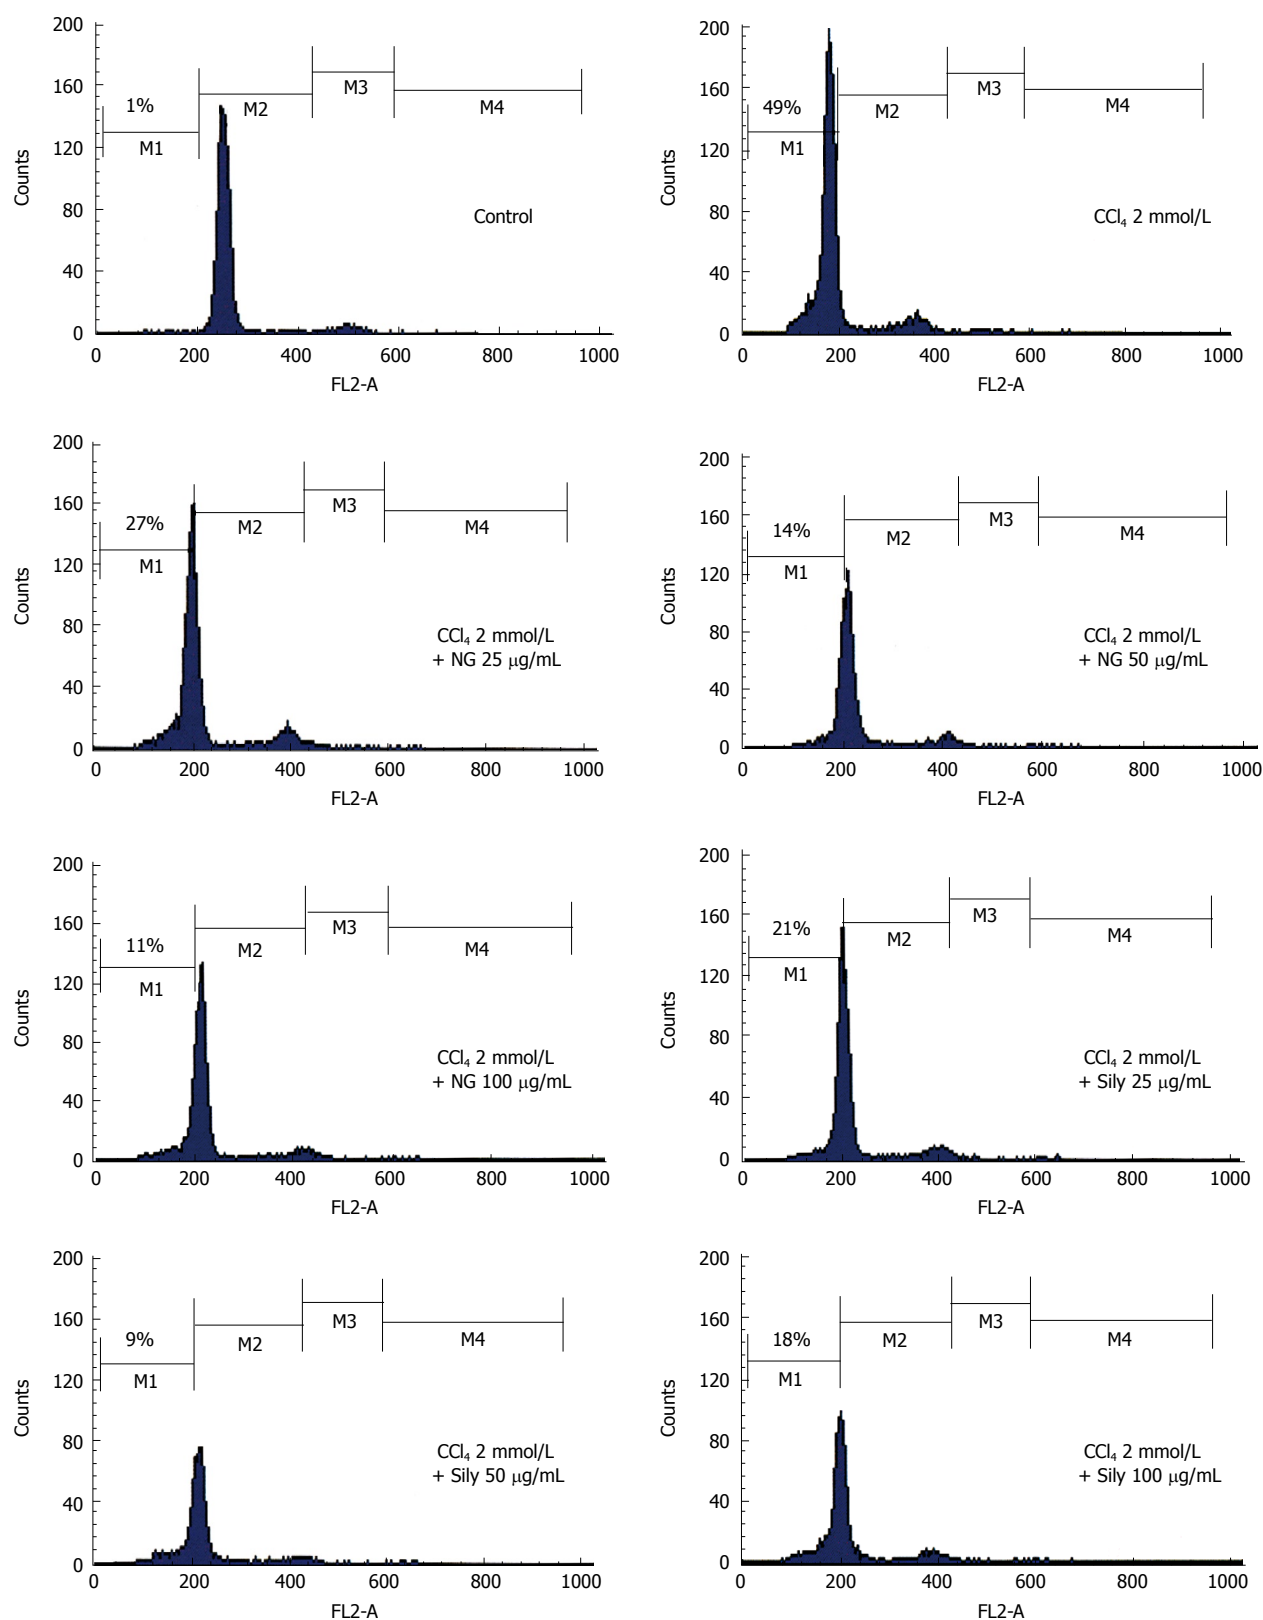

**Figure 11** Effect of NG and silymarin against  $\text{CCl}_4$ -induced loss of mitochondrial membrane potential ( $\Delta\psi\text{m}$ ). HuH-7 cells were pre-incubated for 1 h with test materials (NG and silymarin) at mentioned concentrations. The cells were further incubated for 24 h with  $\text{CCl}_4$  (2 mmol/L). Thereafter, cells were stained with Rhodamine-123 and analysed by flow cytometry as described in Materials and Methods section. Representative histograms are shown and the percentage of cells in depolarized zone (M1 zone) are shown.

and without  $\text{CCl}_4$  and then in the presence of  $\text{CCl}_4$  with NG and silymarin. As hypothesized, cAMP levels were significantly reduced by  $\text{CCl}_4$ . Concomitant treatment of HuH-7 cells with NG significantly increased the levels of cAMP. Similar results were evident with treatment with silymarin. Forskolin (100  $\mu\text{mol/L}$ ) was used as a positive inducer of cAMP (Figure 14). On the contrary, phospholipase A2 levels were significantly increased with the  $\text{CCl}_4$  treatment (2.3-fold). NG effectively reduced this increase by 44% at 10 mg/L and 304% at 50 mg/L. Silymarin reduced these levels by 97% at 10 mg/L and 136% at 50 mg/L. Bee venom (1 mg/L) was used as positive control to induce cPLA2 levels (Figure 15).

**Figure 12** Effect of NG and silymarin against  $\text{CCl}_4$ -induced DNA fragmentation. HuH-7 cells were pre-incubated for 1 h with test materials (NG and silymarin) at mentioned concentrations. The cells were further incubated for 24 h with  $\text{CCl}_4$  (2 mmol/L). Thereafter, genomic DNA was extracted from cells and subjected to gel electrophoresis as mentioned in Materials and Methods section. Lanes: 1: Control; 2:  $\text{CCl}_4$  2 mmol/L; 3:  $\text{CCl}_4$  2 mmol/L + NG 30 mg/L; 4:  $\text{CCl}_4$  2 mmol/L + NG 100 mg/L; 5:  $\text{CCl}_4$  2 mmol/L + Silymarin 50 mg/L; 6: Ladder.

**Figure 13** Effect of NG and silymarin against CCl<sub>4</sub>-induced cell cycle arrest. HuH-7 cells were pre-incubated for 1 h with test materials (NG and silymarin) at mentioned concentrations. The cells were further incubated for 24 h with CCl<sub>4</sub> (2 mmol/L). Thereafter, cells were harvested by trypsinization, fixed with ethanol, stained with PI, and analyzed using flow cytometry. Representative histograms are shown, and the percentage of cells in the sub G<sub>0</sub>/G<sub>1</sub> fraction (M1 zone, hypodiploid area) are shown.

#### **Effect of NG and silymarin on CCl<sub>4</sub>-induced depletion of GSH levels in HuH-7 cells**

Figure 16 depicts the effect of CCl<sub>4</sub> on GSH levels and restorative effect of NG and silymarin in a dose-

response manner. Treatment of HuH-7 cells with CCl<sub>4</sub>-depleted the GSH content by 2 folds. Co-exposure with NG and silymarin effectively restored the depleted levels of GSH in a dose response manner. Restorative

**Figure 14** Effect of NG and silymarin against CCl<sub>4</sub>-depleted cAMP levels. Pre-incubated, (1 hour at mentioned concentrations of NG and silymarin) HuH-7 cells were exposed to 2 mmol/L CCl<sub>4</sub> for 24 h. cAMP levels were determined in the cell culture supernatants as described in Materials and Methods. Forskolin (100 µmol/L) was used as positive control. Data are expressed as mean ± SD and are from representative experiments repeated twice and conducted in triplicate. Statistical significance: <sup>b</sup>*P* < 0.001 vs the untreated control. <sup>d</sup>*P* < 0.001 vs CCl<sub>4</sub>-treated cells.

effect of NG was in the range of 17% to 147% at 5 mg/L to 100 mg/L, respectively. Silymarin showed an effect in the range of 23% to 152% at a concentration of 5 to 50 mg/L. However at higher concentration (100 mg/L), there was a slight decrease in this effect. BSO (100 µmol/L) was used as a positive inhibitor of GSH.

#### *In vitro* antioxidant activity of NG and silymarin

Figure 17 is representative of anti-oxidant activity of NG and silymarin. NG showed a strong activity, with I.C. 50 values of 17.31 mg/L for DPPH, 22.75 mg/L for enzymatic reaction, 13.49 mg/L for non-enzymatic reaction and 8.71 mg/L for ABTS assay. The IC 50 values of silymarin for the same assays were 34.07, 24.35, 21.10 and 12.36 mg/L respectively.

## DISCUSSION

Liver cells exposed to various chemicals/drugs (pro-oxidants) appear to be a useful *in vitro* model to characterize the biochemical and toxicological properties of such entities, and the possible protection provided by added agents<sup>[36]</sup>. The main goal of this work was to investigate the influence of an irridoid glycoside compound negundoside (NG) on CYP2E1-mediated toxicity in HuH-7 cells induced by CCl<sub>4</sub>. Overall, the results of the present study indicate that NG is effective in protecting against the toxicity and the loss of viability induced by CCl<sub>4</sub>.

The main mechanism by which CCl<sub>4</sub> is known to mediate its toxic effects is through oxidative stress and oxidative damage due to an increased production of ROS<sup>[37]</sup>. Induction of CYP2E1 by CCl<sub>4</sub> is one of the main pathways by which CCl<sub>4</sub> increases ROS production and generates a state of oxidative stress in the liver<sup>[38,39]</sup>. Since CYP2E1 is a key contributor to injury produced

**Figure 15** Effect of NG and silymarin against CCl<sub>4</sub>-induced cPLA2 levels. Pre-incubated, (1 h with mentioned concentrations of NG and silymarin) HuH-7 cells were exposed to 2 mmol/L CCl<sub>4</sub> for 24 h. cPLA2 levels were determined as described in Materials and Methods. Bee venom (1 µg) was used as positive control. Data are expressed as mean ± SD and are from representative experiments repeated twice and conducted in triplicate. Statistical significance: <sup>b</sup>*P* < 0.001 vs the untreated control; <sup>d</sup>*P* < 0.01; <sup>f</sup>*P* < 0.001 vs CCl<sub>4</sub>-treated cells.

**Figure 16** Effect of NG and silymarin on CCl<sub>4</sub>-induced decrease in GSH levels. HuH-7 cells were pre-incubated with medium containing test materials (NG and silymarin) for 1 h. The cultures were then further incubated in presence and absence of CCl<sub>4</sub> for 24 h. The cells were harvested by scraping and GSH levels were determined as described under Materials and Methods section. BSO (100 µmol/L) was used as positive control. Data are expressed as mean ± SD and are from representative experiments repeated twice and conducted in triplicate. Statistical significance: <sup>b</sup>*P* < 0.001 vs the untreated control; <sup>d</sup>*P* < 0.01; <sup>f</sup>*P* < 0.001; NS = non-significant vs CCl<sub>4</sub>-treated cells.

by CCl<sub>4</sub>, one possible mechanism involved in the prevention of this toxicity by NG could have been an inhibition of CYP2E1 catalytic activity. Results in this study indicate that NG does not affect *p*-nitrophenol metabolism by CYP2E1 in liver microsomes under the experimental conditions (Figure 5 A and B); therefore, the mechanism by which NG affords its protection is not by inhibition of CYP2E1 activity. This is in confirmation to earlier reports in which many plant derived products like, *Scutellariae radix*<sup>[40]</sup>, *Humulus lupulus*<sup>[41]</sup>, green tea compounds<sup>[42]</sup> have also been shown to be hepatoprotective in other systems without any effect on CYP2E1 catalytic activity.

Bio-metals, such as iron are powerful catalysts of

**Figure 17** *In vitro* effect of NG and silymarin on free radicals generation. Free radicals scavenging effect of NG and silymarin was studied against DPPH radicals (stable hydroxyl radical), enzymic, non-enzymic (superoxide radicals) and ABTS radical (stable hydroxyl radical). Percentage anti-oxidant activity (% effect) was determined as described in Materials and Methods section. Values are mean from five independent determinations. <sup>b</sup>*P* < 0.001 versus control. Control O.D. system DPPH, 0.650, system Enzymatic, 0.250 and system Non-enzymatic, 0.300 and system ABTS, 0.750. Data are expressed as mean ± SD and are from a representative experiments repeated twice and conducted in triplicate. Statistical significance: <sup>a</sup>*P* < 0.05; <sup>b</sup>*P* < 0.01; <sup>c</sup>*P* < 0.02; <sup>d</sup>*P* < 0.001; NS = non-significant vs respective controls.

free radical formation and lipid peroxidation processes, and polyunsaturated fatty acids in cellular membranes (microsomes) provide basic substrates for these reactions<sup>[43]</sup>. Scavenging or preventing formation of lipid radicals may prevent damage when cellular antioxidant defense mechanism is strengthened or iron overload is sequestered by exogenous treatment with cytoprotective drugs as NG. As lipid peroxidation (LPO) has been shown to play an important role in the ensuing toxicities in CYP2E1-induced conditions<sup>[44,45]</sup>, in this respect, NG strongly inhibited lipid peroxidation promoted by H<sub>2</sub>O<sub>2</sub>+Fe in microsomes and CCl<sub>4</sub> in HuH-7 cells (Figure 6 A and B). It has been reported that glycosides, such as NG, are potent cytoprotective agents against oxidative stress induced cytotoxicity<sup>[46]</sup>. Therefore, one major mechanism underlying the effectiveness of NG in protecting against the CCl<sub>4</sub>-induced LPO in HuH-7 cells may involve its capability to prevent lipid peroxidation chain reactions as a consequence of scavenging free radicals or chelating iron.

Intracellular calcium has been suggested to play a critical role in the oxidative damage of liver cells. Earlier, it has been reported that treatment of liver cells with CCl<sub>4</sub> increases calcium levels and produce cellular toxicity through calcium dependent pathways. Elevated levels of calcium initiates a cascade of signaling events leading to activation of calcium dependent degradative enzymes as phospholipases A2, endonucleases, or proteases<sup>[47]</sup>. Our results are in corroboration with this

and showed that CCl<sub>4</sub>-induced cell death in HuH-7 cells was mediated by release of intracellular calcium with subsequent activation of caspase 3 and cPLA2 (Figures 9 and 15) and simultaneous inhibition of cAMP levels (Figure 14). Increased intracellular calcium, activation of PLA2 and inhibition of cAMP were almost parallel to toxicity. Oxidative stress-mediated LPO is suggested to be the initiator of intracellular calcium release<sup>[25]</sup>, which later influences down stream apoptotic signaling processes. cAMP levels are known to be regulated by catalytic activity of adenylate cyclase and phosphodiesterase. Increasing concentration of intracellular cAMP has been directly associated with inhibition of phosphodiesterase, reduced release of ROS and inhibition of chemotaxis, degranulation and cell death<sup>[48]</sup>. NG restored the calcium and cAMP to normal levels, inhibited lipid peroxidation, activated cPLA2 levels were inhibited and cytotoxicity was reversed without altering CYP2E1 levels. Therefore we hypothesize that NG inhibits CCl<sub>4</sub>-induced oxidative stress and, hence LPO, which increases intracellular calcium and PLA2 activation and converge on mitochondria, inducing mitochondrial damage. All these downstream events of CYP2E1 mediated toxicity were effectively inhibited by NG, thus demonstrating its strong anti-oxidant capacity. We also suggest that inhibition of intracellular calcium release mediated cPLA2 activation, increase in cAMP levels, and restoration of MMP are the key factors in cytoprotection afforded by NG. Recently, it has been

**Figure 18** Proposed sequence of events and mechanism involved in the toxicity of CCl<sub>4</sub> and cytoprotection offered by NG. CCl<sub>4</sub> is activated by CYP 450 2E1 system and converted into trimethyl CCl<sub>3</sub> radicals inducing oxidative stress (increased ROS inducing membrane lipid peroxidation) and disturbed cellular Ca<sup>2+</sup> homeostasis. Increase in intracellular Ca<sup>2+</sup> concentrations leads to activation of phospholipase A2 and a decline in cAMP levels. All these signaling events converge onto the mitochondrial-initiating mitochondrial pore transition and ultimately to cellular injury. The highly increased levels of ROS is, in part, the consequence of the increase in Ca<sup>2+</sup>, and also as a result of mitochondrial permeabilization resulting in activation of Ca<sup>2+</sup>-dependent proteases. NG exerts a protective effect via inhibition of oxidative stress, maintenance of disrupted intracellular calcium homeostasis and inactivation of Ca<sup>2+</sup>-dependent proteases.

suggested that calcium levels do not play a direct role in toxicity<sup>[26]</sup>, but that activation of PLA2, promotion of the mitochondrial permeability transition and loss of mitochondrial function, which are secondary manifestations of increased calcium levels, form a general pathway involved in the toxicity: all these events were restored to normal by NG.

As the main antioxidant inside mammalian cells, GSH plays a pivotal role in preventing oxidative stress and mitochondrial damage caused by numerous toxins<sup>[49]</sup>. Therefore, the effect of CCl<sub>4</sub> in the absence or presence of NG on GSH content was evaluated. CCl<sub>4</sub> treatment drastically depleted intracellular GSH in HuH-7 cells, an effect prevented in the presence of NG (Figure 16). Accordingly, the maintenance of intracellular GSH levels by NG may help in protecting against the oxidative toxicity induced by CCl<sub>4</sub> in HuH-7 cells and avoid cell degeneration and death. Previously as well, depletion of GSH has been shown to enhance CYP2E1 resulting in CYP2E1-derived ROS leading to toxicity<sup>[50]</sup>.

Decreased MMP has been proposed to be a key mechanism by which CYP2E1-dependent LPO causes loss in cell viability. Mitochondria are a main source for generating ROS and, hence, a target for damage by oxidative stress<sup>[51]</sup>. In this respect, CCl<sub>4</sub> treatment caused a decrease in the MMP in HuH-7 cells, and this effect was prevented by NG as well as by silymarin (Figure 11). These results suggest that NG and silymarin may protect the cells by preventing oxidant-induced MMP transition leading to pathogenesis of necrotic or apoptotic cell death<sup>[52]</sup>. It has been proposed earlier that mitochondrial injury derived from oxidative damage can lead not only to necrosis by depleting ATP, but also to apoptotic cell

death by inducing the release of mitochondrial factors such as cytochrome C, which activates the caspase cascade<sup>[53, 54]</sup>.

Regardless of its precise mechanism of action, numerous studies in various animal models and in humans describe protective effects of NG against oxidative stress-related disease states<sup>[2-15]</sup>. This enhances its potential usefulness as a preventive agent toward oxidative damage involved in the development of liver injury caused by oxidative stress. Since NG acts as a very potent membrane stabilizer, it is also suggested that NG, may be acting as amphipathic substance, localizing near the membrane surface, trapping any radicals generated in the lipid environment of the membranes as well as in the cytosol. Such localization is suggested from the fact that CYP2E1 is found in the microsomes, and mitochondria appear to be a target for the CYP2E1-mediated damage in the presence of hepatotoxins such as CCl<sub>4</sub>, which was effectively inhibited by NG. Moreover, NG is well tolerated without adverse health effects by humans even after oral administration at high doses as evident from its use in Asian traditional medicine practices for various ailments.

In conclusion, this report shows that NG can protect against CCl<sub>4</sub>-induced toxicity and oxidative stress. The mechanism of protection involves decreased production of ROS and lipid peroxidation when the CYP2E1 mediated oxidative stress was produced in HuH-7 cells with pro-oxidant as CCl<sub>4</sub>. The main mechanism involved in the cytoprotection of NG seems to be its ability to protect the mitochondria against depletion in its membrane potential, an event that is very critical in the loss of cell viability as a consequence of oxidative stress. This mechanism has been postulated in the Figure 18. NG has been shown to prevent CCl<sub>4</sub>-induced liver injury, which may be, in part, due to the protection against CYP2E1-dependent oxidative stress as demonstrated in this study. NG supplementation could also prove to be protective against numerous toxicants that involve induction of oxidative stress through increased generation of ROS.

We are grateful to Dr. GN Qazi, Director of this institute for providing constant guidance and support.

## COMMENTS

### Background

*Vitex negundo* is a reputed medicinal herb of Indian sub-continent. All plant parts are considered important in Ayurvedic system of medicine for various indications.

### Research frontiers

Several pharmacological studies validate the medicinal claims of *Vitex negundo*. Diverse chemical constituents have been reported from various parts of this plant which are considered responsible for its varied pharmacological activities. The negundoside seems to be a potential constituent that exerts a protective effect on CYP2E1-dependent toxicity caused by carbon tetrachloride (CCl<sub>4</sub>) via inhibition of lipid peroxidation, followed by an improved intracellular calcium homeostasis and inhibition of Ca<sup>2+</sup>-dependent proteases.

### Innovation and breakthrough

The present investigation shows that negundoside is a potent phytopharmaceutical that acts in a novel way in inhibiting liver toxicity by interfering in the key events that are the main causative factors leading to liver

dysfunction.

### Applications

Negundoside exerts a protective action on CYP2E1-dependent oxidative stress and toxicity that may contribute to preventing chemically-induced liver injury, and may be useful in preventing toxicity by various other hepatotoxins as well.

### Peer review

The authors investigated the anti-apoptotic effect of negundoside (NG), being extracted from leaves of *Vitex negundo*, on cultured human hepatoma cell line, HuH-7G2. The authors performed a large amount of experiments, and found that NG inhibited ROS formation, lipid peroxidation, intracellular calcium elevation, GSH depletion, elevated anti-oxidant activity, declined MMP, cytochrome C release, and finally carbon tetrachloride-mediated apoptosis. The manuscript addressed the authors' hypothesis with sufficient data.

### Abstract

**AIM:** To investigate the peripheral T-lymphocyte subpopulation profile, and its correlations with hepatitis B virus (HBV) replication level in chronic HBV-infected (CHI) individuals with normal liver function tests (LFTs).

**METHODS:** Frequencies of T-lymphocyte subpopulations in peripheral blood were measured by flow cytometry in 216 CHI individuals. HBV markers were detected with ELISA. Serum HBV DNA load was assessed with quantitative real-time PCR. Information of age at HBV infection, and maternal HBV infection status was collected. ANOVA linear trend test and linear regression were used in statistical analysis.

**RESULTS:** CHI individuals had significantly decreased relative frequencies of CD3<sup>+</sup>, CD4<sup>+</sup> subpopulations

and CD4<sup>+</sup>/CD8<sup>+</sup> ratio, and increased CD8<sup>+</sup> subset percentage compared with uninfected individuals (all  $P < 0.001$ ). There was a significant linear relationship between the load of HBV DNA and the parameters of T-lymphocyte subpopulations (ANOVA linear trend test  $P < 0.01$ ). The parameters were also significantly worse among individuals whose mothers were known to be HBV carriers, and those having gained infection before the age of 8 years. In multiple regressions, after adjustment for age at HBV infection and status of maternal HBV infection, log copies of HBV DNA maintained its highly significant predictive coefficient on T-lymphocyte subpopulations, whereas the effect of HBeAg was not significant.

**CONCLUSION:** HBV DNA correlates with modification in the relative T-lymphocyte subpopulation frequencies. High viral load is more powerful than HBeAg in predicting the impaired balance of T-cell subsets.

### INTRODUCTION

Hepatitis B virus (HBV) infection is a global public

health problem. It is estimated that approximately 2 billion people have serological evidence of past or present HBV infection and more than 350 million individuals worldwide are chronically infected with HBV<sup>[1]</sup>. In infected adolescents or adults, 5%-10% will develop into a chronic carrier state, whereas in infected neonates up to 90% develop chronicity<sup>[1-2]</sup>. HBV infection is especially prevalent in African and Asian countries such as Korea, Japan, Taiwan and mainland China because most patients with chronic HBV infection have acquired the infection perinatally from carrier mothers<sup>[3]</sup>. China has the highest prevalence of HBV, with over one-third of the world's total estimated HBV carriers. Out of the chronic HBV-infected patients, 70%-80% could have persistent normal liver function for many years or a lifetime<sup>[1-2]</sup>. Further persistent viral infection can, however, lead to subclinical hepatitis and chronic active hepatitis, even liver cirrhosis and the development of hepatocellular carcinoma<sup>[1-2]</sup>.

The pathogenesis of persistent viral infection and hepatitis B is complex. Generally, it is not HBV itself that damages hepatocytes directly, but the result of function disorder of cell-mediated immunity<sup>[4-6]</sup>. The cellular immune response to HBV is thought to be responsible for viral clearance, and disease pathogenesis during infection. The T-cell response to HBV is vigorous, polyclonal, and multispecific in acutely infected patients who successfully clear the virus, and it is relatively weak and narrowly focused in chronically infected patients<sup>[7-8]</sup>. The outcome of HBV infection would depend upon the balance between development of immunity (leading to virus elimination) and tolerance (leading to chronic viral persistence). HBeAg may play an important role in the interaction of the virus with the immune system. Secreted HBeAg has been proposed to have an immunoregulatory function in uterus by establishing T-cell tolerance to HBeAg and HBcAg that may predispose neonates born to HBV-infected mothers to develop persistent HBV infection<sup>[9]</sup>. Recent studies have further demonstrated an immunomodulatory role of HBeAg in antigen presentation and recognition by CD4<sup>+</sup> cells<sup>[10]</sup>.

It is essential to study the HBV replication status and its effects on cellular immune function in normal LFTs chronic HBV-infected (CHI) individuals. Firstly, they are the majority of chronic HBV-infected individuals; secondly, the understanding of the immune response upon HBV infection is useful to develop appropriate therapeutic strategies for controlling viral hepatitis and disease progression, as well as to improve current knowledge regarding persistent HBV infection prognosis. However, the correlations between HBV-specific T-cell response, and HBV viral load and HBeAg expression in CHI individuals are complicated. So are the effects of age at first infection and maternal HBV infection status. The aim of the work reported herein was to evaluate the peripheral blood T-lymphocyte subpopulation profile, and its correlations with HBV replication level, and to determine further which active marker of HBV active replication, HBV DNA or HBeAg is more powerful in predicting peripheral T-lymphocyte subpopulation in CHI individuals.

## MATERIALS AND METHODS

### *Enrollment of study subjects*

Two hundred and sixteen consecutive CHI individuals with normal LFTs were recruited from the Department of Infectious Diseases and of Hepatology of the First Affiliated Hospital of Kunming Medical University, the Third Municipal People's Hospital of Kunming and the Yunnan General Hospital of The Chinese People's Armed Police Forces, between January 2004 and May 2007.

The following criteria were fulfilled by all individuals:

(1) steady positivity for HBsAg in their serum for at least 12 mo and persistently normal liver function tests; and (2) exclusion of other concomitant causes of liver disease (hepatitis C, D and HIV infection and alcohol consumption of more than 60 g/day) and relatively rare liver disease (autoimmune hepatitis and metabolic liver disease) and treated with immunosuppressive therapy or antiviral therapy for HBV-infection within the recent 12 mo before entry. None of the patients was a drug user, or exposed to hepatotoxin. Informed consent was obtained from each study subject. The study protocol conformed to the guidelines of Declaration of Helsinki and was approved by ethics committees of the Faculty of Medicine of Prince of Songkla University and the First Affiliated Hospital of Kunming Medical University.

One hundred individuals who were free of HBsAg were identified from individuals coming to the outpatient service for a health check-up; 61 of the participants were male, 39 were female; mean age, 33.24 (SD, 10.28) years. These served as the control group for comparison of T-lymphocyte subpopulation with those who had HBV infection.

### *Serological liver function tests and hepatitis B virus markers evaluation*

Serum alanine amino-transferase (ALT), aspartate transaminase (AST) and total bilirubin (TBil) were tested with routine automated techniques (upper limit of normal: 40 U/L, 40 U/L and 17.1  $\mu$ mol/mL, respectively) (AU2700, Japan). HBV markers (HBsAg, HBsAb, HBeAg, HBeAb, HBcAb, and anti-HBcAb IgM) were measured at a virological laboratory with enzyme-linked immunosorbent assay (ELISA) (Anthos 2010, Austria). The experimental methods followed those specified within the reagent kit (Sino-American Biotech Co., Ltd) package insert.

### *Quantitative measurement HBV DNA (viraemia)*

Serum HBV DNA load in individuals was assessed by the real-time fluorescent quantitative polymerase chain reaction method (Real-Time-PCR) using a Lightcycler PCR system (FQD-33A, Bioer) with a lower limit of detection of approximately 1000 viral genome copies/mL. The handling procedures were performed in strict accordance with the reagent kit (Shenzhen PG Biotech Co., Ltd.) package insert. The primer was provided in the kit, the reaction volume was 40  $\mu$ L, and the reaction condition was 37°C for 5 min, 94°C for 1 min then 40 cycles as 95°C for 5 s and 60°C for 30 s.

**Peripheral blood T lymphocyte subsets measurement**

The key components of cellular immunity are T-lymphocyte and its subpopulations. CD3<sup>+</sup>, CD4<sup>+</sup> and CD8<sup>+</sup> cells are major functional subgroups of T cells, and play an important role in response to HBV infection, which can reflect the situations of cellular immune function and immunoregulation, and are usually regarded as a valuable index to forecast the changes of patients' immunity<sup>[4-5]</sup>. These indices were chosen in our study for evaluating cellular immune function status of normal LFTs CHI individuals.

Blood samples were collected in heparinized vacutainer tubes. Whole blood samples were analyzed with a Multi-Q-Prep processor (Coulter, USA) and thereafter Epics-XL flow cytometry (FCM) (Coulter, USA). Lymphocytes were analyzed using a gate set on forward scatter versus side scatter, and a three color flow cytometry to combination reagent of CD3, CD4 and CD8. Anti-human monoclonal antibodies CD3-PE-CY5/CD4-FITC/CD8-PE were purchased from Immunotech, Ltd, USA. The detection was analyzed with the CELLQuest software (Coulter, USA) for each sample. The results were expressed as the percentages of CD3<sup>+</sup>, CD3<sup>+</sup>/CD4<sup>+</sup> (short for CD4<sup>+</sup> below) and CD3<sup>+</sup>/CD8<sup>+</sup> (short for CD8<sup>+</sup> below) cells found to be positive for the marker antigen in the total T-cell population. The handling procedures were performed in strict accordance with the instructions within the reagent kit package insert.

**Maternal HBV infection status (MH)**

All mothers of the subjects were reviewed in medical records for previous HBV infection and most of those who were infected could be identified. In addition, all of them were invited to undergo HBV-marker tests. For those with a positive result, a second set of tests was conducted 3 mo after the first test to confirm chronic HBV carrier status. If the mother had died, the cause of death was investigated based on medical records and history taking whether it was from HBV-related liver diseases such as chronic hepatitis B, HBV-related liver cirrhosis or hepatocellular carcinoma. If so, the MH was classified as positive.

**Age at HBV infection**

In the recent three decades in China, all children have been obligated to be tested for HBV markers when they first enter kindergarten and elementary schools. Subsequent obligatory tests are made when they apply for university or for a job. The results of these tests were obtained from medical records and interview. Based on this setting, we classified the age of first positive test as before 8 years, between 8-20 years and after 20 years.

**Statistical analysis**

Initial calculation came up with a sample size of 50 subjects with HBV DNA positive and the same number of HBV DNA negative group. This could provide the study with a statistical power of 80% at the 0.025 level

of significance to detect a difference in T-cell variation values of 33 *versus* 38. However, to cover the problem of being potentially confounded by other variables and to have enough subjects for stratifying levels of HBV DNA load to examine dose-response relationship, we ultimately recruited 216 CHI individuals and 100 controls.

Descriptive statistics were used to examine the age, gender, serum HBV viral load, HBeAg status, age at HBV-infection and maternal HBV infection status. The levels of T-lymphocyte subpopulation in normal individuals (HBsAg-negative) were summarized as means and standard deviation to serve as a control reference. Effects of various independent demographic, clinical and serological variables on T-cell profile were analyzed only among HBsAg-positive individuals. In univariate analysis, breakdown of these profiles by individual independent variables was carried out. Independent *t* test was done for 2-level independent variables and one-way ANOVA for more than 2-level variables. The relationship of HBV replication level and peripheral T-lymphocyte subpopulation was analyzed by correlation analysis and ANOVA linear trend test. Finally, multiple linear regression models were employed in multivariate analysis to assess the independent effects of variables on peripheral blood T lymphocytes. Variables yielding a *P* value  $\leq 0.2$  in the univariate analysis were included in the multivariate analysis, and the models were refined by backward elimination guided by the change in log likelihood of successive models. A final *P* value of less than 0.05 was considered statistically significant. Computations were carried out with the aid of R software version 2.5.1<sup>[11]</sup>.

**RESULTS****Demographic characteristics and clinical features of CHI individuals**

Demographic, serological, and clinical characteristics of the CHI individuals are summarized in Table 1. They were predominated by male (57.9%). One hundred and twenty four (57.4%) were less than 30 years old.

Of the CHI individuals, 37% got the infection before the age of 8 years. Almost three quarters had detectable serum levels of HBV DNA. Among these, the majority (68.4%, 93/136) had over 10<sup>7</sup> copies per milliliter. Just over half of them were HBeAg positive (56.5%).

Around 60% of the individuals' mothers were HBV positive. Among these individuals, nearly half had young age of infection and five-sixths had detectable serum levels of HBV DNA, of whom the majority (79.2%) had high viral load. Over 75% were HBeAg positive, whereas non-MH individuals were characterized by high age of infection, low viral load and low positivity of HBeAg.

Of those who had young age at infection, 80% (64/80) were HBeAg positive, and the majority (69/80) had detectable serum levels of HBV DNA, of whom nearly 74% (51/69) had high viral load.

### Peripheral T lymphocyte subpopulation composition in CHI individuals with normal LFTs

CHI individuals had significantly decreased relative frequencies of CD3<sup>+</sup> and CD4<sup>+</sup> subpopulations and CD4<sup>+</sup>/CD8<sup>+</sup> ratio, and increased CD8<sup>+</sup> subset percentage compared with the control group. Univariate analyses showed that the impaired balance of T-cell subsets was significantly associated with high viral load, presence of serum HBeAg expression, history of maternal HBV-infection and low age at HBV-infection (Table 2). Linear dose-response relationship between the level of T-lymphocyte subpopulation and log copies of HBV DNA was also highly significant (linear trend test *P* value < 0.01). Correlation between T-lymphocyte subpopulations and viral load is also shown in Figure 1

(*r* = -0.67, -0.54, 0.61, -0.67, respectively, for CD3<sup>+</sup>, CD4<sup>+</sup>, CD8<sup>+</sup> and CD4<sup>+</sup>/CD8<sup>+</sup> ratio; all *P* < 0.0001) and Figure 2.

### Linear regression predicting peripheral blood T-lymphocyte subpopulation from relevant parameters

In Table 3, linear regression models are separately summarized for CD3<sup>+</sup>, CD4<sup>+</sup> and CD8<sup>+</sup> cells and CD4<sup>+</sup>/CD8<sup>+</sup> ratio, which are the dependent variables. After adjustment for all independent variables listed in the table, serum level of HBV viral load was the only significant predictor for each outcome variable, whereas the effects of HBeAg and other variables were not significant.

Figure 3 shows the relationship between T-lym-

**Figure 1** Correlation between peripheral T-cell subsets and serum HBV viral load. The numbers in the boxes refer to correlation coefficients. There is a negative correlation between the CD3<sup>+</sup> and CD4<sup>+</sup> cells and CD4<sup>+</sup>/CD8<sup>+</sup> ratio and serum viral load in CHI individuals with normal LFTs ( $r = -0.67, -0.54, -0.67$ ;  $P < 0.0001$ ), and a positive correlation between the levels of CD8<sup>+</sup> cells and viral load ( $r = 0.61$ ,  $P < 0.0001$ ).

$\beta$ : Coefficients from the model; SE: Standard error. <sup>1</sup>Continuous variable; <sup>2</sup>control group, < 8 yr of age at HBV infection.

phocyte subpopulations and viral load stratified by age at HBV infection. There was no significant difference of T-cell subsets among groups of age at HBV infection after adjustment for serum level of HBV viral load. A similar pattern is also seen in the figures that show the relationship between T-lymphocyte subpopulations and viral load stratified by maternal HBV carrier status and by HBeAg status in CHI individuals with normal LFTs respectively.

## DISCUSSION

This study demonstrated an impaired balance of the T-cell subsets related to an increased proportion of CD8<sup>+</sup> T-lymphocytes and decreased proportion of CD4<sup>+</sup> T-lymphocytes and CD4<sup>+</sup>/CD8<sup>+</sup> ratio in CHI individuals who had normal liver function tests. The level of the T-cell impairment had a linear dose-response relationship with the load of HBV DNA. The study also

**Figure 2** Peripheral T-lymphocyte subpopulations by serum HBV viral load. Composition of T-cell subpopulations from peripheral blood of patients with various serum HBV viral loads. Results are expressed as percentage of cells for each phenotype. Top of the box represents the 75th percentile, the bottom of the box represents the 25th percentile, and the solid line in the middle of the box represents the median. Whiskers above and below the box indicate the 90th and 10th percentiles, while circles represent outliers. Linear dose-response relationship between the level of T-lymphocyte subpopulations and copies of HBV DNA was highly significant (linear trend test,  $P$  value < 0.001). On the figure, the marks "< 1.0e+03", "e+03-e+05", "e+05-e+07" and "> 1.0e+07" denote "< 10<sup>3</sup>", "10<sup>3</sup>-10<sup>5</sup>", "10<sup>5</sup>-10<sup>7</sup>" and "> 10<sup>7</sup>", respectively.

illustrated the strong independent effects of HBV DNA, which eliminate the effects of maternal carrier status, younger age of infection and HBeAg positivity.

Our findings indicate that normal LFTs chronic HBV-infected individuals have an impaired balance of T-cell profile. The same finding also has been proved by previous researches in patients with chronic hepatitis B (CHB) that the chronicity of HBV infection is caused by a deficiency in cellular immune function, and hepatocytic damage is mainly caused by immunological injury<sup>[12-21]</sup>. However, the mechanism has not been defined<sup>[5]</sup>. Recently, the results have been reported by Tian *et al*<sup>[22]</sup> that CD4<sup>+</sup> and CD8<sup>+</sup> T cells decreased in both 33 CHB patients and 21 asymptomatic HBV carriers. Thus, most evidence has come from research in experimental animals<sup>[23-25]</sup> and in CHB patients<sup>[26-30]</sup>.

Our results reveal that T-cell impairment was significantly associated with viral replication level. The substantial linear dose-response relationship and strong independent predictive ability of HBV DNA, but not of other variables, on T-cell subpopulations suggests a close proximity between them in the causal pathway. However, cross-sectional study nature of our data does not allow us to identify the temporal direction of the causal relationship between these two variables. Mizukoshi

*et al*<sup>[31]</sup> suggested that antiviral therapy of persistently infected patients appeared to increase the frequency of HBV-specific CD4<sup>+</sup> T cell responses during the first year of treatment. Boni *et al*<sup>[32-35]</sup> reported that antiviral treatment can overcome CD8<sup>+</sup> T cell hypo-responsiveness in subjects with chronic HBV infection, suggesting that the T cells are present, but suppressed. It was reported by Pham *et al*<sup>[36]</sup> in 21 CHB patients that the ratio of CD4<sup>+</sup>/CD8<sup>+</sup> liver-derived lymphocytes, and not of peripheral blood lymphocytes appeared to be related to the level of HBV replication, and it revealed a positive correlation with viral load. The evidence that efficient antiviral T cell response can be restored by mono-antiviral treatment in CHB patients concurrently with reduction of viremia, indicates the importance of viral load in the pathogenesis of T cell hypo-responsiveness in these patients.

The stronger independent effect of viral load on the T-cell impairment and viral factor (viral variants) might explain the disappearance of the effect of other variables in multivariate analysis. Among our research subjects, the majority were characterized by young age of first HBV infection, maternal carrier status and high viral load in serum, and also high HBeAg expression. As a matter of fact, in addition to HBV DNA, HBeAg is also a seromarker for high viral replication which plays

**Figure 3** Correlation between T-cell subsets and viral load stratified by age at HBV infection. Three separate regression lines (with different slopes) are drawn for different groups of age at HBV infection. The coefficients of the interaction term "HBV DNA: age-at-HBV-infection" are not statistically significant for each parameter of T lymphocyte subpopulations (all  $P > 0.05$ ). The  $P$  value indicates no significant influence of age at HBV infection on peripheral T-cell subpopulations.

a crucial role in chronicity of HBV infection and high viral load by inducing immunological tolerance to HBV in the fetus. The tolerating effect of HBeAg has been well characterized in mice<sup>[37-39]</sup> and likely contributes to the low level of core-specific T-cell responses present in HBeAg<sup>+</sup> chronic patients<sup>[4,5]</sup>. Clinical evidence supports the tolerogenic effect of HBeAg<sup>[4,40]</sup>. Also, viral mutations that abrogate or antagonize antigen recognition by virus-specific T cells have been reported in patients with chronic HBV infection<sup>[41-42]</sup>, although the results from univariate analysis in our study showed that dysfunction of T-cell was significantly related with HBeAg, which later disappeared in multivariate analysis. One possible reason is that some of the subjects were infected with pre-C stop codon mutation virus (pre-C/C mutant), which resulted in a loss of HBeAg. In these patients, therefore, viral replication may persist despite elimination of HBeAg and seroconversion to anti-HBe. While the loss of HBeAg appears irrelevant for the biology of the virus, it may play an important role in the interaction of the virus with the immune system. This may weaken the independent association between HBeAg and the T-cell impairment so that the sample size in our study cannot detect this magnitude of association. Those who had maternal carrier history usually got infection at a

younger age (Table 1) and a higher HBV viral load was detected in the majority of those who had infection at a younger age. This phenomenon suggests that infection from the mother and/or at younger age predisposes to tolerance to HBV infection and, thus, higher viral load.

The strength of this study lies in the large sample size of CHI individuals with normal LFTs and the measurements of T-lymphocyte subpopulations using modern advanced flow cytometric technology and viral load by the quantitative real-time PCR method. A limitation of this study is the unknown age at HBV-infection of 22 individuals, the specificity of T-lymphocyte subpopulations, and liver-derived T-lymphocyte were not explored concurrently. Although the strong relationship of T-lymphocyte subpopulations with viral load is illustrated, further studies are needed to confirm the causal relationship between them.

Our results, which suggest that high viral load contributes to the impaired balance of the T-cell subsets in normal LFTs CHI individuals, have practical implications for understanding of pathogenesis and controlling of persistent viral infection, disease progression and prognosis because these individuals are also at risk of persistent viral infection leading to sub-clinical hepatitis, and chronic active hepatitis, even

liver cirrhosis and the development of hepatocellular carcinoma<sup>[1-3]</sup>. Perhaps, we should take this contribution into account in designing interventional strategies such as anti-viral therapeutic and/or immunotherapeutic strategies to prevent the progression and long-term consequences, which have been proved effective in CHB patients. Further clinical studies are needed to explore this possibility not only in CHB patients but also in normal LFTs chronic HBV-infected individuals.

In conclusion, we found that a strong independent predictive effect of HBV DNA load on T-lymphocyte subpopulations suggests a close proximity in the causal pathway between HBV viral load and the T-cell impairment. This information is of great interest because, first, it will be possible to predict the variation of T-lymphocyte subpopulations in peripheral blood in the future by measuring serum viral load level in chronic HBV-infected individuals with normal LFTs and second, this parameter can be monitored in blood easily and cheaply. Therefore, the measurement of viral load in serum of individuals suffering from chronic HBV infection could represent a simple parameter for the evaluation of cellular immune function status.

## COMMENTS

### Background

Hepatitis B virus (HBV) infection is a serious public health problem worldwide and a major cause of chronic hepatitis, liver cirrhosis, and hepatocellular carcinoma. HBV infection is especially prevalent in African and Asian countries because most patients with chronic HBV infection have acquired the infection perinatally from carrier mothers. The pathogenesis of persistent viral infection is very complex and has not been clarified until now. Generally, it is not HBV itself that damages hepatocytes directly, but the results of disorder of cell-mediated immunity. The outcome of HBV infection would depend on the balance between development of immunity (leading to virus elimination) and tolerance (leading to chronic viral persistence).

### Research frontiers

Outcome of HBV infection, and the pathogenesis of liver disease are determined by immune-mediated host-virus interaction, which have been difficult to fully elucidate because the host range of HBV is limited to man and chimpanzees. The pathogenesis of liver disease and interaction between virus and host remain the research hotspots in this field.

### Innovations and breakthroughs

The pathogenesis and correlation of cellular immune disorder and HBV viral replication level remain unknown. In the present study, peripheral T-lymphocyte subpopulations of chronic HBV-infected (CHI) individuals who had normal liver function tests in big sample size were measured using advanced flow cytometry technology and HBV viral load with sensitive quantitative real-time-PCR method. The results suggest that the impaired balance of T-cell subpopulations was significantly associated with viral replication level. The substantial linear dose-response relationship and strong independent predictive effect of viral load on T-lymphocyte subpopulations suggests a close proximity of the causal pathway between them, and indicates the importance of viral load in the pathogenesis of T-cell impairment in these patients.

### Applications

The results, which suggest that high viral load contributes to the impaired balance of the T-cell subsets in normal liver function tests (LFTs) CHI individuals, have practical implications for understanding of pathogenesis and controlling of persistent viral infection and disease progression and prognosis because these individuals are also at risk of persistent viral infection leading to subclinical hepatitis and chronic active hepatitis, even liver cirrhosis and the development of hepatocellular carcinoma. In addition, it is possible to predict the variation of T-lymphocyte subpopulations in peripheral blood in the future by measuring serum viral load level in chronic HBV-infected patients.

## Peer review

The article is clearly written and demonstrates that high viral load is more powerful than HBeAg in predicting the impaired balance of T-cell subsets.

### Abstract

**AIM:** To compare the demographic and clinical features of different manometric subsets of ineffective oesophageal motility (IOM; defined as  $\geq 30\%$  wet swallows with distal contractile amplitude  $< 30$  mmHg), and to determine whether the prevalence of gastro-oesophageal reflux differs between IOM subsets.

**METHODS:** Clinical characteristics of manometric subsets were determined in 100 IOM patients (73 female, median age 58 years) and compared to those of 100 age- and gender-matched patient controls with oesophageal symptoms, but normal manometry. Supine oesophageal manometry was performed with an eight-channel DentSleeve water-perfused catheter, and an ambulatory pH study assessed gastro-oesophageal reflux.

**RESULTS:** Patients in the IOM subset featuring a majority of low-amplitude simultaneous contractions (LASC) experienced less heartburn (prevalence 26%), but more dysphagia (57%) than those in the IOM subset featuring low-amplitude propagated contractions (LAP; heartburn 70%, dysphagia 24%; both  $P \leq 0.01$ ). LASC patients also experienced less heartburn and more dysphagia than patient controls (heartburn 68%, dysphagia 11%; both  $P < 0.001$ ). The prevalence of heartburn and dysphagia in IOM patients featuring a majority of non-transmitted sequences (NT) was 54% ( $P = 0.04$  vs LASC) and 36% ( $P < 0.01$  vs controls), respectively. No differences in

age and gender distribution, chest pain prevalence, acid exposure time (AET) and symptom/reflux association existed between IOM subsets, or between subsets and controls.

**CONCLUSION:** IOM patients with LASC exhibit a different symptom profile to those with LAP, but do not differ in gastro-oesophageal reflux prevalence. These findings raise the possibility of different pathophysiological mechanisms in IOM subsets, which warrants further investigation.

### INTRODUCTION

The term ineffective oesophageal motility (IOM), the most common variant of oesophageal dysmotility, was introduced in 1997 to replace the term “non-specific oesophageal motility disorder”<sup>[1]</sup>, as the former term appears to better reflect the functional and clinical relevance of manometric alterations<sup>[2,3]</sup>. IOM is defined manometrically as  $\geq 30\%$  of swallow sequences with a contractile amplitude  $< 30$  mmHg in the distal oesophagus<sup>[4]</sup>. Such a definition, however, encompasses three abnormal contractile patterns, namely low-amplitude propagated contractions (LAP), low-amplitude simultaneous contractions (LASC), and non-transmitted contractions. IOM is, therefore, diagnosed if there is a combination of these abnormal contractile patterns.

It is not known if the predominant oesophageal symptom (heartburn, dysphagia, chest pain) experienced by IOM patients is associated with the predominance

of one of these ineffective manometric patterns. In addition, although gastro-oesophageal reflux disease (GORD) has been associated with IOM<sup>[5-7]</sup>, it is not known whether particular manometric subsets of IOM display a higher prevalence of GORD.

This study was thus aimed at (1) comparing the demographic and manometric features of IOM patients with different predominant symptoms (heartburn, dysphagia, chest pain); (2) comparing the demographic and clinical features of different manometric subsets of IOM; (3) comparing the clinical features of IOM subsets with those of patients with oesophageal symptoms, but normal oesophageal manometry; and (4) determining whether the prevalence of gastro-oesophageal reflux differs between the IOM manometric subsets.

## MATERIALS AND METHODS

### Patients

A total of 100 consecutive patients (73 females, mean  $\pm$  SD age  $56 \pm 18$  years) were studied. Patients with oesophageal symptoms were referred to the Gastrointestinal Investigation Unit of the Royal North Shore Hospital. All patients fulfilled the current manometric criteria for IOM:  $\geq 30\%$  of wet swallows with low-amplitude propagated sequences (distal contractile amplitude  $< 30$  mmHg), LASC, or non-transmitted contractions<sup>[4]</sup>. Swallow sequences were considered to be simultaneous when propagation velocity was  $> 8$  cm/s between two or more manometric channels, and were considered to be non-transmitted when contractile amplitude was  $\leq 10$  mmHg at any site. A group of 100 age- and gender-matched patients (73 females, age  $56 \pm 20$  years) referred with oesophageal symptoms, but exhibiting normal oesophageal manometry<sup>[8]</sup> served as a patient control group. Patients in the two groups had undergone upper gastrointestinal endoscopy and/or barium studies to exclude structural disease of the oesophagus, apart from the presence of reflux oesophagitis and sliding hiatus hernia. Patients with systemic diseases that could alter oesophageal motility, such as diabetes mellitus or scleroderma, were excluded. The study was approved by the Human Research Ethics Committee of the Northern Sydney Area Health Service.

### Symptom assessment

A standardized symptom assessment was completed by all patients. This assessment comprised the Rome II Integrative Questionnaire<sup>[9]</sup> with an additional evaluation of oesophageal symptoms. This additional evaluation determined the predominant (i.e. most troublesome) oesophageal symptom (heartburn, dysphagia, chest pain, or others)<sup>[10]</sup> and the time period since its first appearance. The usual intensity, frequency, and duration of all reported symptoms were assessed, and symptom severity scores for heartburn, dysphagia, and chest pain were calculated as the product of these intensity, frequency, and duration data.

### Oesophageal manometry

All patients were studied after an overnight fast. Oesophageal manometry was performed using an eight-channel DentSleeve water-perfused manometric catheter with an external diameter of 4.5 mm (DentSleeve Pty. Ltd., Belair, SA, Australia) and a computer-based data acquisition and charting system (Acquidata, Neomedix Systems, Warriewood, NSW, Australia). The catheter was introduced transnasally and swallowing was recorded via a port positioned in the pharynx, 25 cm above the proximal end of the hydraulic sleeve segment of the catheter. Oesophageal contractions were measured by ports located 5, 10, 15, and 20 cm above the proximal end of the sleeve and gastric pressure by a side hole 1 cm below the distal end of the 6 cm long sleeve. Each patient made approximately 10 swallows, each of 5 mL water of room temperature, in the seated position to acclimatize to the procedure. The patient was then placed in the supine position, and a minimum of 10 supine water swallows, each of 5 mL water, with at least 30 s in between swallows, were performed. A station pull-through technique was then used to accurately locate the position of the lower oesophageal sphincter (LOS). The LOS function was assessed by measuring mid-respiratory LOS resting pressure and swallow-induced LOS relaxation<sup>[8]</sup>.

### 24-h pH monitoring

A subset of patients (54 IOM, 72 patient controls with normal manometry) underwent an ambulatory oesophageal pH study. A probe with an antimony pH sensor (Flexilog, Oakfield Instruments Ltd., Eynsham, England) was introduced transnasally and the sensor was positioned 5 cm above the upper edge of the LOS, which was determined manometrically as described above. The probe was connected to a data logger (Digitrapper Mark II, Synectics, Sweden), which sampled pH at 5-s intervals for approximately 24 h. Mealtimes, symptom events, and supine periods were recorded in a patient diary. The computerized analysis (Esophagram, Synectics, Sweden) included the percentage of time pH was below 4 (Acid Exposure Time, AET)<sup>[11]</sup>, and the symptom association probability (SAP)<sup>[12]</sup> was calculated when possible.

### Data analysis

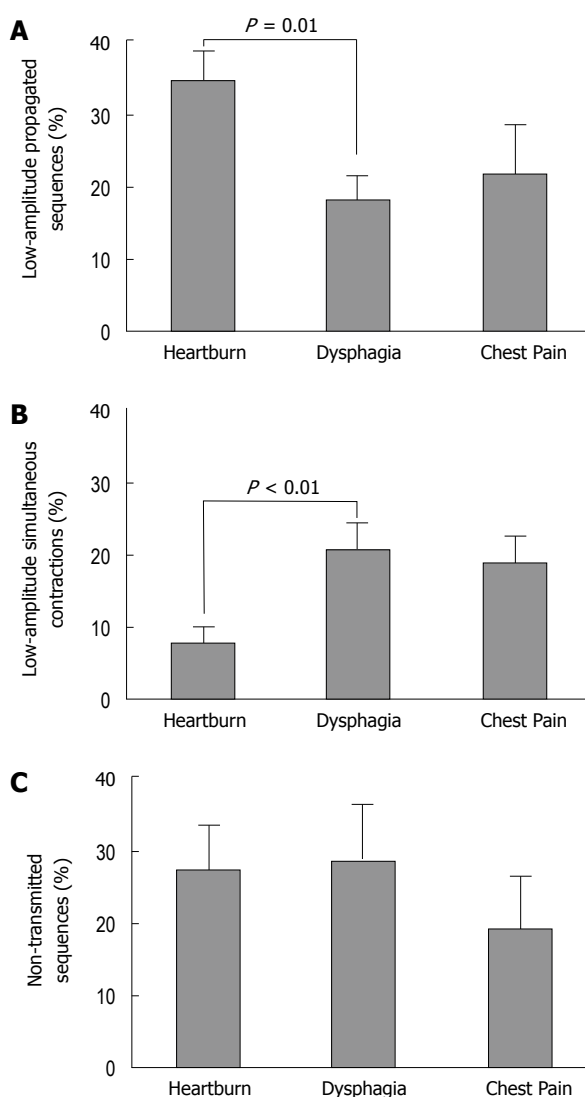

**Analysis based on predominant symptom:** Proportions of total abnormal swallows, and proportions of LAP, LASC, and non-transmitted sequences (NT) were calculated for each of the three main predominant symptoms (heartburn, dysphagia, chest pain). Differences in proportions were then determined between symptom subgroups.

**Analysis based on predominant contractile abnormality:** All IOM manometric studies were further categorized into the following three subsets according to the predominant contractile abnormality contributing to the 30% or more abnormal swallows: those exhibiting a majority of LAP, those exhibiting a majority of LASC,

**Table 1** Gender, age, time since onset of symptom, and proportion of total abnormal swallows in IOM patients according to the predominant oesophageal symptom<sup>1</sup>

	Gender (F:M)	Median age [yr (range)]	Median time since symptom onset (yr)	Total abnormal swallows (mean $\pm$ SD) (%)
Heartburn	37:16	57 (26-82)	6.7	69 $\pm$ 22
Dysphagia	28:8	63 (19-86)	2.5	68 $\pm$ 22
Chest pain	8:1	59 (31-76)	6.1	61 $\pm$ 25

<sup>1</sup>Two male patients reported "other" predominant symptoms (hiccoughs, halitosis).

**Figure 1** Proportions of low-amplitude propagated sequences (A), LASC (B), and NT (C) in the three predominant symptom subgroups. Proportions are expressed as (mean  $\pm$  SE) % of total swallows.

and those exhibiting a majority of NT. Differences in clinical features between these three subsets were then determined.

**Statistical analysis:** Results are presented as mean  $\pm$  SE, unless otherwise stated.  $\chi^2$  and Fisher's exact tests were used to determine differences in gender distribution

between symptom subgroups, and differences in symptom prevalence between manometric subsets. Age differences between subsets, and between IOM patients and patient controls, were determined via Kruskal-Wallis tests with post-hoc Mann-Whitney U comparisons. Similarly, differences between symptom subgroups in proportions of contractile abnormalities and in LOS pressure and AET were determined via one-way analysis of variance (ANOVA) with post-hoc Scheffe tests. Correlation and regression analysis was used to describe relationships between variables. All analyses were performed using the SPSS statistical program (Release 14, SPSS Inc., Chicago, IL), with  $P < 0.05$  considered significant.

## RESULTS

### Analysis based on the predominant symptom

**Symptom, gender, and age distribution:** The prevalence of predominant heartburn, predominant dysphagia, and predominant chest pain in IOM patients was 53%, 36%, and 9%, respectively. The prevalence of heartburn was significantly lower in IOM patients than in patient controls (68%,  $P = 0.03$ ), and the prevalence of dysphagia was significantly higher in IOM patients than in patient controls (11%,  $P < 0.001$ ).

There were no significant differences in gender and age distribution, and in time period since symptom onset, between the three symptom subgroups in IOM (Table 1).

**Proportions of abnormal swallows:** The mean proportion of LAP was significantly higher in patients with heartburn than in those with dysphagia, and the mean proportion of LASC was significantly higher in patients with dysphagia than in those with heartburn. The mean proportion of NT was similar across the three symptom subgroups (Figure 1; ANOVA and post-hoc tests). The proportion of total abnormal swallows did not differ between the three symptom subgroups (Table 1).

When all reported symptoms were considered (i.e. predominant symptom plus additional symptoms), the relationships between symptom severity scores and proportions of abnormal sequences were examined. There were positive correlations between dysphagia severity score and proportion of LASC ( $r = 0.2$ ,  $P = 0.05$ ), and between chest pain severity score and proportion of LAP ( $r = 0.22$ ,  $P < 0.05$ ).

**LOS mid-respiratory resting pressure:** Mean LOS pressure was significantly higher in patients with predominant dysphagia ( $12.5 \pm 1.2$  mmHg) than in those with heartburn ( $9.2 \pm 0.6$  mmHg;  $P = 0.03$ ). The mean value for chest pain patients was  $11.1 \pm 1.0$  mmHg.

**Ambulatory pH data:** The gender and age distribution of the patients who underwent a pH study closely reflected that of the total subject pool, and mean LOS pressures of subgroups were almost identical to those of the total subject pool. There were no significant

**Table 2** Gender and age distribution, and ambulatory oesophageal pH data<sup>1</sup>, for IOM manometric subsets and for patient controls who exhibited normal manometry

	Gender (F:M)	Median age [yr (range)]	AET <sup>2</sup> (%)	Abnormal AET <sup>3</sup> (%)	SAP+ <sup>4</sup> (%)
IOM-LAP	25:12	58 (26-77)	8.8 ± 1.8	58	52
IOM-LASC	17:7	60 (29-86)	14.7 ± 5.1	90	60
IOM-NT	31:8	61 (19-76)	11.6 ± 2.5	81	33
Patient controls	73:27	58 (19-91)	8.6 ± 0.8	69	51

<sup>1</sup>pH data was available in 54 IOM patients and 72 patient controls; <sup>2</sup>AET (% of time pH < 4), reported as mean ± SE; <sup>3</sup>% of patients with an AET > 4%;

<sup>4</sup>Expressed as % of patients with a significant SAP value.

differences between the three subgroups in terms of AET or proportion of patients with an abnormal AET, or proportion with significant SAP values.

### Analysis based on predominant contractile abnormality

**Gender and age distribution:** The gender and age distribution for the three IOM manometric subsets and the patient controls is shown in Table 2. There were no statistical differences in gender and age distribution between patient controls and any of the IOM manometric subsets, or between IOM subsets.

**Predominant symptoms:** Figure 2 shows the distribution of predominant symptoms for the three manometric subsets and for patient controls. Heartburn was highly prevalent (70%) in the LAP subset, but was significantly less common (26%) in the LASC subset. Conversely, dysphagia was more prevalent in LASC (57%) than in LAP (24%) ( $\chi^2$  tests). There were no significant differences between IOM subsets, however, in severity scores for heartburn, dysphagia or chest pain, or in time since the onset of the primary symptom.

**LOS mid-respiratory resting pressure:** There were no statistically significant differences between the mean LOS pressures of the IOM subsets: values for LAP, LASC, and NT were  $10.1 \pm 0.9$ ,  $11.3 \pm 1.4$ , and  $10.9 \pm 0.8$  mmHg, respectively. There was a trend ( $P = 0.05$ ) for the LAP subset to have a lower value than that of patient controls ( $12.0 \pm 0.5$  mmHg).

**Ambulatory pH data:** There were no significant differences in the prevalence of abnormal AET between IOM subsets. Analysis of mean AET values between the IOM subsets, and compared to patient controls, also revealed no significant differences (Table 2). Similarly, there were no differences in upright and supine AET values between subsets and groups. There were no significant SAP differences between the IOM subsets or in comparison to the control group (Table 2).

## DISCUSSION

Despite almost 10 years of usage of the category IOM, and recent studies evaluating IOM with combined intraluminal impedance and manometry<sup>[3]</sup>, the extent

**Figure 2** Prevalence of predominant symptoms in the three manometrically-determined IOM subsets, and in patient controls (CON) who exhibited normal manometry. <sup>1</sup>CON significantly higher than LASC ( $P < 0.001$ ); <sup>2</sup>CON significantly lower than LASC ( $P < 0.001$ ) and NT ( $P < 0.01$ ) ( $\chi^2$  tests).

to which the various contractile patterns of IOM differ according to the predominant symptom has remained largely unexplored. Our study in a large patient cohort shows that IOM is indeed a heterogeneous clinical entity with regard to the predominant symptom reported. We focused on the type of contractile abnormality, rather than solely considering the contractile amplitude. The novel finding was that two specific contractile patterns, namely LASC and LAP, were closely related to predominant dysphagia and predominant heartburn, respectively. Additional analyses provided further support for these findings in that as the proportion of LASC increased, the dysphagia severity score also increased. Consistent with these findings, there were notable differences in symptom distribution between IOM manometric subsets, categorized according to the most frequent type of contractile pattern in an individual patient. Differences were particularly prominent between patients with low-amplitude propagated sequences and those with LASC; the latter experienced more dysphagia and less heartburn than the former patients.

We did not find a difference in age distribution between manometric subsets. Others have noted that simultaneous contractions are more likely to occur in older than in younger patients<sup>[13,14]</sup>, especially in the presence of severe GORD<sup>[15]</sup>. The effect of age in relation to the occurrence of simultaneous contractions in healthy volunteers, however, remains unclear, as one study revealed no relationship between simultaneous contractions and age<sup>[16]</sup>, whereas a more recent study did find a direct correlation between the proportion of simultaneous contractions and age<sup>[17]</sup>. The most recent study revealed differences in muscle thickness between similarly-categorized IOM subsets, and a significant correlation between muscle thickness, and the occurrence of simultaneous contractions<sup>[14]</sup>. Whether muscle thickness actually plays a causative role in the pathophysiology of simultaneous contractions remains unclear, and this needs to be further evaluated. It is possible that the clinical profile of IOM patients with a majority of LASC is similar to that of patients with diffuse oesophageal spasm (DOS), a disorder that also features intermittent simultaneous (but moderate- to

high-amplitude) contractions<sup>[4]</sup>. Hence, treatments currently considered for DOS patients<sup>[18-20]</sup> may prove beneficial for selected IOM patients, and this should also be further evaluated.

In the subset of IOM patients with mainly non-transmitted swallow patterns, it is feasible that this pattern could represent an evolving achalasia-like dysmotility, although these patients exhibited only a modest prevalence of dysphagia. As long-term follow-up of IOM patients has scarcely been reported<sup>[21]</sup>, findings regarding disease progression remain inconclusive, and further studies are needed.

Neither the prevalence nor the severity of gastro-oesophageal acid reflux differed between IOM subsets. In addition, we found no significant differences in symptom/reflux association or heartburn severity score between IOM subsets, despite some differences in LOS resting pressure. A low LOS tone and transient LOS relaxation<sup>[22]</sup> are regarded as the main mechanisms of gastro-oesophageal reflux. As the LOS tone was lower in IOM patients with low-amplitude propagated sequences compared with patient controls, and heartburn prevalence was highest in this IOM subset, these patients could be expected to have the highest acid exposure. This was not the case, and our findings are consistent with those of Lemme *et al.*, who found that the proportion of low-amplitude swallows did not differ between IOM patients with erosive *versus* non-erosive GORD<sup>[23]</sup>. It is feasible that the presence of propagating (albeit low-amplitude) sequences equates to more efficient clearance<sup>[24]</sup> of refluxate in these patients, and novel approaches to stimulating clearance<sup>[25]</sup> may prove beneficial in this IOM subset. Another explanation for the high heartburn prevalence is that these patients exhibit oesophageal hypersensitivity<sup>[26]</sup>. Despite the lack of difference in acid exposure between IOM subsets, pooled analyses of all IOM patients showed that a low LOS tone was associated with both high heartburn severity scores and high AETs. These findings indicate the complex interactions between LOS characteristics, oesophageal body dysfunction and symptomatology in IOM patients with gastro-oesophageal reflux, which require further investigation.

The current study focused primarily on oesophageal body dysmotility in IOM. LOS swallow-induced relaxation is assessed via manometry, but does not feature in the diagnosis of IOM. Conchillo *et al.* have recently shown that, in addition to inadequate LOS relaxation, a shorter duration of LOS relaxation could contribute to abnormal bolus transit in IOM patients<sup>[27]</sup>. This might represent an additional manometric discriminator of dysmotility, and warrants further investigation.

In summary, we have examined subsets of IOM patients based on symptoms and manometrically-determined oesophageal body dysmotility. These subsets differ in regard to symptom profile, but do not differ in acid exposure or symptom/reflux association. Patients with LASC experience more dysphagia, but less heartburn, than IOM patients with low-amplitude, but propagated sequences. These findings raise the

possibility of different pathophysiological mechanisms in IOM subsets, and this warrants further investigation.

## COMMENTS

### Background

The term ineffective oesophageal motility (IOM) encompasses a variety of symptoms and three types of abnormal oesophageal body peristalsis.

### Research frontiers

The pathogenesis of IOM remains unknown, particularly whether it is related to GORD or represents a primary oesophageal motor disorder.

### Innovations and breakthroughs

This study raises the possibility of different pathophysiological mechanisms in the different subsets of IOM.

### Applications

Further study of the IOM subsets using novel technologies such as impedance and topographic manometry is required.

### Terminology

IOM refers to low-amplitude, simultaneous, or non-transmitted oesophageal body contractions.

### Peer review

The authors compared the demographic and clinical features of different manometric subsets of ineffective oesophageal motility and determined whether the prevalence of gastro-oesophageal reflux differs between IOM subsets. This is an interesting and well-written study.

## Abstract

**AIM:** To determine the outcome of esophageal cancer patients referred for palliative care, in Gorgan and Gonbad gastrointestinal clinics, northeast of Iran.

**METHODS:** This cross-sectional study was done on inoperable esophageal cancer cases referred to gastrointestinal clinics in Gorgan and Gonbad city (2005-2006). Demographic data were collected during the procedure and cases were followed up every one month. Improvement proportion was calculated with 95% confidence interval, to determine the rate of improvement. Survival analysis and Kaplan-Meier methods were used to estimate the duration of palliative care effectiveness.

**RESULTS:** We recruited 39 cases into the study. Squamous cell carcinoma was the most prevalent (92.3%). The middle third of the esophagus was involved predominantly (51.3%). Dilation was the most preferred method (89.7%) and stenting was done in 4 cases. Decreasing dysphagia score was not related to palliation method or pathology type of carcinoma. Age of the patients was significantly related to the improvement of dysphagia score. Mean survival time was 137.6 d and median was 103 d.

**CONCLUSION:** Results of this study showed a low survival rate after palliative care in esophageal cancer cases despite dysphagia scores' improvement after dilating or stenting.

## INTRODUCTION

Esophageal cancer patients have poor prognosis. Due to the lack of widespread screening methods, diagnosis is usually made at advanced stages; therefore, they have a short survival when diagnosed. The 5-year survival rate of patients with esophageal cancer is < 20%<sup>[1]</sup>.

This is more obvious especially in some regions like the northeast of Iran, where the prevalence rate of esophageal cancer is high.

Esophageal cancer five-year survival has slightly increased during past 20 years (5%-9%), but still remains low. Most patients present with locally advanced, unresectable or metastatic disease. At the time of diagnosis, 60% of the patients are only suitable for palliative therapy. Recent advances in therapeutic endoscopy have allowed improving dysphagia, and quality of life. Endoscopic techniques are chosen according to tumor characteristics, since the diagnosis is often made at an advanced stage, when radical treatment is unfeasible<sup>[1-3]</sup>.

Dysphagia, or the inability to swallow, is one of the most distressing and debilitating symptoms in patients with cancer-related oesophageal obstruction. Dysphagia leads to nutritional compromise, pain, and deterioration of quality of life<sup>[1,4-5]</sup>.

As the quality of life, and to some extent the quantity of life remaining to these patients depends to a large degree on their ability to swallow, the relief of dysphagia plays a vital role in the palliation of this disease<sup>[5]</sup>.

Endoscopic palliation aims to restore swallowing,

avoid re-intervention and reduce hospitalization<sup>[1,4-5]</sup>.

Palliation is an important goal of esophageal cancer therapy. Current management options for the palliation of dysphagia include: esophageal dilation, intraluminal stents, Nd:YAG laser therapy, photodynamic therapy, argon laser, systemic chemotherapy, external beam radiation therapy, brachytherapy, and combined chemoradiation therapy. The clinical situation, local expertise, and cost effectiveness play an important role in choosing the appropriate treatment modality<sup>[1]</sup>.

Treatment should ensure that the majority of these patients could avoid the consternation of total dysphagia, regardless of which stent is offered<sup>[5]</sup>.

Palliative treatment methods for esophageal and cardiac cancer include dilation, laser vaporization and other thermal methods, alcohol injection, and stent insertion. None of these procedures, however, has proved to be a simple, well-tolerated, and lasting method<sup>[5]</sup>. The aim of this study was to determining the rate of recovery after two methods of palliation in patients with inoperable esophageal carcinoma, in Golestan province, northeast of Iran.

## MATERIALS AND METHODS

This descriptive cross-sectional study was designed in two main and unique clinics of gastroenterology in the province (located in the central and eastern part of Golestan Province) and all inoperable esophageal cancer cases which referred from January 2005 to March 2007 were recruited. A basic checklist was completed for each case before the procedure and their demographic data were registered.

Dysphagia was graded as follows: 0 = able to eat normal diet/no dysphagia; 1 = able to swallow some solid foods; 2 = able to swallow only semi solid foods; 3 = able to swallow liquids only; 4 = unable to swallow anything/total dysphagia<sup>[5]</sup>.

Subjects were followed up every month, and the endpoint was considered as death or finishing the 6-mo period, due to the short survival of them. Improvement in dysphagia was evaluated 1 wk after stent placement and during monthly interviews.

Complications of palliative therapy were defined as major (aspiration, bleeding, stent misplacement or dislocation, perforation) or minor (reflux esophagitis, chest pain, pharyngeal discomfort). Tumor ingrowth or overgrowth was considered a treatment failure<sup>[6]</sup>.

The decrease in dysphagia severity for at least one degree was registered as dysphagia recovery.

After coding data and entering into the computer, improvement proportion was calculated with 95% confidence interval, to determine the rate of improvement. Survival analysis and Kaplan-Meier methods were used to estimate the duration of palliative care effectiveness.

## RESULTS

Thirty and nine cases fulfilled the inclusion criteria. Male to female ratio was 1.6 to 1. Mean age was  $67.5 \pm 13.7$  years. Among these cases, 89.7% were palliated with

**Table 1 Report of dysphagia after palliative care in patients suffering from inoperable esophageal cancer in Golestan province, northeast of Iran**

Dysphagia	Frequency	Percent
Recovery		
The first degree	18	46.2
The second degree	7	17.9
No recovery	4	10.3
Dysphagia aggravation	3	7.7
Not available	7	17.9
Total	39	100

**Table 2 Dysphagia relief after palliative care regarding the different variables in patients suffering from inoperable esophageal cancer in Golestan province, northeast of Iran**

Dysphagia relief	Variables	No recovery		Recovery	
		<i>n</i>	%	<i>n</i>	%
Type of palliative care	Stent	1	25	3	75
	Dilation	13	37.1	22	62.9
	Total	14	35.9	25	64.1
Age (yr)	< 65	3	21.4	11	78.6
	≥ 65	10	40	15	60
Pathology	SCC	13	36.1	23	63.9
	Adenocarcinoma	1	33.3	2	66.7

dilation method, and others ( $n = 3$ ) with stenting. Most of them (92.3%) were diagnosed as having SCC. The middle third of the esophagus was the most (51.3%) involved site.

At the beginning of the study, 22 cases (56.4%) had grade three dysphagia (dysphagia to water) and other 17 had complete or grade four dysphagia.

At the first follow up (one month after procedure), seven cases were not available (died). They passed away between 6-31 d (Table 1).

We considered these deaths as non-recovery of dysphagia, and then categorized the cases into two groups: 1, recovered and 2, not recovered (death, dysphagia aggravation or no change in dysphagia) and evaluated the relation between various variables with this condition (Table 2).

No significant relation was seen between relieving dysphagia, and method of palliative care or pathology type of the esophageal cancer ( $P = 0.96$ ). Age of the patients and the dysphagia recovery was not significantly related, too ( $P = 0.238$ ). Mean dysphagia score was significantly improved in the first follow up ( $3.37$  vs  $2.43$ ; 95% CI, 0.62-1.25;  $P < 0.0001$ ).

Among other 32 cases which were available at the first follow up, 25 were free of dysphagia. Survival analysis method was used to estimate the length of dysphagia relieving persistency after palliation. Aggravation of dysphagia at any time was considered as recurrence.

The mean time of persistent recovery was 172.1 d, and the median was 120 d. Among these 25 patients, only in ten cases no recurrence of dysphagia was reported up to the end of follow-up. At the end of 6-mo follow-up, only 6 (15.4%) patients were alive. The overall mean and median survival time was 137.6 d and 103 d after palliation, respectively.

In the recovered group, mean and median survival

**Figure 1** Survival function dysphagia recovery after palliative care by Kaplan-Meier method.

time were 177.1 d and 135 d after palliation, respectively; while it was 60.7 d and 31 d in the other group; respectively. Kaplan-Meier survival analysis and Log-rank used to evaluate the relation between dysphagia relief and the survival rate of the cases and significant differences were reported ( $\chi^2 = 13.21$ ,  $P < 0.0001$ ; Figure 1).

## DISCUSSION

Diagnostic and therapeutic management of esophageal cancer is a multidisciplinary challenge. Male to female ratio in our patients was 1.6 to 1. This proportion is reported in other similar studies<sup>[5]</sup>.

The most involved part of the esophagus was the middle third, and SCC was the most prominent type. While, in Western countries, the distal third is involved most<sup>[2,3]</sup>, maybe the higher incidence of adenocarcinoma, and its potentiality to appear in the distal part can explain this discrepancy. Among 39 recruited cases, 25 (64%) reported a relief in dysphagia. One grade decrease in dysphagia was seen in 46.2% and 2 grade in 17.9%.

In a study in France, a total of 120 patients treated in a single center by insertion of SEMS (Self-expanding Metal Stent), dysphagia scores decreased in 89.1% of patients, with median scores decreasing from 3.0 to 1.0 ( $P < 0.05$ )<sup>[7]</sup>. In the present study, mean dysphagia score in the first follow-up decreased significantly compared to pre-operation (from 3.37 to 2.43). Mean survival time after procedure was 177 d (5.9 mo) in recovered group, and 60.7 d (2 mo) in the other group, which was much lower than reported in other studies<sup>[8-10]</sup>.

In a study in the Netherlands (2006), data from 78 patients, rendered incurable at exploration, and who subsequently underwent palliative interventions, were analyzed retrospectively. Overall, intraluminal stenting was the palliative measure of dysphagia in 25 patients (32.3%). The median survival in the whole group was 8.9 (1-105) mo. Patients treated with chemotherapy had a higher median survival of 11.6 mo compared to that of the other palliatively-treated patients: 8.4 mo ( $P = 0.003$ ). They concluded that patients with incurable oesophageal carcinoma have a poor overall survival of less than 9 mo<sup>[8]</sup>.

In India (2006), thirty patients with inoperable esophageal carcinoma were treated with SEMS. Quality of life score improved significantly from 62-94 before stenting to 80-133 after the procedure. There was improvement in dysphagia grades. Pain was the most common complaint noted on follow up. There was no major morbidity or mortality related to the procedure<sup>[11]</sup>.

In the present study, no complaints were reported immediately after procedure and in the next follow-up, except for the seven cases that reported aggravation or no recovery of dysphagia. One important and disappointing result of this investigation was the high mortality rate of esophageal cancer in our area. Seven deaths occurred between procedures until the first follow-up (one-month later) and at the end of the study, only 6 cases were alive. Ross *et al* (USA, 2007) studied ninety-seven patients with malignant dysphagia who had SEMS placed from 2000 to 2003. Dysphagia scores improved in 86%. Early unexpected deaths occurred in 2 patients. Adenocarcinoma and female sex were factors associated with increased odds of a major complication. Median survival was 77 d<sup>[10]</sup>.

In the present study, dysphagia aggravation and re-dilation was implicated in 7.7%. This is a usual problem seen in all other investigations<sup>[9,11]</sup>. In a study in Norway (2006), 37 patients with unresectable esophageal and cardiac carcinoma treated with SEMS (January 1997-May 2004) were retrospectively analyzed. One patient died the day the stent was introduced. The median time to repeated hospital contact was 25 d, most often due to recurrence of dysphagia. Ten patients underwent repeated stent insertion. The median survival time after the first stent insertion was 88 d<sup>[9]</sup>.

In an Italian report (2007), in 60 cases with malignant dysphagia due to the various etiologies stent insertion was done. The mean dysphagia score of 2.8 improved to a mean score of 1.0 after stenting ( $P < 0.001$ ). Overall median survival time was 4.6 mo<sup>[4]</sup>. In Germany (2007), stent insertion was done in eighteen patients with esophageal carcinoma. Seventeen of 18 stents were placed technically successful in a single endoscopic procedure. Mean dysphagia score improved from 2.2 to 0.6. In 10 patients, a re-intervention was necessary mainly due to dislocation of the stent<sup>[12]</sup>.

Although placement of a stent is technically feasible, its application is hampered by frequent stent migration and insufficient prevention of gastroesophageal reflux. Further technical improvements of stents or alternative methods like brachytherapy are required for satisfactory palliation of malignant gastroesophageal stenosis<sup>[12,13]</sup>.

Comparing dilation and stenting in the present survey showed that dysphagia recovered in 63.6% after dilation and in 75% after stent insertion.

Although, dysphagia relief and median survival rate were lower in our study, maybe due to the delay in referring and the developed stages at the presentation; however, it seems that palliative care is effective in relieving dysphagia of inoperable esophageal carcinoma, and is suggested for increasing quality of life in the

remaining life-span of the patients.

Implantation of stents proved to be an effective and safe method in palliating severe dysphagia in patients with obstructing esophageal cancer<sup>[14-16]</sup>; but dilation seems more popular especially in our area; while stents are more expensive, and dilation is more preferred by patients and physicians.

Larger studies with higher sample size and facilities for screening in the lower dysphagia stages and evaluating other factors that impact on the survival rate of the patients are necessary.

Accurate and expanded results could not be achieved in the present report, due to the unavailability of some data and deaths occurred between the procedure and the first follow-up. Also, all included patients had grade 3 and 4 dysphagia, which can itself have an important impact on survival rate, because of prolonged inability of swallowing and the resulting malnutrition.

## ACKNOWLEDGMENTS

Authors tend to appreciate all who assist us in gathering data from Atrak clinic (Gonbad city) and 5th Azar endoscopy center (Gorang city).

## COMMENTS

### Background

Esophageal cancer 5-year survival has slightly increased during past 20 years (5%-9%), but still remains low. Most patients present with locally advanced, unresectable or metastatic disease. At the time of diagnosis, 60% of the patients are only relevant for palliative therapy. As the quality of life, and to some extent the quantity of life remaining to these patients depends to a large degree on their ability to swallow, the relief of dysphagia plays a vital role in the palliation of this disease.

### Research frontiers

The clinical situation, local expertise, and cost effectiveness play an important role in choosing the appropriate treatment modality in these patients. Treatment should ensure that the majority of these patients could avoid the consternation of total dysphagia, regardless to which stent is offered.

### Innovations and breakthroughs

Although, dysphagia relief and median survival rate were lower in our study, maybe due to the delay in referring and developed stages at the presentation time; however, it seems that palliative care is effective in relieving dysphagia of inoperable esophageal carcinoma, and is suggested for increasing quality of life in the remaining life-span of the patients.

### Applications

Implantation of stents proved to be an effective and safe method in palliating severe dysphagia in patients with obstructing esophageal cancer; but dilation seems more popular especially in our area; while stents are more expensive and dilation is more preferred by patients and physicians.

### Peer review

Inoperable esophageal cancer cases face many challenges due to the difficulty in eating. When the tumor is considered not resectable, palliative care would be performed to provide a temporary canal for patients. Our area is placed on the esophageal cancer belt of the world, thus, investigators try to determine different aspects of this cancer in the region and help patients have a better life expectancy. Here, we assessed the outcome of esophageal cancer patients which underwent ballooning and stenting as a palliation for their dysphagia.

## Abstract

**AIM:** To examine the possible effects of honey supplementation on hepatic damage due to obstruction of the common bile duct in an experimental rat model.

**METHODS:** The study was performed with 30 male rats divided into three groups: a sham group, an obstructive jaundice group, and an obstructive jaundice plus honey group. At the end of the study period, the animals were sacrificed, and levels of nitric oxide (NO), and NO synthase (NOS) activities were measured in liver tissues, and levels of adenosine deaminase (ADA) and alanine transaminase (ALT) activities were measured in serum.

**RESULTS:** Blood ALT and ADA activities were significantly elevated in the jaundice group as compared to those of the sham group. In the obstructive jaundice plus honey group, blood ALT and ADA activities were significantly decreased as compared to those of the jaundice group. In erythrocytes and liver tissues, NO levels were found to be significantly higher in the obstructive jaundice plus honey group compared to those of the sham group. Additionally, NO levels were found to be significantly higher in liver tissues from the animals in the obstructive jaundice plus honey group than those of the jaundice group.

## INTRODUCTION

Honey is produced by honeybees. They obtain nectar from various flowers, and digest it in their bodies, enrich it with their salivary and enzymatic secretions, and put it in honeycombs, so that ripe honey is formed<sup>[1]</sup>. Since ancient times, honey has been known as both flavorful food and a traditional therapeutic material. It has rich flavonoid components, such as luteolin, quercetin, apigenin, fisetin, kaempferol, isorhamnetin, acacetin, tamarixetin, chrysin, and galangin, and therefore, exhibits antioxidant activity. Additionally, honey provides antibacterial, anti-inflammatory, immune-stimulant, anti-ulcer and wound/burn healing (regenerative) effects<sup>[2]</sup>.

Free radicals lead to oxidative damage in many molecules, such as lipids, proteins and nucleic acids. Many complications have been attributed to oxidative damage, including atherosclerosis, aging, and cancerous diseases. Antioxidant foods that are rich in flavonoids are protective agents against these ailments<sup>[3]</sup>.

Obstructive jaundice leads to oxidative injury and inflammation in hepatocytes<sup>[4,5]</sup>. Over production of hydroxyl radicals in blood and liver from rats with obstructive jaundice has been reported<sup>[6]</sup>.

Nitric oxide synthase (NOS) converts arginine to

citrulline and nitric oxide (NO). Nitric oxide leads to activation of guanylyl cyclase, formation of cyclic guanosine 3',5'-monophosphate (cGMP), stimulation of cGMP-protein kinases, and subsequent relaxation in smooth muscle. It has been reported that NOS gene knockout in mice causes an elevation in blood pressure and increased synthesis of cGMP prevents platelet aggregation<sup>[7]</sup>.

Adenosine deaminase (ADA; E.C. 3.5.4.4) is an enzyme that catalyses conversion of adenosine to inosine and ammonia<sup>[8]</sup>. ADA activity has been found to increase in cirrhotic patients, and increased ADA activity has been suggested as a nonspecific hepatic marker for disease with liver damage<sup>[9]</sup>.

Alanine transaminase (ALT; E.C. 2.6.1.1) is a transaminase enzyme that catalyzes the inter-conversion of the amino acid L-alanine to L-glutamate and vice versa. In liver diseases associated with hepatic necrosis, ALT levels characteristically are elevated<sup>[10]</sup>.

In this study, we investigated the effects of honey on the NO pathway and ADA enzyme activity in rats that had induced obstructive jaundice.

## MATERIALS AND METHODS

Thirty male Wistar albino type rats of 12 wk old ( $250 \pm 25$  g in weight) were housed individually in wire cages under constant temperature ( $21^\circ\text{C} \pm 2^\circ\text{C}$ ) with a 12 h light-dark cycle. Twelve hours before anesthesia animals were deprived of food, but had free access to water until 2 h before anesthesia. No enteral or parenteral antibiotics were administered at any time. The animals were divided randomly into 3 groups of 10 rats each: the sham group (group I), the obstructive jaundice group (group II) and the obstructive jaundice plus honey group (group III). The animals were anesthetized by intramuscular injection of 30 mg/kg ketamine hydrochloride (Ketalar; Parke-Davis, Istanbul, Turkey) and 5 mg/kg xylazine (Rompun, Bayer, Istanbul, Turkey). Midline laparotomy was performed under sterile conditions. In group I, the common bile duct (CBD) was freed from the surrounding soft tissue, and was manipulated without ligation and transection. In groups II and III, the CBDs of the rats were identified, double ligated with 5-0 silk, and divided between the ligatures. Group III was nourished with honey 10 mg/kg per day by using a nasogastric tube that was inserted daily and removed after honey supplementation (Balpamak LTD, Istanbul, Turkey). The animals were sacrificed on postoperative day 7 with high-dose diethyl ether inhalation. Subsequently, their liver tissues were removed and blood samples were obtained. The blood samples were put in tubes, and then centrifuged at 2000 g for 5 min. Upper clear supernatant (serum) was taken and used in the enzymatic analyses. The liver tissues were first homogenized in physiologic saline (1 g in 5 mL) and then were centrifuged at 4000 g for 20 min. Upper clear supernatants were removed to use in the analyses. Protein levels of the supernatants were determined using Lowry's method<sup>[11]</sup> were adjusted to equal concentrations

before analyses.

NO levels and NOS enzyme activities were measured in liver tissues, and ADA and ALT enzymes activities were measured in serum.

The level of NO was estimated by the method based on the diazotization of sulfanilic acid by NO at acid pH, and subsequent coupling to N-(1-naphthyl-ethylene diamine) (Griess reaction) as described previously<sup>[12]</sup>. Since nitrate anion does not give a diazotization reaction with sulfanilic acid, the samples were treated by cadmium (a reducing agent) to reduce nitrate anions into nitrite anions before the NO estimation<sup>[13]</sup>. The results were expressed as  $\mu\text{mol}/\text{mg}$  protein. The total NOS activity (IU/mL) method is based on the Griess reaction<sup>[12]</sup>. The results were expressed as IU/mg protein.

Adenosine deaminase activity was studied by the method of Guisti based on spectrophotometric detection of ammonia formation<sup>[8]</sup>. The results were expressed as IU/L.

Serum ALT levels were determined by using a spectrophotometric method<sup>[14]</sup>. The results were expressed as U/L.

The histopathological analyses were carried out in the Histology and Embryology Department of Ankara University School of Medicine. Histopathological examination was performed by using light microscopic analyses. The samples were obtained from the liver and fixed in 10% neutral buffered formalin solution for 2 d. Tissues were washed in flowing water, and were dehydrated with rising concentrations of ethanol (50%, 75%, 96% and 100%). After dehydration, specimens were put into xylene to obtain transparency and were then infiltrated with, and embedded in paraffin. Embedded tissues were cut into sections of 5  $\mu\text{m}$  thicknesses by Leica RM 2125 RT and were then stained with hematoxylin and eosin. Histopathologic examinations were performed and photographed by Nikon Eclipse E 600.

In the statistical evaluation of the results, one-way ANOVA, and post hoc LSD tests were used. *P* values of less than 0.05 were considered as significant.

## RESULTS

The results are given in Table 1. Serum ALT and ADA enzymes activities were significantly elevated in group II compared to those of the sham group. In group III, serum ALT and ADA enzymes activities were found to be significantly decreased compared to those of group II. In liver tissues, NO levels were found to be higher in group III than those of the sham group. Additionally, NO levels were found to be significantly higher in liver tissues of group III compared to those of group II. There were no significant differences between groups for NOS activities.

In group I, there were no morphological alterations in the portal tract and whole liver tissue (Figure 1A). Group II tissues displayed some histopathological changes in the portal tract, such as proliferation of the duct epithelial cells, and looping and reduplication of

**Figure 1** Portal areas of liver biopsies shown for group I (A), group II (B) and group III (C). Bile ducts (arrow heads) and the degenerating and regressing of bile ducts (\*) viewed with HE staining by light microscope.

**Table 1** The biochemical parameters for each group (mean  $\pm$  SD,  $n = 10$ )

Parameters	Group I	Group II	Group III
Serum			
ALT (U/L)	28.98 $\pm$ 7.24 <sup>a</sup>	59.49 $\pm$ 13.42 <sup>c</sup>	17.40 $\pm$ 5.71
ADA (IU/L)	6.13 $\pm$ 4.40 <sup>a</sup>	11.02 $\pm$ 3.14 <sup>c</sup>	6.05 $\pm$ 3.69
Liver			
NO ( $\mu$ mol/mg)	0.281 $\pm$ 0.080 <sup>a</sup>	0.265 $\pm$ 0.065 <sup>c</sup>	0.396 $\pm$ 0.085
NOS (IU/mg)	0.175 $\pm$ 0.031	0.183 $\pm$ 0.048	0.180 $\pm$ 0.032

ADA: Adenosine deaminase; ALT: Alanine transaminase; NO: Nitric oxide; NOS: NO synthase. Group I: Sham operated; Group II: Obstructive jaundice; Group III: Obstructive jaundice + honey. <sup>a</sup> $P < 0.05$  vs II; <sup>c</sup> $P < 0.05$  vs III.

the ducts and ductules. The surrounding hepatocytes were enlarged (Figure 1B). Histopathological evidence showing bile ductule proliferation was markedly reduced in group III. Regression of the bile duct epithelial cells, and phagocytosis of the debris from dying bile duct epithelial cells were observed. We also examined the conspicuous reduction in the size of enlarged hepatocytes (Figure 1C).

## DISCUSSION

Since ancient times, honey has been known to have antibacterial and antioxidant properties due to its phenolic compounds<sup>[3]</sup>. It has been emphasized that honey has a rapid wound healing property<sup>[15]</sup>. Gethin *et al* demonstrated that honey has repairing potential in leg ulceration when wounds are dressed with honey<sup>[16]</sup>. The antimicrobial property of honey on some microbial isolates has also been reported<sup>[17]</sup>. Moreover, the antibacterial effect of honey on ocular flora has been displayed<sup>[18]</sup>. Furthermore, the scolicidal efficacy of propolis, which is a resinous material obtained by honey bees from plants or flowers, has been shown in cystic hydatid disease<sup>[19]</sup>. Recently, it has been found that honey leads to increased levels of NO in biological fluids and to reduced liver enzymes, such as AST and ALT, in blood<sup>[20]</sup>.

In the obstructive jaundice group in our study, elevated serum ALT and ADA activities indicated liver damage. Additionally, reduced serum ALT and ADA activities in the obstructive jaundice plus honey group showed significant improvement in liver tissues.

Histopathological examination also showed damage in the obstructive jaundice group with improvement in the obstructive jaundice plus honey group.

Our results showed the protective potential of honey with liver damage. It is possible that NO levels increased in the liver tissue due to the rich NO content of the honey itself, which is supported by our finding of unchanged NOS activity in liver tissue. Increased NO levels in the obstructive jaundice plus honey group may contribute to the protective result possibly through the elimination of toxic free radicals by NO.

In conclusion, we suggest that honey supplementation may give beneficial results in the prevention of hepatic damage induced by obstruction of the common bile duct.

## COMMENTS

### Background

In liver diseases associated with hepatic necrosis, the enzyme level characteristically is elevated. In this study, it was aimed to investigate the effects of honey on NO pathway, and adenosine deaminase (ADA) enzyme activity in rats which have induced obstructive jaundice.

### Research frontiers

The authors suggest that honey supplementation may give beneficial results to prevent the hepatic damage induced by obstruction of common bile duct.

### Innovations and breakthroughs

This study tries to elucidate possible mechanism for honey supplementation in the hepatic damage induced by obstruction of common bile duct.

### Applications

Histopathological examination was performed by using light microscopic analyses.

### Peer review

This is a valuable study indicating hepatocellular damage in obstructive jaundice group and protective potential of honey in this process. It's a well-designed and important paper.

### Abstract

**AIM:** To construct eukaryotic expression plasmids of full-length Hepatitis B Virus (HBV) genotype C genome, which contain lamivudine-resistant mutants (YIDD, YVDD) or wild-type strain (YMDD), and to observe the expression of HBV DNA and antigens [hepatitis B surface antigen (HBsAg) and hepatitis B e antigen (HBeAg)] of the recombinant plasmids in HepG2 cells.

**METHODS:** Three HBV full-length genomes were amplified from the plasmids pMD18T-HBV/YIDD, pMD18T-HBV/YVDD and pMD18T-HBV/YMDD, using PCR. Three recombinant plasmids were generated by inserting each of the PCR products into the eukaryotic expression vector pcDNA3.1 (+), between the *EcoRI* and *HindIII* sites. After being characterized by restriction endonuclease digestion, and DNA sequence analysis, the recombinant plasmids were transfected into HepG2 cells. At 48 and 72 h post-transfection, the levels of intracellular viral DNA replication were detected by real-time PCR, and the expression of HBsAg and HBeAg in the cell culture supernatant was determined by ELISA.

**RESULTS:** Restriction endonuclease digestion and DNA sequence analysis confirmed that the three

recombinant plasmids were correctly constructed. After transfecting the plasmids into HepG2 cells, high levels of intracellular viral DNA replication were observed, and HBsAg and HBeAg were secreted into the cell culture supernatant.

**CONCLUSION:** Eukaryotic expression plasmids pcDNA3.1 (+)-HBV/YIDD, pcDNA3.1 (+)-HBV/YVDD or pcDNA3.1 (+)-HBV/YMDD, which contained HBV genotype C full-length genome, were successfully constructed. After transfection into HepG2 cells, the recombinant plasmids efficiently expressed HBV DNA, HBsAg and HBeAg. Our results provide an experimental basis for the further study of HBV lamivudine-resistant mutants.

Construction and expression of eukaryotic plasmids containing lamivudine-resistant or wild-type strains of Hepatitis B Virus genotype C. *World J Gastroenterol* 2008; 14 (23): 3733-3738 Available from: URL: <http://www.wjgnet.com/1007-9327/14/3733.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.3733>

### INTRODUCTION

Hepatitis B Virus (HBV) infection has become one of the most serious health problems worldwide. In China, HBV prevalence is especially high. Presently, eight genotypes of HBV (A-H) have been identified, based on divergence over the entire genomic sequence of  $\geq 8\%$ <sup>[1-4]</sup>. Different HBV genotypes have specific geographical distributions<sup>[2,5]</sup>. According to previous studies, genotypes B and C are predominant in China<sup>[6,7]</sup>. In Heilongjiang Province in northern China, HBV genotype C is dominant<sup>[8,9]</sup>.

Lamivudine, a potent, non-toxic inhibitor of HBV replication in chronically infected patients, is currently one of the most effective anti-HBV drugs in the clinic.

Unfortunately, it has been found that long-term use of lamivudine leads to emergence of HBV YMDD mutants, which has been demonstrated to be associated with lamivudine resistance<sup>[10,11]</sup>. In YMDD variants, the methionine of the YMDD motif in HBV polymerase is substituted with either isoleucine, designated as YIDD, or valine, designated as YVDD. Much clinical data has indicated that patients who have developed HBV YMDD mutations show deterioration of their physical condition, and rebound of virus load in their serum<sup>[12-14]</sup>. In this study, we constructed the eukaryotic expression plasmids of HBV genotype C full-length genome, which contained wild-type, YVDD mutation or YIDD mutation, respectively. All these recombinant plasmids were shown to be able to express HBV DNA and antigens *in vitro*.

## MATERIALS AND METHODS

### Materials

Platinum Pfx DNA polymerase, T4 DNA ligase, and Lipofection 2000 reagent were purchased from Invitrogen (Carlsbad, CA, USA). Restriction endonucleases *Eco*RI and *Hind*III were purchased from New England Biolabs (Beijing, China). Dulbecco's modified Eagle's medium (DMEM) was purchased from GIBCO BRL (Gaithersburg, MD, USA). PCR primers were synthesized by Shanghai Sangon Biological Engineering, Technology and Services (Shanghai, China). DNA sequencing was performed by Invitrogen (Beijing, China). Enzyme immunoassay kit was purchased from Shanghai Kehua Biochemical Laboratory (Shanghai, China). Quantitative HBV PCR Fluorogenic Diagnostic Kit was purchased from PG Biotechnology (Nanjing, China). Axygen DNA Mini kit was purchased from Axygen Biosciences (Union City, CA, USA). The recombinant plasmids pMD18T-HBV were constructed in our laboratory. The HBV genotype C full-length genome of wild-type strain or YIDD, YVDD mutants were obtained from serum of chronic HBV patients, and inserted into the vector pMD18T. The expression vector pcDNA3.1 (+), HepG2 cells and *Escherichia coli* DH5 $\alpha$  were maintained in our laboratory.

### Construction of the recombinant plasmids

The HBV full-length genome of wild-type HBV DNA, YVDD or YIDD mutants was amplified from the plasmids pMD18T-HBV, by PCR using a primer set that consisted of a sense primer: 5'TACCATGGCCCTTTTTCACCTCTGCCTAATC-3', and an antisense primer: 5'CGAGCTCTTCAAAAAGTTGCATGGTGCTGG-3'. Amplification was performed for 30 cycles using the Platinum Pfx DNA Polymerase. The PCR hot-start procedure was as follows: 95°C for 6 min, 94°C for 40 s, 68°C for 3 min, plus 1 min after each 10 cycles, and 68°C for 10 min. The *Hind*III/*Eco*RI-digested PCR products were ligated into *Hind*III/*Eco*RI-digested pcDNA3.1 (+) vector using T4 DNA ligase. The recombinant plasmids were then transformed into *Escherichia coli* (*E. coli*) DH5 $\alpha$  and confirmed by restriction endonuclease

digestion and DNA sequence analysis. The sequences were aligned using the Gene Runner version 3.05 (Hastings Software Inc., Hastings, NY, USA).

### Cell culture and transfection

HepG2 cells were cultured in DMEM, supplemented with 10% fetal calf serum, penicillin (100 U/mL) and streptomycin (100 g/mL) at 37°C in a humidified incubator with 5% CO<sub>2</sub>. HepG2 cells in the exponential phase of growth were strictly counted and seeded onto 24-well culture plates with  $1.0 \times 10^5$  cells/well. After 24 h, cells at 80%-90% confluence were transfected with the recombinant plasmids using Lipofection 2000 reagent, following the manufacturer's guidelines. The transfected cells and supernatants were then harvested after 48 or 72 h. Vector pcDNA3.1 (+) was used as a mock transfection control.

### Assays of hepatitis B surface antigen (HBsAg) and hepatitis B e antigen (HBeAg)

At 48 or 72 h post-transfection, the culture supernatant was collected, centrifuged at 3000 r/min for 5 min to remove cellular debris, and transferred to a clean tube for further analysis. The expression levels of HBsAg and HBeAg were separately assayed using an enzyme immunoassay kit. According to the instructions, a ratio of sample/negative (S/N)  $\geq 2.1$  was considered as a positive response to HBsAg or HBeAg antigen.

### Real-time fluorimetry PCR analysis of HBV DNA

Real-time fluorimetry PCR using TaqMan probe was performed to quantify HBV DNA at 48 or 72 h post-transfection. HBV DNA was extracted from the intracellular core particles using Axygen DNA Mini kit, and then examined by Quantitative HBV PCR Fluorogenic Diagnostic kit. According to the instructions, an HBV DNA level  $\geq 5.0 \times 10^2$  copies/mL was considered as a positive response.

### Statistical analysis

All experiments were performed at least three times. All data were indicated as mean  $\pm$  SD. Data analysis was performed by SPSS 10.0 software (Spss Inc., Chicago, IL, USA).

## RESULTS

### Construction and characterization of recombinant plasmids pcDNA3.1 (+)-HBV/C-YMDD, YIDD or YVDD

As shown in Figure 1A, the PCR products had the expectant molecular weight (3.2 kb). The target genes were cloned to the expression vector pcDNA3.1 (+), and transformed into *E. coli* DH5 $\alpha$ , which generated the reconstructed plasmids pcDNA3.1 (+)/HBV/C-YMDD, YIDD or YVDD. After amplification by *E. coli*, the recombinant plasmids were extracted from the positive clones, and then characterized by digestion with restriction enzymes *Hind*III/*Eco*RI (Figure 1B, lanes 2-4) and *Eco*RI (Figure 1C, lanes 2-4). Vector pcDNA3.1 (+),

**Figure 1** A: Electrophoresis of PCR results of HBV genotype C full-length genomes. M: Marker; lanes 1-3: PCR products of YMDD, YIDD and YVDD, respectively; B: Electrophoresis of digestion with *EcoRI* / *HindIII*. M: marker; lane 1: pcDNA3.1 (+)/*EcoRI* ; lane 2: pcDNA3.1 (+)/HBV-YMDD/*EcoRI* / *HindIII* ; lane 3: pcDNA3.1 (+)/HBV-YIDD/*EcoRI* / *HindIII* ; lane 4: pcDNA3.1 (+)/HBV-YVDD/*EcoRI* / *HindIII* ; C: Electrophoresis of digestion with *EcoRI* . M: marker; lane 1: pcDNA3.1 (+)/*EcoRI* ; lane 2: pcDNA3.1 (+)/HBV-YMDD/*EcoRI* ; lane 3: pcDNA3.1 (+)/HBV-YIDD/*EcoRI* ; lane 4: pcDNA3.1 (+)/HBV-YVDD/*EcoRI* .

used as a negative control, was also digested with *EcoRI*, which yielded a product of approximate 5.4 kb in size (Figure 1B and C, lane 1). The digested products of the recombinant plasmids were visualized on 7 g/L agarose gel (Figure 1B), which demonstrated that recombinant plasmids were digested to 5.4 and 3.2 kb DNA fragments, which corresponded to the lined vector pcDNA3.1 (+) (5.4 kb) and the target gene HBV full-length genome (3.2 kb), respectively. As shown in Figure 1C, the fragment digested from the recombinant plasmids by *EcoRI* was approximate 8.6 kb in size, as expected.

#### DNA sequence analysis of recombinant plasmids

DNA sequence analysis of positive clones confirmed the result. The inserted HBV full-length genome had the correct reading frame and length. Compared with the sequence of the recombinant plasmids that contained wild-type strain (Figure 2A), it was clearly shown that, in the HBV YIDD mutant (Figure 2B), the 741th base G mutated to T, and in the HBV YVDD mutant (Figure 2C), the 739th base A mutated to G. These mutations resulted in replacement of the methionine residue (amino acid 204) by isoleucine (rtM204 I), or valine (rtM204 V), respectively.

#### Extracellular expression of HBsAg and HBeAg

At 48 or 72 h post-transfection, culture supernatants were collected. The expression levels of HBV HBsAg and HBeAg were then detected by ELISA. According to the instructions, an S/N ratio  $\geq 2.1$  was considered as positive HBeAg response. As shown in Table 1, our results indicated that each of the recombinant plasmids could express the antigens, HBsAg and HBeAg in HepG2 cells. The blank control group had a negative HBsAg and HBeAg response.

#### Intracellular expression of HBV DNA

At 48 or 72 h post-transfection, HepG2 cells were harvested and real-time fluorimetry PCR was then performed. As shown in Table 2, the three transfection groups could be considered as positive (all  $\geq 5.0 \times 10^2$  copies/mL), which indicated that HBV DNA was

expressed efficiently. The blank control group was negative.

## DISCUSSION

Lamivudine, a potent inhibitor of HBV replication has been the main therapeutic option for treatment of chronic hepatitis B. It functions by interfering with HBV reverse transcriptase activity, and leads to a marked decrease in serum HBV DNA levels, a significant increase in the rate of HBeAg seroconversion, as well as improvement in serum alanine aminotransferase (ALT) levels<sup>[15]</sup> and liver histopathological parameters<sup>[16]</sup>. Several data have revealed that lamivudine can efficiently promote the treatment of hepatitis B in the short term. However, the long-term effectiveness of lamivudine is hampered by the development of viral resistance<sup>[15,17]</sup>. Lamivudine resistance is associated with mutations in the highly conserved YMDD motif of the reverse transcriptase, in which, methionine 204 is replaced by either isoleucine (rtM204 I, YIDD variant) or valine (rtM204 V, YVDD variant).

It has been reported that the rate of HBV YMDD mutation increases with the duration of lamivudine therapy, with an increase from 15% in one year to 38% and 53% after two and three years of treatment, respectively<sup>[18]</sup>. Our previous research has also indicated that in northern China, the YMDD mutation rate is approximate 56.3% after four years of lamivudine treatment<sup>[8]</sup>. YMDD mutations not only result in a reduction in the susceptibility to lamivudine, but also cause virological and biochemical breakthrough, which are represented as rebound of HBV DNA and ALT levels<sup>[19,20]</sup>. Moreover, acute exacerbation of hepatitis and hepatic failure may occur after the emergence of YMDD mutants. Therefore, the antiviral treatment of YMDD mutants has become a crucial issue in the clinic.

HBV genotypes have distinct geographical distributions and are potential factors that affect virus replication, virus variation, clinical course, and therapy of HBV infection. In northern China, genotype C is predominant, and accounts for 77%-88% of cases of chronic hepatitis B<sup>[6,8]</sup>. Sugiyama reported that the

**Figure 2** Sequence analysis of wild-type strain and YMDD mutants (YIDD, YVDD). **A:** Wild-type strain: 739th base is A; 741th base is G. **B:** YIDD mutant: 741th base G mutated to T. **C:** YVDD mutant: 739th base A mutated to G.

replication capacity of HBV in transfected Huh7 cells varied among genotype A and B, as well as C and D, with genotype C having the highest replication capacity<sup>[21]</sup>. HBV genotype C is associated with more severe histological liver damage and low-grade responses to interferon therapy<sup>[22]</sup>. Moreover, patients with genotype C show poor responses to embolization therapy and may die from hepatic failure because of rapid hepatocellular carcinoma (HCC) progression<sup>[23]</sup>. Another study has reported that HBV genotype C has more rapid selection of lamivudine resistance than genotype B<sup>[17]</sup>. Therefore, further studies of HBV YMDD mutants with genotype C are of great significance.

To date, many *in vitro* studies on lamivudine resistance have been reported<sup>[24-27]</sup>. In most of these, recombinant plasmids containing HBV full-length or fragment genome were constructed first, and then expressed in liver-derived cell lines. For example, Gunther *et al* have reported an original and efficient method of amplifying full-length HBV genomes by PCR<sup>[24]</sup>. Chen *et al* have described a

**Table 1** HBsAg and HBeAg in transfected HepG2 cells determined by ELISA

Clone	HBsAg (Sample/Negative)		HBeAg (Sample/Negative)	
	48 h	72 h	48 h	72 h

method of constructing baculovirus recombinants that contain multiple HBV lamivudine-resistant mutations, introduced by successive rounds of site-directed mutagenesis in laboratory strains<sup>[25]</sup>. However, in all these studies, either one type of HBV YMDD mutant or wild-type strains was included in the plasmids without specification of HBV genotype. Therefore, to date, serial plasmids that contain a specific HBV genotype, such as genotype C, and lamivudine-resistant sequences, which allow systematic studies on the combined effects of HBV genotype together with lamivudine-resistant mutations, have not been reported.

In this study, we successfully constructed a series of eukaryotic expression plasmids that contained genotype C HBV strain with either wild-type, YVDD or YIDD mutation, namely the plasmids pcDNA3.1 (+)-HBV/C-YMDD, pcDNA3.1 (+)-HBV/C-YVDD and pcDNA3.1 s(+)-HBV/C-YIDD, respectively. In order to achieve high-level expression *in vitro*, the Kozak sequence, ACCATGGCC-which has been found to contribute to the fidelity and efficiency of initiation and expression<sup>[28]</sup>-was coupled to the 5' end of the sense primer. Moreover, to further assure high fidelity, the PCR analyses were performed following a hot-start protocol and using high-fidelity enzymes. After transfecting the constructed plasmids into HepG2 cells, we analyzed the expression levels of HBsAg and HBeAg by ELISA, and the replication level of HBV DNA by real-time PCR. It was found that both HBV DNA and the antigens were expressed in the transfected cells, but not in the negative control cells transfected with pcDNA3.1 (+). As shown in Table 1, all the recombinant plasmids could express HBsAg in HepG2 cells. At 48 and 72 h, the expression levels of HBeAg were 8.723 ± 0.0585 and 8.77 ± 0.256,

respectively, in YMDD strains and  $5.03 \pm 0.132$  and  $5.3 \pm 0.117$  in YVDD mutants. However, HBeAg expression levels in YIDD mutants were only  $2.06 \pm 0.318$  and  $2.18 \pm 0.028$  at 48 and 72 h, respectively. This difference was probably caused by the emergence of BCP mutations (A1762T/G1764A) in YIDD mutants, while this mutation was not present in YVDD mutants. Our observation is consistent with previous reports that BCP mutation can result in a decrease in HBeAg levels<sup>[29]</sup>. In addition, HBV DNA expression levels of each of the recombination plasmids were  $\geq 10^8$  copies/mL in HepG2 cells (Table 2), which indicates that the three recombinant plasmids can be expressed efficiently. Successful construction of the three eukaryotic plasmids pcDNA3.1 (+)-HBV/C-YMDD, pcDNA3.1 (+)-HBV/C-YVDD and pcDNA3.1 (+)-HBV/C-YIDD, provides an experimental basis for the establishment of stable expression system of HBV genotype C lamivudine-resistant mutants. The results may contribute to future *in vitro* antiviral studies of HBV genotype C lamivudine-resistant mutants.

## ACKNOWLEDGMENT

We thank Dr. Wei Ming Xu from Columbia University Medical Center (New York, NY, USA) for her helpful suggestions when it came to written English.

## COMMENTS

### Background

HBV infection remains a major public health problem worldwide. Lamivudine is currently one of the most effective anti-hepatitis B virus (HBV) drugs in use clinically. However, the long-term use of lamivudine leads to the emergence of lamivudine-resistant mutants (YMDD mutants). It was reported that the rate of YMDD mutations was up to 70% after three years of treatment. The development of YMDD mutants has hampered anti-HBV therapy.

### Research frontiers

*In vivo* and *in vitro* studies on the HBV drug-resistance mechanism have been of great interest. *In vivo* studies have mainly focused on the rate, types and detection method of YMDD mutation. However, there is still little known about the effects of YMDD mutations *in vitro*.

### Innovations and breakthroughs

Appropriate and effective eukaryotic expression plasmids that are able to efficiently express HBV DNA and antigens are necessary for further *in vitro* investigations. However, to date, serial plasmids that contain a specific HBV genotype, such as genotype C, and a certain lamivudine-resistance mutation, which allow systematic studies of the combined effects of HBV genotype, together with lamivudine-resistance mutations, have not been reported. In this study, authors successfully constructed eukaryotic expression plasmids pcDNA3.1 (+)-HBV/C-YMDD, pcDNA3.1 (+)-HBV/C-YVDD and pcDNA3.1 (+)-HBV/C-YIDD, which contained genotype C HBV strain with either wild-type, YVDD or YIDD mutations, respectively, and had the ability to express HBV DNA and antigens *in vitro* with a high capacity.

### Applications

The successful construction of three eukaryotic plasmids, pcDNA3.1 (+)-HBV/C-YMDD, pcDNA3.1 (+)-HBV/C-YVDD and pcDNA3.1 (+)-HBV/C-YIDD, provides an experimental basis for the establishment of a stable expression system of HBV genotype C lamivudine-resistant mutants. The results may contribute to further *in vitro* antiviral studies of HBV genotype C lamivudine-resistant mutants. This could include establishing a stable expression system for HBV genotype C lamivudine-resistant mutants for studying the mechanism of HBV lamivudine resistance.

### Terminology

HBV genotype C is predominant in China, and is associated with more severe

histological liver damage, lower response to anti-HBV treatment, and more rapid development of lamivudine resistance.

### Peer review

The paper describes a technique for constructing eukaryotic expression plasmids of HBV genotype C with lamivudine-resistant mutants. This is an interesting topic and the manuscript is well written.

### Abstract

**AIM:** To investigate the relationship between the expression of P120 and the clinicopathologic parameters in intrahepatic cholangiocarcinoma (ICC).

**METHODS:** An immunohistochemical study of E-cadherin and P120 catenin was performed on 42 specimens of ICC with a Dako Envision kit.

**RESULTS:** The expression of E-cadherin and P120 was reduced in 27 cases (64.3%) and 31 cases (73.8%), respectively. Both E-cadherin and P120 expressions were significantly correlated with the tumor histological grade ( $\chi^2 = 9.333, P = 0.009$  and  $\chi^2 = 11.71, P = 0.003$ ), TNM stage ( $\chi^2 = 8.627, P = 0.035$  and  $\chi^2 = 13.123, P = 0.004$ ), intrahepatic metastasis ( $\chi^2 = 7.292, P = 0.007$  and  $\chi^2 = 4.657, P = 0.041$ , respectively) and patients' survival ( $\chi^2 = 6.351, P = 0.002$  and  $\chi^2 = 4.023, P = 0.000$ , respectively). In addition, the expression of P120 was in concordance with that of E-cadherin ( $\chi^2 = 13.797, P = 0.000$ ), indicating that the expression of P120 may be dependent on that of E-cadherin. Finally, only P120 expression was found to be an independent prognostic factor in Cox regression model ( $r = 0.088, P = 0.049$ ).

**CONCLUSION:** Down-regulated expression of E-cadherin and P120 occurs frequently in ICC and contributes to the progression and development of tumor. Both of them may be valuable biologic markers

### INTRODUCTION

P120-catenin is a member of the Armadillo (ARM)/ $\beta$ -catenin gene family and is essential for mesenchymal cadherin-mediated regulation of cell motility and invasiveness<sup>[1,2]</sup>. Cadherin, one of the transmembrane cell-cell adhesion receptors involved in development, and morphogenesis of ICC<sup>[3]</sup>, is necessary and sufficient for P120 targeting cell-cell junctions.

A main function of P120 is to stabilize cadherins at the cell membrane by regulating cadherin turnover and degradation. In this way, P120 level acts as a set point mechanism underlying cell-cell adhesive interactions. P120 may function as a "cap" to bind to the cadherin cytoplasmic tail and prevent cadherin interactions with endocytic membrane trafficking machinery. Alternatively, P120 may stabilize cell junctions or regulate membrane trafficking machinery through interactions with small GTPases, such as Rho A, Rac and Cdc42. Through these mechanisms, P120 exerts its influence over a wide range of biological processes that are dependent upon tight regulation of cell surface cadherin levels<sup>[4]</sup>.

Intrahepatic cholangiocarcinoma (ICC) is the second most common tumor of primary liver cancers in adults worldwide, accounting for about 15% of liver cancers, and its incidence has increased in recent years<sup>[5]</sup>. Despite

improved diagnostic and operative techniques, the prognosis of ICC remains poor. In addition, molecular events involving the development of ICC are not well understood. Some studies examined the expression of E-cadherin/catenin complex in ICC, but the conclusion is still controversial. Moreover, to our knowledge, no study has demonstrated the expression characteristics of P120 and the relationship between the expression of P120, and the clinicopathologic parameters in ICC. Therefore, in the present study, we used immunohistochemical staining for the E-cadherin/P120 complex in primary ICC to correlate its expression with its clinicopathologic features.

## MATERIALS AND METHODS

### *Selection of patients and definition of clinicopathologic parameters*

In this study, we selected 42 specimens of intrahepatic cholangiocarcinoma collected and diagnosed at the Eastern Hepatobiliary Surgery Hospital, the Second Military Medical University from October 1997 to March 2004. The patients were consisted of 32 men and 10 women. Their age ranged from 27 to 73 years, with an average age of 51 years. Cancer tissue and non-tumorous liver tissue were obtained from each patient for pathological examination. The detailed pathologic data were obtained from the Department of Pathology of Eastern Hepatobiliary Surgery Hospital. Background liver showed cirrhosis in 19 (45.2%) patients, and chronic hepatitis in 15 (35.7%) patients.

Clinicopathologic parameters included histological grade, pTNM stage, tumor size, capsular and vascular invasion, satellite nodules, intrahepatic metastasis, lymph node status and patients' survival. Histological grade of ICC was sub-classified into well, moderately and poorly differentiated ICC based on the criteria for a liver cancer study in Japan<sup>[6]</sup>. Tumor staging was performed according to the pTNM staging system of the International Union against Cancer UICC<sup>[7]</sup>.

### *Immunohistochemistry*

Formalin-fixed and paraffin-embedded tissues were cut to 5- $\mu$ m thick sections. Immunohistochemical staining for E-cadherin and P120 was performed with a Dako EnVision™ kit (Dakocytomation Company, Denmark). The sections were dewaxed, incubated with methanol containing 30% H<sub>2</sub>O<sub>2</sub> for 20 min to block endogenous peroxidase activity, immersed in 0.01 mol/L citrate buffer (pH 6.0), heated at 100°C in a microwave oven for 20 min, washed three times with distilled water and blocked with 1% BSA for 30 min. The sections were then incubated overnight at 4°C with rabbit polyclonal IgG of E-cadherin (H-297, SC-7870, Santa Clauze Corporation, USA) and rabbit polyclonal IgG of P120 (H-90, SC-13957, Santa Clauze Corporation, USA) at a 1:200 dilution. A subsequent reaction was carried out using second antibodies (Dakocytomation Company, Denmark) at 37°C for 30 min. Then, the sections were washed three times with

phosphate-buffered saline (PBS) and subsequently the color was displayed with DAB (Dakocytomation Company, Denmark) for about 5 min. Nuclei were lightly counterstained with hematoxylin. No staining was obtained when immune serum or PBS was used instead of primary antibodies, thus confirming the specificity of each primary antibody.

### *Evaluation of immunostaining*

A scoring system was used to semiquantitatively evaluate the immunoexpression of E-cadherin and P120 in ICC as described previously<sup>[8]</sup>. The expression of E-cadherin and P120 in nontumorous tissue was used as an internal control. Briefly, immune activities of E-cadherin and P120 were assessed by the extent (broadness) and intensity (color strength). Depending on the percentage of positive cells, the extent was scored as follows: 0 = no positive cells or less than 5%, +1 = 5%-25% positive cells, +2 = 26%-50% positive cells, +3 = 51%-75% positive cells, and +4 = 76%-100% positive cells. The intensity was also scored as follows: 0 = no immunoreaction, +1 = mild immunoreaction, +2 = moderate immunoreaction, +3 = marked immunoreaction. E-cadherin or P120 expression was defined as positive when the composite score was 6 or 7, and as "absent or loss" when the total score was 0.

### *Statistical analysis*

Results from immunohistochemistry were analyzed by  $\chi^2$  or Fisher's exact test.  $P < 0.05$  was considered statistically significant. Survival analysis was performed using the log-rank test ( $P < 0.05$ ). Survival curves were plotted according to the method of Kaplan and Meier. The prognosis value of E-cadherin and P120 for ICC was evaluated with univariate (log-rank test) and multivariate analysis (Cox regression model). SPSS 10.1 software package for Windows (SPSS, Inc., Chicago, IL) was used.

## RESULTS

### *Observation under microscope*

In nontumorous liver tissue, both E-cadherin and P120 were expressed strongly on cell membranes, but the staining intensity was gradually decreased. In addition, these molecules were normally expressed on cell membranes of bile ducts, proliferating ductules and intra-hepatic vessels. No expression was found in other types of cells in the liver.

In ICC, the expression of E-cadherin and P120 catenin was reduced in 27 (64.3%) and 31 cases (73.8%), being absent in 8 and 10 cases, respectively. In addition, P120 was expressed in 17 cases (40.5%) (Figure 1).

### *Relationship between expression of E-cadherin/P120 and histological features of ICC*

As shown in Table 1, the membranous expression of E-cadherin and P120 was significantly correlated with the tumor grade ( $P = 0.009$  and  $P = 0.003$ , respectively).

**Figure 1** Immunoreactivity of E-cadherin and P120 in intrahepatic cholangiocarcinomas. "Preserved type"(+) (A, D), "reduced type"(-) (B, E), and "complete absent" (C, F) of E-cadherin and P120 induced type"(-) and staining, respectively ( $\times 200$ ).

Table 1 Relationship between expressions of E-cadherin/P120 catenin and histological features of ICC <i>n</i> (%)							
	<i>n</i>	E-cadherin			P120 catenin		
		+	-	<i>P</i> value	+	-	<i>P</i> value
Differentiation grade							
Well	3	3 (100)	0 (0)	0.009	3 (100)	0 (0)	0.003
Mediate	14	7 (50.0)	7 (50.0)		5 (35.7)	9 (64.3)	
Poor	25	5 (20.0)	20 (80.0)		3 (12.0)	22 (88.0)	
pTNM							
I	2	2 (100)	0 (0)	0.035	2 (100)	0 (0)	0.004
II	9	5 (55.6)	4 (44.4)		5 (55.6)	4 (44.4)	
III	25	8 (32.0)	17 (68.0)		4 (16.0)	21 (84.0)	
IV	6	0 (0)	6 (100)		0 (0)	6 (100)	

The expression of E-cadherin and P120 tended to be reduced in poorly-differentiated tumors compared with well- and moderately-differentiated tumors. In addition, the expression of E-cadherin and P120 was inversely associated with the pTNM stage of tumors ( $P = 0.035$  and  $P = 0.004$ , respectively).

**Relationship between expression of E-cadherin and P120 and clinical parameters of ICCs**

As shown in Table 2, the expression of E-cadherin or P120 was significantly associated with intra-hepatic metastasis of ICC ( $P = 0.007$  and  $P = 0.041$ , respectively). No statistically significant difference was observed between the expression level of E-cadherin or P120 and tumor size, capsular and vascular invasion, lymph node permission and satellite nodules.

**Relationship between expressions of E-cadherin and P120 in ICC**

As shown in Table 3, positive and negative expression of E-cadherin and P120 was found in 9 and 25 cases, respectively. However, negative expression of P120 was observed in 7 cases. There was a significant concordance between the expressions of E-cadherin and P120 ( $P = 0.000$ ).

**Relationship between expression of E-cadherin/P120 and survival of ICC patients**

The patients were followed up for 4-67 months. The overall survival rate of patients according to the expression of E-cadherin and P120 in tumor is shown in Figure 2. Analysis of the survival of all patients showed that abnormal expression of E-cadherin and P120 was

significantly correlated with the poor survival of patients ( $P = 0.024$  and  $P = 0.004$ , respectively). However,

when the expression of E-cadherin or P120 and the clinicopathological parameters were analyzed by the Cox regression model, abnormal expression of P120 was found to be an independent prognostic factor for ICC patients ( $P = 0.049$ ) (Table 4).

## DISCUSSION

Usually, ICC is an adenocarcinoma and may arise from the large intra-hepatic bile ducts near the hepatic hilus or from the bile ducts at the border of hepatic parenchyma. It was reported that altered expression of E-cadherin/catenins complex in ICC occurs frequently and is significantly correlated with tumor histological features and/or vascular invasion and metastasis<sup>[9-14]</sup>.

It was recently reported that P120 plays a role in the occurrence of various cancers, and that P120 may behave either as a tumor suppressor or as a metastasis promoter, depending on the loss of E-cadherin and P120. If E-cadherin is lost first, P120 may directly and actively promote metastasis. If P120 is lost first, E-cadherin levels would fall significantly, which is likely to be parallel to

the reduced levels of  $\alpha$ - and  $\beta$ -catenins<sup>[15]</sup>. P120 down-regulation results in a striking dose-dependant loss of endogenous cadherins, indicating that P120 is essential for cadherin stability. Moreover, P120 down-regulation occurs frequently in almost all carcinomas<sup>[16]</sup>. P120 loss is often associated with the stage and poor prognosis of tumors, suggesting that its loss may be associated with biological aggressiveness and progression of tumors. Nevertheless, to our knowledge, no report is available on the expression of P120 in human intrahepatic cholangiocarcinoma.

The present study showed that reduced or absent expression of E-cadherin and P120 was associated with the histological grade of tumors, which is consistent with reported data<sup>[17-21]</sup>. In well-differentiated tumors, there were obvious and strong staining along the cell-cell boundaries, whereas in poorly-differentiated tumors, the immunohistostaining was focally and heterogeneously distributed, with patchy or spotty features along the cell-cell boundaries, indicating that the staining of E-cadherin and P120 is related with the differentiation of ICC, namely both E-cadherin and P120 may be regarded as differentiation markers of tumor. In addition, the staining intensity of the E-cadherin and P120 complex was gradually decreased, suggesting that P120 may play a critical role in ICC progression.

Microscopy revealed that E-cadherin was located on the membrane either in non-tumor tissues or in tumor cells, whereas P120 was expressed on the membrane or in cytoplasm of tumor cells. However, it was reported that P120 is also in nuclei<sup>[22]</sup>, suggesting that P120 plays an important role in cell signal transduction. P120 has an intrinsic nucleocytoplasmic shuttling activity that is modulated, in part, by extrinsic factors such as cadherin binding and interactions with the microtubule network<sup>[22]</sup>. Julia and his colleagues reported<sup>[23]</sup> that P120 displays up-regulation and nuclear expression in pancreatic cancer. No expression of P120 in nuclei of cancer cells, however, was observed in our study, suggesting that it is necessary to further investigate the mechanism underlying P120 expression in nuclei of cancer cells.

In this study, we observed the relationship between reduced expression of E-cadherin and P120 and several clinicopathologic parameters of ICC. The expression of P120 and E-cadherin was significantly associated with tumor pTNM stage and intrahepatic metastasis (IM), but not with tumor stage and size, capsular and vascular invasion, and lymph node invasion. Osada and his colleagues<sup>[24]</sup> revealed that E-cadherin is involved in intra-hepatic metastasis of hepatocellular carcinoma. Asayama *et al.*<sup>[13]</sup> detected the expression of E-cadherin in hepatocellular carcinoma and cholangiocarcinoma, and found that reduced expression of E-cadherin is significantly correlated with the grade and IM of ICC. Therefore, E-cadherin and P120 may be important mediators in tumor progression, and can be considered as invasion and metastasis markers of ICC.

Several studies on other cancers have evaluated the relationship between the expression of E-cadherin/P120 and the survival of patients, but the results remain debatable<sup>[25-29]</sup>. In the present study, reduced expression of

both E-cadherin and P120 was significantly related with the survival of patients. However, when the expression of E-cadherin/P120 and the clinicopathological parameters of ICC were analyzed by the Cox regression model, only the abnormal expression of P120 was found to be an independent prognostic factor for ICC, suggesting that P120 can be considered a valuable biological marker for predicting the prognosis of ICC patients.

In summary, abnormal expression of E-cadherin and P120 catenin occurs frequently in intrahepatic cholangiocarcinoma. Reduced expression of P120 catenin and E-cadherin is correlated with tumor differentiation, pTNM stage, intrahepatic metastasis and survival of patients. Both P120 catenin and E-cadherin may play an important role in the development and progression of human intrahepatic cholangiocarcinoma.

The authors thank Miss Guo LN, International Cooperation Laboratory on Signal Transduction, Eastern Hepatobiliary Surgery Institute, Second Military Medical University, for her valuable advice on cell staining.

## COMMENTS

### Background

P120-catenin is a member of the E-cadherin/catenin complex family and may be associated with biological aggressiveness and progression of tumors. However, no report is available on the expression of P120 catenin in human intra-hepatic cholangiocarcinoma.

### Research frontiers

P120 down-regulation occurs frequently in almost all carcinomas. P120 loss is often associated with the stage and poor prognosis of tumors.

### Innovations and breakthroughs

Our results suggest that down-regulated expression of E-cadherin and P120 catenin occurred frequently in intrahepatic cholangiocarcinoma (ICC) and contributed to the progression and development of tumors. Both E-cadherin and P120 catenin may be valuable biologic markers for predicting tumor invasion, metastasis and survival of patients, but only P120 catenin is an independent prognostic factor for ICC.

### Applications

Because down-regulated expression of P120 contributes to the progression and development of ICC, P120 can be used as a valuable biologic marker for predicting the invasion and metastasis of ICC, and the survival of patients.

### Peer review

This is an interesting report on E-cadherin and P120 catenin in human intra-hepatic cholangiocarcinoma. The study was performed on 42 specimens of ICC with a Dako Envision kit, indicating that. Both E-cadherin and P120 catenin may be valuable biological markers for predicting tumor invasion, metastasis and survival of patients. However, its clinical application should be further studied.

### Abstract

**AIM:** To study the effects of different *Helicobacter pylori* (*H. pylori*) culture filtrates on growth of gastric epithelial cells.

**METHODS:** Broth culture filtrates of *H. pylori* were prepared. Gastric epithelial cells were treated with the filtrates, and cell growth was determined by growth curve and flow cytometry. DNA damage of gastric epithelial cells was measured by single-cell microgel electrophoresis.

**RESULTS:** Gastric epithelial cells proliferated actively when treated by *CagA*-gene-positive broth culture filtrates, and colony formation reached 40%. The number of cells in S phase increased compared to controls. Comet assay showed 41.2% comet cells in GES-1 cells treated with *CagA*-positive filtrates ( $P < 0.05$ ).

**CONCLUSION:** *CagA*-positive filtrates enhance the changes in morphology and growth characteristics of human gastric epithelial tumor cells. DNA damage maybe one of the mechanisms involved in the growth changes.

*Helicobacter pylori*; Single cell microgel electrophoresis

Effects of different *Helicobacter pylori* culture filtrates on growth of gastric epithelial cells. *World J Gastroenterol* 2008; 14(23): 3745-3749 Available from: URL: <http://www.wjgnet.com/1007-9327/14/3745.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.3745>

### INTRODUCTION

Infection with the gastric bacterium *Helicobacter pylori* (*H. pylori*) the causative agent of chronic gastritis is associated with an increased risk of developing gastric cancer<sup>[1-6]</sup>. The international agency for research on cancer has classified *H. pylori* as a type I carcinogen<sup>[7-10]</sup>. A number of studies have pointed to a link between carriage of *CagA*+ strains and an increased risk of gastric cancer<sup>[11-13]</sup>. The mechanism by which *H. pylori* promotes the development of gastric cancer is presently unclear. Studies have shown that *CagA* can bind to other signaling molecules, such as SHP2, GRB2, c-MET and phospholipase C to promote gastric carcinogenesis<sup>[14-19]</sup>, which depends on a type IV secretion system to translocate *CagA* into host cells.

The aim of this study was to investigate the effects of *H. pylori* culture filtrates that contained *CagA* protein on the growth of gastric epithelial cells. *CagA*-gene-positive and negative *H. pylori* culture filtrates were prepared to treat gastric epithelial cells, to observe DNA damage and growth changes.

### MATERIALS AND METHODS

#### Bacterial strains

*H. pylori* strains NCTC11639 (*CagA*-positive, *VacA*-negative) and G50 (*CagA*-negative, *VacA*-negative) were provided by the Chinese Center for Disease Control and Prevention.

#### Production of culture filtrates

*H. pylori* was grown in Brucella broth, supplemented with 5% fetal calf serum (Gibco, Grand Island, NY,

USA), for 24–36 h at 37°C in a thermostatic shaker under microaerophilic conditions. As described by Sommi *et al*<sup>[20]</sup>, when bacterial suspensions reached  $A_{450}$  1.2 (corresponding to a bacterial concentration of  $5 \times 10^8$  CFU/mL), to obtain the *H. pylori* culture filtrate, we then removed bacteria by centrifugation (12 000 *g* for 10 min) and sterilized the supernatants by passage through a 0.22  $\mu$ m cellulose acetate filters (Nalge, Rochester, NY, USA). Uninoculated broth filtrate served as a blank control. To remove ammonia, we dialyzed control and culture filtrates against Hanks' balanced salt solution for 36 h in dialysis tubing, with a 12 kDa molecular mass cutoff (Sigma, St. Louis, MO, USA). The presence of CagA in the culture filtrates was tested by means of SDS-PAGE, followed by Western blotting<sup>[21,22]</sup>. Total protein content was determined by measuring  $A_{280}$ . The conditioned broth was stored at -70°C until use. There were three groups: CagA+, CagA- and blank control.

### Western blotting

Culture filtrates were subjected to 12% SDS-PAGE and transferred to polyvinylidene membranes using standard procedures, and incubated with primary monoclonal anti-CagA antibodies (1:5000) (Santa Cruz Biotechnology, Santa Cruz, CA, USA). Horseradish peroxidase-conjugated secondary antibodies (Boster, China) were used and the immunoreactive proteins were visualized by an ECL detection system (Amersham Biosciences, Uppsala, Sweden).

### Human gastric epithelial cells

GES-1 cells (Beijing Institute for Cancer Research Collection) were maintained in DMEM high-glucose medium (Gibco) containing 10% FCS (Sigma, Poole, UK) and different *H. pylori* culture filtrates (10% v/v), in 24-well plates. Cell cultures were maintained at 37°C in a humidified atmosphere of 95% air and 5% CO<sub>2</sub>, continuously for 1 mo. The culture medium was changed every 3 d.

### MTT assay for cell proliferation

The effect of culture filtrate on endothelial cell proliferation was determined by MTT assay (Sigma). Briefly, GES-1 cells were plated in 24-well plates and cultured overnight in growth medium for 1 mo.  $2.5 \times 10^4$  cells were inoculated in three groups: CagA+, CagA- and blank control. The viable cells were quantified by MTT assay at 1–7 d, following the manufacturer's instructions.

### Flat clone formation test

The gastric epithelial cells in logarithmic phase were digested to produce single-cell suspension by 0.25% trypsin. Five hundred cells were dispersed in a culture dish (diameter 60 mm); culture medium was added, and the cells were cultured for 2 wk. When clones were visible, the supernatant was removed, and fixed in methanol for 15 min. The samples were stained with 0.4% crystal violet for 20 min, rinsed in water, air dried,

and the number of clones that contained above 50 cells was calculated, according to the formula: cloning rate = average clone number/500  $\times$  100%.

### Cell cycle and apoptosis rate analysis by flow cytometry

For analysis of DNA content, cells treated with different *H. pylori* culture broths were harvested after 72 h and fixed with 70% cold ethanol for 4 h. The apoptosis rate was detected by flow cytometry (FACSalibur, BD Biosciences). Briefly,  $1 \times 10^6$  cells/mL were suspended in 0.2% triton X-100/PBS solution containing 1 g/L ribonuclease A. After incubation for 20 min, DNA was stained with 50 mg/L propidium iodide. Flow cytometry was performed to determine the apoptosis rate.

### Single-cell microgel electrophoresis (comet assay)

The alkaline comet assay in single-cell suspensions was performed according to the method of Singh *et al*<sup>[23]</sup>, with some modifications<sup>[24]</sup>. Briefly, 15  $\mu$ L of the single cell suspension ( $2 \times 10^4$  cells) was embedded in 0.5% low-melting-point agarose (Sigma) and spread on agarose-precoated microscope slides. Slides were immersed overnight at 4°C in freshly prepared cold lysis solution [2.5 mol/L NaCl, 100 mmol/L EDTA, 10 mmol/L Tris, 1% sodium salt N-lauryl sarcosine (pH 10), with 1% triton X-100, and 10% DMSO added fresh; all supplied by Sigma]. Subsequently, the cells were exposed to alkaline buffer (1 mmol/L EDTA and 300 mmol/L NaOH, pH 13.4) at 4°C for 40 min, to allow DNA unwinding, and expression of alkali-labile sites. In the same solution, electrophoresis was conducted at 4°C for 20 min, at 25 V and 300 mA. After electrophoresis, the slides were neutralized (0.4 mol/L Tris, pH 7.5), stained with 40  $\mu$ L ethidium bromide (EtBr) (20  $\mu$ g/mL), and analyzed with a fluorescence microscope (Axioplan II; Zeiss, Oberkochen, Germany), under green light at 400 nm, using an image analysis system (Comet Assay II; Perceptive Instruments, Suffolk, UK). Two hundred randomly selected cells (100 from each of two replicate slides) were evaluated from each sample, and the mean of the tail moment was determined. Tail moment according to Comet Assay II is defined as "the product of DNA in the tail, and the mean distance of migration in the tail. It is calculated by multiplying tail intensity/sum of comet intensity by tail center of gravity minus peak position." Using this method, the extent of DNA migration is related to the level of DNA damage in each cell, which creates the comet tail images.

### Gastric epithelial cell morphology

Gastric epithelial cells treated continuously for 1 mo were collected and digested by 0.25% trypsin to yield a cell suspension, centrifuged at 1000 *g* for 10 min. The supernatant was removed, and the precipitate was fixed with 5% glutaraldehyde. Ultrathin sections were cut and observed under an electron microscope (H-600, Hitachi, Japan).

### Statistical analysis

All data were expressed as mean  $\pm$  SE. SPSS 10.0

**Figure 1** Cell proliferation determined by MTT assay.  $P < 0.05$ , CagA+ vs control and CagA+ vs CagA-.

**Figure 2** S-phase cells.  $P < 0.05$ , CagA+ vs CagA-.

software was used for one-way analysis of variance and  $q$  test.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Western blotting of CagA and cell proliferation determined by MTT assay

CagA expression was detected in the CagA+, CagA- and control groups. GES-1 cells proliferated actively when treated by CagA and *H pylori* culture filtrates. There were significant differences between the two groups (Figure 1).

### Flat clone formation test

After treatment with *H pylori* culture filtrates, the flat clone formation test in the CagA+ group showed that the GES-1 clone number was larger than that of the CagA-, and control groups (200 vs 88.12,  $P = 0.005$ ). The clone formation rates were 40%, 17.6% and 2.4%, respectively. Statistical analysis revealed a significant difference between the CagA+ and CagA- groups.

### Effects of culture filtrates on GES-1 cell cycle and apoptosis rate

Flow cytometry showed that the number of S-phase cells increased more in the CagA+ group than in the control group at 1, 3 and 6 d (33.03% vs 9.16%, 53.46% vs 6.83%, and 35.55% vs 8.10%, respectively), which was higher than in the CagA-group ( $P = 0.034$ ). After GES-1 cells had been treated with different *H pylori* culture filtrates

**Table 1** Determination of DNA damage by single-cell microgel electrophoresis

	CagA+	CagA-	Control
Comet cell rate (%)	41.2 <sup>a</sup>	12.5	5
Comet tail length	78.6 ± 5.0 <sup>a</sup>	14.2 ± 6.3	6.8 ± 2.1

<sup>a</sup> $P < 0.05$  vs control and CagA-.

**Figure 3** DNA damage measured by single-cell microgel electrophoresis. A: Comet tails in control group; B: Comet tails in CagA- group; C: Comet tails in CagA+ group.

for 1 mo, the detection of apoptotic cells was carried out by flow cytometry, and repeated eight times. The mean percentage of hypodiploid cells in the CagA+, CagA- and control cells was 5.6%, 4.4% and 3.7%, respectively. Statistical analysis revealed no significant difference among the three groups (Figure 2).

### Determination of DNA damage by single-cell microgel electrophoresis

Single-cell microgel electrophoresis showed in the control group that the ratio of comet cells was 5%, less than that in the CagA+ and CagA- groups. There were more comet cells after treatment with CagA+ broth than in the CagA- group, (41.2% vs 12.5%,  $P = 0.024$ , Table 1). The average comet tail length in the CagA+ group was  $78.6 \pm 5.0$ , which was larger than that in the CagA-group ( $14.2 \pm 6.3$ ,  $P = 0.036$ , Figure 3).

### Cell morphology

Electron microscopy revealed dyskaryosis, nucleolar hypertrophy and karyokinesis in CagA-treated cells (Figure 4C), compared to the control and CagA- groups.

## DISCUSSION

Infection with strains of *H pylori* that carry the *CagA*-gene is associated with gastric carcinoma. The mechanism is still not clear. Recent studies have shown that the *CagA*-gene product is delivered to gastric epithelial cells by the bacterial type IV secretion system to deregulate the SHP2 oncoprotein, which can promote gastric carcinogenesis<sup>[14-19]</sup>.

In the present study, we prepared different *H pylori* culture filtrates containing the CagA protein to treat gastric epithelial cells. We found that GES-1 cells, after being treated with *CagA*-gene-positive culture filtrates, showed dyskaryosis, nucleolar hypertrophy and karyokinesis. The growth curve showed that GES-1 cells proliferated actively, and colony formation reached 40%. The number of S-phase cells obviously increased compared to the

**Figure 4** GES-1 treated with different *H. pylori* filtrates. **A:** Control group; **B:** CagA-group; **C:** CagA+ group.

controls. These results demonstrate that CagA+ filtrates of *H. pylori* can induce carcinogenesis in gastric epithelial cells. Research has shown that reconstruction of CagA fragment induces paraplastic changes in epithelial cells *in vitro*, which supports the suggestion that CagA is involved in gastric carcinogenesis<sup>[20-21]</sup>. All these results support our findings.

Ladeira *et al.*<sup>[25]</sup> have used the comet assay or single-cell gel electrophoresis to investigate the status of DNA damage in gastric epithelial cells from the antrum and corpus in patients with *H. pylori* infection, and gastritis of varying degrees. They have demonstrated that the level of DNA damage in *H. pylori*-infected individuals is significantly higher than that in non-infected individuals, with the levels of DNA damage significantly higher in those aged  $\geq 50$  years.

The DNA repair enzyme human oxoguanine glycosylase 1 (hOGG1) is known to be responsible for the repair of the 8-hydroxy-deoxyguanosine (8-OHdG) region. Of the hOGG1 polymorphisms identified, a Ser $\rightarrow$ Cys polymorphism at position 326 has been found to interact with atrophic gastritis, but not with antioxidant dietary or nutrient intakes. It is likely that this makes patients with atrophic gastritis, who also have the hOGG1 Cys allele, more susceptible to gastric cancer<sup>[26]</sup>. The concentrations of 8-OHdG, inducible nitric oxide synthase (iNOS), nuclear factor  $\kappa$ B, myeloid cell leukemia-1, and inhibitor of apoptosis protein are significantly higher in patients with *H. pylori* infection, and in those with stage 3 and 4 gastric cancer. This points to the pivotal role that oxygen-free-radical-mediated DNA damage caused by *H. pylori* infection plays in the development of gastric carcinoma from chronic gastritis<sup>[27]</sup>. Single-cell gel electrophoresis is a simple and sensitive method for detecting DNA damage in cells. In this study, we found 41.2% of CagA+ cells formed comet tails. This shows that CagA+ culture broth filtrate has the ability to cause DNA breakage or damage, which may lead to the transformation of gastric epithelial cells.

*H. pylori*-associated inflammation related to DNA damage is indicated by increased levels of oxidative DNA damage, increased occurrence of apoptosis and proliferation, as well as increased expression of iNOS, which seems to provide the mechanistic link between

*H. pylori* infection and gastric carcinogenesis<sup>[28,29]</sup>. Upregulation of iNOS expression might contribute to the oxidative DNA damage observed during *H. pylori* infection<sup>[30]</sup>. Yabuki *et al.*<sup>[31]</sup> have investigated cell proliferation and DNA damage in ablation samples from 35 cases of gastric carcinoma, and have indicated that cell damage in *H. pylori*-infected human gastric mucosa increases cell proliferation.

We found that CagA+ culture broth filtrate induced DNA damage in human gastric epithelial cells *in vitro*, which suggests that CagA is involved in DNA damage in gastric epithelial cells. All results showed that CagA+ broth culture filtrates of *H. pylori* could accelerate human gastric epithelial cell growth and alter their morphology. It is not clear that there are other factors apart from CagA involved in the transformation of gastric epithelial cells induced by CagA+ culture broth filtrate.

## ACKNOWLEDGMENTS

We thank Dr. Wei Cheng and Dr. Ji-Zong Zhao and Zheng Lin, Director of General Surgery Laboratory, for their assistance with the culture of *H. pylori*. We are also grateful to Dr. Bo Hu who provided assistance with molecular biology.

## COMMENTS

### Background

It is widely accepted that there is a strong association between *Helicobacter pylori* (*H. pylori* infection) and gastric cancer, but the exact molecular mechanism of the pathogen in gastric carcinogenesis has not yet been clarified. DNA damage is involved in the carcinogenesis process. Single-cell gel electrophoresis is a simple and sensitive method for detecting DNA damage in cells.

### Research frontiers

There has been considerable interest in recent years in virulence factors, such as CagA protein, which predispose individuals to develop gastric carcinoma. Understanding DNA damage in gastric epithelial cells will provide us with a new strategy for effective prevention of gastric cancer induced by *H. pylori* infection. It is also helpful to clarify CagA protein carcinogenesis.

### Innovations and breakthroughs

In this study, the mechanism of *H. pylori* infection in gastric carcinogenesis was explored by studying its effects on DNA damage in gastric epithelial cells *in vitro*. The results suggest that *H. pylori* can induce DNA damage in cultured gastric epithelial cells, and the effect of CagA+ strains was more significant than CagA- strains.

## Applications

This study emphasizes the close relationship between *H pylori*, especially CagA+ strains, and gastric carcinoma. It provides a new approach to elucidating the mechanism of *H pylori* gastric carcinogenesis. It also implies that compounds able to repair DNA damage in *H pylori*-infected cells may be used to create new strategies for the prevention and/or treatment of human gastric malignancy.

## Peer review

This study seems innovative and interesting. Products of DNA damage have been observed in various pathological processes of the digestive tract, including gastric cancer. To the best of our knowledge, there are still many aspects of the mechanism of *H pylori* infection in gastric carcinogenesis to explore, by studying its effects on DNA damage in gastric epithelial cells *in vitro*.

### Abstract

**AIM:** To evaluate the clinical value of serum CA19-9 levels in predicting the resectability of pancreatic carcinoma according to receiver operating characteristic (ROC) curve analysis.

**METHODS:** Serum CA19-9 levels were measured in 104 patients with pancreatic cancer which were possible to be resected according to the imaging. ROC curve was plotted for the CA19-9 levels. The point closest to the upper left-hand corner of the graph were chosen as the cut-off point. The sensitivity, specificity, positive and negative predictive values of CA19-9 at this cut-off point were calculated.

**RESULTS:** Resectable pancreatic cancer was detected in 58 (55.77%) patients and unresectable pancreatic cancer was detected in 46 (44.23%) patients. The area under the ROC curve was 0.918 and 95% CI was 0.843-0.992. The CA19-9 level was 353.15 U/mL, and the sensitivity and specificity of CA19-9 at this cut-off point were 93.1% and 78.3%, respectively. The positive and negative predictive value was 84.38% and 90%, respectively.

**CONCLUSION:** Preoperative serum CA19-9 level is a useful marker for further evaluating the resectability of pancreatic cancer. Obviously increased serum levels of CA19-9 (> 353.15 U/mL) can be regarded as an ancillary parameter for unresectable pancreatic cancer.

### INTRODUCTION

The prognosis of pancreatic cancer is extremely poor and its early diagnosis is difficult<sup>[1,2]</sup>. Surgical resection offers the best chance of cure. However, local vascular involvement, nodal and distant metastases are frequently found at the time of diagnosis, thus losing the opportunity of operation<sup>[3]</sup>. At present, the best way for preoperative staging of pancreatic cancer is bolus-contrast, and triple-phase helical computed tomography, which has been shown to be almost 100% accurate in predicting unresectable disease<sup>[4-6]</sup>. However, approximately 25%-50% of patients with resectable disease on computed tomography are found to have unresectable lesions at laparotomy<sup>[7]</sup>.

CA19-9 is the most widely used pancreatic cancer serum marker. Serum CA19-9 level has been shown to correlate with the thyroid node metastasis (TNM) staging, and tumor size in patients with pancreatic cancer<sup>[8]</sup>. However, little is known about the value of serum CA19-9 level in evaluating the resectability of pancreatic carcinoma.

Receiver operating characteristic (ROC) curve has been widely accepted as the standard method for describing and comparing the accuracy of medical diagnostic tests<sup>[9,10]</sup>. ROC curve is an efficient way to display and assess the predictive value of cut-off points.

In this study, we evaluated the clinical value of serum CA19-9 level in predicting the resectability of pancreatic carcinoma according to ROC curve analysis.

### MATERIALS AND METHODS

We retrospectively reviewed the clinical and imaging data

Table 1 Characteristics of patients (*n* = 104)

Characteristics	Data, <i>n</i> (%)
Age (yr)	59 ± 9 (mean ± SD)
Sex	
Male	72 (69.2)
Female	32 (30.8)
Location of tumors	
Head	86 (82.7)
Body	8 (7.7)
Body and tail	10 (9.6)
Type of operation	
Pancreaticoduodenectomy	48 (46.2)
Distal pancreatectomy	10 (9.6)
Exploratory laparotomy and biopsy	46 (44.2)

Table 2 CA19-9 levels in patients with resectable and unresectable pancreatic cancer

Group	<i>n</i>	CA19-9 (U/mL)			Wilcoxon	
		<i>Q</i> <sub>1</sub>	<i>Q</i> <sub>2</sub>	<i>Q</i> <sub>3</sub>	<i>Z</i>	<i>P</i>
Resectable	58	15.57	130.10	270.25	-5.132	0.000
Unresectable	46	361.30	656.20	1780.00		

including preoperative CA19-9 level in 104 patients with pancreatic cancer who underwent surgical resection at the Affiliated Hospital of Qingdao University Medical College from January 2001 to July 2007. Pancreatic adenocarcinoma was histologically confirmed. Resectability of pancreatic cancer was evaluated at least by preoperative bolus-contrast, triple-phase helical computer tomography (CT) scan.

Resectability was defined as a tumour limited to the pancreas with no invasion of the superior mesenteric artery and vein, portal vein and metastases (celiac lymph, peritoneum or liver).

Serum levels of CA19-9 and total serum bilirubin levels were measured before surgery (normal 0-39.0 U/mL for CA19-9, 3.4-17.1  $\mu$ mol/L for total serum bilirubin).

The data were described using *Q*<sub>1,3</sub>. Differences between groups were detected using the Wilcoxon 2-sample test. Serum CA19-9 levels were used to plot the ROC curve, and calculate the area under the curve (AUC). We chose the point closest to the upper left-hand corner of the graph as the cut-off point. The sensitivity, specificity, positive and negative predictive values of CA19-9 at this cut-off point were calculated. *P* < 0.05 was considered statistically significant.

## RESULTS

Of the 104 patients, 72 were males and 32 were females with a mean age of 59 years (range 41-75 years). The pancreatic tumor was confined to the head, body and tail of the pancreas in 86, 8, and 10 patients, respectively. Forty-eight patients underwent pancreatic-oduodenectomy, 10 patients distal pancreatectomy, and 46 only exploratory laparotomy and biopsy. The general characteristics of the patients are listed in Table 1.

The distribution of preoperative serum CA19-9 levels

Figure 1 Distribution of preoperative serum CA19-9 levels. The horizon marker is set according to the cut-off point of CA19-9 (353.15 U/mL).

Figure 2 ROC analysis of CA19-9. Perfect discrimination has a ROC plot passing through the upper left corner (100% sensitivity, 100% specificity). The closer the ROC plot to the upper left corner, the higher the overall accuracy of the test (AUC: 0.9-1 indicating excellent; 0.8-0.9 indicating very good; 0.7-0.8 indicating good; 0.6-0.7 indicating average; 0.5-0.6 indicating poor). The AUC of CA19-9 was 0.918.

is shown in Figure 1. The *Q*<sub>2</sub> (median) preoperative serum CA19-9 level in patients with unresectable tumor was 5-fold higher than that in patients with resectable tumor (Table 2). The difference between two groups was significant (*P* < 0.01). The mean total serum bilirubin level in patients with resectable and unresectable tumor was 28.6  $\mu$ mol/L and 34.4  $\mu$ mol/L, respectively (*P* > 0.05). Therefore, the CA19-9 levels were not adjusted.

Figure 2 shows the ROC curve. The AUC was 0.918 and 95% CI was 0.843-0.992, suggesting that changes in serum CA19-9 levels may have a direct relation to resectability<sup>[11,12]</sup>. When the cut-off value of CA19-9 was 353.15 U/mL according to the point closest to the upper left-hand corner of the graph, the sensitivity and specificity were 93.1% and 78.3%, respectively. The preoperative resectability according to the cut-off point was compared with the actual operation, and the positive and negative predictive value of CA19-9 was 84.38% and 90.00%, respectively (Table 3).

## DISCUSSION

Pancreatic cancer is one of the most common causes for

**Table 3** Positive and negative predictive values of CA19-9 at the cut-off point

	Resection		Total	Predictive value
	Yes	No		
CA19-9 (U/mL)	≤ 353.15	54	10	64
	> 353.15	4	36	40
Total	58	46	104	

cancer-related death. The overall five-year survival rate ranges from 0.4% to 4%, the lowest for any cancer<sup>[1,13]</sup>. Early diagnosis of pancreatic cancer is difficult because its early symptoms are usually non-specific. Local vascular involvement, nodal and distant metastases are frequently found at the time of diagnosis<sup>[14]</sup>.

Recently, considerable improvements in radiological imaging make it possible to limit surgery for patients who will benefit<sup>[15,16]</sup>. The current methods of choice for diagnosing and staging pancreatic cancer are thin section, contrast-enhanced, and triple-phase helical computed tomography<sup>[17,18]</sup>. However, approximately 25%-50% of patients with resectable disease on computed tomography are found to have unresectable lesions at laparotomy<sup>[7,19]</sup>. Although magnetic resonance imaging is increasingly used in the evaluation of pancreatic tumor, it was reported that it offers no significant diagnostic advantage over computed tomography<sup>[20]</sup>. Endoscopic retrograde cholangio pancreatography (ERCP) is more controversial for patients with a mass on CT<sup>[21]</sup>. B-mode ultrasonography is operator-dependent and may be inaccurate due to factors such as large body habitus, presence of ascites, or overlying bowel gas. Therefore we should find other ways to further evaluate the resectability of pancreatic cancer.

CA19-9 is a tumor-associated antigen, initially described by Koprowski *et al*<sup>[22]</sup>. The sensitivity and specificity of CA19-9 for the diagnosis of pancreatic cancer are higher than those of CEA, CA50 and CA242<sup>[23-25]</sup>. CA19-9 has become a predominant tumor marker for the diagnosis of pancreatic adenocarcinoma. It was reported that CA19-9 level is useful in diagnosis and prognosis of pancreatic cancer<sup>[26,27]</sup>. However, little is known about the value of serum CA19-9 levels in evaluating the resectability of pancreatic carcinoma<sup>[28]</sup>. This study was to find whether preoperative serum CA19-9 is a useful marker for evaluating the resectability of pancreatic cancer.

In the present study, the differences between patients with resectable and unresectable pancreatic cancer were significant ( $P < 0.01$ ). The AUC was 0.918 and 95% CI was 0.843-0.992, suggesting that the preoperative serum CA19-9 level is an efficient marker for evaluating the resectability of pancreatic carcinoma. When the cut-off value of CA19-9 was 353.15 U/mL according to the point closest to the upper left-hand corner of the graph, the sensitivity, specificity, positive and negative predictive value was 93.1%, 78.3%, 84.38% and 90%, respectively, indicating that increased serum levels of CA19-9 ( $> 353.15$  U/mL) can be regarded as an ancillary parameter for the unresectable pancreatic cancer<sup>[29]</sup>. Pancreatic

cancer was resectable only in 4 patients whose preoperative serum CA19-9 level was over 353.15 U/mL (Table 3 and Figure 1).

Kilic *et al*<sup>[30]</sup> reported that the sensitivity, specificity, positive and negative predictive value are 82.4%, 92.3%, 91.4% and 83.9%, respectively, in 51 patients, and the cut-off value of CA19-9 is 256.4 U/mL. Their results are similar to our data, but the cut-off value was lower than that in our study (256.4 U/mL *vs* 353.15 U/mL). The discrepancy may be due the sample size, and the unadjusted CA19-9 level according to the bilirubin level.

In conclusion, a preoperative serum CA19-9 level is a useful marker for evaluating the resectability of pancreatic cancer. Increased serum levels of CA19-9 ( $> 353.15$  U/mL) can be regarded as an ancillary parameter for unresectable pancreatic cancer.

## COMMENTS

### Background

At present, the best way of preoperative staging of pancreatic cancer is bolus-contrast and triple-phase helical computed tomography. However, approximately 25%-50% of patients with resectable disease on computed tomography are found to have unresectable lesions at laparotomy.

### Research frontiers

CA19-9 is the most widely used serum marker of pancreatic cancer. CA19-9 has been shown to correlate with the thyroid node metastasis (TNM) staging and tumor size in patients with pancreatic cancer. However, little is known about the value of serum CA19-9 levels in evaluating the resectability of pancreatic carcinoma.

### Innovations and breakthroughs

Receiver operating characteristic (ROC) curve analysis was used to evaluate the clinical value of serum CA19-9 levels in predicting the resectability of pancreatic carcinoma.

### Applications

Preoperative serum CA19-9 level may be a useful marker for evaluating the resectability of pancreatic cancer. Increased serum level of CA19-9 ( $> 353.15$  U/mL) may be regarded as an ancillary parameter for unresectable pancreatic cancer.

### Terminology

CA19-9 is a tumor-associated antigen initially described by Koprowski *et al* and has been widely used as a serum marker of pancreatic cancer. ROC curve has been widely accepted as the standard method for describing and comparing the accuracy of medical diagnostic tests. ROC curve is an efficient way to display and assess the predictive value of cut-off points.

### Peer review

This is a very interesting study. The authors used ROC analysis as an appropriate statistical method for defining the cut-off value of serum CA19-9 to discriminate between resectable and unresectable pancreatic cancer.

### Abstract

**AIM:** To evaluate the inhibitory effects of human fragile histidine triad (FHIT) gene on cell proliferation and apoptosis in human hepatocellular carcinoma line Hep3B *in vitro*.

**METHODS:** A recombinant pcDNA3.1 (+)/FHIT including the functional region of FHIT gene was constructed and transferred into human hepatocellular carcinoma cells *in vitro*. mRNA and protein expression of the FHIT gene in the transfected cells was detected by RT-PCR and Western blot, respectively. The effect of FHIT on proliferation was detected by MTT assay. Changes in cell cycle and apoptosis were assayed by flow cytometry. Five mice received subcutaneous transplantation of Hep3B-FHIT; 5 mice received subcutaneous transplantation of normal Hep3B and Hep3B-C as controls. The body weight of nude mice and tumor growth were measured.

**RESULTS:** RT-PCR and Western blot analysis showed that the expression level of FHIT-mRNA and FHIT protein was higher in Hep3B cells after infection with

pcDNA3.1 (+)/FHIT. The growth of Hep3B cells treated with pcDNA3.1 (+)/FHIT was significantly inhibited. The pcDNA3.1 (+)/FHIT-transfected Hep3B cells showed a significantly higher cell rate at G<sub>0</sub>-G<sub>1</sub> phase and increased apoptosis in comparison with controls ( $P < 0.05$ ). The growth of transplanted tumor was inhibited markedly by FHIT. Tumors arising from the Hep3B-FHIT cells occurred much later than those arising from the Hep3B and Hep3B-C cells. The growth of Hep3B-FHIT cells was slow and the tumor volume was low.

**CONCLUSION:** Transduction of FHIT gene inhibits the growth of human hepatocellular carcinoma cells and induces cell apoptosis *in vivo* and *in vitro*.

Effect of fragile histidine triad gene transduction on proliferation and apoptosis of human hepatocellular carcinoma cells. *World J Gastroenterol* 2008; 14(23): 3754-3758 Available from: URL: <http://www.wjgnet.com/1007-9327/14/3754.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.3754>

### INTRODUCTION

Fragile histidine triad (FHIT) gene has been successfully cloned on chromosome 3p14.2 using an exon trapping method for gene capture<sup>[1-4]</sup>. It was reported that abnormal FHIT gene exists in majority of tumors, and is an important candidate tumor-suppressing gene<sup>[5-10]</sup>. In the hepatoma cell line Hep3B, the FHIT gene, mRNA, and protein are abnormal<sup>[11]</sup>. We constructed a recombinant pcDNA3.1 (+) /FHIT vector containing human (FHIT) gene, which was used to transfect human hepatoma Hep3B cells *in vitro* and *in vivo* to explore the

effect of *FHIT* gene on proliferation or apoptosis of hepatocellular carcinoma cells.

## MATERIALS AND METHODS

### **Bacteria, plasmids and cells**

*E. coli* DH5 $\alpha$  and eukaryotic expression vector pcDNA3.1 (+) were routinely kept in our laboratory. PBluescript SK *FHIT* plasmid with a full-length *FHIT* cDNA was kindly given by Professor Xiao-Fan Wang, Duke University, USA. Hep3B cells were purchased from the Chinese Academy of Sciences in Shanghai.

### **Main reagents**

A reverse transcription-polymerase chain reaction (RT-PCR) kit was purchased from Takara, Japan. *FHIT* antibody was purchased from Zymed, USA. A cell cycle assay kit was purchased from Becton Dickinson, USA.

### **Enzyme cutting and identification of DNA sequence**

To establish an enzyme-cutting reaction, pcDNA3.1 (or PBluescript SK *FHIT*), *Bam*H I and *Xba* I were mixed in a water bath at 37°C for 2 h. The mixture was electrophoresed, and 1.0 kb *FHIT* gene fragments, and a 5.4 kb linear pcDNA3.1 were retrieved separately with electrophoresis coagulation plastic boxes. For constructing the pcDNA3.1 (+) /*FHIT* vector, *FHIT* gene fragments, linear pcDNA3.1 and T4 ligase were mixed in an Eppendorf tube at 16°C for 12 h to establish a recombinant plasmid reaction. The pcDNA3.1 *FHIT* vector was transferred into competent bacteria DH5, and the clones were cultured and identified.

### **Cell culture and transfection**

Hep3B cells were cultured at 37°C in Dulbecco's modified Eagle's medium containing 10% fetal calf serum (Gibco), 1.0 mmol/L sodium pyruvate, 0.1 mmol/L non-indispensable amino acid and 5% CO<sub>2</sub>, at a saturated humidity. Hep3B cells with strong growth were seeded in 6-well plates. pcDNA3.1 (+) /*FHIT* was transfected into the Hep3B cells at the density of 70% with Lipofectamine 2000 (liposome transfection kit) following its manufacturer's instructions. After transfection, the cells were screened using G418 (500 mg/L) and the screening was maintained with G418 (250 mg/L). Hep3B cells transfected with *FHIT* gene and empty vector were named Hep3B-*FHIT* and Hep3B-C, respectively. Parent Hep3B cells were used as an untransfected control.

### **RT-PCR**

*FHIT* gene was amplified with primers (P1: 5'-ATGTCGTTTCAGA-3', P2: 5'-CTGAAAGTACAC-3') using the Hep3B-*FHIT* cells screened by G418<sup>[12]</sup>. Total RNA was extracted with TRIZOL method and underwent reverse-transcription PCR. The PCR products were electrophoresed on a 1% agarose gel. One  $\mu$ L of the resulting cDNA was added into the PCR reaction mixture (containing 1.0  $\mu$ L of forward primer (10 pmol/ $\mu$ L), 1.0  $\mu$ L of reverse primer (10 pmol/ $\mu$ L),

1.0  $\mu$ L of dNTPs (10 mmol/L), 0.5  $\mu$ L Taq DNA polymerase). PCR was performed for 30 cycles, each amplification cycle consisting of denaturation at 94°C for 1 min, primer annealing at 44°C for 1 min, and extension at 72°C for 45 s. The PCR products were analyzed on 10 g/L agarose gel containing ethidium bromide.

### **Western blot**

The screened Hep3B-*FHIT* cells were lysed with a cell-lysing solution. The protein concentration in the supernatant after centrifugation was measured by Bradford assay. The supernatant was electrophoresed on a 12% SDS-polyacrylamide gel. The electrophoresed proteins were transferred to nitrocellulose membrane, blocked with calf serum, combined with *FHIT* antibody and horseradish peroxidase secondary antibody, developed by enhanced chemiluminescence (ECL) and photographed.

### **Measurements of growth capacity of transfected cells by thiazolyl tetrazolium (MTT) assay**

Ten thousand cells/well were seeded in 96-well plates (200  $\mu$ L/well), with 6 wells for each cell group and 3 wells for control. MTT (5 g/L) was used as an incubation solution. DMSO was added to the cell culture for 4 h. The luminous absorbance was measured by ELISA (wavelength of 570 nm). The measurement was repeated once a day for 6 days.

### **Flow cytometry analysis of cell cycle and apoptosis**

After trypsinization, the cells were washed twice with phosphate-buffered saline (PBS), fixed with cold ethanol (70%) overnight, suspended in PBS after ethanol was purged from PBS, and stained with propidium iodide (50  $\mu$ g/mL). The samples were examined by flow cytometry.

### **Animal experiments**

After forty-eight hours, 2  $\mu$ g of pcDNA3.1 (+) and pcDNA3.1 (+)/*FHIT* plasmid was transfected with Lipofectamine 2000 into Hep3B cell lines, and clones were obtained by screening with G418 for 14 d. The clones were cultured. The study was approved by the Experimental Animal Committee of Tongji Medical College, Huazhong University of Science and Technology, and all animal experiments adhered to the Animal Welfare Committee Guidelines. Male athymic BALB/c nu/ nu mice (4-6 wk old) were obtained from the Institute of Materia Medica (Tongji Medical College, Wuhan, China) and housed in laminar-flow cabinets under specific pathogen-free (SPF) conditions. Fifteen male mice were randomized into Hep3B-*FHIT*/nude, Hep3B-C/nude and Hep3B/nude groups, 5 in each group. A suspension of Hep3B-*FHIT* or Hep3B-C or Hep3B cells (10<sup>7</sup> cells in 0.15 mL Hanks' solution) was injected into the back of mice in each group. After implantation, tumor growth was detected weekly by measuring its diameter with a Vernier caliper. Tumor volume (TV) was calculated using the following formula: TV (mm<sup>3</sup>) = d<sup>2</sup>  $\times$  D/2, where d is the shortest diameter and D

is the longest diameter. Animals were sacrificed 7 wk after implantation, and samples were harvested. The body weight of mice, and tumor growth were measured.

### Statistical analysis

The data were expressed as mean  $\pm$  SD. Student's two-sided *t*-test was used to compare the values of the test and control samples by software SPSS11.5. *P* < 0.05 was considered statistically significant.

## RESULTS

### Identification of plasmid

The sequence of PBluescript SK FHIT detected in Shanghai Biological Engineering Company was identical to that of FHIT mRNA in GenBank (Lot. Number: NM-002012). After enzyme-cut, agarose gel electrophoresis showed two DNA bands of plasmid PBluescript FHIT (1.0 kb and 2.7 kb), two DNA bands of plasmid pcDNA3.1 (+)/FHIT (1.0 kb and 5.4 kb) (Figure 1); thus, pcDNA3.1 (+)/FHIT was successfully constructed.

### FHIT-mRNA expression in transfected cells

After transfected with pcDNA3.1 (+)/FHIT, RT-PCR showed a 400 bp band of Hep3B-FHIT cells. However, the empty vector-transfected, or native cells did not show any band (Figure 2A).

### FHIT protein expression in transfected cells

Western blotting demonstrated FHIT protein (17 kDa) in the cells transfected with pcDNA3.1 (+)/FHIT, but no FHIT protein in empty vector-transfected or native cells (Figure 2B).

### Growth rates before and after transfection

Thiazolyl tetrazolium (MTT) assay showed that the growth rate of transfected cells was significantly lower than that of native or empty vector-transfected cells, especially after the logarithm growth phase (*P* < 0.05, Figure 3A).

### Changes in cell cycle and apoptosis rate

Flow cytometry analysis revealed that the number of Hep3B cells decreased in the G<sub>2</sub>/M and S phases, but increased in the G<sub>0</sub>/G<sub>1</sub> phase. The apoptosis rate was higher for transfected cells than for empty vector-transfected or native cells (*P* < 0.05, Table 1).

### Tumor growth

The growth of transplanted tumor was inhibited markedly by FHIT, showing that tumors arising from the Hep3B-FHIT cells occur much later than those arising from the Hep3B and Hep3B-C cells. Hep3B-FHIT cells grew slowly and their volume was small (Table 2, Figure 3B).

## DISCUSSION

It has been reported that FHIT is the first cancer-suppressive gene which links fragile sites to tumors.

**Figure 1** Identification of pcDNA3.1 (+)/FHIT by enzyme-cutting assay. M1: Marker  $\lambda$ /DNA/EcoR I + Hind III; M2: Marker DL2000, lane 1: pcDNA3.1 (+)/FHIT, lane 2: pcDNA3.1 (+)/FHIT post enzyme cutting.

**Figure 2** Expression of FHIT mRNA and protein in Hep3B-FHIT, Hep3B-C and Hep3B cells. **A:** FHIT mRNA; **B:** FHIT protein. M: 1000 bp marker; Lane 1: Hep3B cells; lane 2: Hep3B-C cells; lane 3: Hep3B-FHIT cells.

Abnormality of the *FHIT* gene is an early event during tumor development<sup>[13-17]</sup>. Fracture at the fragile site results in mutation and inactivation of the *FHIT* gene; thus leading to abnormal cell growth<sup>[18-22]</sup>. Like many other tumors, hepatoma is characterized by highly mutated *FHIT* gene or gene loss. Yuan *et al*<sup>[11]</sup> found that down-regulation of the *FHIT* gene is detected in 64.3% cell lines (four cell lines showing mRNA down-regulation did not express FHIT protein); allelic loss of intron 5 of the *FHIT* gene was detected in 29.4% hepatomas by *in situ* hybridization; structural alterations of chromosome 3p were identified in 61.5% of hepatocellular carcinomas; expression of FHIT protein was not detectable in 50% primary tumors with immunostaining<sup>[11]</sup>.

FHIT may modulate APnA by hydrolysis of APnA to yield adenosine 5'-monophosphate (AMP). Due to mutation of FHIT, loss of APnA hydrolase activity results in elevated AP3A levels, intracellular accumulation of APnA strengthens the growth signal transduction,

**Figure 3** Growth curves. **A:** Growth curves of human hepatocellular carcinoma cells. Luminous absorbance of Hep3B-FHIT, Hep3B-C and Hep3B cells was measured by ELISA (wavelength of 570 nm) after DMSO was added. The measurement was done once a day for 6 d; **B:** Growth curves of tumors after implantation of Hep3B, Hep3B-C or Hep3B-FHIT cells in nude mice. The mice were injected sc with  $1 \times 10^7$  (0.15 mL/mouse) Hep3B, Hep3B-C or Hep3B-FHIT cells. After implantation, tumor growth was detected weekly.

and blocks growth inhibition and apoptosis, thus contributing to carcinogenesis. Additionally, the activity of FHIT on mRNA cap analogs raises the possibility that failure of a decapping function might be tumorigenic<sup>[12,23,24]</sup>.

Gramantieri *et al.*<sup>[13]</sup> examined the mRNA FHIT expression in both cancerous and matched non-cancerous tissues in 28 cases of hepatocellular carcinoma (HCC) and 10 normal livers, and abnormal FHIT transcripts were detected in 13 cases (in cancerous tissue from 11 cases and in non-cancerous tissue from 2 cases). No abnormal FHIT transcripts were found in normal livers. It was recently reported that many other factors can also induce liver carcinogenesis in rats<sup>[25-29]</sup>.

Siprashvili *et al.*<sup>[30]</sup> found that transduction of wild-type FHIT or mutative FHIT with no hydrolase activity into tumor cells lacking FHIT gene did not show any advantage to cell growth, and no difference was found in suppression of tumorigenicity, suggesting that FHIT suppresses the tumorigenicity through FHIT protein in combination with its substrate rather than through hydrolysis of APnA. Its more precise mechanism needs to be further explored.

In this study, the full-length of the FHIT cDNA eukaryotic expression vector was transfected into human hepatocellular carcinoma cell line, Hep3B, to manipulate FHIT expression, which alters the biological features of Hep3B cell line. The results indicate that successfully

**Table 1** Effect of FHIT gene on cell growth and apoptosis in human hepatocellular carcinoma (mean  $\pm$  SD)

Cell type	G <sub>0</sub> /G <sub>1</sub>	S	G <sub>2</sub> /M	Apoptosis rate (%)

Hep3B-C/nude	3.08 $\pm$ 0.34	3.94 $\pm$ 0.39
Hep3B-FHIT/nude	12.17 $\pm$ 1.19	0.60 $\pm$ 0.04
Total <i>F</i> value	72.38	168.36
Total <i>P</i> value	0.00	0.00

transfected Hep3B cells could express FHIT mRNA and FHIT protein, whereas the empty-vector transfected Hep3B or native cells did not express them. Moreover, cell proliferation and differentiation were significantly decreased at the G<sub>2</sub>/M and S phases, and cell apoptosis increased at the G<sub>0</sub>/G<sub>1</sub> phases of Hep3B cells transfected with FHIT gene as compared with the control group, suggesting that FHIT gene plays an important role in blocking cell growth at the G<sub>1</sub> phase, and in inducing cell apoptosis synergized by other apoptosis-inducing factors. Furthermore, transfer of FHIT gene could inhibit the growth of human hepatocellular carcinoma cells, and induce cell apoptosis *in vivo*.

In conclusion, FHIT mRNA, and protein are expressed in FHIT-infected Hep3B cells, thus leading to low proliferation, and high apoptosis of HCC cells. Transfection of FHIT gene into human hepatocellular carcinoma cells is a promising therapeutic approach to HCC.

## COMMENTS

### Background

Abnormal fragile histidine triad (FHIT) gene, an important candidate tumor-suppressing gene, exists in a majority of tumors. In the hepatoma cell line Hep3B, the FHIT gene, mRNA, and protein is abnormal. Therefore, we constructed a recombinant pcDNA3.1 (+)/FHIT vector containing human fragile histidine triad (FHIT) gene, which was used to transfect human hepatoma Hep3B cells *in vitro* and *in vivo* to explore the effect of FHIT gene on proliferation or apoptosis of hepatocellular carcinoma cells.

### Research frontiers

Application of gene transfer technologies in treatment of cancer has led to the development of new experimental strategies like inhibition of oncogenes, restoration of tumor-suppressor genes and enzyme/prodrug therapy (GDEPT). These strategies are being evaluated for the treatment of primary and metastatic liver cancer.

### Innovations and breakthroughs

In this study, we constructed a recombinant pcDNA3.1 (+)/FHIT vector containing human FHIT gene, which can be used to transfect human hepatoma Hep3B cells (FHIT null) *in vitro* and *in vivo*. Transfection of FHIT gene could

inhibit the growth of human hepatocellular carcinoma cells, and induce cell apoptosis.

### Applications

Transfection of *FHIT* gene into human hepatocellular carcinoma cells is a promising therapeutic approach to HCC.

### Peer review

In this paper, the authors evaluated the effect of human *FHIT* gene on cell proliferation and apoptosis in hepatocellular carcinoma *in vitro* and *in vivo*. It is a very interesting paper, and the study is well designed. It provides a potential therapeutic target for hepatocellular carcinoma.

### Abstract

Neurenteric cysts are extremely rare congenital anomalies, often presenting in the first 5 years of life, and are caused by an incomplete separation of the notochord from the foregut during the third week of embryogenesis. They are frequently accompanied with spinal or gastrointestinal abnormalities, but the latter may be absent in adults. Although usually located in the thorax, neurenteric cysts may be found along the entire spine. We present a 24-year-old woman admitted for epigastric pain, nausea, vomiting, low grade fever and leucocytosis. She underwent cystogastrostomy for a loculated cyst of the distal pancreas at the age of 4 years, which recurred when she was at the age of 11 years. Ultrasound and computer tomography (CT) scan revealed a 16 cm × 15 cm cystic mass in the body and tail of pancreas, with a 6-7 mm thickened wall. Laboratory data and chest X-ray were normal and spinal radiographs did not show any structural abnormalities. The patient underwent a complete cyst excision, and after an uneventful recovery, remained symptom-free without recurrence during the 5-year follow-up. The cyst was found to contain 1200 mL of pale viscous fluid. It was covered by a primitive single-layered cuboidal epithelium, along with specialized antral glandular parenchyma and hypoplastic primitive gastric mucosa. Focal glandular groups resembling

those of the body of the stomach were also seen. In addition, ciliary respiratory epithelium, foci of squamous metaplasia and mucinous glands were present. The wall of the cyst contained a muscular layer, neuroglial tissue with plexogenic nerve fascicles, Paccini corpuscle-like structures, hyperplastic neuro ganglionar elements and occasional psammomatous bodies, as well as fibroblast-like areas of surrounding stroma. Cartilagenous tissue was not found in any part of the cyst. Immunohistochemistry confirmed the presence of neurogenic elements marked by S-100, GFAP, NF and NSE. The gastric epithelium showed mostly CK7 and EMA immunoexpression, and the respiratory epithelium revealed a CK8 and CK18 immunoprofile without CK 10/13 positive elements, though neither CEA or AFP positive cells were found. To our knowledge, this is the first reported case of an abdominally located neurenteric cyst with no associated spinal anomalies.

### INTRODUCTION

Foregut duplications can be classified into three groups: enteric cysts (lined with intestinal epithelium), bronchogenic cysts (lined with respiratory epithelium), and neurenteric cysts (where enteric cysts are associated with vertebral anomalies or communications with the nervous system)<sup>[1,2]</sup>.

Neurenteric cysts are extremely rare congenital anomalies, usually diagnosed in infancy<sup>[3,4]</sup> and tend to be located in the right upper posterior mediastinum, but can be found anywhere along the spine or even intracra-

nially<sup>[1,5,6]</sup>. They may be associated with spinal anomalies such as hemivertebrae and anterior spina bifida<sup>[5]</sup>, and esophageal atresia<sup>[7,8]</sup>, though these associated abnormalities may be absent in adults<sup>[5]</sup>.

We describe the first reported case of an abdominal neurenteric cyst, with no associated spinal anomalies.

## CASE REPORT

A 24-year-old woman presented to our unit in 2001 with epigastric pain, nausea, vomiting, low grade fever and leucocytosis.

Her medical history and case notes showed that she underwent surgery for an 8 cm multi-loculated cyst in the region of the distal pancreas at the age of 4 years, and this was anastomosed to the posterior wall of the stomach. At the age of 11 years, a 2.5 cm recurrent cyst was found, though no significant enlargement was noted over the following decade, and she was largely symptom-free in almost 20 years.

On examination she was found to have a tender palpable mass in the upper left epigastrium. Ultrasonography (US) and computer tomography (CT) scan revealed a cystic mass in the region of the body and tail of the pancreas, measuring 16 cm × 15 cm, with a 6-7 mm thickened wall, and filled with dense fluid (Figure 1). Laboratory data and chest X-ray were normal and spinal radiographs did not show any structural abnormalities. Barium swallow revealed that the stomach displaced to the right and anteriorly, and a gastroscopy did not show any sign of the previous cystogastrostomy on the posterior wall of the stomach.

With a working diagnosis of a mucinous cystadenoma of the pancreas, the patient underwent laparotomy. The cystic tumor was located in the body and tail of the pancreas, and was adherent to the stomach, splenic vessels, prevertebral fascia, and spine. The pancreatic parenchyma in the region of the cyst was completely atrophied, and the previously performed anastomosis was obliterated. The cyst was completely excised, and was found to contain 1200 mL of pale viscous fluid. Laboratory analyses did not show any elevation of amylase or polymorphonuclear cells, and no growth occurred on microbiological culture.

The postoperative recovery was uneventful, the pre-operative symptoms completely resolved, and the patient remained symptom-free, without recurrence during the 5-year follow-up.

Macroscopically, the cyst wall, dark brown in color, was up to 14 mm in thickness and partly hyalinized. The inner surface of the cyst was smooth with some coarse sections, and some areas of the cyst wall also contained smaller cysts. Microscopic examination showed organoid organization resembling tissues, and organs similar to the embryonic foregut, including intestinal wall epithelial formation, partly covered by a primitive single-layered cuboidal epithelium, along with specialized antral glandular parenchyma, and hypoplastic primitive gastric mucosa. Focal glandular groups resembling those of the body of the stomach were also seen. In addition, ciliary

**Figure 1** Axial CT scan showing a large bilocular cyst in the region of the body and tail of the pancreas (A) and a second more caudal axial CT slice (B).

respiratory epithelium, foci of squamous metaplasia, and mucinous glands were present. The wall of the cyst contained a muscular layer, neuroglial tissue with plexogenic nerve fascicles, Paccini corpuscle-like structures, hyperplastic neuro ganglionic elements, and occasional psammomatous bodies, as well as fibroblast-like areas of surrounding stroma (Figures 2 and 3).

Immunohistochemistry confirmed the presence of neurogenic elements marked by S-100, GFAP, NF and NSE. The gastric epithelium showed mostly CK7 and EMA immunoreactivity, and the respiratory epithelium revealed a CK8 and CK18 immunoprofile without CK 10/13 positive elements, though neither CEA or AFP positive cells were found (Figure 4A-D).

## DISCUSSION

Neurenteric cysts may appear at any age, but are usually discovered during the first five years of life<sup>[4,9]</sup>. They are thought to develop early in the course of embryogenesis either due to incomplete separation of the notochord from the embryonic foregut (which are apposed), or due to herniation of the endoderm of the embryonic foregut into the dorsal ectoderm<sup>[10,11]</sup>. This attachment of the cyst to the notochord may prevent fusion of the vertebral bodies and lead to spinal anomalies<sup>[1,5]</sup>, indeed one third of patients have associated anomalies of the central nervous system or gastrointestinal tract<sup>[5]</sup>.

Neurenteric cysts may be multiloculated or septate, lined with ciliated, non-ciliated, columnar or cuboidal epithelium, and may resemble intestinal, duodenal or gastric mucosa. These cells are usually PAS-positive and

**Figure 2** Histological slides showing the full spectrum of epithelia within the cyst lining.

**Figure 3** Histological slide showing elements of an abortive muscular layer and focal irregular neuronal hyperplasia in the cyst wall (A) and a more irregular configuration of the cyst with various ganglio-neuronal elements including Paccinian corpuscles (B).

can contain mucus and globules, with occasional squamous cell metaplasia. A basal membrane is always present and the capsule consisting of fibrovascular tissue is fragile. The wall of the cyst may contain ganglionar cells, lymphatic tissue, pancreatic tissue, salivary glands or muscular tissue without serosa<sup>[1]</sup>. Cartilaginous tissue is never present<sup>[6]</sup>. The cysts usually contain clear, pale, yellowish or green viscous or mucinous fluid, depending on the presence or absence of previous hemorrhage<sup>[5]</sup>.

They are classified into Types A-C according to the histology. Type A cysts, the most described in the literature<sup>[5]</sup>, consist of simple lined cuboidal or columnar epithelium with or without cilia. Type B cysts include more complex gastrointestinal or tracheobronchial elements,

**Figure 4** Histological slides showing more specialized epithelia with consistent immunoreactivity to anti-cytokeratin 7 (A), anti-cytokeratin 18 (B), CA19-9 (C), and mixed abundant neuro-ganglionic/neuro-glial elements that were immunohistochemically verified (immunostaining is with the monoclonal antibody to glial fibrillar acidic protein) (D).

including mucous glands and smooth muscle cells in the cyst walls. In addition to these elements, type C cysts also contain ependymal and/or glial tissue<sup>[5]</sup>. Our patient had a septated type C cyst containing respiratory epithelium, gastric epithelium, and ependymal and glial tissue.

The clinical presentation usually depends on the size and location of the cyst. The patient, typically a small infant, often presents with respiratory distress, dyspnoea, stridor or a persistent cough, caused by pressure of the cyst on the lung. Respiratory distress is usually found with a mediastinal mass, and a vertebral anomaly coexisting

in more than 70% of pediatric patients with neurenteric cysts<sup>[3,9]</sup>. When located intraspinally, the cysts may cause motor and sensory neurological disturbance<sup>[9]</sup>. Chest pain, cardiac arrhythmias and dysphagia can also present, and in the rare cases of ulcer formation in ectopic gastric mucosa in the cyst wall, the patient can present with melaena or perforation of the cyst<sup>[1,12]</sup>.

The diagnosis is usually made by US, which characterizes the cyst and can evaluate for chest masses, and with the advent of high resolution US, these cysts can be detected as early as 18 wk gestation<sup>[1,5,13]</sup>. CT and nuclear magnetic resonance imaging (MRI) also have their place<sup>[14]</sup>, though the final diagnosis is based on histopathological examination.

Complete cyst excision is the recommended treatment<sup>[6,15]</sup>, with some patients requiring a simultaneous laminectomy<sup>[16]</sup>. If the cyst consists of two components, the symptomatic cyst should be excised first. If there is a combination of asymptomatic intraspinal and extraspinal cysts, the spinal cyst should be excised first in order to avoid any neurological deterioration which might occur during mediastinal cyst excision<sup>[6]</sup>.

Our patient underwent a cystogastrostomy at the age of 4 years, presumably with an underlying misdiagnosis of a pancreatic pseudocyst. However, the cyst was covered with an epithelial layer, and recurred. This case nicely demonstrates that the cyst should have previously been completely excised, and when this was finally done, the patient's symptoms resolved, with no cyst recurrence.

### INTRODUCTION

Gastrointestinal stromal tumor (GIST) is the most common soft tissue tumor of the gastrointestinal tract. It was reported that GIST derived from interstitial cells of Cajal is characterized by the expression of CD34 and c-kit (CD117). Immunohistochemical positivity for c-kit gene product-CD117, a tyrosine kinase receptor, reflects the presence of gained function of c-kit gene mutation<sup>[1]</sup>. Imatinib mesylate (IM) (Glivec; Novartis Pharmaceuticals, Basel, Switzerland) is a small-molecule tyrosine kinase inhibitor that suppresses the mutated c-kit product<sup>[2]</sup>. Clinical trials<sup>[3,4]</sup> for recurrent or metastatic GIST have demonstrated that the partial response (PR) rate is 47% to 54% based on radiographic evaluation. However, a complete response (CR) is rarely reported. Pathologically verified cases showing therapeutic efficacy have been rarely reported. Up to present, only seven cases of locally advanced or metastatic GIST with a pathologic CR to IM treatment have been reported in the literature<sup>[5-10]</sup>.

The initial treatment for a metastatic GIST is to use IM, and then surgical treatment directing toward complete resection is to be considered when the tumor has responded and reduced in size<sup>[11-13]</sup>. However, neither the adequate intervals between the start of treatment with IM and operation, nor the significance of surgical resection for the patients with metastatic GIST who have been treated with IM, has been completely elucidated.

In this paper, we present a case of GIST with meta-

### Abstract

A 39-year-old male underwent distal gastrectomy for a high grade gastrointestinal stromal tumor (GIST). Computed tomography (CT) and magnetic resonance imaging (MRI) 107 mo after the operation, revealed a cystic mass (14 cm in diameter) and a solid mass (9 cm in diameter) in the right and left lobes of the liver, respectively. A biopsy specimen of the solid mass showed a liver metastasis of GIST. The patient received imatinib mesylate (IM) treatment, 400 mg/day orally. Following the IM treatment for a period of 35 mo, the patient underwent partial hepatectomy (S4 + S5). The effect of IM on the metastatic lesions was interpreted as pathologic complete response (CR). Pathologically verified cases showing therapeutic efficacy of IM have been rarely reported.

chronous liver metastasis treated with IM, and describe confirmed the therapeutic efficacy of such a molecular targeting drug as IM, which was confirmed by virtue of pathologic CR following complete surgical resection.

## CASE REPORT

A 39-year-old male complaining of epigastralgia was found to have a 3 cm  $\times$  2 cm submucosal tumor on the anterior surface of the body along the lesser curvature of the stomach, and underwent partial gastrectomy. Pathological examination of the surgical specimen revealed a high grade leiomyosarcoma showing spindle cells with 20 mitoses/10HPF and 17% in the MIB-1 index. The patient was subsequently diagnosed as having an uncommitted type of high grade GIST, since he was immunohistochemically positive for CD34 and CD117 (Figure 1). One hundred and seven months after the initial operation, the patient developed right upper

**Figure 2** Contrast-enhanced CT scan (A) and MRI (B) on T1-weighted image 107 mo after the initial operation.

quadrant pain during exercise. Physical examination revealed marked hepatomegaly and the lower margin of the liver could be palpated at five-finger widths below the costal margin. Computed tomography (CT) and magnetic resonance imaging (MRI) showed a cystic mass (14 cm in diameter) and a solid mass (9 cm in diameter) in the right and left lobes of the liver, respectively (Figure 2). Open biopsy was attempted and specimens were obtained from the solid tumor mass in the left lobe of the liver. Pathologically, spindle cells were positive for CD34 and CD117 with 15 mitoses/10 HPF and 15% in the MIB-1 index, which was indicative of a metastatic GIST of the liver (Figure 3). Only fluid was obtained from the cystic mass in the right lobe. A drainage tube was inserted into the cystic mass through the abdominal wall. Cytological examination of the fluid showed that the cystic mass was Class II. Since the cystic and solid tumors in the liver were considered too huge to be resected entirely and curatively, molecular targeting therapy using a daily dose of 400 mg of IM was started 3 mo after the liver biopsy. The drainage tube inserted into the cystic mass was removed after a three-week treatment with IM. A follow-up abdominal CT, one month after the start of IM treatment, showed apparent reduction in size of both the cystic and solid masses. The reduction of the solid mass in the left lobe was a partial response (PR). MRI, 30 mo after the treatment with IM, showed that the contrast-enhanced wall of the solid mass became thinner and central necrosis increased in size (Figure 4A). Although CT, 34 mo after the treatment, showed a 5 cm ring-enhanced mass in the left lobe (S4) and a 6 cm enhanced mass in the right lobe (S5) of the liver, the total volume of the

**Figure 3** Scanning view of metastatic GIST (× 15) (A), histological study revealed spindle cells with mitoses (HE, × 200) (B), immunohistochemistry findings revealed positive staining for CD117 (C) and CD34 (× 200) (D) in metastatic GIST of the liver obtained from liver biopsy.

**Figure 4** MRI on T1-WI 30 mo after treatment with Imatinib (A) and contrast-enhanced CT 34 mo after the treatment with Imatinib (B). The metastatic lesions (S4 + S5) are indicated.

neoplastic masses in the liver was sufficiently reduced after the curative resection of the masses (Figure 4B). The IM treatment was interrupted after 35 mo, and then the patient underwent partial hepatectomy (S4 + S5). The cut-surface of the resected specimens from S5 and S4 showed a homogenous yellow-white hard mass and a necrotic soft mass, respectively, forming a scrollwork structure, containing hemorrhagic foci, and surrounded by a yellow-white hard layer (Figure 5). Pathologically, most of the specimens were replaced with hyaline-degenerated tissue, adjacent to which, cystic-degenerated tissue and necrotic tissue with hemorrhage and macrophages containing hemosiderin granules stained with Berlin blue were observed. Since no viable tumor cells stained with CD34 or CD117 were observed in any of the whole sections at the maximum cut surface of the resected specimen, the effect of the IM treatment on the metastatic GIST was interpreted as the pathologic CR (Figure 6).

One week after the operation, oral administration of 400 mg IM daily for 12 mo was performed. Fourteen months after the partial hepatectomy at the time of writing this paper, no recurrent lesion was observed on CT and MRI examinations.

## DISCUSSION

The efficacy of aggressive surgical resection for locally advanced or metastatic GIST has been reported before the development of IM treatment<sup>[14,15]</sup>. Furthermore, clinical studies on the surgical resection after Imatinib treatment have also been reported<sup>[5,6,9-12,16,17]</sup>. Indeed, surgical resection of GIST makes it possible to elucidate the histopathologic effect of IM treatment on advanced or metastatic GIST. However, biopsy specimens from the lesion alone are usually not enough to assess the histopathologic effect of IM treatment on GIST.

As far as we know, only six clinical reports on the

**Figure 5** Serous and cut-surface views of resected specimen obtained from partial hepatectomy (S4 + S5) after treatment with Imatinib.

pathological effect of IM treatment on locally advanced or metastatic GIST have been published<sup>[5,6,9,10,16,18]</sup>. According to Gronchi *et al*<sup>[18]</sup>, no case with a pathological CR was obtained in a series of 38 patients, although the degree of pathologic changes varied widely. Furthermore, Andtbacka *et al*<sup>[10]</sup> pointed out that radiographic and metabolic CR based upon <sup>18</sup>F-fluorodeoxyglucose positron emission tomography (FDG-PET) are not always concordant with a pathologic CR; therefore, it should be born in mind that the pathological evaluation on the surgically resected materials obtained from patients treated with IM might be indispensable for the elucidation of the therapeutic effect of IM on GIST. They also emphasized that the changes in the degree as well as the extent of contrast-enhancement, and the internal structure within the solid tumor should be carefully evaluated on CT and MRI<sup>[10]</sup>. According to their categorization, our case presented in this paper is compatible with 'initial regression then stabilization' on CT and MRI. MRI, five months prior to the operation in our case, disclosed thickening of the enhanced wall and a change of the signal intensity of the internal structure of the mass in the left lobe of the liver. In fact, the changes in internal density reflected the central necrosis on the cut-surface of the resected mass. Histopathologic changes induced by IM in GIST have been reported to be hyaline degeneration, myxoid degeneration, and appearance of scattered inflammatory cells, hemosiderin granules and foamy cells, but seldom necrosis<sup>[3,5-8]</sup>. Bauer *et al*<sup>[6]</sup> who found no necrosis in a series of twelve patients treated with IM, speculated that IM would mainly induce apoptosis, but not so much necrosis. As for the timing of surgical resection in patients with recurrent or metastatic GIST, Andtbacka *et al*<sup>[10]</sup> have reported a complete resection rate of 31.4% after IM therapy for a period of 6.9-37.5 mo (mean, 10 mo). They also emphasized that surgical resection for the IM-responsive recurrent or metastatic GIST should be considered as early as possible before the development of progression and secondary resistance to IM<sup>[10]</sup>. Surgical resection, 6-12 mo after the start of IM treatment, is recommended among responders<sup>[9]</sup>. Although the time of operation in our case was markedly

**Figure 6** Histological study showing no viable tumor cells and hyaline degenerative tissues (HE, × 200) (A) and immunohistochemistry findings revealing negative staining for CD117 (× 200) (B) in the resected specimen after treatment with Imatinib.

delayed (35 mo) in comparison with the time suggested by other investigators, it is thought to be adequate for avoidance of the secondary resistance to IM treatment.

In summary, we report a case of GIST with meta-chronous liver metastases who underwent complete surgical resection following IM treatment. The resected specimen was pathologically proven as a CR. Preoperative radiographic CT, MRI, findings and microscopic findings of the resected specimen were described from the view point of the effect of the molecular targeting therapy.

### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (*World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly open access peer-reviewed journal supported by an editorial board consisting of 1208 experts in gastroenterology and hepatology from 60 countries. The aim of the journal is to deliver the most clinically relevant original and commentary articles to readers, and to make the full text publicly available to all clinicians, scientists, patients and biomedical students on an unrestricted platform, so that they can access and learn about the most recent key advances in the field.

In addition to the open access nature, another key characteristic of *WJG* is its reading guidance for each article which includes background, research frontier, related reports, breakthroughs, applications, terminology, and comments of peer reviewers for the general readers.

*WJG* publishes articles on esophageal, gastrointestinal, hepatobiliary and pancreatic tumors, and other esophageal, gastrointestinal, hepatic-biliary and pancreatic diseases in relation to epidemiology, immunology, microbiology, motility & nerve-gut interaction, endocrinology, nutrition & obesity, endoscopy, imaging and advanced hi-technology.

The main goal of *WJG* is to publish high quality commentary articles contributed by leading experts in gastroenterology and hepatology and original articles that combine the clinical practice and advanced basic research, to provide an interactive platform for clinicians and researchers in internal medicine, surgery, infectious diseases, traditional Chinese medicine, oncology, integrated Chinese and Western medicine, imaging, endoscopy, interventional therapy, pathology and other basic medical specialties, and thus eventually improving the clinical practice and healthcare for patients.

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, Index Medicus, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology and Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

### Published by

The WJG Press

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjgnet.com>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjgnet.com](mailto:submission@wjgnet.com), or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was carried out; author contributions; disclosure of any financial support for the research; and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (remove all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s), and full family name.

**Author contributions:** The format of this section should be like this: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed research; Wang CL, Zou CC, Hong F and Wu XM performed research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed data; and Wang CL, Liang L and Fu JF wrote the paper.

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

#### Abstract

An informative, structured abstract of no more than 350 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipment, and the experimental procedures should be included. RESULTS: The observed and experimental results, including data, effects, outcome, *etc.* should be included. Authors should present *P* value where necessary, and also include any significant data. CONCLUSION: Accurate view and the value of the results should be included.

The format for structured abstracts can be found at: <http://www.wjgnet.com/wjg/help/11.doc>.

#### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

#### Text

For articles of these sections, original articles, rapid communication

and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, should be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

### Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ... *etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

### Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P* < 0.05 and <sup>d</sup>*P* < 0.01 are used. A third series of *P* values can be expressed as <sup>e</sup>*P* < 0.05 and <sup>f</sup>*P* < 0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, ▲, △, *etc.*, in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

### PMID requirement

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information for journal citations is very important. Using the reference testing system, the authors and editor should check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in an ASP file so that the readers can immediately access the abstract of the citations online.

### DOI requirement

A CrossRef DOI® (Digital Object Identifier) name is a unique string created to identify a piece of scholarly content in the online environment. The author should supply the DOIs for journal citation (doi:10.3748/wjg.13.6458). This link (<http://www.crossref.org/SimpleTextQuery/>) allows you to retrieve Digital Object Identifiers (DOIs) for journal articles, books, and chapters by simply cutting and pasting the reference list into the box. You may use the form with any reference style, although the tool works most reliably if references are formatted in a standard style such as shown in this example: Assimakopoulos SF, Scopa CD, Vagianos CE. Pathophysiology of increased intestinal permeability in obstructive jaundice. *World J Gastroenterol* 2007; 13(48): 6458-6464

The accuracy of the information of journal citations is very important. We will interlink all references with DOI in ASP file so that readers can access the abstracts of cited articles online immediately.

### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

### Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those linked with a hyphen when the difference between the two numbers is greater than five. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered inappropriate references. Authors should not cite their own unrelated published articles.

### Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

### Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as *v* (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

### Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose)  $6.4 \pm 2.1$  mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5  $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: <http://www.wjgnet.com/wjg/help/15.doc>.

### Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of

Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

### Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindI*, *BamHI*, *Kho I*, *Kpn I*, etc.

Biology: *H pylori*, *E coli*, etc.

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

### Editorial Office

#### World Journal of Gastroenterology

Editorial Department: Room 903

Ocean International Center, Building D

No. 62 Dongsihuan Zhonglu

Chaoyang District, Beijing 100025, China

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

Telephone: +86-10-59080039

Fax: +86-10-85381893

### Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

### Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/9.doc>.

### Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/10.doc>.

### Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

### Links to documents related to the manuscript

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

### Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

### Publication fee

Authors of accepted articles must pay a publication fee.

EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.

### Abstract

Carcinomas of the stomach and gastroesophageal junction are among the five top leading cancer types worldwide. In spite of radical surgical R0 resections being the basis of cure of gastric cancer, surgery alone provides long-term survival in only 30% of patients with advanced International Union Against Cancer (UICC) stages in Western countries because of the high risk of recurrence and metachronous metastases. However, recent large phase-III studies improved the diagnostic and therapeutic options in gastric cancers, indicating a more multidisciplinary management of the disease. Multimodal strategies combining different neoadjuvant and/or adjuvant protocols have clearly improved the gastric cancer prognosis when combined with surgery with curative intention. In particular, the perioperative (neoadjuvant, adjuvant) chemotherapy is now a well-established new standard of care for advanced tumors. Adjuvant therapy alone should be carefully discussed after surgical resection, mainly in individual patients with large lymph node positive tumors when neoadjuvant therapy could not be done. The palliative treatment options have also been remarkably improved with new chemotherapeutic agents and will further be enhanced with targeted therapies such as different monoclonal antibodies. This article reviews the most relevant literature on the multidisciplinary management of gastric and gastroesophageal cancer, and discusses future strategies to

### INTRODUCTION

Gastric and esophageal cancers are among the leading causes of cancer-related death worldwide. Even if the incidence of distal gastric cancer has been decreasing over the past decades, the incidence of newly diagnosed proximal cancers (localized at cardia and gastro-esophageal junction), including Barrett's carcinoma, has dramatically increased<sup>[1]</sup>. Despite considerable progress in surgical resection as the primary curative treatment for gastric cancer in Japanese and Western countries, more than half of all patients with advanced UICC stage disease undergoing radical primary tumour resection relapse and die within five years<sup>[2]</sup>. The prognosis of these curatively resected cancer patients remains poor due to high rates of local recurrences as well as early lymph node and systemic metastases. Therefore, new perioperative, neoadjuvant, adjuvant and palliative chemotherapy strategies are of great importance in handling these patients.

### MULTIDISCIPLINARY STRATEGIES FOR DIAGNOSIS AND STAGING

Until recently, the standard diagnostic approach after endoscopic and histological diagnosis of localized advanced gastric adenocarcinoma was to perform only limited staging procedures with sonography and chest X-ray, followed nearly always by attempted surgical

resection. These limited diagnostic tools resulted in a non-optimal description of the local tumor extension and the detection of regional and distant metastases, often not allowing an optimal treatment selection.

It became accepted during the last decade that the lack of co-operation between different medical disciplines prevented an improvement in available therapies. Patient care often consisted of fragmented strategies and lacked long-term planning. The multidisciplinary management of gastric and gastroesophageal cancers, in diagnosis as well as in treatment strategies, gains now even more ground after results of recent randomised studies became available. The time has come for the launch of multimodal treatments to increase the chance of better outcome, longer survival or even cure<sup>[3]</sup>. By using this team approach, all diagnostic and therapeutic disciplines, such as the gastroenterologist, surgeon, oncologist, radiologist and radiotherapist, will be instrumental in planning the effective administration of their treatment modalities. The diagnostic arsenal, i.e. CT scan, endoscopic ultrasound (EUS), mini-laparoscopy, MRI and PET, allows improved pre- or postoperative staging<sup>[4,5]</sup>. For endoscopically large tumors and tumors of the gastro-esophageal junction in particular, CT scan of the abdomen/thorax and EUS are mandatory for an exact preoperative tumor and node metastases staging. EUS allows the differentiation between small and large tumours as well as staging or biopsies of mediastinal and celiac lymph nodes<sup>[6,7]</sup>. In addition, mini-laparoscopy is a valuable tool, as peritoneal carcinosis is found in about 20% to 30% of all gastric cancer patients at first diagnosis<sup>[8]</sup>. As PET scan has also been shown to effectively predict clinical response in esophageal and gastric cancer, it might potentially allow better allocations and adjustments for further individualized and optimized treatment strategies<sup>[9]</sup>. Staging with PET may best be used either in patients with locally advanced disease who may benefit from curative resection, if distant metastases are not found, or in patients with high grade stenosis, where EUS is not applicable.

## CURATIVE INTENT-THE OPTIMAL RESECTION

To date, the mainstay of curative treatment of gastric cancer has been radical surgical dissection (ESMO clinical recommendations 2007). However, high rates of local recurrences, early lymph node and systemic metastases highlight the need of further efforts to standardize and optimize the surgical treatment. Thus, the type of resection (subtotal *vs* total gastrectomy) and the role of extensive lymphadenectomy have been subjects of international debates. For distal gastric cancers, subtotal gastrectomy has been shown to have an equivalent oncologic result with significantly fewer complications when compared with total gastrectomy<sup>[10]</sup>. Even if the surgical procedure of choice for proximal gastric cancers is more controversial, because both proximal gastrectomy and total gastrectomy are associated with postoperative nu-

tritional impairments, the oncologic outcome of patients with proximal gastric cancer is independent of the type of gastric resection performed<sup>[11]</sup>. Currently, total gastrectomy for proximal (cardia) tumors is recommended in Europe.

The extent of regional lymphadenectomy required for optimal results is still debated. Several prospective randomised trials examining the role of more extended lymph node dissections (D1 *vs* D2) did not find clinically relevant improvements in overall survival. However, the interest in extended lymphatic dissections (D2 and greater) has not waned. A retrospective multicentre observation study in Germany found a significant survival advantage in patients undergoing extended lymphadenectomy<sup>[1]</sup>. In contrast, however, at least two prospective European trials compared D1 with D2 dissection: one in the Netherlands, by the Dutch Gastric Cancer Group (DGCG), and one in the UK, by the Medical Research Council (MRC)<sup>[12,13]</sup>. Even though the results have been debated differently, both trials found that extended lymphadenectomy associated with significantly higher morbidity and mortality rates compared with limited lymphadenectomy. Likewise, splenectomy and pancreatectomy were associated with a significantly increased risk of operative mortality. Interestingly, no significant survival difference was found for either group in the final results of the DGCG study after 11 years of follow-up<sup>[14]</sup>. As defined in this study, for patients with N2 disease an extended lymph node dissection may offer cure, but it remains difficult to identify patients who have N2 disease. Morbidity and mortality are greatly influenced by the extent of lymph node dissection, pancreatectomy, splenectomy and age. Extended lymph node dissections may thus be of benefit if morbidity and mortality can be avoided. Recently, the Japan Clinical Oncology Group (JCOG) presented an ambitious trial comparing D2 lymph node dissection with more extensive lymphadenectomy<sup>[15]</sup>. Here, the mortality rate was remarkably low (1%). Thus, a surgical option that may decrease postoperative morbidity and mortality is an "over-D1" lymphadenectomy with preservation of the pancreatic tail without splenectomy<sup>[16]</sup>.

With improvements in endoscopic techniques (endoscopic mucosal resection) and minimal access surgery, there has been interest in applying these modalities to early gastric cancer. Node-negative T1 tumors are associated with a 5-year survival of more than 90%<sup>[17]</sup>. As such, there is interest in performing more limited resection for these tumors. Endoscopic resection should be accepted as the treatment of choice in most patients with high-grade intraepithelial neoplasia and mucosal carcinoma in the esophagus. Low morbidity (1%-3%) and mortality (0%) and better quality of life, due to organ preservation, are points in favor of endoscopic resection and against surgical in cases of early oesophageal carcinoma (Barrett's)<sup>[18]</sup>. Here proper patient selection is paramount. The probability of lymph node metastasis in early gastric cancer is influenced by tumor factors and is correlated with increasing tumor size, submucosal, lymphatic and vascular invasion and poorly differentiated tumors<sup>[19]</sup>.

To improve the acceptance of endoscopic treatment, further prospective trials with long-term data are necessary. Regardless of the technique used for resecting early gastric cancer, complete excision with negative margins is required.

## ADJUVANT STRATEGIES

Because of the high rates of local recurrences and distant metastases, different adjuvant chemotherapy protocols have been compared with surgery alone in advanced gastric cancer in Europe, Asia and the United States. In a recent review of these studies the 5-year survival results suggested only a moderate improvement following adjuvant treatment<sup>[20]</sup>. However, the majority of the chemotherapeutic regimens used in these studies are regarded as suboptimal today.

Two recent phase III trials again support adjuvant chemotherapy. Sasako *et al* examined the adjuvant efficacy of single-agent S-1 compared with surgery alone in a study with 1059 patients with Stage II/III disease, after potentially curative D2 gastrectomy (ACTS-GC study). After 3-year follow-up and rare grade 3/4 toxicities, overall survival and relapse-free survival favored the S-1 arm, with 81.1% *vs* 70.1% ( $P = 0.0015$ ) and 72.2% *vs* 60.1% ( $P = 0.0001$ ), respectively<sup>[21]</sup> (Figure 1). The Italian Gruppo Oncologico dell'Italia Meridionale (GOIM) study found also in trend some positive results for epirubicin/etoposide/5-FU/folinic acid (FA) in > D1 resected patients<sup>[22]</sup>.

Adjuvant radiotherapy alone has failed over the last decades to improve treatment results and patient outcome. In the British Stomach Cancer Group trial, no survival advantage has been shown for 436 patients randomized between surgery only and surgery with 45 Gy-50 Gy radiotherapy or surgery with FAM chemotherapy<sup>[23]</sup>. This debate was further stimulated by the presentation of the SWOG 9008 group study, with combined radiochemotherapy in resected stage IB-IV gastric cancers<sup>[24]</sup>. After randomisation to either observation or to 2 cycles of FA/5-FU (Mayo-clinic regimen) followed by radiation + FA/5-FU and another 2 cycles FA/5-FU, a statistical significant difference in disease-free and overall survival in favor of the chemoradiation was shown. The absolute increase in median survival of 9 mo was hampered by suboptimal surgery (less than D1 in majority of patients) and radiotherapy; 35% protocol deviations. Additionally, in the multimodality arm, the local relapse rate was reduced from 90% to 29%. However, there was no difference in the risk of distant metastasis for either group. Despite positive data, several concerns have been raised concerning that in both arms the patients had high risk for relapse (more than 2/3 had T3 or T4 tumors and 85% positive lymph node metastases), the suboptimal surgery (54% of below D1) was counterbalanced by adjuvant chemoradiation and the number of patients (only 64%) who received the full schedule of chemotherapy and radiation.

In addition, Park and colleagues investigated a similar protocol in 290 patients, all of whom were curatively re-

**Figure 1** Survival of S-1 monotherapy versus surgery alone for stage II/III gastric cancer patients after curative D2 gastrectomy (ACTS-GC study)<sup>[22]</sup>.

sected with extensive D2 lymph node dissection<sup>[25]</sup>. After a median follow up of 49 mo, 43% of patients relapsed, with 67% local relapses and 36% distant metastases. The five-year overall and relapse free survival rates were 60% and 57%, better than in the SWOG trial, respectively<sup>[25]</sup>. Therefore, it is still questionable whether Japanese or European patients undergoing D2 resection may benefit of postoperative chemoradiation.

## PERIOPERATIVE MULTISCIPLINARY APPROACHES

### Neoadjuvant chemotherapy

Many reasonable rationales justify the application of neoadjuvant chemotherapy, which is particularly interesting as a short-term therapy (i.e. two cycles of 6-8 wk) given simultaneously and/or sequentially with radiochemotherapy. Possible advantages of neoadjuvant therapy +/- adjuvant strategies are: (1) Tumour vascularisation results in higher therapeutic efficacy and downstaging. (2) Excision of chemoradiated areas can result in lower long-term toxicity. (3) Early systemic therapy allows better control of tumour micrometastases. (4) Operation may not be compromised with higher morbidity and mortality.

Neoadjuvant chemotherapy aims at downstaging patients, improving curative resectability of locally advanced disease, and eventually increasing patient survival. It can also provide important information for the postoperative use of chemotherapeutic agents, by evaluating the response of the resected primary tumor, and it is also considered effective in reducing occult micrometastases. Theoretically, introducing chemotherapy at an early phase of the disease may facilitate delivery of drugs towards the primary lesion without impairing vascularization. In addition, major surgery such as total gastrectomy delays the start of postoperative systemic chemotherapy by a month or more, potentially giving microscopic residual diseases an opportunity to proliferate. On the other hand, it has been suggested that patho-

**Table 1** Ongoing important phase III clinical trials, including monoclonal antibodies and signal transduction/tyrosine kinase inhibitors

Name	Design	Indication
TOGA	XP or FP +/- trastuzumab	Advanced gastric cancer HER2-positive
AVAGAST	XP +/- bevacizumab	Metastatic gastric cancer
REAL-3	EOX +/- panitumumab	Advanced esophagogastric cancer
FFCD 03-07	ECX followed by FOLFIRI <i>vs</i> FOLFIRI followed by ECX	Advanced esophagogastric cancer
EXPAND	XP +/- Cetuximab	Advanced/Metastatic gastric cancer
MAGIC-B	Perioperative ECX +/- bevacizumab	Neo-adjuvant gastric cancer
CLASSIC	XELOX <i>vs</i> observation	Adjuvant gastric cancer

logical non-staging of the tumor could be the major disadvantage of neoadjuvant strategies. However, since modern imaging technologies such as CT, MRI and EUS plus fine-needle biopsies allow preoperative clinical staging for locoregional lymph node spread, overtreatment of patients with gastric cancer is less likely compared with earlier trials.

Patients responding to neoadjuvant treatment presented with a better performance status during their remission without compromising the subsequent operation with higher morbidity and mortality<sup>[26]</sup>. Although a number of randomised (mainly phase II) studies for neoadjuvant chemotherapy alone have suggested improved survival compared with historical controls, evidence from a randomised phase III trial were still missing<sup>[27,28]</sup>.

Apart from the newly updated version of the neoadjuvant MRC trial<sup>[29,30]</sup>, two large phase III studies have now clearly proved the preoperative concept to be beneficial for patients with gastric and gastro-oesophageal cancers<sup>[31,32]</sup>. The recently published MAGIC trial was the first large randomised study of perioperative chemotherapy to be conducted with an adequate follow-up period. It was initiated to compare surgery alone *versus* surgery with perioperative chemotherapy in which patients received three preoperative and three postoperative cycles of ECF<sup>[31]</sup>. After enrolment of 503 patients with resectable gastric (74%) or lower oesophageal cancer (26%), the proportion of patients with curative resection was larger in the chemotherapy plus surgery arm (79% *vs* 69%,  $P = 0.018$ ). After 5 years, the overall survival rate clearly favored the chemotherapy plus surgery arm over the surgery alone arm (hazard ratio for death, 0.75; 95% CI, 0.60-0.93;  $P = 0.009$ ; 5-year survival rate, 36% *vs* 23%), as did the progression-free survival rate (hazard ratio for progression, 0.66; 95% CI, 0.53-0.81;  $P < 0.001$ ).

The French FFCD (Federation Française de Cancérologie Digestive) Group trial confirmed these important data with their phase III study in which they randomized 224 patients to perioperative FUP (5-FU/cisplatin; surgery; 5-FU/cisplatin) or surgery alone. With the same postoperative mortality rates for both arms, the perioperative group presented with significantly higher R0 resection rates. In addition, 3-year disease-free survival increased by 15% (40% *vs* 25%) and 5-year survival improved (38% *vs* 24%)<sup>[32]</sup>.

To generate additional neoadjuvant data on tumors of the gastro-oesophageal junction, three randomised studies for oesophageal cancer included high percentages

of adenocarcinomas of the lower oesophagus or the cardia region<sup>[33]</sup>. In contrast to one large negative phase III trial with chemotherapy/surgery *vs* surgery alone<sup>[34]</sup>, one study showed a significant survival benefit and one study found a trend for improved 3-year survival for radio-chemotherapy<sup>[35,36]</sup>. Additionally, the recently updated MRC trial with 802 patients demonstrated a long lasting benefit in median survival (16.8 mo *vs* 13.3 mo) and the increase in 2-year survival of 9% for the chemotherapy group, with no difference in the rate of perioperative death or postoperative complications<sup>[29,30]</sup>.

The identification of an effective chemotherapy regimen and optimal treatment schedule for locally advanced disease has been another important issue in neoadjuvant treatment for gastric cancer. There is optimism that the use of multiple targeted therapies in gastric cancer will produce further improved results. Thus, various phase I / II clinical trials, including monoclonal antibodies and signal transduction/tyrosine kinase inhibitors for EGFR, monoclonal antibodies to the HER-2/*neu* receptor and VEGF-ligand, and other novel drugs acting on intracellular signaling pathways, are under way, like bevacizumab<sup>[37]</sup> or cetuximab or panitumumab (Table 1).

### Neoadjuvant radiation

With regard to optimizing locoregional tumour control, radiotherapy in the neoadjuvant setting recently came into focus. Preoperative radio-chemotherapy has the advantage that the location of the primary cancer is known more precisely, which facilitates the planning of more accurate and effective radiation fields. In addition, the preoperative approach may allow significant time to observe high-risk patients for future growth of advanced cancers or metastases.

The German Oesophageal Cancer Study Group recently analysed the additional contribution of preoperative radiotherapy to neoadjuvant chemotherapy (POET study)<sup>[38]</sup> (Figure 2). Patients with locally advanced oesophagogastric adenocarcinomas (Stage T3-T4 NX M0 according to EUS, CT and laparoscopy) were randomised to 2.5 courses of chemotherapy (cisplatin/FA/5-FU weekly) *versus* two courses of the same chemotherapy followed by 3 wk of chemo-radiotherapy (30 Gy/cisplatin/etoposide). Despite some increased postoperative mortality after chemo-radiotherapy (five *vs* two patients), the median survival (32.8 mo) and the 3-year survival rate (43%) were

**Figure 2** Overall survival of patients with locally advanced oesophagogastric cancers with preoperative neoadjuvant chemoradiation (Arm B) vs neoadjuvant chemotherapy alone (Arm A, POET study)<sup>[38]</sup>.

significantly improved in this group compared with patients who received chemotherapy alone (21.1 mo and 27%, respectively).

Pathological responses of oesophageal cancers strongly correlated with disease-free survival after preoperative radio-chemotherapy<sup>[39,40]</sup>. Ajani *et al* investigated the effects of induction chemotherapy combined with preoperative radio-chemotherapy. Taxanes, cisplatin and 5-FU were followed by radiation with 45 Gy (25 fractions in 5 wk) plus 5-FU infusions<sup>[41]</sup>. Interestingly, pCR/pPR response rates were 64% in all operated patients, with a significantly longer median survival (64 mo *vs* 30 mo) in patients with pathological remissions. In a second multicentre study of Ajani and colleagues, the pCR and R0 resection rates were 26% and 77%, respectively. At 1 year, more patients with pCR (82%) were alive compared with those with < pCR (69%). Again, these parameters were closely associated with better progression-free and overall survival<sup>[42]</sup>. Furthermore, it has still to be determined whether any radiation escalation by hyperfractionation (more than one fraction of radiotherapy per day) or acceleration (shortening of treatment duration) may improve local control whilst maintaining a similar risk of late normal tissue damage<sup>[43]</sup>.

In addition to cisplatin/5-FU, new anticancer drugs such as taxanes, irinotecan and oxaliplatin have been reported to induce even higher objective response rates of up to 70% in recent years, and an improvement in overall median survival of up to 12 mo in palliative treatment<sup>[44]</sup>. The taxanes, docetaxel or paclitaxel promote microtubule stabilisation by increasing tubulin polymerization. As a result, they may also enhance radiosensitivity by causing cell cycle arrest in the G2/M phase<sup>[45]</sup>. These new chemotherapy regimens may be additional combinations to intensify localized multidisciplinary approaches in resectable or unresectable advanced diseases to further decrease incomplete resection rates as well as morbidity and mortality rates.

Additionally, results of other tumor entities, such

as the JCOG 9907 study for esophageal squamous cell cancers, clearly favour a combined modality approach in the neoadjuvant setting<sup>[46]</sup>. Even more, some randomized trials of chemo-radiotherapy *vs* radiotherapy alone in head and neck, oesophageal or anal cancer showed better locoregional control and overall survival rates for the multimodal protocols. Thus, direct comparisons between neoadjuvant and postoperative adjuvant strategies will be worthwhile in the near future.

## TREATMENT OF METASTATIC DISEASE (STAGE IV)

Chemotherapy has increasingly justified its role in the treatment of metastatic disease, with the survival of treated patients being significantly better than that for patients receiving best supportive care. To date, 5-FU derivatives combined with cisplatin have been accepted as the most useful form of palliative chemotherapy, often additionally modulated by combinations with other anti-cancer drugs, such as epirubicin or leucovorin (FA)<sup>[44,47]</sup>. In a Cochrane review of randomised trials in advanced gastric cancer, the best survival rates were achieved with anthracyclines, cisplatin and 5-FU, both independently and in combination<sup>[48]</sup>. Within these combinations, ECF proved to be the best tolerated. Other trials have shown improved overall survival with palliative regimens, such as docetaxel/cisplatin/5-FU<sup>[49]</sup>, oxaliplatin/FA/5-FU<sup>[50]</sup> and irinotecan/FA/5-FU<sup>[51,52]</sup>. However, continuous infusion of 5-FU is considered cumbersome because it requires the implantation of central venous catheter and the use of portable infusion pumps, which are associated with complications such as thromboses and wound infections. Capecitabine and S1, prodrugs and oral analogues of 5-FU, can mimic 5-FU continuous infusions and are at least equally effective in tumor control and less toxic than intravenous 5-FU in gastric cancer patients<sup>[53,54]</sup>. Remarkably, just recently Cunningham and colleagues evaluated capecitabine and oxaliplatin as alternatives to infused 5-FU and cisplatin for untreated advanced esophagogastric cancer and depicted at least similar effectiveness for both regimens<sup>[55]</sup>.

Moreover, the use of multiple targeted therapies renewed hope for more effective and better tolerated chemotherapy regimes in the palliative setting to further improve efficacy and survival. Pinto *et al* combined Cetuximab + FOLFIRI (FOLCETUX) in a phase II study and they demonstrated an overall response rate (ORR) of 44.1%, with a median TTP of 8 mo and a median OS time of 16 mo<sup>[56]</sup>. The major toxicity appeared to be limited to neutropenia (42.1% of grade 3-4), together with the typical side effects associated with cetuximab (skin 21.1%/grade 3-4). Two additional German AIO trials recently support the efficacy of cetuximab, favouring the analysis of standard therapy with or without EGFR inhibitors in advanced cancers<sup>[57,58]</sup>.

Additionally, response rate (65%), time to disease progression (8.3 mo), and overall survival (12.3 mo) were encouraging when bevacizumab was combined with

Irinotecan/Cisplatin in a multicenter phase II study<sup>[37]</sup>. Ongoing studies testing novel agents will further assess the potential improvement in the treatment of patients with metastatic gastric or gastroesophageal junction adenocarcinoma advanced gastric cancer.

## CONCLUSION

With respect to the new perioperative and neoadjuvant achievements in improving the treatment options for advanced gastric cancer, multidisciplinary strategies should be integrated into the daily practice of a patient's work-up<sup>[54,59]</sup>. Clinical co-operative groups of local comprehensive cancer centers and international study groups, such as the JCOG, SWOG, EORTC, MRC, AIO, FFCD and others, have shown that complex preoperative strategies can be implemented. Thus, patients should be included into the aforementioned innovative studies whenever possible. However, if the local clinical setting does not allow participation in such trials, regionally organized treating physicians, e.g. general practitioner, gastroenterologist, surgeon, radiotherapist and oncologist, should meet regularly, ideally weekly, to decide the multimodal therapeutic concepts, integrating pre-operative and post-operative strategies. With all these clinical and scientific efforts, these treatment strategies will definitely continue to further improve the outcome of gastric cancer patients.

### Abstract

The aetiology of primary sclerosing cholangitis (PSC) is not known and controversy exists as to whether PSC should be denominated an autoimmune disease. A large number of autoantibodies have been detected in PSC patients, but the specificity of these antibodies is generally low, and the frequencies vary largely between different studies. The presence of autoantibodies in PSC may be the result of a nonspecific dysregulation of the immune system, but the literature in PSC points to the possible presence of specific antibody targets in the biliary epithelium and in neutrophil granulocytes. The present review aims to give an overview of the studies of autoantibodies in PSC, with a particular emphasis on the prevalence, clinical relevance and possible pathogenetic importance of each individual marker.

### INTRODUCTION

Primary sclerosing cholangitis (PSC) is a chronic inflammatory disease of the intra- and extrahepatic biliary tree leading to progressive bile duct strictures and liver cirrhosis<sup>[1]</sup>. No effective medical treatment is currently available<sup>[2]</sup> and PSC is a major indication for liver transplantation<sup>[3]</sup>. The PSC population is heterogeneous, comprising subgroups of regular “large-duct” PSC, patients with “small-duct” affection only<sup>[4]</sup> and an “overlap-syndrome” between PSC and autoimmune hepatitis (AIH)<sup>[5]</sup>. Up to 80% of the PSC patients have concurrent inflammatory bowel disease (IBD)<sup>[6]</sup>. According to standard endoscopic and histological criteria, the IBD is most often classified as ulcerative colitis (UC), but there is also an association with colonic Crohn’s disease (CD)<sup>[7,8]</sup>.

The aetiology of PSC is unknown (Figure 1). Immune responses against self antigens in the bile ducts have been proposed to play an important role in the pathogenesis, although controversy exists as to whether PSC should be denominated an autoimmune or merely immune mediated disease<sup>[9]</sup>. On one side, there are several lines of evidence supporting classification of PSC as an autoimmune disease<sup>[10]</sup>. This evidence includes (1) association with other autoimmune diseases in the same individual<sup>[11]</sup> and first degree relatives<sup>[12]</sup>, (2) infiltration of T-lymphocytes in the portal tracts<sup>[13]</sup> with restriction in T cell receptor V gene usage<sup>[14]</sup>, (3) a statistical association with particular human leukocyte antigen (HLA) haplotypes<sup>[15]</sup> and (4) the presence of autoantibodies<sup>[16]</sup>. On the other side, there is no documented effect of immunosuppressants in PSC<sup>[2]</sup>, and in contrast to the female predominance of many diseases regarded as autoimmune, approximately 2/3 of PSC patients are male<sup>[17]</sup>. These notions suggest that additional pathogenetic factors may exist (e.g. bile acid toxicity<sup>[18]</sup>), and to what extent and at what disease stage autoimmune mechanisms contribute to the bile duct damage observed in PSC is not known.

In many autoimmune diseases, autoantibodies serve as markers of disease activity, may aid in the diagnosis of patients, and provide important insight into the pathogenesis. In clinical practice, a good

**Figure 1** Schematic illustration of key elements of PSC pathogenesis. Initiation (upper right): The initiating factor(s) of PSC pathogenesis are unknown. Immunogenetic factors (including the presentation of autoantigens on PSC associated HLA molecules), an infectious trigger, and toxic or immunological effects from bile acids have been proposed. Recruitment (lower right): Autoantibodies produced by B-lymphocytes bind to biliary epithelial cells (BECs), leading to inflammation when there is concomitant stimulation of toll like receptors (TLRs) by bacterial products [LPS and other pathogen-associated molecular patterns (PAMPs)] from the gut. Recruitment of gut-primed ( $\alpha 4\beta 7$ ) T-lymphocytes in inflammatory bowel disease may contribute to the inflammation because of aberrant expression of the MadCAM-1 ligand in the endothelium and production of the CCL25 chemokine by BECs. Inflammation (lower left): T-lymphocytes and natural killer (NK) cells predominate in PSC affected livers, but neutrophils and macrophages are also recruited. Together with activated BECs they are sources of the cytokines and chemokines that perpetuate the inflammation in PSC. A specific cellular component of neutrophils (tubulin beta 5 chain), has been hypothesized to serve as an autoantigen in this inflammatory process, possibly cross-reacting with the bacterial homolog FtsZ and leading to the generation of anti-neutrophil cytoplasmic antibodies (ANCA). Fibrosis (upper left): Characteristically in PSC, there is extensive fibrosis and stricturing of the bile ducts. Resulting from the inflammation and possibly concomitant bile leakage, pro-fibrotic factors [e.g. transforming growth factor beta (TGF- $\beta$ )] from macrophages and/or stellate cells are ultimately responsible for the fibrotic obliteration of the bile ducts and liver cirrhosis in PSC.

marker is sensitive and specific and yields prognostic information [e.g. anti-cyclic citrullinated proteins (anti-CCP) antibodies in rheumatoid arthritis (RA)]. In studies of pathogenetic mechanisms, a good marker is tissue specific and closely linked to other observations regarding the pathogenesis (e.g. TSH receptor antibodies in Graves' disease). In PSC patients, a large number of different autoantibodies have been reported (Table 1). Some of these autoantibodies react with biliary or colonic epithelial antigens, others with constituents of neutrophil granulocytes, and some even with various ubiquitously expressed self antigens.

One of the most consistent findings regarding the aetiology of PSC is the disease association with genetic variants within the HLA-complex on chromosome 6<sup>[15]</sup>. HLA class I and II genes encode molecules which present antigens to CD8<sup>+</sup> and CD4<sup>+</sup> T-lymphocytes, respectively, resulting in an immune response against the antigen when appropriate co-stimulation is present<sup>[19]</sup>. A relationship between particular autoantibodies and disease associated HLA variants has been detected in other autoimmune diseases<sup>[20]</sup>, but in PSC the pathogenetic importance of most of the identified

autoantibodies is poorly defined. The present editorial aims to give an overview of the studies of autoantibodies in PSC, with a particular emphasis on the prevalence, clinical relevance and possible pathogenetic importance of each individual marker.

## ANTIBODIES AGAINST BILIARY AND COLONIC EPITHELIAL ANTIGENS

The identification of antibodies against well defined biliary antigens in PSC would strongly support the hypothesis of an autoimmune aetiology. Given the high frequency of colitis among the patients, such antigens could potentially also be expressed in the colonic mucosa.

One autoantibody of this type was proposed by Das *et al*<sup>[21]</sup>, who identified an antigenic protein expressed in both colonic and biliary epithelium, in addition to eye, skin and cartilage<sup>[22]</sup>. This 40 kDa protein was identified as human tropomyosin isoform 5 (hTM5)<sup>[23-25]</sup>. A monoclonal antibody (Das-1) was developed, and serum from UC and PSC patients inhibited the binding of Das-1 to the epithelium, indicating antibodies

PSC: Primary sclerosing cholangitis; Anti-BEC: Antibodies against biliary epithelial cells (measured with flow cytometry); PANCA: Perinuclear antineutrophil cytoplasmic antibodies; ANA: Antinuclear antibodies; SMA: Smooth muscle antibodies; ASCA: Anti *saccharomyces cerevisiae* antibodies; AMA: Anti-mitochondrial antibodies; Anti-LKM: Liver-kidney microsomal antibodies; Anti-SLA/LP: Antibodies against soluble liver antigen/liver pancreas; AECA: Anti-endothelial cell antibodies; Anti-TPO: Antibodies against thyroid peroxidase; Anti-GBM: Antibodies against the glomerular basement membrane; Anti-GSTT1: Antibodies against glutathione S transferase theta 1. <sup>1</sup>In the largest cohort investigated, ANAs and/or SMAs were detected in 22% (24/111) of the PSC patients, but the frequency of each type was not given<sup>[143]</sup>.

against hTM5 related epitope(-s) in the sera<sup>[22,26]</sup>. In the cell membrane hTM5 is found complexed with a 200 kDa colonic epithelial protein (CEP), and this complex is speculated to serve as the true target for the Das-1 antibody<sup>[27]</sup>. Antibodies against hTM5 have been detected in UC patients without PSC<sup>[28]</sup>, and anti-hTM5 in UC sera has recently been shown to induce cytotoxicity against colonic epithelial cells *in vitro*<sup>[29]</sup>. In PSC patients without concomitant UC, a single study identified antibodies against a 9-amino acid sequence from hTM (not isoform specific) in 100% (8/8) of patients as compared with 69% (33/48) of UC patients and 0/6 PBC patients<sup>[30]</sup>. The findings of Das *et al* have been partly reproduced by others<sup>[31]</sup>, but given a number of critical concerns<sup>[32-35]</sup>, further studies are required to conclusively confirm and elaborate the importance of the hTM5-CEP antigen in the pathogenesis of PSC.

A Swedish group has reported on the presence of antibodies against isolated biliary epithelial cells (BEC) at high frequencies in sera from PSC (63%) and PBC (37%) patients, *versus* 8% of controls (1/12)<sup>[36]</sup>. A 40 kDa antigenic protein was identified, but this protein did not react with tropomyosin antibodies, which implies that either the 40 kDa protein in this study is not a tropomyosin isoform or the antibody used reacts with other tropomyosin isoforms. Anti-BEC from PSC sera (and to a lesser extent PBC sera) induced isolated BEC to produce IL-6 and the adhesion molecule CD44, strongly suggesting pathogenetic importance. Recently the group also showed that sera from PSC patients with anti-BEC stimulated BEC to express toll-like receptors (TLR), leading to BEC cytokine production upon exposure to lipopolysaccharide (LPS, endotoxin) from gram negative bacteria<sup>[37]</sup>. This means that both LPS and antibodies against BEC are necessary to activate BEC and generate cytokine release. An association between the presence of the anti-BEC and PSC

associated HLA haplotypes (DR2 and DR3) was also suggested. The relevance of the Swedish findings are further strengthened by a higher frequency of acute liver transplant rejection in patients with anti-BEC prior to transplantation (all liver diseases) than in patients with no anti-BEC<sup>[38]</sup>. However, it needs to be noted that in this study there was a high prevalence of anti-BEC in all end stage liver patients (HCV 32%, PSC 56%, PBC 75%, HBV 57%, AIH 57%, and alcoholic cirrhosis 71%). This raises concerns as to the PSC specificity of the antibody, which clearly needs to be characterised prior to further studies.

Taken together, the findings of Das *et al* and the Swedish group suggest that antigens expressed in the biliary epithelium may induce self-reactive immune responses under certain conditions. Whether the antigenic epitope(s) lie within the hTM5-CEP complex or elsewhere remains to be elucidated, and the clinical significance of the corresponding autoantibodies must be established.

## ANTIBODIES AGAINST NEUTROPHILS

Antibodies against cytoplasmic constituents of neutrophils (ANCAs) were initially described in patients with glomerulonephritis and systemic vasculitis<sup>[39,40]</sup>. In UC patients, antibodies against nuclear antigens were reported by Calabresi *et al* in 1961<sup>[41]</sup> and Nielsen *et al* in 1983 (granulocyte specific-ANA)<sup>[42]</sup>. In PSC such antibodies were reported by Snook *et al* in 1989<sup>[43]</sup>. These antibodies are also present in a large proportion of patients with AIH<sup>[44]</sup> and the name ANCA was applied due to the close resemblance to ANCAs found in several of the vasculitides<sup>[45,46]</sup>. ANCA is analyzed by incubating fixated human neutrophil slides with patient serum, and subsequently with secondary antibodies conjugated to a fluorophore. The indirect immunofluorescence

PSC: Primary sclerosing cholangitis; IBD: Inflammatory bowel disease; UC: Ulcerative colitis; CD: Crohn's disease; AIH: Autoimmune hepatitis; PBC: Primary biliary cirrhosis; HC: Healthy controls; MT: Method and titre considered positive (cut-off); IIF: Indirect immunofluorescence; AP: Alkaline phosphatase method. <sup>1</sup>No distinction between classical/atypical; <sup>2</sup>The single largest study of autoantibodies in PSC reported ANCAs among 84% (61/73) of the patients, but this study did not apply IIF, meaning that this figure is the total of patients with any ANCA sub specificity<sup>[78]</sup>; <sup>3</sup>Atypical pANCA (as opposed to classical pANCA or cANCA); <sup>4</sup>autoimmune hepatitis type 1 and 2; <sup>5</sup>Calculated from article values; <sup>6</sup>Autoimmune hepatitis not subclassified (1 or 2); <sup>7</sup>ANCA "type 1 pattern" is interpreted as pANCA, including both IgA/IgM/IgG; <sup>8</sup>Significant difference between PSC +IBD and PSC -IBD (*P* value not given); <sup>9</sup>Details not given, correspondence, not peer-reviewed; <sup>10</sup>Calculated sum of 4 patient populations from different countries; <sup>11</sup>Autoimmune hepatitis type 1.

(IIF<sup>7</sup>) pattern is classified as cytoplasmic (cANCA) or perinuclear (pANCA)<sup>[47,48]</sup>. Billing *et al*<sup>[49]</sup> and Terjung *et al*<sup>[50-52]</sup> have made an additional contribution to this nomenclature, documenting that the main ANCA pattern in PSC, AIH and UC is "atypical". This means that the likely antigen is located in the nucleus rather than in the cytoplasm. The names anti-neutrophil nuclear antibodies (ANNAs)<sup>[51]</sup> and nuclear anti-neutrophil antibodies (NANAs) have thus been proposed<sup>[49]</sup>.

The prevalence of ANCA (subtype not specified) in PSC patients ranges from 42% to 93%<sup>[45,53-61]</sup>, and that of the pANCA subtype from 26% to 94% (Table 2). Comparable prevalences of ANCA are reported in AIH and UC (Table 2). No definite evidence links ANCA to the genetic susceptibility of PSC in terms of

particular HLA haplotypes<sup>[62]</sup>. One study has reported on an increased prevalence of ANCA in PSC relatives as compared with healthy controls<sup>[63]</sup> while another study could not confirm this<sup>[64]</sup>.

### Nuclear specificities of the neutrophil antigens

Multiple neutrophil antigens contribute to different ANCA IIF patterns (Table 3). A study published in abstract form by Terjung *et al*<sup>[65]</sup> in 2005 proposed that the main antigen of atypical pANCA in AIH, UC and PSC patients is tubulin beta 5 chain (TBB5), a nuclear membrane-associated protein present in myeloid cell lines. Further studies of anti-TBB5 are necessary to characterise the clinical and pathogenetic relevance of these findings. Other nuclear antigens have also been

**Table 3** Prevalence of antibodies against a selection of specific neutrophil antigens in PSC patients

Antibody	Frequency range % (median)	No. of patients range (median)	Number of studies

Anti-TBB5 <sup>1</sup>			

PSC: Primary sclerosing cholangitis; Anti-BPI: Antibodies against bactericidal/permeability increasing protein; Anti-h-lamp-2: Antibodies against human lysosomal-associated membrane protein 2; Anti-TBB5: Antibodies against Tubulin beta-5 chain. <sup>1</sup>No prevalence studies published.

proposed as nuclear targets of pANCA in AIH and UC, notably the high mobility group (HMG) non-histone chromosomal proteins HMG1 and HMG2<sup>[66-68]</sup> and Histone H1<sup>[69]</sup>. These have not been studied in patients with PSC.

### Cytoplasmic specificities of the neutrophil antigens

A variety of cytoplasmic proteins have also been proposed to be targets for ANCAs in PSC. In ANCA-associated small vessel vasculitis (Wegener's disease, microscopic polyangiitis and Churg-Strauss syndrome) the main proportion of specific ANCAs are directed against proteinase 3 (PR3, mainly cytoplasmic IIF pattern) and myeloperoxidase (MPO, mainly perinuclear IIF pattern)<sup>[70]</sup>. In these diseases, increased ANCA levels may predict clinical relapse, but there is limited correlation between titres and disease activity. The prevalence of anti-PR3 and anti-MPO in PSC patients is low (Table 3).

Bactericidal/permeability increasing protein (BPI) has functional domains which bind the inner core region of LPS<sup>[71]</sup>. This binding triggers anti-bacterial activity, neutralization of endotoxin and delivery of endotoxin rich particles to host cells<sup>[72]</sup>. Anti-BPI is detected in many clinical settings. In PSC, anti-BPI has been found in 5% to 46% of the patients (Table 3), which is similar to UC (3%-39%)<sup>[59,73-77]</sup>, compared with 0% to 5% of healthy controls<sup>[57,78]</sup>. Anti-BPI is also reported in RA, systemic lupus erythematosus (SLE) and systemic sclerosis<sup>[79]</sup>, and interestingly there is a high prevalence of anti-BPI in cystic fibrosis patients colonized with gram negative bacteria<sup>[80]</sup>.

Another LPS-binding ANCA target is lactoferrin, which is released from neutrophils during inflammation and has bactericidal and immune modulating effects<sup>[81]</sup>. Antibodies against lactoferrin have been detected in several autoimmune diseases including RA<sup>[82]</sup>, SLE<sup>[83]</sup>, reactive arthritis<sup>[82]</sup> and ankylosing spondylitis. The reported prevalence of anti-lactoferrin in PSC (4%-54%, Table 3) is similar to that in UC (4%-50%), and considerably higher than in CD (0%-9%)<sup>[73,75,76,84-86]</sup> and healthy controls (0%)<sup>[87,88]</sup>.

Antibodies against the proteases elastase and

cathepsin G are found in up to 35% of patients with PSC (Table 3). Catalase prevents cell damage from reactive oxygen-derived free radicals, and antibodies against catalase have been detected in up to 60% of PSC patients, compared with up to 10% of healthy controls<sup>[57,89]</sup>. Finally, human lysosomal-associated membrane protein 2 (h-lamp-2) is a target of ANCA in vasculitides<sup>[90]</sup>. In a single study, anti-h-lamp-2 was detected in a large proportion of PSC patients (71%) *versus* only 15% of healthy controls<sup>[78]</sup>. No disease controls were investigated. This finding has not yet been reproduced.

### Pathogenetic role of ANCAs

The large range of different ANCAs in PSC (Table 3) has been critically interpreted as the ANCAs serving as nonspecific epiphenomena of an immune response against dying neutrophils at an inflammatory site<sup>[91,92]</sup>. ANCAs (i.e. anti-MPO and anti-PR3) may, however, activate neutrophils<sup>[70]</sup>, and anti-BPI may inhibit clearance of LPS<sup>[93]</sup>. Also, widely and even ubiquitously expressed antigens sometimes serve as antigens in tissue specific autoimmunity [e.g. anti-mitochondrial antibodies (AMAs) in PBC].

Another possibility is related to the predominant theory on UC and CD, which involves an aberrant response to gut luminal antigens in genetically susceptible hosts<sup>[94]</sup>. A series of antibodies against bacterial antigens have been detected in IBD patients, and ANCAs may represent such antibodies<sup>[94]</sup>. One study from 1995 indicated that colonic lamina propria B-cells in UC produce pANCA<sup>[95]</sup>. In another study, absorption of human pANCA-positive sera with enteric bacterial antigens reduced or abolished the specific perinuclear staining<sup>[96]</sup>. The targets of these pANCAs are not known, but a study published in abstract form in 2006 indicates that antibodies giving rise to the atypical pANCA pattern have dual reactivity against both TBB5 and the microbial tubulin FtsZ<sup>[97]</sup>. How these cross-reacting antibodies may lead to hepatobiliary pathology can only be speculated upon.

### Diagnostic and clinical relevance of ANCAs

The sensitivity of ANCA in PSC is high in some studies,

whereas specificity is low. In one study of the diagnostic precision of autoantibodies in liver diseases, atypical pANCA with cut-off titre 1:40 had a specificity of 78% and sensitivity of 61% for PSC (AUC, 0.69; 95%CI, 0.61-0.77)<sup>[44]</sup>. Identification of the principal antigenic target of ANCAs in PSC would allow prospective studies to define this diagnostic role further. Currently, ANCA does not contribute diagnostically or during the clinical follow-up of PSC patients.

In terms of correlation between ANCA and particular clinical characteristics of PSC, no clear interpretation can be made from available data. If ANCAs were to represent markers for intestinal affection in PSC, a higher ANCA prevalence should be detected in PSC patients with IBD than in patients without IBD. This has only been shown in one small study by Seibold *et al*<sup>[98]</sup>. In another study, anti-lactoferrin was more prevalent in PSC with UC than without<sup>[99]</sup>. A few papers relate ANCA positivity to biliary tract complications like biliary calculi or cholangiocarcinoma<sup>[100]</sup>, or more extensive involvement of the biliary tree (both intra- and extrahepatic as compared with intrahepatic only)<sup>[101]</sup>. The presence of pANCA has also been found to correlate with disease stage (cirrhosis or liver transplantation)<sup>[100,102]</sup>, and in one study anti-BPI and anti-cathepsin G were more prevalent in PSC patients with cirrhosis<sup>[99]</sup>. Most other papers reported no difference in ANCA positivity between early and advanced PSC, and found no correlation between titres and disease activity<sup>[45,57,99,103]</sup>. ANCAs seem to persist after liver transplantation<sup>[98,104]</sup>, even though the titres may vary during follow-up<sup>[103]</sup>.

## AUTOANTIBODIES SPECIFIC TO LIVER DISEASES OTHER THAN PSC

AMA may be considered one of the most useful autoantibodies in the diagnosis of cholestatic liver disease, since AMAs are virtually absent in PSC patients (Table 1) compared with a 90%-95% prevalence in PBC<sup>[105]</sup>. The AMA antigens are different epitopes of the pyruvate dehydrogenase complex (PDC), especially the PDC-E2<sup>[106,107]</sup>. Mitochondrial antigens are expressed in all nucleated cells, and AMAs are classically detected by IIF. The presence of AMAs in PBC is an example of how autoimmunity against a ubiquitous antigen may be involved in the pathogenesis of a highly tissue specific disease. One of several proposed theories in PBC hypothesizes that in biliary epithelial cells the main AMA-antigen (PDC-E2) is not glutathiolated (as opposed to in other cells), causing persisting antigenicity of PDC-E2 when biliary epithelial cells undergo apoptosis<sup>[108]</sup>. Modification of AMA antigens in the liver by xenobiotics may also contribute<sup>[108]</sup>. A similar post-translational modification of proteins is known to contribute to antigenicity in several autoimmune diseases (e.g. antibodies against citrullinated proteins in RA)<sup>[109]</sup>.

Anti-liver kidney microsomes type 1 (anti-LKM1), anti-soluble liver antigen/liver pancreas antigen (anti-

SLA/LP) and anti-liver cytosolic protein type 1 (anti-LC1) are autoantibodies used in diagnosis of AIH<sup>[105]</sup>. These have not been detected in PSC patients (Table 1).

## ANTINUCLEAR (ANAS) AND SMOOTH MUSCLE ANTIBODIES (SMAS)

ANA and SMA are directed against ubiquitous antigens. ANA is the hallmark of SLE and other connective tissue diseases, but are also among the most prevalent autoantibodies in AIH<sup>[110]</sup>. ANAs may represent a large number of nuclear targets while SMAs are similarly undefined and directed against actin and other cytoplasmic filamentous proteins. ANA is reported in 8%-77% of the PSC patients (Table 1). No particular ANA subspecificities seem to predominate; anti-dsDNA has been reported in 3%-29%<sup>[61,78,87,111]</sup>, anti-ENA in 4%-12%<sup>[78,111,112]</sup>, anti SSA/B in 1%-28%<sup>[78,87]</sup> and anti-RNP, anti-SCL70, anti-Sm and anti-ssDNA in a minority of patients<sup>[87]</sup>. SMAs have been reported in 0%-83% of PSC patients (Table 1) but the prevalence is also high in AIH, various malignancies and infections<sup>[107]</sup>. ANA and SMA often co-exist, they lack organ and disease specificity, and should probably be concluded as irrelevant for the diagnostic process and pathogenesis in PSC.

## ANTIBODY AGAINST SACCHAROMYCES CEREVISIAE (ASCA)

ASCA is an antibody against baker's yeast (microbial antigens) and therefore does not represent a typical autoantibody. ASCA was first described in patients with CD in 1988<sup>[113]</sup>. The antigenic epitope of ASCA is located on the *S. cerevisiae* mannan, which is a polymer of mannose<sup>[114]</sup>. In a single study, 44% (11/25) of PSC patients were ASCA positive (57% with concurrent IBD and 39% without IBD) compared with 23% (28/123) of PBC and 18% (12/67) of AIH patients<sup>[113]</sup>. The presence of ASCA is interesting as a specific example of immune responses towards gut luminal antigens in IBD. As a serological marker in PSC, however, ASCA does not seem to contribute.

## ANTI-PHOSPHOLIPID ANTIBODIES

Anti-phospholipid antibodies are directed against phospholipids or phospholipid associated proteins, and are associated with thromboembolic disease. They are commonly detected in connective tissue disorders (e.g. SLE) but also in 1% to 5% of healthy subjects and during infections<sup>[116]</sup>. Three studies have investigated the presence of anti-cardiolipin antibodies in PSC with the prevalence ranging from 4% to 63% (Table 1). Interestingly, Angulo *et al*<sup>[78]</sup> found a positive correlation between anti-cardiolipin titres and Mayo risk score and histological disease stage, and there are anecdotal reports of an elevated risk of thrombosis in PSC patients<sup>[117]</sup>. An increased risk of hepatic artery thrombosis post liver transplantation has also been proposed<sup>[118]</sup>. Anti-

cardiolipin antibodies have also been reported at low frequencies in UC (16%-26%)<sup>[119-121]</sup> and CD (16%-27%) patients<sup>[120,121]</sup>.

## OTHER AUTOANTIBODIES

In addition to ANA and SMA, several other non-specific autoantibodies are detected in PSC. Rheumatoid factor is detected in connective tissue diseases, infections and lymphoproliferative diseases<sup>[122]</sup>, but is only found in 15% of PSC patients<sup>[78]</sup>. Anti-endothelial cell antibodies (AECAs) are directed against antigens in endothelial cells and have been reported in 35% of PSC patients in a single small study<sup>[87]</sup> but are observed in many other clinical conditions including vasculitis, SLE, systemic sclerosis and IBD<sup>[123,124]</sup>. The clinical and pathogenetic roles of AECAs are not clear<sup>[123,124]</sup>.

A few autoantibodies in PSC are probably related to co-morbidity. In one study, the prevalence of thyroid diseases in PSC patients was 8%<sup>[11]</sup>. This probably explains the elevated levels of anti-thyroid peroxidase (Table 3) and other thyroid related antibodies in PSC patients<sup>[54,78,87]</sup>. An association between PSC and celiac disease has been reported<sup>[125-127]</sup>. Recently the celiac disease related anti-tissue transglutaminase was detected in 7% of PSC patients in a large pre-transplant cohort from the Mayo Clinic (11/155), *versus* 6% (7/112) of PBC and 35% (15/43) of AIH<sup>[128]</sup> patients. This may in part be explained by shared susceptibility HLA-alleles (DQ2 and DQ8)<sup>[129]</sup>. Finally, in a single small study, antibodies against the glomerular basement membrane (anti-GBM) were detected in 17% of patients with PSC, while all healthy controls were negative<sup>[87]</sup>. The significance of this finding is not known.

Antibodies against sulfite oxidase were detected by Preuss *et al.* in 33% (13/39) of PSC patients compared with 5% (5/96) of PBC and 9% (7/77) of AIH patients<sup>[130]</sup>. Sulfite oxidase is a mitochondrial enzyme previously thought to be the antigen of anti-M4 (an AMA subtype)<sup>[131]</sup> but this does not seem to be correct<sup>[132]</sup>. The authors report lower prevalence in PSC patients treated with UDCA but the role of anti-sulfite oxidase antibodies in PSC remains to be established<sup>[130]</sup>.

Glutathione S-transferase theta 1 (GSTT1) was recently investigated as a candidate autoantigen in PSC by Ardesjö *et al* using immunoscreening<sup>[133]</sup>. This group created a cDNA library based on mRNA from human ductus choledochus<sup>[133]</sup>. The GSTT1 antigen was identified screening one single PSC patient serum for antibodies against bacteria expressing the cDNA encoded proteins. Upon testing in a larger population of PSC patients ( $n = 58$ ), antibodies against GSTT1 were only found in three patients, thus concluding GSTT1 as unlikely to serve as an important autoantigen in PSC. Nevertheless, the study points to the possible need for the application of broader screening methods in the search for autoantigens in PSC. The role of autoantibodies and B-cells in other autoimmune diseases has gained renewed interest the last few years<sup>[134]</sup>, not

only as pathogenetic factors<sup>[135]</sup>, but also as therapeutic targets (e.g. Rituximab)<sup>[136]</sup>. It is thus likely that further insight into the role of autoantibodies in PSC may be of clinical importance and further studies are warranted.

## CONCLUSION

A large number of autoantibodies have been detected in PSC patients. The specificity of these antibodies is generally low and the frequencies vary largely between different studies. Interpretation of the literature is difficult because of small patient sample sizes and variable methodology for antibody detection. The presence of autoantibodies in PSC is often attributed to a nonspecific dysregulation of the immune system, but the literature in PSC points to the possible presence of specific antibody targets both in the biliary epithelium and in neutrophils. Further characterisation of such targets would probably yield important insight into the pathogenesis of PSC. The investigation of larger populations may also further define the role of autoantibodies in PSC as diagnostic tools.

### Abstract

Epithelial-mesenchymal transition (EMT) is a highly conserved process that has been well characterised in embryogenesis. Studies have shown that the aberrant activation of EMT in adult epithelia can promote tumour metastasis by repressing cell adhesion molecules, including epithelial (E)-cadherin. Reduced intracellular adhesion may allow tumour cells to disseminate and spread throughout the body. A number of transcription proteins of the Snail superfamily have been implicated in EMT. These proteins have been shown to be over-expressed in advanced gastrointestinal (GI) tumours including oesophageal adenocarcinomas, colorectal carcinomas, gastric and pancreatic cancers, with a concomitant reduction in the expression of E-cadherin. Regulators of EMT may provide novel clinical targets to detect GI cancers early, so that cancers previously associated with a poor prognosis such as pancreatic cancer can be diagnosed before they become inoperable. Furthermore, pharmacological therapies designed to inhibit these proteins will aim to prevent local and distant tumour invasion.

### INTRODUCTION

Epithelial-mesenchymal transition (EMT) is a well-characterised embryological process that has been considered to play a vital role in tumour progression<sup>[1-5]</sup>. EMT has been shown to occur during gastrulation, as well as during the development of the neural crest, heart and the musculoskeletal system<sup>[6]</sup>. In the process of EMT, epithelial cells undergo a phenotypic switch to form mesenchymal cells that are similar in appearance to fibroblasts<sup>[2,3]</sup>. The change in cell type results in the loss of polarity and also the loss of tight intracellular adhesions maintained by epithelial cells *via* adherens junctions<sup>[1-3]</sup>. This is thought to allow dynamic cellular migration and increase embryogenic diversity<sup>[5]</sup>. However, *in vitro* evidence has outlined a role for the aberrant induction of EMT in adult epithelia during tumour metastasis<sup>[6,7]</sup>. In primary tumours, the induction of EMT can lead to structural changes involving cell adhesion molecules, and in particular epithelial-cadherin (E-cadherin)<sup>[8-10]</sup>. E-cadherin is a transmembrane glycoprotein that is localised in the adherens junction typically found in epithelial cells, and plays an important role in maintaining the structural integrity of epithelial sheets<sup>[11]</sup>. The loss of E-cadherin expression has been reported in several GI cancers including advanced colorectal carcinomas, oesophageal adenocarcinomas, gastric and pancreatic cancers<sup>[12-15]</sup>. Interestingly, experiments used to silence the expression of E-cadherin not only showed a morphological shift from an epithelial to a fibroblastoid phenotype, characteristic of EMT, but also a concomitant increase in invasive cell behaviour<sup>[16]</sup>. The loss of E-cadherin has been considered to augment cellular dissemination and tumour metastasis.

The mechanisms by which E-cadherin has been shown to be inactivated include gene mutations, promoter hypermethylation, chromatin remodelling,

post-translational modification and transcriptional repression<sup>[17-19]</sup>. The major proteins implicated in the transcriptional repression of E-cadherin include the zinc finger proteins Snai1 (Snail) and Snai2 (Slug),  $\delta$ EF (ZEB-1), Smad interacting protein 1 (SIP1) or ZEB-2, and a basic helix-loop-helix (bHLH) protein called Twist<sup>[20-22]</sup>. Snail was initially described in *Drosophila melanogaster* and was shown to be essential for dorsal-ventral patterning and mesoderm formation<sup>[23]</sup>. Knockout studies revealed that mice lacking the *Snail* gene died at gastrulation due to defective EMT<sup>[24]</sup>. *Snail* was found to down-regulate epithelial markers such as claudins, occludens, desmoplakin and cytokeratins, in addition to E-cadherin, and up-regulate mesenchymal markers including fibronectin and vitronectin during EMT<sup>[25,26]</sup>. Its homologue, Slug was discovered in developing chick embryos, and was found to be abundantly expressed in cells undergoing EMT in the primitive streak, neural crest and other mesenchymal tissue<sup>[26]</sup>. Over expression of Slug in mice induced the formation of mesenchymal tumours that were mainly leukaemias and sarcomas<sup>[27]</sup>. It was discovered that both Snail and Slug are able to bind directly to E-box motifs (CANNTG) on target gene promoters, and in particular the *CDH1* gene in order to down-regulate E-cadherin expression<sup>[20]</sup>. The zinc finger proteins ZEB-1 and SIP1 were also shown to be able to repress E-cadherin by binding to similar DNA sites as Snail on the E-cadherin promoter region<sup>[28]</sup>. Furthermore, microarray analysis revealed Twist as another strong candidate for the acquisition of invasive properties of tumour cells, although its mechanism of action is less clear<sup>[22]</sup>.

## ROLE OF E-CADHERIN REPRESSORS IN CANCERS OF THE UPPER GASTROINTESTINAL TRACT

Cancers of the upper GI tract, including oral, oesophageal and gastric tumours, are associated with significant mortality worldwide<sup>[29-31]</sup>. Tumours arising in the oral cavity are predominantly squamous cell carcinomas (SCC) in origin and have a tendency to spread rapidly<sup>[32]</sup>. Oral cancer accounts for around 197 000 deaths each year, throughout the world<sup>[33]</sup>. E-cadherin expression in normal oral mucosa, compared to pre-cancerous oral lesions and primary oral SCC has been shown to be sequentially lower in each of these stages, respectively<sup>[34]</sup>. Moreover, Snail-mediated repression of E-cadherin has been confirmed in oral SCC cell lines<sup>[35]</sup>. Further analysis of primary and recurrent oral SCC, showed that the over-expression of Snail in the primary oral SCC lead to ZEB-1 and SIP1 up-regulation with a concomitant loss of E-cadherin<sup>[36]</sup>. This expression profile, now matching that of the recurrent oral SCC, may suggest that Snail is able to regulate the function of other E-cadherin repressors such as ZEB-1 and SIP1 in oral SCC.

Repression of E-cadherin has also been reported for advanced human oesophageal cancers<sup>[37]</sup>. These

tumours are known to be particularly aggressive and have a 5-year survival rate of around 8% in the United Kingdom<sup>[38]</sup>. Oesophageal cancer is histologically divided into squamous cell carcinomas and adenocarcinomas. Oesophageal SCC commonly arises in the upper third of the oesophagus and its predominant aetiological factors include alcohol and nicotine abuse<sup>[39]</sup>. Analysis of tissue samples from patients with oesophageal SCC suggests that Snail is associated with repressed E-cadherin expression in these primary tumours<sup>[40]</sup>. In addition, Slug has been shown to be over-expressed in primary oesophageal SCC, correlating with depth of tumour invasion, lymph node metastasis and poorer clinical outcome<sup>[41]</sup>. Similarly, evaluation of Twist in oesophageal SCC revealed significantly higher Twist expression relative to non-neoplastic tissue<sup>[42]</sup>.

Conversely, oesophageal adenocarcinomas arise in the lower third of the oesophagus<sup>[39]</sup>. The strongest known risk factor for the development of oesophageal adenocarcinoma is the presence of Barrett's metaplasia<sup>[43]</sup>. This is a pre-malignant state that is characterised by the replacement of native squamous oesophageal epithelium by columnar cells, and is considered to occur secondary to prolonged reflux of gastric content in the lower part of the oesophagus<sup>[44]</sup>. A recent study by Jethwa *et al* has reported an over-expression of nuclear Slug in oesophageal adenocarcinoma relative to both normal squamous and Barrett's metaplasia specimens<sup>[45]</sup>. Interestingly, no such association was observed for both Snail and Twist<sup>[45,46]</sup>.

Gastric carcinomas also form part of the upper GI cancers, and although the incidence of these tumours seems to be declining, they are still responsible for around 700 000 deaths per annum, worldwide<sup>[47]</sup>. According to Lauren's classification, gastric cancer can be subdivided into two morphologically distinct groups; diffuse and intestinal gastric cancers<sup>[48]</sup>. The aetiology of gastric cancer has been mainly linked to E-cadherin mutations, promoter hypermethylation and *H pylori* infection, but there is scarce literature on the role of E-cadherin repressors in these tumours<sup>[49,50]</sup>. Snail-regulated repression of E-cadherin has been reported for diffuse gastric cancer<sup>[25]</sup>, and over-expression of Slug has been shown in both diffuse and intestinal gastric carcinoma<sup>[51]</sup>. Previous work has also shown that in diffuse gastric carcinomas, raised Twist expression correlates with reduced E-cadherin levels, whereas in intestinal gastric cancer, SIP1 is mainly associated with reduced expression of E-cadherin<sup>[25]</sup>. Interestingly, a strong correlation between neuronal-cadherin (N-cadherin) and Twist expression has been reported in diffuse-type gastric carcinoma<sup>[25]</sup>. The up-regulation of N-cadherin has been associated with an invasive tumour phenotype and is considered to over-ride the function of E-cadherin<sup>[52]</sup>. Therefore, it is suggested that Twist may be implicated in mediating a switch from E-cadherin to the N-cadherin, in order to increase tumour cell motility<sup>[25]</sup>. A more recent study has confirmed this by using human gastric carcinoma cell lines to show that the suppression of Twist leads to a loss of cellular migration as well as N-cadherin expression<sup>[53]</sup>.

**Figure 1** Evidence for the role of EMT regulators in gastrointestinal cancer.

## COLORECTAL CANCER PROGRESSION

Colorectal cancer (CRC) is the third most common malignancy worldwide<sup>[54]</sup>. Its pathogenesis is characterised by clinical and histopathological changes known as the adenoma-carcinoma sequence, where normal colonic epithelium becomes hyper-proliferative and forms adenomatous polyps that progress to malignant disease<sup>[55]</sup>. The adenoma-carcinoma sequence is considered to occur as a result of sequential genetic changes involving defined oncogenes and tumour suppressor genes, as proposed by Fearon and Vogelstein in 1990<sup>[56]</sup>. Several studies have reported mutations of the tumour suppressor adenomatous polyposis coli (APC) gene in CRC<sup>[57-59]</sup>. These mutations are amongst the earliest genetic events found in the majority (up to 80%) of sporadic cases of CRC<sup>[60,61]</sup>. The main tumour suppressor function of APC has been shown to be in its ability to mediate the proteosomal degradation of intracellular  $\beta$ -catenin, a key member of the Wnt signalling cascade<sup>[62]</sup>. Physiologically, Wnt factors are able to induce the stabilization of cytosolic  $\beta$ -catenin, which then associates with T cell factor/lymphoid enhancer factor-1 (TCF) proteins in the nucleus to initiate the transcription of Wnt target genes<sup>[61-63]</sup>. These include genes such as c-myc, cyclin D1, Ephrin B2 and matrilysin<sup>[63]</sup>. In CRC, mutations of both APC and  $\beta$ -catenin (in 10% of cases) cause deregulation of intracellular  $\beta$ -catenin levels which leads to the nuclear accumulation of  $\beta$ -catenin<sup>[62]</sup>. This causes aberrant and constitutive expression of Wnt target genes, and thus the development of CRC<sup>[63]</sup>. Interestingly,  $\beta$ -catenin can

also interact with the cytoplasmic domain of E-cadherin, providing a link to the actin cytoskeleton *via* its binding to  $\alpha$ -catenin<sup>[64]</sup>. However, it is unclear whether the loss of this interaction with  $\beta$ -catenin, in more aggressive forms of CRC where E-cadherin is down-regulated, promotes TCF-dependent transcription<sup>[65]</sup>.

Several mechanisms of E-cadherin repression have been reported in CRC, including gene mutations and promoter hypermethylation. However, transcriptional repression of E-cadherin and associated up-regulation of Snail is also considered to play a role in the progression of CRC<sup>[66-68]</sup>. Analysis of Snail in human CRC has shown that 78% of the tumour samples examined over-expressed this protein<sup>[68]</sup>. Slug expression has been shown to be positive in 37% of cases of primary CRC, which correlated significantly with metastatic spread of the cancer<sup>[69]</sup>. Evidence for ZEB-1, SIP1 and Twist-mediated repression of E-cadherin has not yet been established in CRC<sup>[70]</sup>.

## OTHER SOLID TUMOURS OF THE GASTROINTESTINAL SYSTEM

Pancreatic cancer confers possibly the worst prognosis of the GI cancers, since it presents very late<sup>[71,72]</sup>. Evidence suggests that both Snail and Slug are over-expressed in pancreatic tumours<sup>[72]</sup>. A recent study explored Twist expression in invasive ductal carcinoma (IDC) of the pancreas and its associated pre-malignant lesion intraductal papillary mucinous neoplasia (IPMN). Although it was limited by sample size, Twist expression

was found to be significantly higher in IDC compared to matched non-tumourous and IPMN samples<sup>[73]</sup>. SIP1 expression has also been shown to be raised in pancreatic tumours<sup>[74]</sup>.

Studies have also reported the over-expression of Snail in Hepatocellular carcinomas (HCC)<sup>[75,76]</sup>. Twist expression has also been shown to be raised in HCC, which correlates with the metastatic potential of this type of tumour<sup>[77]</sup>. Miyoshi *et al* outlined the role of SIP1 in HCC by showing that transfection of SIP1 into HCC cell lines induced cellular dedifferentiation as well as E-cadherin repression. Vimentin and fibronectin, along with various matrix metalloproteinases (MMPs), were also up-regulated, and it was hypothesised that MMP up-regulation augments SIP1-induced HCC progression<sup>[78]</sup>.

## CONCLUSION

EMT is a context dependent process that is considered to be involved in the progression of GI tumours<sup>[5-7]</sup>. Snail and associated repressors of E-cadherin have been implicated in EMT, and the evidence for their role in GI cancer is summarised in Figure 1. Transcriptional repressors of E-cadherin may be useful therapeutic targets for the prevention of local invasion and distant metastasis in GI malignancies. Inhibition of these proteins may also, for the first time, allow early detection of GI cancers associated with a fatal prognosis such as pancreatic cancer to enable early intervention and avoid the situation where this type of cancer becomes inoperable. The same principle can also be applied to other pre-malignant lesions such as Barrett's metaplasia to improve the management of oesophageal adenocarcinomas. However, it is important to consider that these transcriptional repressors of E-cadherin, or EMT regulators, also have other cellular functions. Both Snail and Twist have been associated with anti-apoptotic functions and Snail has also been implicated in cell adhesion and migration<sup>[79,80]</sup>. Furthermore, some evidence suggests that the expression of E-cadherin is higher in metastatic foci, such as in CRC, thus the reverse process of EMT, or mesenchymal-epithelial transition (MET), may be required in the formation of distant metastases<sup>[8]</sup>. Therefore, the grade and location of different GI cancers will also need to be considered before commencing any pharmacological treatment targeting regulators of EMT.

Future studies should also consider the various signalling molecules that activate EMT, including the Epidermal growth factor (EGF) family members, Fibroblastic growth factors (FGF), Insulin-like growth factors (IGF), bone morphogenic proteins (BMP) and Wnt factors<sup>[79]</sup>. It is necessary to explore the interactions between these molecules, their signalling pathways, and the Snail super-family of proteins in GI tumours. This may allude to novel combined treatment regimes to improve clinical outcome. Whilst it is clear that Snail and associated regulators of EMT are implicated in GI carcinogenesis, the role of EMT in cancer is further complicated by the fact that a number of novel EMT

regulators have been identified, including molecules such as MMP-3, Met, Goosecoid, Kaiso, TGF- $\beta$ , FOXC2, GSK3 $\beta$ , Smad-3, Pez and ILK<sup>[4]</sup>. Additional research is required to support the growing literature regarding the process of EMT, in order gain full insight into its role in GI cancer progression.

## Abstract

Self expanding metal stents (SEMS) play an important role in the management of malignant obstructing lesions in the gastrointestinal tract. Traditionally, they have been used for palliation in malignant gastric outlet and colonic obstruction and esophageal malignancy. The development of the polyflex stent, which is a removable self expanding plastic stent, allows temporary stent insertion for benign esophageal disease and possibly for patients undergoing neoadjuvant chemotherapy prior to esophagectomy. Potential complications of SEMS insertion include perforation, tumour overgrowth or ingrowth, and stent migration. Newer stents are being developed with the aim of increasing technical and clinical success rates, while reducing complication rates. Other areas of development include biodegradable stents for benign disease and radioactive or drug-eluting stents for malignant disease. It is hoped that, in the future, newer stents will improve our management of these difficult conditions and, possibly, provide prognostic as well as symptomatic benefit in the setting of malignant obstruction.

## INTRODUCTION

Self expanding metal stent (SEMS) insertion has an important role in the management of malignant gastrointestinal obstruction. There are several types and sizes of SEMS on the market. Each has its own characteristics in terms of radial forces exerted, foreshortening on deployment, and flexibility. SEMS are made of either stainless steel [e.g. Z-stent (Cook)] or alloys such as Nitinol [e.g. Ultraflex (Boston Scientific), Alimaxx E (Alveolus)] or Elgiloy [e.g. Wallstent (Boston Scientific)]<sup>[1]</sup>. Stent insertion is also increasingly used in benign esophageal disease, such as non-malignant strictures and anastomotic leaks. The Polyflex stent (Boston Scientific) is a self expanding plastic stent which has been approved for use in the management of benign and malignant esophageal strictures.

Enteral SEMS, i.e. for the duodenum and colon, are generally inserted through the scope (TTS). These are deployed over a guidewire under direct vision, usually with fluoroscopic guidance. Esophageal stents are not TTS and are deployed under fluoroscopic guidance after delineating the margins of the stricture endoscopically.

In this article, we review the current state of play with respect to enteral and esophageal stents, the latest developments, and possible future directions.

## ESOPHAGEAL STENTING

SEMS have been in use for malignant dysphagia and trache-esophageal fistulae (TEF) since the early 1990s when they replaced rigid plastic stents. They are relatively easy to deploy, have a high technical success rate and provide rapid relief of dysphagia<sup>[2]</sup>. However, insertion of SEMS has a complication rate of 26%-52%<sup>[3-7]</sup> with 1 in 6 requiring further stents<sup>[8]</sup>. Procedure related mortality is 2%-3%<sup>[7,8]</sup>. Complications associated with esophageal stent insertion include perforation, bleeding,

stent migration, reflux, chest pain, recurrent dysphagia due to tumour overgrowth or ingrowth, migration, and food bolus impaction. Although SEMS insertion is still the treatment of choice for TEF, it appears not to be the safe, one-off treatment for malignant dysphagia that it was once hoped to be.

Comparisons between SEMS and brachytherapy for esophageal malignancy have shown improved dysphagia scores at 30 d with reduced complications<sup>[9]</sup> and improvements in quality of life, dysphagia, and eating scales<sup>[10]</sup> for brachytherapy. It has been suggested that, as stent re-intervention is likely to be increased for those who live longer, SEMS should be considered for those with a poorer prognosis, and chemo/radiotherapy, with temporary stent placement, for those with a longer life expectancy<sup>[12]</sup>. A Korean group inserted a removable nitinol stent in 47 patients who had concurrent radiotherapy and extracted the stent in 24 patients after 4 wk, leaving the stent in place in the remaining patients<sup>[11]</sup>. The complication and re-intervention rates were significantly lower in the group in which the stent was extracted, while the dysphagia-progression-free and overall survival rates were significantly longer. No randomized trials have yet been conducted with the Polyflex stent, which is the only removable stent licensed in the USA in this setting. Further randomized trials of SEMS in combination with other treatment modalities would help determine the optimal management strategy in terms of symptom control and overall survival. Drug-eluting and radioactive stents may also have a future role in the management of esophageal malignancy; these have been tested with success in animal models<sup>[12,13]</sup>.

In cases where the distal margin of the stent crosses the gastro-esophageal (GE) junction there are now SEMS available with an anti-reflux mechanism. Survival has been shown to be reduced in patients in whom the stent crossed the GE junction<sup>[14]</sup>. A study which compared an open stent with the Z-stent with Dua antireflux valve found that 96% of patients with the open stent had reflux symptoms, compared with 12% with the antireflux mechanism<sup>[15]</sup>. Several other SEMS with antireflux mechanisms have been manufactured. Further work will be required to determine the overall efficacy and complication rates of these stents for distal esophageal and cardia tumours.

Many of the available SEMS are covered to reduce the risk of tumour in-growth and to seal TEF. As the risk of stent migration is higher with covered stents, many have flared ends and uncovered segments at both ends to anchor on to the tissue. Fully covered SEMS may prove useful in benign disease as they are potentially removable but further experience in this area is required.

The Polyflex stent is the only stent currently licensed for benign disease but there has been an interest in the development of biodegradable stents. These would theoretically exert their effect before slowly breaking down and subsequent stent extraction, which can be stressful for the patient and physician, is avoided. A small case series from Japan had promising results when

a biodegradable stent constructed from poly-L-lactic acid monofilaments was used to treat benign esophageal stenoses<sup>[16]</sup>.

## GASTRIC OUTLET OBSTRUCTION (GOO) AND DUODENAL STENTING

Stent placement for GOO was first described in 1992<sup>[17]</sup>. Patients with GOO are generally very ill and in the terminal phase of a malignant process. Gastrojejunostomy (GJJ) has traditionally been the procedure of choice for GOO. However, insertion of a SEMS for GOO offers a relatively safe and much less invasive alternative to gastrojejunal bypass. Most trials comparing GJJ with SEMS insertion for GOO are prospective or retrospective comparative studies or case series evaluating either SEMS insertion or GJJ. A summary of the prospective and larger retrospective case series is given in Table 1. A more recent comprehensive review of stent insertion *versus* GJJ for GOO included a total of 1046 patients undergoing stent insertion and 297 undergoing GJJ<sup>[39]</sup>. There was no difference between SEMS insertion and GJJ in terms of technical success (96% *vs* 100%), early (7% *vs* 6%) and late (18% *vs* 17%) major complications, or persisting symptoms (8% *vs* 9%). Initial symptom relief was higher for SEMS (89% *vs* 72%). Recurrent obstructive symptoms were higher for SEMS (18% *vs* 1%) but hospital stay was shorter (13 d *vs* 7 d) with a mean survival of 105 d after stent placement and 164 after GJJ. These results suggest that stent placement may be the preferred option for patients with a shorter life expectancy but GJJ is preferable for patients with a more favourable prognosis.

Several stents are available for gastroduodenal use including the Wallstent Enteral, Wallflex Enteral Duodenal (Boston Scientific), Choo stent (Solco Intermed Co. Ltd. and Mi Tech Co. Ltd), and the Song stent (Stentech). The aim of stent manufacturers is to produce a SEMS which is easy to insert, is clinically effective and carries a low complication and migration rate. The use of the new Nitinol Wallflex stent was investigated by Van Hooft *et al*<sup>[40]</sup> who inserted a total of 66 Wallflex stents in 62 patients. with a clinical success rate of 85%. Median hospital stay was 6 d, and 10 of 60 patients (17%) who had follow up data for 30 d developed complications. They concluded that the new stent was effective and relatively safe.

Other recently developed stents include the Niti-S enteral stent (Taewoong Medical Co.) which has a woven rather than the usual braided design, leading to improved flexibility and reduced foreshortening and, it is hoped, reduced migration, as well as dual stents (e.g. Niti-S Comvi, Taewoong Medical Co., and the dual expandable nitinol stent, S&G Biotech). These have a covered layer to reduce tumour ingrowth and an uncovered layer to reduce migration. These newer stents have shown promising results in case series<sup>[32,33,37]</sup> but randomized comparisons with conventional stents are required to further assess their efficacy.

nr: Not reported.

Increasingly innovative techniques for stent insertion are also being pioneered. The development of double balloon enteroscopy has allowed us to perform therapeutic procedures in areas that were previously beyond our reach. Ross *et al* successfully inserted a SEMS in the distal duodenum for a patient with metastatic lung cancer using double balloon enteroscopy<sup>[41]</sup>. This raises the possibility of stent insertion in patients with a single point of malignant small bowel obstruction that is beyond the reach of conventional endoscopes.

## COLONIC STENTING

The use of SEMS in the palliation of malignant colonic obstruction was first described in 1991<sup>[42]</sup>. The current stents available are uncovered but there have been reports on the use of uncovered and covered esophageal stents in the colon. Overall technical success rates are generally in excess of 95% with relief of obstructive symptoms in 85%-90% for palliative stenting<sup>[1]</sup>. In a comprehensive review of 58 publications on colorectal stent publications from 1990 to 2000<sup>[43]</sup> stent insertion was successful in 551 of 598 cases (92%). There was a 4% rate of perforation, 10% migration rate and 10% re-obstruction rate. Stent migration was associated with laser pre-treatment, concurrent chemotherapy, covered stent use, and benign disease. The perforation rate was higher in the studies in which balloon pre-dilation was performed (10% *vs* 2%), suggesting that this should not be performed routinely. A variety of stents were used in the different studies but most of them were uncovered. One study, which used partially or fully covered stents, had a migration rate of 22%<sup>[44]</sup>.

Many earlier series used esophageal stents for colonic stenting and it is hoped that specifically designed

colorectal stents will have lower rates of migration. For example, in a prospective study with 44 patients<sup>[45]</sup> the nitinol Ultraflex precision colonic stent migrated in one patient (2%) who had commenced chemotherapy shortly after stent insertion. There was a technical success rate of 95% and a 6 mo clinical success rate of 81%. There have been very few comparisons between different stent types. A small retrospective study comparing the Ultraflex stent and the Wallstent found that they both provided adequate relief of obstruction but the Ultraflex had a significantly lower rate of delayed complications, need for re-intervention, and a non-significant reduction in early migration and occlusion<sup>[46]</sup>.

In recent years there has been a move towards SEMS insertion as a “bridge” to surgery for patients who present with acute malignant obstruction. In the event that a patient is subsequently deemed unsuitable for a curative resection, the stent provides palliation. 10%-30% of patients with colonic cancer present with obstructive symptoms<sup>[47]</sup> and in many centres surgical decompression remains the primary management option for such patients, either due to local preference or resources. Morbidity and mortality rates have been quoted at 32%-64% and 15%-34%, respectively, for patients who undergo emergency surgery<sup>[48-52]</sup>. Up to 40% of these patients are left with a permanent colostomy<sup>[53]</sup>. For those patients who are subsequently found to have operable disease they then need a second surgical procedure. Stent insertion is appealing as it allows these patients to have adequate rehabilitation and preparation before an elective procedure, while avoiding invasive surgery for palliative patients.

Martinez-Santos *et al*<sup>[50]</sup> performed a prospective study investigating the results of colonic stenting *versus* emergency surgery in 72 patients presenting with left

sided malignant colorectal obstruction. Forty-three patients had preoperative stent insertion followed by elective surgery (if necessary) and 29 had emergency surgical treatment. Surgical resection was subsequently found not to be indicated in 18 of the patients who had SEMS insertion and in 3 from the control group. SEMS insertion was clinically successful in 41 cases (95%). Of those patients with colonic stents who proceeded to surgery 85% had a primary anastomosis, compared to 41% in the non-stent group ( $P = 0.0025$ ), with a lower need for a colostomy (15% *vs* 59%). There were also significantly reduced severe complications, re-intervention rates, total hospital stay, and ICU stay. Overall, stent placement prevented 17 of 18 (94%) unnecessary operations. In a long-term follow up study there was no difference in 3 years (48% *vs* 50%) and 5 years (40% *vs* 44%) survival in the SEMS and emergency surgery groups respectively, but post-operative complications were significantly lower in the stent group<sup>[51]</sup>. Therefore, stent insertion as a bridge to surgery is technically and clinically successful, relatively safe, and cheaper than emergency surgery for patients who present with malignant left sided obstruction.

SEMS insertion is not currently approved for benign disease of the colon, primarily because of high failure and complication rates, as well as an inability to remove the stent endoscopically<sup>[54]</sup>. In one study there was a failure rate of 63% for 8 patients<sup>[55]</sup>. In the largest series to date 23 patients had an SEMS placed for benign colonic disease<sup>[56]</sup>. There was a 100% technical success rate and 95% (22/23) clinical success rate. Eight of the 23 patients (38%) had major complications, 7 of which (87%) occurred within the first week. Sixteen of the 19 patients who underwent a colectomy were successfully converted from an emergency procedure to an elective one; 8 patients did not require a colostomy. SEMS insertion should probably not be considered as a definitive treatment option for benign colonic strictures, in view of the high rate of complications in the limited published data available. However, in the setting of colonic obstruction it may be appropriate as a temporary measure to facilitate decompression with subsequent elective surgery, rather than proceeding to emergency colectomy.

## CONCLUSION

Endoscopic stenting remains an important tool in the management of malignant conditions of the esophagus, gastric outlet, and colon. As newer stents are developed, randomised trials are required to determine which provides the most benefit. For esophageal malignancy the evidence suggests that SEMS insertion may be appropriate for patients with a poorer prognosis, with temporary SEMS and chemoradiotherapy for those with a longer life expectancy. However, further trials are required to clarify the optimum management of these patients. For patients undergoing neo-adjuvant therapy prior to esophagectomy, a small retrospective trial reported favourable results for temporary placement

of the Polyflex stent<sup>[57]</sup>. The Polyflex stent is being increasingly used for benign esophageal strictures and has also been used with success in the management of post-operative esophageal leak<sup>[58]</sup>. Another novel use for temporary esophageal stent placement was in the management of acute esophageal variceal bleeding<sup>[59]</sup>. Although the findings of this small study were positive, a large comparative trial would be required before SEMS could replace the current therapy for bleeding varices.

Colonic stenting should be considered for palliation in malignant obstruction and as a bridge to surgery in the setting of acute obstruction. The results of further randomized controlled trials, such as the Dutch Stent-in 2 study<sup>[60]</sup>, are awaited to bolster the existing evidence. Covered stents and pre-deployment dilatation appear to increase the complication rate. The development of stents with longer delivery systems will hopefully make the right colon more accessible also. Double balloon enteroscopy may also allow stent insertion in areas that were previously beyond our reach.

As stenting devices and our skills develop, endoscopic capabilities will continue to expand. Bioabsorbable stents may allow a safe and effective method of temporary stent placement, without the need for a further procedure. Radioactive and drug-eluting esophageal stents have already been trialled in animal models; it is hoped that such stents in the future will have prognostic as well as symptomatic benefit for patients with malignant obstruction. We await these new developments with anticipation.

## Abstract

**AIM:** To discuss the possible effect of *PTEN* gene mutations on occurrence and development of gastric cancer.

**METHODS:** Fifty-three gastric cancer specimens were selected to probe *PTEN* gene mutations in genome of gastric cancer and paracancerous tissues using PCR-SSCP-DNA sequencing method based on microdissection and to observe the protein expression by immunohistochemistry technique.

**RESULTS:** PCR-SSCP-DNA sequencing indicated that 4 kinds of mutation sites were found in 5 of 53 gastric cancer specimens. One kind of mutation was found in exons. AA-TCC mutation was located at 40bp upstream of 3' lateral exon 7 (115946 AA-TCC). Such mutations led to terminator formation in the 297th codon of the *PTEN* gene. The other 3 kinds of mutation were found in introns, including a G-C point mutation at 91 bp upstream of 5' lateral exon 5(90896 G-C), a T-G point mutation at 24 bp upstream of 5' lateral exon 5 (90963 T-G), and a single base A mutation at 7 bp upstream of 5' lateral exon 5 (90980 A del). The *PTEN* protein expression in gastric cancer and paracancerous tissues detected using immunohistochemistry technique indicated that the total positive rate of *PTEN* protein expression was 66% in gastric cancer tissue, which was significantly lower than that (100%) in paracancerous tissues ( $P < 0.005$ ).

**CONCLUSION:** *PTEN* gene mutation and expression may play an important role in the occurrence and development of gastric cancer.

## INTRODUCTION

The occurrence and development of gastric cancer, like other malignant tumors, are a complicated process involving participation of polygene and many factors<sup>[1-4]</sup>. It is generally considered that protein tyrosine phosphatase level plays an important role in the process. Mutation of the *PTEN* gene encoding for protein tyrosine phosphatase and abnormal expression of protein are significantly correlated with the occurrence and development of malignant tumors such as glioblastoma, prostate cancer, malignant melanoma, and breast cancer, etc<sup>[5-11]</sup>. However, only few studies are available on *PTEN* gene mutation and protein expression in gastric cancer<sup>[3,12-15]</sup>. The aim of this study was to detect the *PTEN* gene mutation in gastric cancer and paracancerous tissue from 53 patients by PCR-SSCP-DNA sequencing method and to observe the protein expression by immunohistochemistry technique in order to find the effect of *PTEN* gene on the occurrence and development of gastric cancer.

## MATERIALS AND METHODS

### Objects

Fifty-three gastric cancer and corresponding paracancerous normal tissue samples were obtained at surgery. All the samples were formalin fixed, paraffin embedded, and pathologically confirmed. Of the 53 patients, 41 were males and 12 were females with a mean age of

Table 1 Primer sequence, length and annealing temperature of exons 5-8 in *PTEN* gene

	Primer sequence	Primer length (bp)	Amplification fragment length (bp)	Annealing temperature (°C)

65.6 years, ranging 39-81 years. The tumor diameter was greater than 3 cm in 37 patients. The tumor was located in gastric antrum of 30 patients, in gastric body of 16 patients, and in gastric cardia of 7 patients, respectively. Invasion was restricted in mucosa and submucosa of 2 patients (I), in muscular layer of 12 patients (II), in chorion and subchorion of 15 patients (III), in neighboring organs of 24 patients through chorion (IV). Lymph node metastasis was found in 32 patients, distant metastasis in 8 patients, embolization in 45 patients. Well-differentiated tumor was found in 1 patient, moderately-differentiated tumor in 35 patients, and poorly-differentiated tumor in 27 patients. pTMN stage I was identified in 13 patients, stage II in 6 patients, stage III in 26 patients, and stage IV in 8 patients.

### Reagents

Tris base, EDTA, 2H<sub>2</sub>O-Na<sub>2</sub>, Taq DNA polymerase and Taq I were purchased from Shanghai Sangon Biological Engineering Technology and Service Co. Ltd. SDS was purchased from AMRESCO Inc. Protein enzyme was purchased from Jingmei Biotechnology Co. Ltd. dNTPs was purchased from Pharmacia Inc. Polyclonal rabbit anti-PTEN antibody and immunohistochemistry staining reagent kit (Rabbit SP Kit) were purchased from Zymed Laboratories Inc. DAAB kit and citrate buffer were purchased from Beijing Zhongshan Biotechnology Co. Ltd. Phosphate-buffered saline (PBS) was purchased from Fuzhou Maixin Biotechnology Co. Ltd.

### Genome DNA extraction from paired gastric cancer and paracancerous tissues

Three paraffin slices (7 µm) were dried in a galvanothermy box at 60°C for 30 min, hydrated in gradient ethanol after deparaffinized in dimethylbenzene, adequately rinsed with tap water and naturally dried. Necrotic tissues were removed under inverted microscope and no carcinoma cells were found in paracancerous tissues. Gastric cancer and paracancerous tissues were put into a 1.5 mL eppendorf tube into which 50 µL digest buffer solution was added. The tube was overturned several times to blend it adequately, bathed in water for 8 h at 65°C and shaken several times. Protein enzyme k was deactivated at 95°C for 8 min and then centrifuged at 10000 r/min for 10-15 min. Transfer supernatant, namely genome DNA, was transferred to another antiseptic tube and stored at 4°C for application.

### PCR amplification of sequence of exons 5-8 in *PTEN* gene

PCR system is composed of 5 µL PCR buffer solution, 5 µL dNTP (2.5 mmol/L), 2 µL primer (F) (10 pmol/µL), 2 µL primer (R) (10 mmol/L), 2 µL DNA template, 1 µL Taq DNA polymerase (5 units/µL), 33 µL ddH<sub>2</sub>O. PCR conditions were at 94°C for 4 min × 1 cycle, at 94°C for 30 s, at 52°C (fifth, sixth and eighth exons) at 58°C (seventh exon) for 30 s, at 72°C for 30 s × 30 cycles, at 72°C for 7 min × 1 cycle. Five µL of the PCR amplified product was put on a 2% agarose gel containing 0.5 g/L EB, 100 bp DNA ladder as a standard reference, electrophoresed for 45 min at 100 V. The results were observed with an ultraviolet transmission reflect analysis instrument and photo was taken with an automatic gel documentation system. Primers used for detecting the mutation of exons 5-8 in the *PTEN* gene are listed in Table 1.

### Enzyme cut reaction with Taq I

Enzyme cut reaction is composed of 3.2 µL ddH<sub>2</sub>O, 1.5 µL buffer Taq I, 10.0 µL PCR, 0.3 µL Taq I (10 unit/µL), and a total volume of 15.0 µL. The mixture was centrifuged for 15 s and heated for 3.5 h at 65°C. Ten µL enzyme cut product was put on a 2% agarose gel containing 0.5 g/L EB, 100 bp DNA ladder as a standard reference, electrophoresed for 45 min at 100 V. The results were observed with an ultraviolet transmission reflect analysis instrument and photo was taken with an automatic gel documentation system to evaluate the enzyme cut reaction.

### SSCP analysis

Eight percent neutral polyacrylamide gel electrophoresis was performed as previously described<sup>[16]</sup>. In brief, 3 mL 40% acrylamide solution, 3 mL 5 × TBE solution, 3 mL 50% glycerin, 6 mL ddH<sub>2</sub>O, 75 µL 10% ammonium persulfate, 7 µL TEMED, were blended adequately and poured into the gel, then concreted for 1 h at room temperature. Four µL PCR product (eighth exon enzyme cut product of exon 8) and 6 µL formamide sample were mixed. The mixture was centrifuged for 15 s, denatured at 95°C for 10 min, bathed in ice for 10 min, put on an 8% neutral polyacrylamide gel, and electrophoresed with 1 × TBE buffer for 8 h at 14°C and 300 V. The fixation

solution was infused into a flat utensil, into which gel was immersed, vibrated for 10 min, and washed 3 times (2 min each time) with ddH<sub>2</sub>O. The gel was immersed into a staining solution, vibrated for 10 min, washed 3 times (20 s each time) with ddH<sub>2</sub>O. The gel was then immersed into a display solution, vibrated until the sample signal became brown and the background became transparent yellow, and rinsed with tap water to stop display. The staining results were observed and photographs were taken.

According to the PCR-SSCP results of genome DNA, the difference in the single strand strip number and electrophoresis transference location, also known as the mobility shift, was considered PCR-SSCP positive.

### DNA sequencing

Genome DNA from positive PCR-SSCP samples was amplified again in 80  $\mu$ L reaction system. The product was identified by electrophoresis for bidirectional DNA sequencing.

### Immunohistochemical staining

PBS was used instead of the primary antibody for blank and normal non-immunized rabbit serum was used instead of the primary antibody for negative. Following the specifications provided with the SP staining reagent box, the deparaffinized tissues were cut into 5  $\mu$ m thick sections, washed 3 times (5 min each time) with PBS, incubated at room temperature in 3% H<sub>2</sub>O<sub>2</sub> to eliminate the endogenous peroxidase activity, then wash additional 3 times (3 min each time) with PBS. Antigens were repaired with microwave (citrate buffer pH 6.0), naturally refrigerated to room temperature, washed 3 times (3 min each time) with PBS, incubated at room temperature with normal non-immunized serum solution for 15 min to indicate the non-specific sites, then incubated at room temperature with the primary antibody solution and horse radish peroxidase (HRP) tagged streptavidin for 15 min respectively, washed 3 times (3 min each time) with PBS. DAE stain was rinsed with PBS for 3 min, counter stained with hematoxylin for 1 min, rinsed with tap water for 2 min, differentiated with 1% hydrochloric ethanol, rinsed with tap water for 5 min, dehydrated with gradient alcohol, transparentized with dimethylbenzene. The sections were coated with neutral balata.

### Criteria for positive PTEN protein immunohistochemical staining

Ten high power fields (50-300 cells/HP) were randomly selected for each section to measure histology (H) scores according to the percentage (P) and intensity (I) scores of positive cells (  $H = P \times I$ , P: percentage lower than 10% for score 0, 11%-40% for score 1, 41%-70% for score 2, and higher than 71% for score 3. I: intensity null for score 0, weak (faint yellow) for score 1, moderate (yellow) for score 2, strong (brown) for score 3. H measurement: score 0 or 1 for negative, score 2 or more for positive).

**Figure 1** PCR-SSCP showing exons 5 (A) and 7 (B) in *PTEN* gene. T7, T16, T19 and T37: Positive SSCP; T1: Negative SSCP; T32: Positive SSCP; T31 and T33: Negative SSCP. N: Paracancerous tissue samples; T: Gastric cancer tissue samples.

### Statistical analysis

Fisher's exact probability and chi-square test were used in statistical analysis.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Mutation of exons 5-8 in *PTEN* gene

Detection of the *PTEN* gene exons 5-8 of genome DNA in 53 paired gastric cancer and paracancerous tissue samples indicated that the amplified PCR product had no gene homozygous alteration and no large and/or alteration in the alleles.

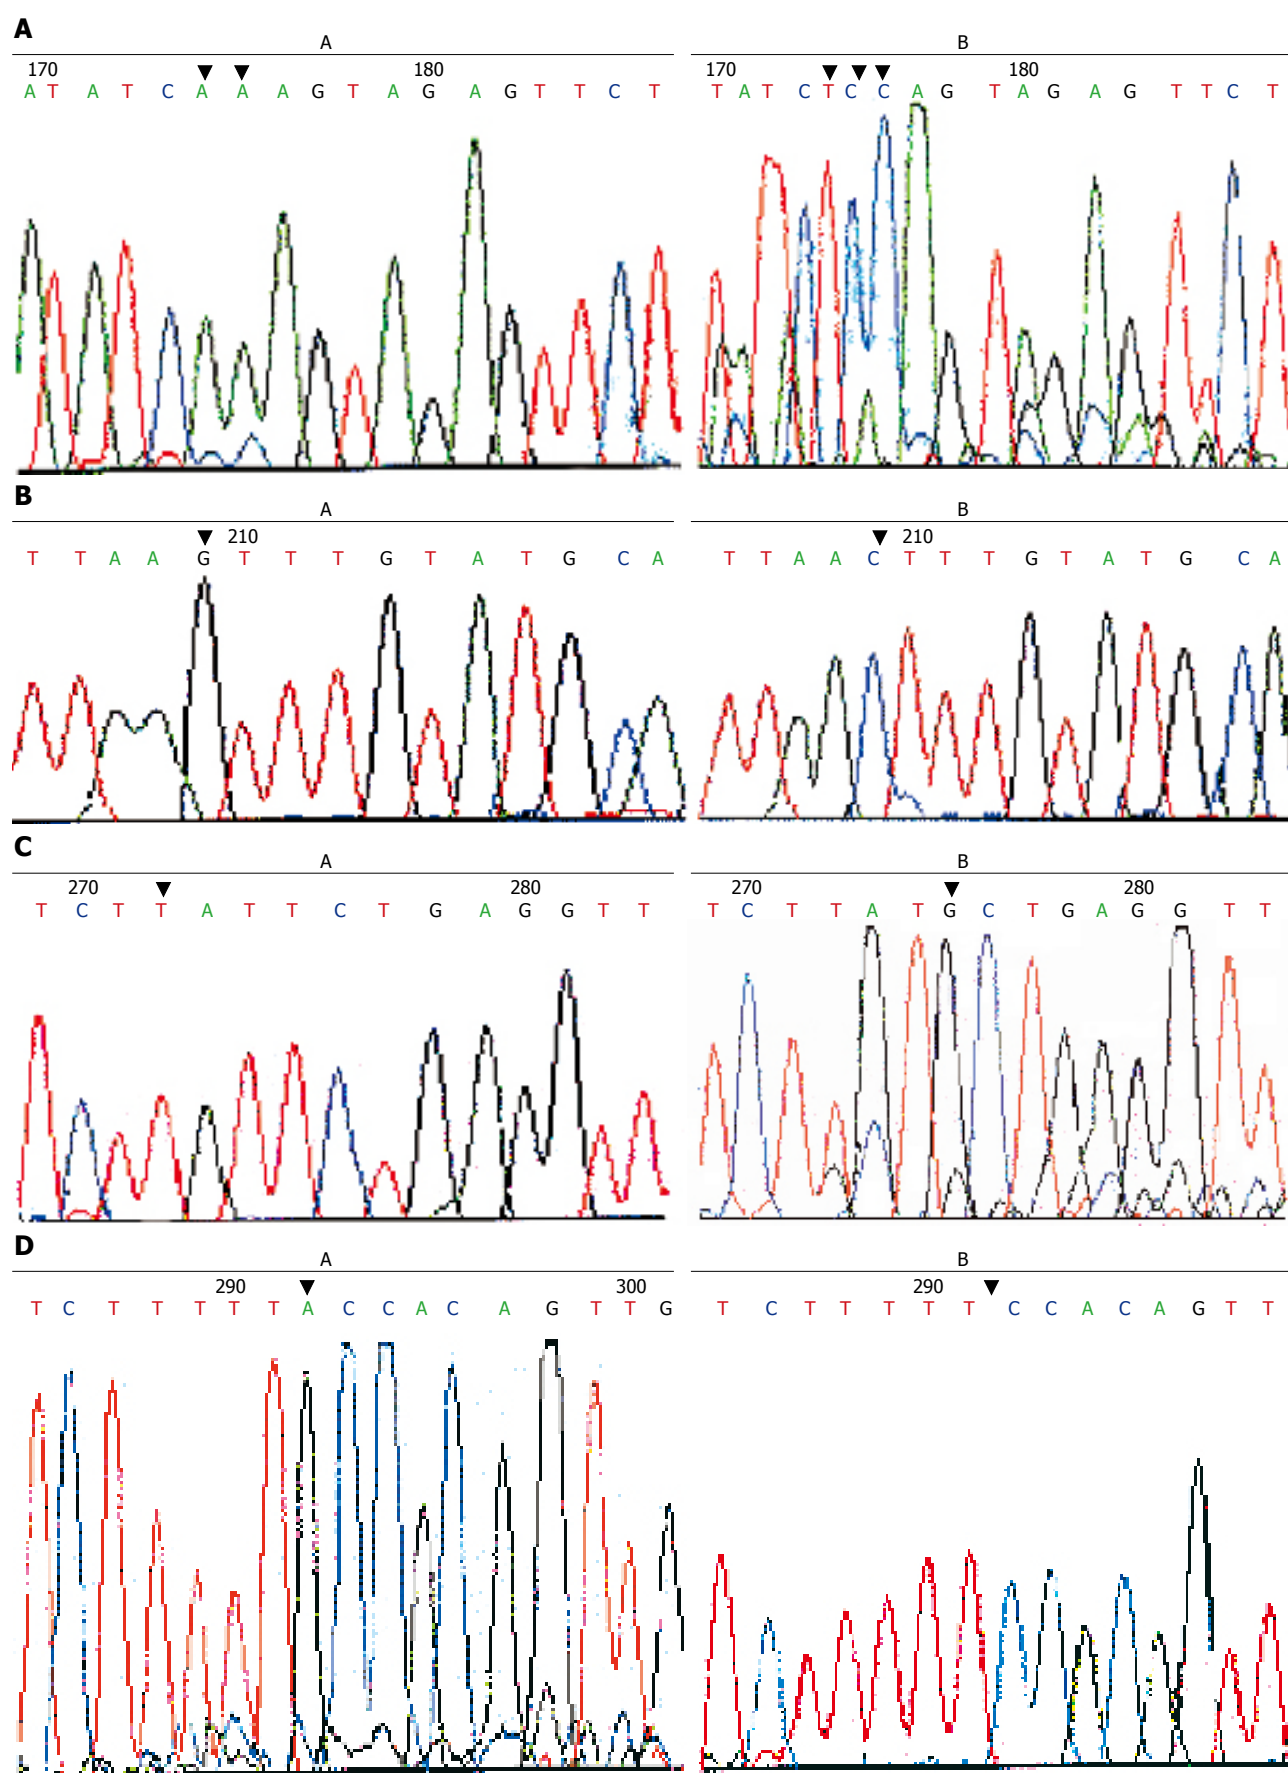

Ten  $\mu$ L reaction product of PCR amplified exon 8 and Taq I enzyme cut reaction on a 2% agarose gel containing 0.5 g/L EB, 100 bp DNA ladder were used as a standard reference. The results indicated that the number and size were in accordance with the theory. The 281 bp, 247 bp, 30 bp segments were relatively justified as the complete enzyme cut reaction.

### SSCP detection

In terms of mutation of exons-5-8 in the *PTEN* gene, positive PCR-SSCP was considered abnormal single strand number and mobility location. Of the 53 gastric cancer tissue samples, mutation occurred in 5 samples, the mutation rate was 9.4%. A surplus shift strip of exon 5 was found in 4 samples, the mutation rate was 7.5% (Figure 1A). Abnormal motility velocity (single strand strip mobility location) was observed in 1 sample at exon 7, the mutation rate was 1.9% (Figure 1B). There was no abnormal SSCP strip in exons 6 and 8.

### DNA sequencing

Genome DNA from positive PCR-SSCP samples was amplified for bidirectional DNA sequencing. The results indicated that only one mutation was found in exons. As in the sample, AA-TCC mutation was located at

**Figure 2** AA-TCC mutation at 40 bp upstream of 3' lateral in exon 7 (A), G-C point mutation at 91 bp upstream of 5' lateral exon 5 (B), T-G point mutation at 24 bp upstream (C) and single base A mutation at 7 bp upstream (D) of 5' lateral exon 5 in paired paracancerous and gastric cancer tissue samples.

Table 2 PTEN protein expression in gastric cancer and paracancerous tissue samples and intensity distribution *n* (%)

Clinicopathological parameters	Cases	PTEN protein expression				<i>P</i>
		-	+	++	+++	
Paracancerous	53	0 (0.0)	10 (18.9)	18 (34.0)	25 (47.2)	< 0.005
Gastric cancer	53	18 (34.0)	17 (32.1)	15 (28.3)	3 (5.7)	
Differentiation extent						< 0.005
Moderate and high differentiation	26	4 (15.4)	6 (23.1)	10 (38.5)	6 (23.1)	
Low differentiation	27	14 (51.9)	8 (29.6)	3 (11.1)	2 (7.4)	

40 bp upstream of 3' lateral in exon 7 (Figure 2A). Such mutations led to terminator formation in codon 297 of the *PTEN* gene. The other 3 kinds of mutation were found in introns, including a G-C point mutation at 91bp upstream of 5' lateral in exon 7 (Figure 2B), a T-G point mutation at 24 bp upstream of 5' lateral in exon 5 (Figure 2C), single base A mutation was deleted at 7 bp upstream of 5' lateral in exon 5 (Figure 2D).

#### PTEN protein expression in gastric cancer and paracancerous tissues

The PTEN protein was expressed in gastric cancer and paracancerous tissue samples. The expression of PTEN protein in gastric cancer samples was 66.0% and 100% in gastric cancer and paracancerous tissue samples, respectively ( $P < 0.005$ , Table 2).

#### Correlation between PTEN protein expression and clinicopathological parameters in gastric cancer patients

PTEN expression was not significantly correlated with the clinicopathological parameters in gastric cancer patients, such as gender and age of the patients, location and size of the carcinoma, distant metastasis, and embolization ( $P > 0.05$ ), but was significantly correlated with infiltrating depth, lymph node metastasis, and pTMN staging ( $P < 0.05$ , Table 3). There was also a significant difference between the moderate and high differentiation groups ( $P < 0.005$ , Table 1).

## DISCUSSION

Protein tyrosine phosphatase level, one of the multi-factors interacting in the period of normal cell growth and division, is determined between protein tyrosine kinase and protein tyrosine phosphatase. The imbalance between the two enzymes affects cell signal transference and cell division, thus leading to malignance of the cells. The occurrence and development of gastric cancer, as other malignant tumors, are an uncontrolled growth and differentiation process of multi-factors involving participation of many genes, including mutation and/or low expression of tumor suppressor gene. At present, researches on structure alteration of tumor suppressor genes in tumor tissues and tumor cell lines, including point mutation, deletion, insertion, cut point, *etc*, indicate that the mutation rate of tumor suppressor genes is 33%-50% in endometrial cancer, 25% in glioblastomas, 21% in ovarian cancer, 13% in prostate cancer, less than 5% in breast and thyroid cancer<sup>[5-11]</sup>.

It was reported that PTEN protein expression is decreased in normal gastric mucosa, intestinal metaplasia, dysplasia and gastric cancer, which is significantly higher in normal gastric mucosa and intestinal metaplasia than in dysplasia and gastric cancer<sup>[17,18]</sup>.

In order to identify the exact role of *PTEN* mutations in occurrence and development of gastric cancer, we used PCR-SSCP-DNA sequencing technique to isolate cancer cells from non-cancer cells to study the sequences of exons 5-8 and certain introns which are frequently mutated. The results indicate that the total mutation rate was 9.4% (5/53), with 3 mutations in introns, including a G-C point mutation at 91 bp upstream, a T-G point mutation of at 24 bp upstream, and a single base A mutation at 7 bp upstream of 5' lateral exon 5. The other AA-TCC mutation was found at 40 bp upstream of 3' lateral exon 7, leading to terminator formation in codon of the *PTEN* gene and pre-termination of the open read frame with the PTEN protein product lacking of the C end that regulates the stability and activity of PTEN protein. Therefore, this mutation may play an important role in the occurrence and development of gastric cancer. The mutation in introns may have effects on the differentiated cut of PTEN transcription product due to the 3 point mutations in introns of the *PTEN* gene.

Furthermore, the study showed that PTEN protein expression in the 53 gastric cancer tissue samples was not significantly correlated with the clinicopathological parameters, such as gender and age of the patients, location and size of the carcinoma, distant metastasis, and embolization, but was significantly correlated with infiltrating depth, lymph node metastasis, and pTMN staging ( $P < 0.05$ ). Along with the increasing infiltrating depth from level I to level IV, the positive expression rate was gradually decreased from 92.9% to 54.2% ( $P < 0.025$ ). There was a significant difference in lymph node metastasis ( $P < 0.05$ ) between negative and positive PTEN expressions (88.9% *vs* 45.7%). The positive PTEN protein expression rate was significantly higher at pTMN stages I and II than at pTMN stages III and IV ( $P < 0.005$ ). These results suggest that PTEN may play an important role in regulation of infiltration and metastasis of gastric cancer cells. Abnormal expressions of PTEN may predict the metastasis and prognosis of gastric cancer<sup>[19-21]</sup>. Furthermore, positive PTEN protein rate was significantly higher in well-and moderately-differentiated gastric cancer than in poorly-differentiated gastric cancer ( $P < 0.025$ ). There was also a significant difference in PTEN protein expression intensity among

**Table 3** Correlation between *PTEN* protein expression and clinicopathological parameters in gastric cancer patients

well, moderately and poorly differentiated gastric cancers ( $P < 0.005$ ), suggesting that *PTEN* protein expression is significantly correlated with histological differentiation of gastric cancer. It is generally accepted that differentiation extent is an indicator for the prognosis of gastric cancer<sup>[22]</sup>. The gene is important in the process of inducing tumor differentiation and *PTEN* protein expression is of certain significance in the prognosis of gastric cancer patients.

In the present study, the mutation rate of gastric cancer was 9.4% (5/53), suggesting that except for gene mutations, other mechanisms are involved in the descending process of *PTEN* protein expression, such as over methylation of nucleotides C and G in promoter or enhancer. Abnormal methylation of CpG islands in promoter is considered one of the important mechanisms underlying gene deactivation and accumulation. The abnormal methylation is considered one of the main pathways promoting occurrence of gastric cancer because over methylation of tumor suppressor genes or other tumor-related genes, such as Rb, APC, p16, p15, hMLH1, E-cadherin, are found in malignant tumors. Another cause might be the abnormal regulation of *PTEN* protein decomposition pathways. Analysis of *PTEN* protein structure revealed that

there were two homologous PESTs and one PSD-95/Dlg/20-1 (PDZ) binding module at the C end of *PTEN* protein. Deletion or structure alteration in the region might result in *PTEN* protein prone to be decomposed. Because the total length of *PTEN* gene DNA is 218 bp including 9 exons and 8 introns, the exact mutation rate of the *PTEN* gene might be higher than 9.4%. The results of this study indicate that expression and mutation of the *PTEN* protein play an important role in the occurrence and development of gastric cancer.

It was reported that inactivation of *PTEN* induces infiltration and metastasis of tumors<sup>[23-28]</sup>. *PTEN* restrains attack and metastasis of tumor cells by regulating matrix metalloproteinases (MMPs) and vascular endothelial growth factor (VEGF)<sup>[29]</sup>. Abnormal expression of *PTEN* protein increases synthesis of MMPs and VEGF, thus leading to attack and metastasis of tumor cells. *PTEN* can also selectively increase dephosphorylation of focal adhesion kinase (FAK) to reduce cell transference by phosphated FAK<sup>[25,30-32]</sup>. Besides, *PTEN* protein and tensin have a homologous sequence<sup>[33]</sup>. Tensin is a cell matrix protein, which participates in adhesion to cells and extracellular matrix (ECM). Our study showed that *PTEN* could restrain cell transference as tensin.

In conclusion, abnormal expression of *PTEN*

protein is usually found in gastric cancer and related to tumor differentiation, infiltrating depth, lymph node metastasis and pTMN staging. PTEN may play an important role in the occurrence and development of gastric cancer. PTEN protein expression phenotype can be considered an indicator for the pathophysiological behavior of gastric cancer.

## COMMENTS

### Background

The occurrence and development of gastric cancer, like other malignant tumors, are a complicated process involving participation of polygene and many factors. It is generally considered that protein tyrosine phosphatase level plays an important role in the process. Mutation of the *PTEN* gene encoding for protein tyrosine phosphatase and abnormal expression of the PTEN protein are significantly correlated with the occurrence and development of malignant tumors, such as glioblastoma, prostate cancer, malignant melanoma, and breast cancer.

### Research frontiers

Discovery of the *PTEN* gene is another important landmark in the field of anti-oncogenes. The relationship between *PTEN* gene and gastric carcinoma was analyzed for the genetic structure, expression and interaction with other genes in this study.

### Innovations and breakthroughs

Few studies on *PTEN* gene mutation and protein expression in gastric cancer are available. However, cancer cells have not been isolated from normal cells that may lead to undetectable *PTEN* gene mutations because of plenty of normal genome DNAs.

### Applications

PTEN protein phenotype can be used as an object index to judge the action of gastric carcinoma based on the cancer cells isolated from normal cells. In this study, we researched the *PTEN* gene mutations using PCR-SSCP-DNA sequencing technology, which can increase the detection rate of *PTEN* gene mutation, suggesting that it can be extended to research other tumor-related genes.

### Peer review

This article describes mutation of the *PTEN* gene in patients with gastric carcinoma. The results indicate that *PTEN* gene plays an important role in the occurrence and development of gastric cancer.

## Abstract

**AIM:** To disclose the mechanisms that accelerate or limit tumor invasion and metastasis in gastric cancer patients.

**METHODS:** The heparanase expression, continuity of basement, degree of infiltration by dendritic cells and lymphocytes in gastric cancer tissues from 33 the early and late stage patients were examined by immunohistochemistry, *in situ* hybridization and transmission electron microscopy.

**RESULTS:** Heparanase mRNA expression in the late stage patients with gastric cancer was stronger than that in the early stage gastric cancer patients. In the early stage gastric cancer tissues, basement membrane (BM) appeared intact, whereas in the late stage, discontinuous BM was often present. The density of S100 protein positive tumor infiltrating dendritic cells (TIDC) in the early stage gastric cancer tissues was higher than that in the late stage. The infiltrating degree of tumor infiltrating lymphocytes (TIL) in the early stage patients whose tumor tissues contained a high density of TIDC was significantly higher than that in the late stage gastric cancer tissues patients with a low density of TIDC. There were few cancer cells penetrated through the continuous BM of cancer nests in the early stage gastric cancers, but many cancer cells were found outside of the defective BM of cancer nests in the late stage.

**CONCLUSION:** Our results suggest that strong

heparanase expression is related with the degradation of BM which allows or accelerates tumor invasion and metastasis. However, high density of TIDC and degree of infiltration by TIL are associated with tumor progression in human gastric cancers.

## INTRODUCTION

Gastric cancer is one of the most aggressive malignant tumors, and its incidence is higher than that of any other gastrointestinal malignancy. The prognosis of patients with gastric cancer is often poor, due to tumor invasion and metastasis which are the most common causes of death in gastric cancer<sup>[1,2]</sup>.

Degradation of basement membrane (BM) and extracellular matrix (ECM) around tumor is considered to be associated with invasion and metastasis of gastric cancer<sup>[3]</sup>. Heparanase is an endo- $\beta$ -D-glucuronidase that specifically cleaves carbohydrate chain of heparan sulfate proteoglycans (HSPG)<sup>[4]</sup>. HSPGs are the main component of extracellular matrix and basement membrane which play a barrier to prevent tumor cells from invasion and metastasis<sup>[5]</sup>. Previous studies

have shown that heparanase, produced by malignant tumor cells, mediates degradation of heparan sulfate proteoglycans in the extracellular matrix and basement membrane around tumors, and their expression correlates with the degree of tumor invasion and metastasis in several human malignant tumors<sup>[6-8]</sup>.

Progression of malignant tumors is also restricted by host defense mechanisms<sup>[9,10]</sup>. The tumor infiltrating dendritic cells and lymphocytes are chief immunocytes that inhibit malignant tumor cells from invasion and metastasis. Many authors reported that the infiltration grade of tumor infiltrating dendritic cells are associated with patient survival and prognosis in a large variety of human malignancies<sup>[10-15]</sup>. Recent studies have shown that the number of tumor infiltrating lymphocytes is correlated with the progression of human carcinoma<sup>[16-18]</sup>. However, to our knowledge, the correlation between heparanase expression and infiltration degree of tumor infiltrating dendritic cells and lymphocytes has not been reported so far. The present study was, therefore, undertaken to clarify the relationships between heparanase mRNA expression, degree of degradation of basement membrane, density of tumor infiltrating dendritic cells, infiltrating degree of tumor infiltrating lymphocytes, and tumor invasion and progression in human gastric cancer patients.

## MATERIALS AND METHODS

### Tumor samples

Tissue samples were obtained from 33 patients with primary gastric cancer who underwent curative surgery in the Second Clinical Hospital of Harbin Medical University (Harbin, China). Ten patients had stage I, 8 stage II, 7 stage III, 8 stage IV cancer according to the TNM classification (UICC, TNM classification, 5th Edition, 1997)<sup>[19]</sup>. Histological stage grouping was evaluated. Stages I and II ( $n = 18$ ) were referred to the early stage, stages III and IV ( $n = 15$ ) were referred to the late stage. All fresh tumor tissues were divided into two parts, one part was fixed in 0.1 mol/L phosphate buffer (pH 7.4) containing 4% paraformaldehyde for immunohistochemistry and *in situ* hybridization, the other part was immersed in 0.1 mol/L phosphate buffer (pH 7.4) containing 2.5% glutaraldehyde for transmission electron microscopy.

### In situ hybridization

Paraffin-embedded tissue sections were prepared for heparanase staining. Following reagents were purchased from Maxim Biotech (South San Francisco, CA, USA). Tissue sections (4  $\mu$ m) were deparaffinized, dehydrated and incubated in 0.2 mol/L HCl for 20 min. After washed with  $2 \times$  SSC, the sections were incubated with proteinase K for 10 min at 37°C, fixed with PBS containing 4% paraformaldehyde for 5 min, washed with  $2 \times$  SSC, and then prehybridized for 2 h at 63°C in a buffer containing 50% deionized formamide,  $4 \times$  SSC,  $2 \times$  Denhardt's solution and 250  $\mu$ g/mL RNA. Hybridization was performed in 50% deionized formamide,  $4 \times$  SSC,  $2 \times$  Denhardt's

solution, 10% dextran sulfate and 500  $\mu$ g/mL RNA. The final concentration of DIG-labeled heparanase probe was about 500 ng/mL. The probe was placed on the section, covered with parafilm and incubated at 63°C overnight in a moisture chamber. After hybridization, excess probes were removed by washing in  $2 \times$  SSC followed by RNase treatment with 100 U/mL RNase T1 at 37°C for 30 min. The sections were washed at 65°C in  $2 \times$  SSC for 10 min, washed three times in  $0.2 \times$  SSC and 50% deionized formamide (10 min each time), and incubated with an anti-DIG antibody conjugated with alkaline phosphatase. For the following color reaction, 5-bromo-4-chloro-3-indolyl phosphatase was used. Finally, the sections were counterstained with Mayer's hematoxylin.

### Immunohistochemistry

Paraffin-embedded specimens were prepared for S100 protein immunohistochemical staining. The specimens were cut into 5- $\mu$ m thick sections and mounted on glass slides. The sections were then deparaffinized in xylene for 20 min and dehydrated in ascending concentrations of ethanol. Endogenous peroxidase was blocked by incubating the sections with 3.0% H<sub>2</sub>O<sub>2</sub> in methanol. After incubated in normal bovine serum for 10 min, the sections were incubated with anti-S100 protein antibody (Sigma, St. Louis, MO, USA) for 2 h at 37°C. After washed with PBS, the sections were incubated with biotinylated immunoglobulin and streptavidin conjugated to horseradish peroxidase (ABC kit, Sigma, St. Louis, MO, USA). Immunostaining was developed using DAB/ H<sub>2</sub>O<sub>2</sub> solution. Finally, the sections were lightly counterstained with hematoxylin.

### Transmission electron microscopy

Specimens fixed in 0.1 mol/L phosphate buffer (pH 7.4) containing 2.5% glutaraldehyde were rinsed with the phosphate buffer and postfixed in 0.1 mol/L phosphate buffer containing 1% OsO<sub>4</sub> for 2 h, dehydrated through ascending concentrations of ethanol, and embedded in Epon 812 using aclar film (Nisshin EM, Tokyo, Japan). Semi-thin sections were stained with toluidine blue and observed under a light microscope. Ultrathin sections were stained with uranyl acetate and lead citrate and examined under a H-600 transmission electron microscope (Hitachi, Tokyo, Japan).

### Statistical analysis

Under the light microscope, S100 protein immunohistochemistry and heparanase mRNA stained sections were examined using the image analysis system computer software (BeiHan Image Centre, Beijing, China). Twenty sections from each kind of staining were analyzed, two high-power fields ( $\times 400$ ) (each field is 0.255 mm<sup>2</sup>) were randomly selected from each section. The number and area density of positive cells in each section were automatically calculated by the computer. The results were expressed as mean  $\pm$  SD. Student's *t*-test was used to compare the S100 protein positive cells and heparanase expressing cells in the early stage gastric

**Figure 1** Expression and distribution of S100 protein and heparanase mRNA in gastric cancer tissues. Immunohistochemical staining of S100 protein ( $\times 400$ ) with a high density of tumor infiltrating dendritic cells positively stained for S100 protein in the early stage gastric cancer tissues (A) and a low density of such cells in the late stage gastric cancer tissues (B), heparanase mRNA expression by in situ hybridization ( $\times 400$ ) with a low heparanase mRNA expression level in the early stage gastric cancer tissues (C) and a high heparanase mRNA expression level in the late stage gastric cancer tissues (D) (Arrows: Positively expressed cells).

**Table 1** Densities of S100 positive TIDC and heparanase expression in early and late gastric cancer tissues (mean  $\pm$  SD)

	Densities of S100 positive TIDC			Heparanase expression

cancer tissues with those in the late stage gastric cancer tissues.  $P < 0.05$  was considered statistically significant.

## RESULTS

### **Distribution and density of tumor infiltrating dendritic cells in gastric cancer tissue**

S100 protein positive cells showing typical morphology of dendritic cells and distinct cytoplasmic processes or veils, were detected in tissues from patients with gastric cancer at the early or late stage (Figure 1A and B). S100 protein positive cells were found mainly in stroma around the nests of cancer cells and connective tissue surrounding the tumor. In addition, S100 protein positive tumor infiltrating dendritic cells were also scattered among the cancer cells. Patients with gastric cancer at the early stage showed a high density of S100 protein positive tumor infiltrating dendritic cells (Figure 1A), while those at the late stage had a low density of S100 protein positive tumor infiltrating dendritic cells (Figure 1B). There was a significant difference in the density of S100

protein positive tumor infiltrating dendritic cells between gastric cancer patients at the early and late stage ( $P < 0.01$ , Table 1). The density of tumor infiltrating dendritic cells was significantly correlated with tumor invasion and clinical stage.

### **Heparanase mRNA expression in gastric cancer tissue**

Heparanase mRNA positive labeling occurred mainly in cytoplasm and nuclei of gastric cancer cells. Heparanase mRNA was weakly expressed in the early stage gastric cancer tissues (Figure 1C) and strongly expressed in the late stage gastric cancer tissues (Figure 1D). The density of heparanase mRNA positive cells was significantly higher in the late stage gastric cancer tissues than in the early stage gastric cancer tissues ( $P < 0.01$ , Table 1). Heparanase mRNA expression was significantly correlated with invasion and TNM stage of gastric cancer.

### **Transmission electron microscopy (TEM)**

The basement membrane was intact in the early stage

**Figure 2** Transmission electron microscopy micrographs of the human gastric cancer tissues. (A)-(D) showing the early stage cancer tissues (Arrows indicate basement membrane). **A:** The continuous basement membrane which consisted of the electron-dense outer layer and the electron-lucent inner layer was observed. The numerous tumor infiltrating lymphocytes (L) were located in one side of the basement membrane ( $\times 2500$ ); **B and C:** The intact basement membrane was found on the margin of cancer nests. The tumor infiltrating lymphocytes (L) appeared around the cancer cell (Ca) (B  $\times 4000$ ; C  $\times 3000$ ); **D:** The cancer cell (Ca) was surrounded by the tumor infiltrating lymphocytes (L), and the basement membrane is clearly visualized ( $\times 2500$ ); (E)-(H) showing the late stage cancer tissues. **E:** The relationships were displayed between cancer cells (Ca) or tumor infiltrating lymphocytes (L) and tumor infiltrating dendritic cells (D). Note the tumor with absent basement membrane ( $\times 4000$ ); **F:** A higher magnification of E exhibited the contact relationship between the cancer cell (Ca) and tumor infiltrating dendritic cell (D) ( $\times 20000$ ); **G:** The tumor infiltrating dendritic cell (D) was surrounded by several tumor infiltrating lymphocytes (L), and formed the dendritic cell-lymphocyte cluster ( $\times 5000$ ); **H:** The tumor infiltrating lymphocyte (L) appeared near the cancer cell (Ca), and the discontinuous or defective basement membrane of cancer nest can also be seen (double arrow) ( $\times 5000$ ).

gastric cancer tissue (Figure 2A-D). The continuous and well-formed basement membrane was found at the margin of

cancer nests in the early stage gastric cancer tissue (Figure 2B and C). The basement membrane was consisted of an electron-dense outer layer and an electron-lucent inner layer (Figure 2A and D). In contrast, the basement membrane at the rim of cancer nests was discontinuous and defective or absent in the late stage gastric cancer tissue (Figure 2E and H). Numerous tumor infiltrating lymphocytes were observed in the surrounding tissues of cancer nests and cells of the early stage gastric cancer (Figure 2B, C and D). In addition, many tumor infiltrating lymphocytes were arranged along one side of the basement membrane (Figure 2A). Lymphocytes in blood vessels were found near the cancer nests (Figure 2B), and invasion of cancer cells was noted outside of cancer nests (Figure 2C). The infiltrating degree of tumor infiltrating lymphocytes was high in the early stage gastric cancer tissues with intact basement membrane and few lymphocytes infiltrated into the tumor-surrounding tissue of the late stage gastric cancer with discontinuous basement membrane. Few cancer cells penetrated through the intact basement membrane of cancer nests in the early stage gastric cancer tissues, but many cancer cells were observed outside of the discontinuous basement membrane of cancer nests in the late stage gastric cancer tissues. There was a close contact between cancer cells or tumor infiltrating lymphocytes and tumor infiltrating dendritic cells (Figure 2E), and the contact between cancer cells and tumor infiltrating dendritic cells was also observed (Figure 2F). Many tumor infiltrating lymphocytes were distributed around the tumor infiltrating dendritic cells, forming a dendritic cell-lymphocyte cluster. Tumor infiltrating dendritic cells were closely contacted with tumor infiltrating lymphocytes (Figure 2G). Tumor infiltrating lymphocytes were also found near the cancer cells (Figure 2H).

## DISCUSSION

It is generally accepted that one principal reason for the poor prognosis of patients with malignant tumors is the invasion and metastasis of cancer cells. The basement membrane plays an important role as a barrier in preventing cancer cells from invasion and metastasis<sup>[9]</sup>. The previous studies have demonstrated that heparanase which can degrade the basement membrane is one of the key enzymes involved in the tumor invasion and metastasis *in vivo*, such as pancreatic cancer, head and neck cancers, esophageal cancer, gastric cancer and colon cancer<sup>[7,8,20-22]</sup>. The heparanase can also shows *in vitro* human squamous cell carcinoma cell lines<sup>[23]</sup>. In the present study, we examined heparanase mRNA expression in the early and late stages of human gastric cancer by *in situ* hybridization. Our results show that heparanase mRNA expression was significantly higher in the late stage than in the early stage gastric cancer tissues ( $P < 0.01$ ), and that heparanase mRNA expression was correlated significantly with tumor invasion and TNM stages of cancer.

Whether high expression of heparanase can promote the invasion of cancer cells by degrading the basement membrane remains unclear. Our TEM study has showed

that intact basement membrane of cancer nests appeared in regions where heparanase expression was low in the early stage gastric cancer tissues, whereas discontinuous basement membrane of cancer nests was often present in places where heparanase expression was high in the late stage gastric cancer tissues. Our morphological observation directly proved that heparanase activity was associated with degradation of basement membrane. Lipponen<sup>[9]</sup> reported that invasion of superficial bladder cancer is related to the loss of continuous basement membrane, which is in agreement with our present TEM study.

In the present study, few cancer cells were observed to penetrate through the continuous basement membrane of cancer nests in the early stage gastric cancer tissue, but many cancer cells could be found outside of discontinuous basement membrane of cancer nests in the late stage gastric cancer tissue. These results suggest that the state of basement membrane, which is determined by heparanase mRNA levels, correlates with invasion of cancer cells. The present study also suggested that the discontinuity of basement membrane facilitate the invasion of cancer cells<sup>[23]</sup>. The discontinuity of basement membrane could probably results from the degradation of basement membrane by proteolytic enzymes, such as heparanase, which are presumably actively secreted by cancer cells<sup>[24]</sup>.

The present study also showed that the state of basement membrane as a mechanical barrier and host immune defense system were interrelated. The immune defense system plays a critical role in preventing and limiting the development of malignant tumors<sup>[24]</sup>. The tumor infiltrating immunocytes situated around the tumor were considered a key factor for maintaining the status of local antitumor immunity<sup>[25]</sup>. The tumor infiltrating dendritic cells and lymphocytes are the main components of immunocytes in the tumor-surrounding tissues. Reportedly, the quantity of tumor infiltrating dendritic cells correlates with the clinical outcome of different tumor types<sup>[11,12,14,15]</sup>. Zeid and Muller demonstrated that the density of S100 positive dendritic cells in lung tumors is related to tumor subtype and differentiation, and a high dendritic cell density is associated with enhanced patient survival<sup>[11]</sup>. S100 protein has been widely used as a marker for identification of dendritic cells<sup>[26-28]</sup>. Tsujitani *et al* showed that the infiltration of dendritic cells is related to tumor invasion and lymph node metastasis in human gastric cancer<sup>[12]</sup>. A high number of dendritic cells in tumor tissue correlate with a good prognosis<sup>[29]</sup>. The present study showed that the density of S100 protein positive cells was higher in the early stage than in the late stage gastric cancer tissue ( $P < 0.01$ ), suggesting that the density of tumor infiltrating dendritic cells correlates significantly with tumor invasion and clinical stages.

It was reported that invasion and metastasis of malignant tumor are related with the infiltrating degree of tumor infiltrating lymphocytes in tumor tissues<sup>[30]</sup>. Ropponen *et al* have shown the relationship between the number of tumor infiltrating lymphocytes and the prognosis of patients with colorectal cancer<sup>[31]</sup>. Aaltomaa *et al* demonstrated that a high number of

tumor infiltrating lymphocytes in tumor tissue correlate with a good prognosis of patients with breast cancer<sup>[32]</sup>. In the present study, the infiltrating degree of tumor infiltrating lymphocytes in the early stage gastric cancer patients whose tumor tissues contained a high density of tumor infiltrating dendritic cells was significantly higher than that in the late stage gastric cancer patients with a low density of these cells, indicating that the infiltrating degree of tumor infiltrating lymphocytes is associated with the progression of gastric cancer. These results suggest that there exists a certain relation between tumor infiltrating dendritic cells and lymphocytes. When the tumor becomes large, dendritic cells and lymphocytes in the whole body are overwhelmed by a large number of tumor cells. In addition, these increased tumor cells will also prevent and limit infiltration by dendritic cells and lymphocytes. Thus, the decreases in tumor-infiltrating DCs and TILs may not be due to tumor development, but due to tumor growth.

Suzuki *et al* showed that dendritic cells are attached to groups of lymphocytes and form dendritic cell-lymphocyte clusters to promote T-cell activation for the generation of tumor-specific immunity in the invasive margin of the colorectal cancer stroma<sup>[33]</sup>. Dendritic cells present antigen to lymphocytes, stimulate naïve T lymphocyte proliferation and activation to kill tumor cells<sup>[34]</sup>. Bell *et al*<sup>[35]</sup> suggested that the peritumoral clustering of mature dendritic cells reflects a state in which they interact directly with clusters of tumor infiltrating lymphocytes to generate an antitumor immune response. In the present study, tumor infiltrating lymphocytes were distributed around tumor infiltrating dendritic cells and formed dendritic cell-lymphocyte cluster, and the close contacts were found between tumor infiltrating dendritic cell and tumor infiltrating lymphocytes. The contact between tumor infiltrating dendritic cells and lymphocytes may indicate the process that tumor infiltrating dendritic cells present antigen to lymphocytes to activate them for antitumor immunity<sup>[36,37]</sup>.

Loss of integrity in basement membrane results from high heparanase expression. In the present study, few cancer cells were observed to penetrate through the continuous basement membrane of cancer nests in the early stage gastric cancer tissue, but many cancer cells could be found outside of the discontinuous basement membrane of cancer nests in the late stage gastric cancer tissue. These results suggest that the state of basement membrane, which is determined by heparanase, correlates with invasion of cancer cells. In the late stage gastric cancer tissue, increased cancer cells outside of discontinuous basement membrane of cancer nests could prevent and limit infiltration by dendritic cells and lymphocytes. Thus, heparanase expression or loss of integrity in basement membrane is associated with the infiltrating degree of tumor infiltrating dendritic cells and lymphocytes.

In summary, heparanase expression, degradation of basement membrane, density of tumor infiltrating dendritic cells and infiltrating degree of tumor infiltrating lymphocytes are associated with tumor

invasion, TNM stages and progression in human gastric cancer. When the tumor has reached an advanced stage, discontinuous basement membrane, degraded by high expression heparanase, allows cancer cells to penetrate and is favorable to tumor invasion and metastasis, and can predict a poor prognosis of patients with gastric cancer. Moreover, at the late stage, a low degree of infiltration by dendritic cells and lymphocytes reflecting the presence of a weak local antitumor immune response in gastric cancer tissues also indicates that patients with less infiltrating immunocytes gastric cancer would have a poor prognosis, whereas the result is contrary in the early gastric cancer tissue. These factors including interactions between heparanase and basement membrane as well as between tumor infiltrating dendritic cells and lymphocytes may play a crucial role in tumor invasion and metastasis. Further study is required to understand the precise mechanism of interactions between both of them in the process of tumor invasion and metastasis.

## COMMENTS

### Background

The prognosis of patients with gastric cancer is often poor, due to tumor invasion and metastasis which are the most common causes for death of gastric cancer patients. It is crucially important to disclose the mechanisms underlying tumor invasion and metastasis. Heparanase, tumor infiltrating dendritic cells (TIDC) and tumor infiltrating lymphocytes (TIL) play a critical role in preventing and limiting the development of malignant tumors.

### Research frontiers

Recent investigations have shown that heparanase expression which can degrade the basement membrane is one of the key enzymes involved in tumor invasion and metastasis, but few studies are available on the relationship between heparanase expression, basement membrane degradation, density of dendritic cells, infiltrating degree of lymphocytes, and tumor invasion and progression in gastric cancer patients.

### Innovations and breakthroughs

High heparanase expression levels are related with the degradation of basement membrane which allows or accelerates tumor invasion and metastasis. However, high TIDC density and TIL infiltration degree are associated with progression of gastric cancer.

### Applications

The study defined the mechanisms underlying tumor invasion and metastasis. Heparanase expression, basement membrane degradation, and TIDC and TIL infiltration degree, can be used as prognostic biomarkers for gastric cancer.

### Terminology

Heparanase is an endo- $\beta$ -D-glucuronidase that specifically cleaves the carbohydrate chain of heparan sulfate proteoglycan (HSPG). HSPG is the main component of extracellular matrix and basement membrane, which as a barrier can protect tumor cells from invasion and metastasis.

### Peer review

This is a histopathological analysis of heparanase expression, dendritic cells and lymphocytes infiltrating to tumor in patients gastric cancer at the early or late stage. In addition, the authors showed the electron microscopic pictures of gastric cancer tissue infiltrated by dendritic cells and lymphocytes. This is an interesting report on heparanase expression in human gastric cancer.

## Abstract

**AIM:** To evaluate the synergistic targeting and killing of human hepatocellular carcinoma (HCC) cells lacking p53 by the oncolytic autonomous parvovirus (PV) H-1 and chemotherapeutic agents and its dependence on functional promyelocytic leukemia protein (PML).

**METHODS:** The role of p53 and PML in regulating cytotoxicity and gene transfer mediated by wild-type (wt) PV H-1 were explored in two pairs of isogenic human hepatoma cell lines with different p53 status. Furthermore, H-1 PV infection was combined with cytostatic drug treatment.

**RESULTS:** While the HCC cells with different p53 status studied were all susceptible to H-1 PV-induced apoptosis, the cytotoxicity of H-1 PV was more

pronounced in p53-negative than in p53-positive cells. Apoptosis rates in p53-negative cell lines treated by genotoxic drugs were further enhanced by a treatment with H-1 PV. In flow cytometric analyses, H-1 PV infection resulted in a reduction of the mitochondrial transmembrane potential. In addition, H-1 PV cells showed a significant increase in PML expression. Knocking down PML expression resulted in a striking reduction of the level of H-1 PV infected tumor cell death.

**CONCLUSION:** H-1 PV is a suitable agent to circumvent the resistance of p53-negative HCC cells to genotoxic agents, and it enhances the apoptotic process which is dependent on functional PML. Thus, H-1 PV and its oncolytic vector derivatives may be considered as therapeutic options for HCC, particularly for p53-negative tumors.

## INTRODUCTION

Abrogation of function of tumor suppressors such as p53 or the promyelocytic leukemia protein (PML) are common events in human tumors and lead to more aggressive cancer phenotypes<sup>[1,2]</sup>. At early stages during the process of carcinogenesis, activated oncogenes sensitize primary cells towards the p53-dependent stress response, in which the nuclear phosphoprotein p53 serves as a ge-

nostic stabilizer, inhibitor of cell cycle progression and angiogenesis, and facilitator of apoptosis<sup>[3-5]</sup>. In order to overcome this endogenous defense mechanism, cancer cell variants are strongly selected for p53 mutations, with p53 gene alterations identified in approximately half of all human tumors<sup>[6-8]</sup>. Thus, loss of p53 function usually results in a more aggressive cancer phenotype and worse clinical outcome. Studies using *in vitro* cell cultures and *in vivo* animal models demonstrated that the deficiency of p53 correlates with enhanced tumorigenesis, tumor-induced angiogenesis, and an increased resistance towards intracellular stresses which is mainly due to abrogation of an effective apoptotic response to chemotherapy or radiation<sup>[9]</sup>.

The tumor suppressor PML is predominantly localized in distinct nuclear domains that are termed PML-nuclear bodies (PML-NBs), and consist of multiprotein complexes implicated in apoptosis regulation, cellular senescence, and antiviral response<sup>[10,11]</sup>. PML expression results in potent growth-suppressive<sup>[12]</sup> and apoptosis-inducing effects<sup>[13,14]</sup>, and PML-deficient mice and cells exhibit defects in multiple apoptosis pathways<sup>[15]</sup>. One major goal of therapeutic oncology is to identify ways to kill the tumor cells that became resistant to conventional treatments due to their lack of functional p53 or PML<sup>[16]</sup>. The rapid expansion of the field of gene transfer technologies led to the development of retroviral or adenoviral p53 expression vectors and their use to restore sensitivity to genotoxic agents or to directly induce apoptosis in preclinical tumor models<sup>[17-20]</sup>.

Promising new approaches to tumor-directed therapy include oncolytic parvoviruses (PVs), which are of particular interest, since they are endowed with oncolytic properties and also increase the host immune response by priming effector immune cells against the tumors<sup>[21-24]</sup>. The autonomous PV of the rat (H-1 PV) and its close relatives, such as the minute virus of mice (MVM) and in addition the most commonly used herpes simplex virus and adenovirus are emerging as promising candidates because of a number of their properties<sup>[25]</sup>.

Notably, these viruses preferentially replicate in and kill transformed and tumor-derived cells in culture<sup>[21,22,26,27]</sup>. In addition, recombinant PVs have recently been produced with the aim to increase the anti-tumor effect of the natural viruses<sup>[28]</sup>. In particular, PVs may be suitable to target and kill tumor cells and simultaneously deliver appropriate transgenes, e.g. genes coding for immuno-stimulatory factors<sup>[25]</sup>. As H-1 PV is seldom pathogenic to its natural adult hosts<sup>[29]</sup> and infects humans without any apparent consequences<sup>[21,28]</sup>, the prospects for the clinical use of PVs are intriguing. *In vivo*, these viruses may combat tumor development or repress established tumors, what makes them promising tools in cancer therapy<sup>[25]</sup>.

The factors controlling the sensitivity of target (in particular human) cells to PV-induced killing are still largely unknown. Cells transformed with oncogenes display both an enhanced capacity for accumulating the viral cytotoxic nonstructural (NS) protein<sup>[22]</sup> and a greater intrinsic responsiveness to NS1-mediated killing<sup>[30]</sup>. On

the other hand, our previous investigation of the cytotoxicity of H-1 PV in hepatoma cell cultures failed to go into a requirement for functional p53. So far, the inactivation of p53 was only found in human leukemia cells and transformed rat fibroblasts and correlates with a greater susceptibility to H-1 PV-induced cell killing<sup>[31]</sup>.

Thus, in order to better understand the role of the cell genetic background and effector pathways in the H-1 PV-induced cytotoxicity, we compared two isogenic pairs of p53-positive *versus* negative human tumor cell lines of hepatocellular carcinoma (HCC) origin. This system allowed us to assess the impact of p53 on the susceptibility of host cells to both H-1 PV gene expression and killing activity, and H-1 PV vector-reduced reporter gene transduction. To further understand the molecular mechanism underlying H-1 PV-induced cell killing, another tumor suppressor, the PML, was investigated for its influence on H-1 PV infection. We used RNA interference to knock down PML expression in the described cellular systems, and determined the consequences for the outcome of H-1 PV infection with regard to the host cell p53 status.

The present study shows that H-1 PV triggers an apoptotic type of death in human HCC cells, and that p53 is dispensable for this process. In contrast, PML, which is induced by H-1 PV infection, helps PV killing carcinoma cells, irrespective of their p53 status. Given the known dependence of apoptosis induction by radio-chemotherapeutic agents on the target cell p53 status<sup>[32]</sup>, PVs appear to be suitable adjuvants to eliminate tumor cell populations resistant against these agents by means of combined treatments.

## MATERIALS AND METHODS

### Tumor cells

The Hep3B cells were derived from a HCC<sup>[33]</sup> and HepG2 cells from a human hepatoblastoma<sup>[32]</sup>. HepG2 cells were propagated in Dulbecco's modified Eagle medium (DMEM; Life Technologies GmbH, Karlsruhe, Germany), and Hep3B in Eagle minimal essential medium (Eurobio GmbH, Raunheim, Germany). Both media were supplemented with 10% fetal calf serum (FCS), 5 mol/L glutamine, 100 µg/mL penicillin, and 5 mol/L Hepes<sup>[21]</sup>. The Hep3B4P line is a Hep3B derivative stably transfected with tamoxifen-regulated wt p53-estrogen receptor chimera (p53-mERTm-pBabepuro)<sup>[34]</sup>. p53-mERTm-pBpuro contains the *Bam*HI fragment of human cDNA p53 cloned in frame with and N-terminally to a modified estrogen receptor containing a gly to arg mutation at residue 525<sup>[35]</sup>. This mutation renders the hormone binding domain insensitive to estradiol but responsive to the synthetic estrogen 4-OH-tamoxifen<sup>[35]</sup>. To induce p53 in the experiments, tamoxifen was added at a concentration of 750 nmol/L 1 d before H-1 PV infection.

HepG2 303 is a HepG2 derivative stably transfected with a dominant-negative p53 mutant (dn-p53) kindly provided by A. Levine (ΔV143A) as described by Schuler *et al*<sup>[36]</sup>. Since the dn-p53 transfection plasmid contained the puromycin resistance gene, HepG2 303 cells were

selected with puromycin (0.5 µg/mL) for 4 wk (4 consecutive days each week).

### **Virus infection**

For infection, H-1 PV was produced in NB-E cells and purified over cesium chloride gradients as described earlier. Wild-type (wt) H-1 PV titration by plaque assays was performed according to published methods<sup>[26]</sup>. The multiplicity of infection (MOI) is given by the number of plaque-forming units (pfu) inoculated per cell. For experimental infections, exponentially growing cell cultures were incubated for 1 h with H-1 PV at indicated MOIs. Cells were cultured for up to 8 d post infection (p.i.).

### **Cell treatments**

For combined treatment with H-1 PV and chemotherapeutics, cells were first infected with H-1 PV (MOI = 20 pfu/cell) in complete medium. One hour after infection, the chemotherapeutic agents Irinotecan (100 µg/mL), 5-Fluorouracil (5-FU) (5 µg/mL), or Cisplatin (0.25 µg/mL) were added, and cells were further incubated for 3 d at 37°C. Apoptosis rates were then quantitatively determined by FACS. Herein, the treated cells were harvested *via* trypsinization, washed with PBS, stained with propidium iodide and annexin V, and apoptosis levels were assessed, using the FACScan flow cytometry with CellQuest software (Becton Dickinson, San Jose, CA). Anticancer agents were purchased from Pfizer (Irinotecan), Hexal AG (5-FU), and Gry Pharma GmbH (Cisplatin).

### **Analysis of virus protein expression**

Cultures were infected with H-1 PV at a MOI of 20 pfu/cell. After washing with PBS, cells were lysed in RIPA buffer (10 mol/L Tris-HCl, 150 mol/L NaCl, 1 mol/L EDTA, 1% Nonidet P-40, 0.5% sodium deoxycholate, 5% SDS) containing protease inhibitors. Protein concentrations were determined using the Bio-Rad protein assay (Bio-Rad, Munich, Germany). Total proteins (50 µg) were diluted into an equal volume, subjected to SDS-polyacrylamide gel electrophoresis (SDS-PAGE) and transferred onto a nitrocellulose membrane (Amersham Pharmacia Biotech, Freiburg, Germany). Non-specific binding sites were blocked by incubating the membrane for 2 h in PBS containing 10% low-fat milk powder and 0.2% Tween-20 (Sigma, Deisenhofen, Germany). The blot was further incubated with the rabbit polyclonal antibody SP8 directed against carboxy-terminal peptides of NS1<sup>[37]</sup>, then with an anti-rabbit peroxidase-conjugated antibody, and processed for enhanced chemoluminescence detection (Amersham Pharmacia Biotech, Freiburg, Germany).

### **Characterisation of the p53 and PML status of human tumor cells**

Cultures grown for 48 h were processed for Western blotting as described above for viral proteins, p53 was detected using the monoclonal DO-7 antibody<sup>[38]</sup>. Actin was used as an internal loading control.

### **RNA interference**

To knock down PML expression by RNA interference, the targeting oligonucleotide 5'-GAGCTCAAG TGC-GACATCA-3' (PML sense) was inserted into the pSUPER vector. This target region is present in all PML isoforms and was verified by BLAST searches to confirm specificity. For control experiments, empty pSUPER vectors were used.

### **Measurement of PV-induced cell lysis**

Hep3B and HepG2 cells were infected with H-1 PV at a MOI of 20 pfu/cell and further grown for 1 to 3 d. Cell permeabilization was then measured by using a standard toxicity assay (Toxilight, Cambrex Bio Science, Rockland Inc., USA) assessing the concentration of cellular adenylate kinase (AK) in culture supernatants according to the manufacturer's recommendations<sup>[39]</sup>.

### **FACScan analysis of apoptosis**

For quantification of the percentage of apoptotic cells in H-1 PV-infected cultures (MOI = 20 pfu/cell), adherent cells were dissociated with 0.25% trypsin and collected, together with cells floating in the medium, by centrifugation at 800 g. Cells were washed twice with PBS and stained with propidium iodide and annexin V (Becton Dickinson, Heidelberg, Germany). Fluorescence was measured with a minimum of 10 000 events per sample in a FACScan according to the manufacturer's instructions (Becton Dickinson). Data analysis was performed using the software Cell Quest (Becton Dickinson)<sup>[21]</sup>.

### **Analysis of mitochondrial membrane potential**

To measure the mitochondrial transmembrane potential, the cationic lipophilic fluorochrome JC-1 (5, 5, 6, 6-tetrachloro-1, 1, 3, 3-tetraethylbenzimidazolyl-carbocyanine iodide) (Molecular Probes, Inc., Eugene, OR) was used. JC-1 exists as a monomer in solution, emitting green fluorescence. In a reaction driven by the mitochondrial transmembrane potential, JC-1 can adopt a dimeric configuration and emit red fluorescence<sup>[40,41]</sup>. Mock- or H-1 PV-infected cultures ( $5 \times 10^4$  cells/mL) were incubated with JC-1 (5 µg/mL) for 20 min at room temperature in the dark, washed once in PBS and immediately analyzed by flow cytometry (FACScan, Becton Dickinson, Heidelberg, Germany) using Cellquest software. The red fluorescence of JC-1 indicates intact mitochondria, whereas green fluorescence shows monomeric JC-1 that remained unprocessed due to breakdown of the mitochondrial membrane potential<sup>[42]</sup>. After gating out small sized (i.e., non-cellular) debris, 10 000 events were collected for each analysis. The emitted green fluorescence signals were used as a measure for the loss of mitochondrial membrane potential<sup>[43]</sup>.

### **Statistical analysis**

Protein and (real time) gene expression values were analyzed for differences, using the one-sided Student's *t*-test. A *P*-value lower than 0.05 was considered as statistically significant.

## RESULTS

### Characterization of the p53 status in the hepatoma cell line pairs

In order to validate the system chosen to analyze the role of p53 and its effector pathways in H-1 PV-induced cellular cytotoxicity, we first confirmed the differential activity and expression of p53 in the two pairs of isogenic p53-positive and p53-negative HCC cell lines. The cell line HepG2 expresses functional wt p53 while Hep3B is a p53-null (p53<sup>-/-</sup>) cell line<sup>[44]</sup>. Hep3B4P cells transfected with a tamoxifen-regulated p53-estrogen receptor chimera<sup>[34]</sup> were cultured with different concentrations of 4-OH-tamoxifen to induce p53. Upon transfection of a p53-transactivated luciferase construct (pConluc/pgu-pluc), 4-OH-tamoxifen induced dose-dependent the p53 activity, up to 25 times at 750 nmol/L of 4-OH-tamoxifen (data not shown). At this concentration, the induction of p53 expression was determined to have no detectable effects on the growth of non-infected cells in accordance to previous reports<sup>[38,45]</sup>. The cell lines studied differ in expression of p53 as expected (Figure 1A). HepG2 and HepG2 303 show p53 bands in both cases, because HepG2 303 is a HepG2 derivative stably transfected with a dominant-negative p53 mutant (dn-p53).

### Production of parvoviral non-structural proteins in virus-infected p53 different tumor cells

In order to assess the effect of p53 on H-1 PV replication, expression of the replicative cytotoxic NS1 protein was analyzed in infected tumor cell line pairs. As illustrated in Figure 1B, all cultures were proficient in NS1 accumulation within a few days p.i., as detected by Western blot analysis. It was noteworthy; however the p53 expression somehow impaired the capacity for NS1 production, as apparent from the delayed appearance (HepG2 system) or reduced steady-state level (Hep3B4P system) of NS1 in the p53-positive cells. As previously reported<sup>[21]</sup>, NS1 expression levels were in accordance with the respective amounts of viral DNA intermediates as well as luciferase activities of parvoviral vectors.

### H-1 PV toxicity for human tumor cell pairs differing in their p53 status

We previously observed that a p53-negative hepatoma cell line was lightly susceptible to H-1 PV-induced cytotoxicity<sup>[21]</sup>. This prompted us to compare the p53-deficient cells with their p53-positive counterparts in terms of their relative sensitivities to H-1 PV-induced killing. The levels of cytotoxicity in H-1 PV-inoculated Hep3B4P and HepG2 cultures were first monitored by measuring cell permeabilization through the release of adenylate kinase (AK) in the medium for up to 3 d p.i. (Figure 2A). Compared to their mock-treated controls, increased cell death was observed for all hepatoma cell cultures.

In keeping with their above-mentioned greater efficiency in cytotoxic NS1 production, the p53-negative cell cultures moved to be significantly more sensitive to the toxic effect of H-1 PV than their p53-positive de-

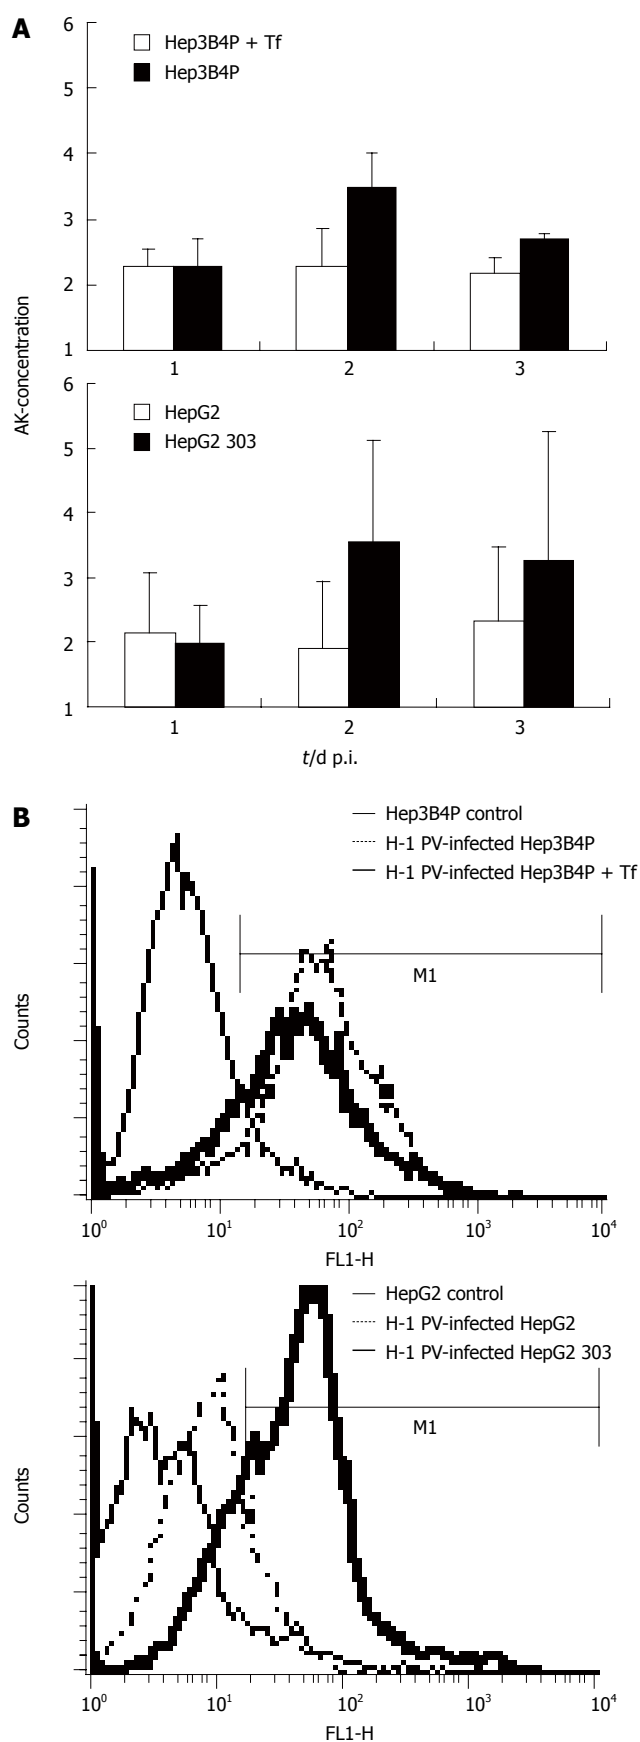

**Figure 1** A: Characterisation of the p53 status and analysis of parvoviral proteins in different human tumor cells by Western blot. Cells were cultured for 2 d and lysed with RIPA buffer, and 50 µg of total protein was subjected to SDS-PAGE. For p53 protein detection, blots were incubated with the monoclonal DO-7 antibody; B: Production of parvoviral proteins in H-1 PV-infected p53 different tumor cells. Hep3B4P and HepG2 cells were H-1 PV-infected (MOI = 20 pfu/cell) and grown for 1 to 3 d. After lysis with RIPA buffer, 50 µg of total proteins were equally diluted and separated on SDS-PAGE. For parvoviral protein detection, blots were incubated with the NS1-specific antibody<sup>[37]</sup>.

rivative. Indeed, supernatants from HepG2 303 cultures contained about twice the amounts of AK than those from the HepG2 parent after H-1 PV infection. Likewise, tamoxifen induction of p53 in the Hep3B4P cells correlated with an increase in their resistance to H-1 PV cytotoxicity.

This difference was confirmed by FACS analysis quantifying the expression of annexin V, a known marker of apoptosis<sup>[30]</sup> (Figure 2B). In agreement with the above viability assay, H-1 PV infection induced annexin V in all hepatoma cells tested, yet to a higher level in p53-negative compared to p53-positive lines. Thus, p53 status correlated with sensitivity of hepatoma cells to the induction of H-1 PV-mediated apoptosis.

### H-1 PV infection enhances depolarization of the inner mitochondrial membrane

The depolarization of the inner mitochondrial membrane has been associated with apoptosis in tumor cells exposed to different cytostatic agents or viruses<sup>[46]</sup>. This prompted us to investigate the effect of H-1 PV infection on this parameter in hepatoma cells. To this end, the profiles of JC-1 fluorescence were compared between mock- and H-1 PV-infected Hep3B4P cells. As illustrated in Figure 3, H-1 PV infection correlated with a striking increase in the fraction of hepatoma cells displaying depolarized mitochondrial membranes. In keeping with above data, this change occurred as soon as 1 d p.i. (Figure 3A) in p53-negative (Hep3B4P) in contrast to positive (Hep3B4P + Tf) cells. The p53-positive cells show an increase

**Figure 2** **A:** Cytotoxicity and induction of apoptosis in H-1 PV-infected p53 different tumor cell line pairs. The early damage of tumor cells upon H-1 PV infection was measured with a standardized toxicity test via supernatant adenylate kinase (AK) concentration; **B:** Induction of apoptosis in H-1 PV-infected tumor cells is shown in histograms for annexin V (FL1-H) of Hep3B4P and HepG2 cells. Data are given as mean values of triplicates.

of the depolarization of membran potential not before 2 d p.i. (Figure 3B).

### Interplay of the tumor suppressor PML and H-1 PV infection

With the intention to identify factors influencing the sensitivity of hepatoma cells for H-1 PV, we determined whether the expression of the tumor suppressor protein PML was affected by H-1 PV-inoculation, and conversely, whether it had an impact on the outcome of infection. As shown in Figure 4, H-1 PV infection caused a strong increase in PML expression both on the protein (Figure 4A) and on the RNA (Figure 4B) level. To assess a possible role of PML in the control of H-1 PV-induced apoptosis in hepatoma cells, PML expression was reduced by RNA interference through expression of a short hairpin (sh) RNA (pSUPER-PML) which specifically targets PML. In contrast to the control pSUPER vector, the shPML construct strongly inhibited expression of endogenous PML in transfected HepG2 cells, irrespective of their p53 status (Figure 4B). Interestingly, knocking down of PML expression was found to correlate with a marked reduction of the efficiency of H-1 PV in inducing apoptosis in both HepG2 cells and their p53-negative HepG2 303 derivatives (Figure 4C). This result reveals PML to be centrally involved in regulation of apoptosis of hepatoma cells upon H-1 PV infection.

### Treatment with chemotherapeutic agents combined with H-1 PV infection

The genetic drift of cancer cells leads to the appearance of variants resisting conventional genotoxic anticancer treatments. This prompted us to test whether hepatoma cells escaping chemotherapy may still be killed by H-1 PV, i.e. whether the combination of chemotherapeutics with H-1 PV meant an advantage. In a first step, this possibility was explored *in vitro* by determining whether H-1 PV infection enhanced the fraction of apoptotic hepatoma cells in cultures treated with cisplatin (Cis), irinotecan (Iri), or 5-FU. As illustrated in Figure 5B, in p53-deficient HepG2 303 cultures, H-1 PV was found to cooperate with all three agents in enhancing the overall fraction of treated cells undergoing apoptosis. Interestingly, the beneficial effect of the combined treatment or either of its individual components was not (cisplatin, irinotecan) or hardly (5-FU) significant in the p53-positive parental line HepG2 (Figure 5A). Therefore, p53 appeared to impair the cooperation of H-1 PV with genotoxic agents, possibly due to the fact that the chemotherapeutic agents enhanced the above-mentioned negative impact of p53 on the parvoviral life cycle. It is noteworthy that the p53-deficient HepG2 303 cells were less (irinotecan, 5-FU) or even more (cisplatin) sensitive to the chemotherapeutic tested, compared with the p53-positive HepG2 parent (Figure 5). This was surprising, given the usually lower susceptibility of p53-negative cells to the induction of apoptosis by genotoxic agents, but is not without precedent as p53 can be functionally replaced by re-

**Figure 3** Analysis of mitochondrial membrane potential. Kinetics of reduction of the mitochondrial membrane potential. Hepatoma cells were left untreated (control) or infected (H-1 PV) for the indicated periods of time and analyzed by flow cytometry using the fluorochrome JC-1. The percentage of cells with decreased mitochondrial membrane potential is shown. After one (A) and two (B) days incubation, the percentage of cells with decreased mitochondrial membrane potential were determined by flow cytometry.

**Figure 4** H-1 PV-induced apoptosis is mediated by PML. HepG2 (p53<sup>+</sup>) and HepG2 303 (p53<sup>-</sup>) cells were transfected with pSUPER or pSUPER-PML as indicated, and infected with H-1 PV for 48 h. Cells were harvested and subjected to Western blot (A) or PCR analysis (B). Hepatoma cells were treated as described, harvested, and subjected to cytotoxicity assay. Apoptosis was determined as described in Material and Methods (C).

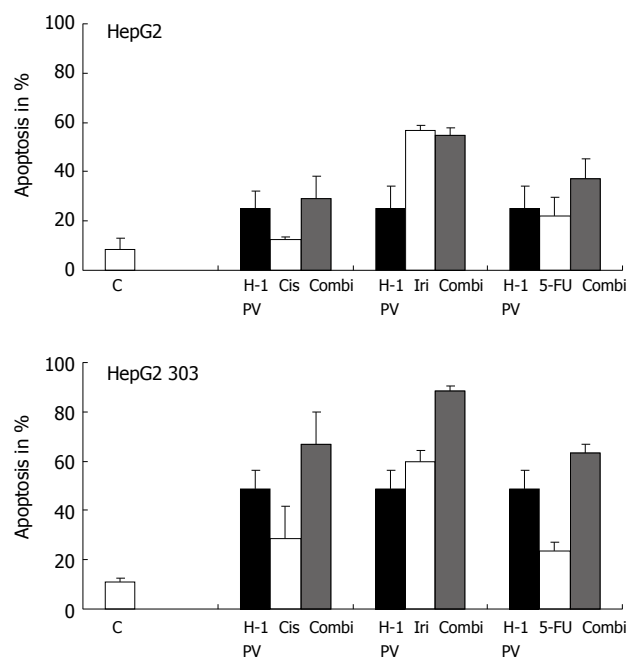

lated products in drug-induced killing of some tumor cells<sup>[47]</sup>.

## DISCUSSION

The development of gene transfer techniques for tumor suppressor protein negative cancers is a rapidly expanding field: For HCC, different viruses have been assessed to specifically target p53-negative tumors or to transfer the wt p53 gene to reconstitute apoptotic pathways in tumor cells<sup>[17-20,44,48-51]</sup>. However, several of the viral delivery systems are limited by their immuno-

suppressor protein negative cancers is a rapidly expanding field: For HCC, different viruses have been assessed to specifically target p53-negative tumors or to transfer the wt p53 gene to reconstitute apoptotic pathways in tumor cells<sup>[17-20,44,48-51]</sup>. However, several of the viral delivery systems are limited by their immuno-

**Figure 5** Treatment of p53 different tumor cells with chemotherapeutic agents. The p53 different HepG2 cells were treated with various chemotherapeutic agents alone or combined with H-1 PV infection (MOI = 20 pfu/cell). H-1 PV- or mock-infected cells were seeded into 6-well plates, and 1 h after infection cultures were treated with chemotherapeutic agents as indicated. Apoptosis was measured on day 3 by FACScan analysis. Data given represent mean values of triplicates.

genic or pathogenic side effects<sup>[52,53]</sup>. We have shown in this paper that oncolytic PV H-1 may be effective in the treatment of HCC. Even more, these oncolytic viruses directly targeting p53-negative carcinomas may be attractive alternative vectors as well as ideal tools for combination with classical chemotherapeutic agents. As the rat PV H-1 is seldom pathogenic to its natural adult hosts and infects humans without any apparent clinical consequences<sup>[28,29]</sup>, we considered the PV H-1 for tumor cell-targeted therapy, in particular in p53-negative tumors. In addition, immune reaction to PVs, such as AAV or H-1 PV might not induce any severe side effects<sup>[21-24]</sup>.

Thus, we first characterized the susceptibility to H-1 PV infection and cell killing of pairs of human tumor cells which differ in their wt p53 levels. In concordance with earlier data<sup>[21]</sup>, H-1 PV-induced killing of tested tumor cells was dependent on MOI and correlated with NS1 expression levels. Similarly, amenability to gene transfer after recombinant PV infection was higher in p53 lacking cells<sup>[21]</sup>. Despite both isogenic HepG2 cells were susceptible to H-1 PV-induced apoptosis, cell death was more pronounced in HepG2 303. As well in other human and rodent cell systems studied so far, susceptibility to H-1 PV-induced cell killing correlated with the capacity of the host cells to sustain both, parvoviral DNA amplification and NS1 protein expression<sup>[20,28,54-56]</sup>. With this regard, earlier data revealed cellular processes underlying the PV-induced tumor cell killing. Further on p53 displayed a key role in the G<sub>1</sub>/S checkpoint in response to DNA damage<sup>[57]</sup> as a regulator of cell cycle

progression and a mediator of apoptosis in many cell lines<sup>[58]</sup>. Thus, p53 could prevent cell progression to S-Phase. According to this some S-phase factors such as p53 have been involved in the regulation of PV DNA replication<sup>[31,35]</sup>. Indeed, the rare H-1 PV-resistant variant clones named KS cells, isolated from the H-1 PV-susceptible human p53-negative erythroleukemia cell line K562, differed from the parental wt p53-positive cells by a reduced oncogenic potential in immunocompromised mice. Similarly, rat fibroblasts overexpressing mutant p53 protein were more sensitive to H-1 PV infection than parental cells<sup>[31]</sup>.

Our data further demonstrate that H-1 PV induces significantly expression of PML on the RNA and protein level and, thus, increases the susceptibility to cell death in H-1 PV-infected tumor cells. The significance of this effect was clearly demonstrated by the knock down of PML in H-1 PV-infected cells with the consequence of impaired apoptosis upon H-1 PV infection. Recently, we showed that the hepatotropic hepatitis C virus (HCV) was able to impair apoptosis in hepatoma cells by inhibition of p53 function *via* interaction with PML<sup>[59]</sup>. Polypeptides from other viruses were also shown to interact with PML, and to disable its biological function in apoptosis regulation, growth suppression and cellular senescence. For example, adenoviral E1A protein abrogates oncogenic Ras- and PML-IV-induced cellular senescence by overriding PML function<sup>[60]</sup>.

Furthermore PODs/PML bodies have been associated with transcription, cell growth, and antiviral responses<sup>[61,62]</sup>. DNA and RNA viruses also frequently target PODs, presumably to facilitate the early stages of transcription and replication<sup>[63-67]</sup>. PODs can also be targeted for reorganization following viral infection<sup>[66]</sup>. For example, adenovirus protein E4-ORF3 localizes to PODs/PML bodies, thereby causing a physical restructuring of the bodies from spherical to extended fibril-like structures termed nuclear tracks<sup>[66]</sup>. Additionally, many viruses induce interferon expression, what increases the size and number of PODs<sup>[62,68]</sup>. Although PV infection did not induce an interferon response, a dramatic relocalization of PODs has been seen late in MVM infection. However, Cziepluch *et al.*<sup>[69]</sup> suggested that H-1 virus does not target known nuclear bodies for DNA replication but rather induced the formation of a novel structure in the nucleus of infected cells. Within that study, PML-expression was not directly investigated.

In addition, PVs were recently reported to replicate in association with distinct nuclear bodies<sup>[69]</sup>, which appear to lately merge with PML and PML-NBs<sup>[70]</sup>. PML may interact with viral products and participate in the regulation of virus replication. PML proteins may thus modulate viral cytopathic effects, in keeping with the above-mentioned involvement of PML in growth inhibition and death processes. As PV H-1 infection enhances PML expression and function, this might be a central molecular mechanism for an effective treatment of HCC.

We furthermore examined the effects of various chemotherapeutic agents in combination with H-1 PV

infection on growth inhibition using isogenic cancer cells with different p53 status. H-1 PV infection enhanced the cytotoxicity of chemotherapeutic agents in the treatment of two HCC. In p53-deficient HepG2 303 cultures, H-1 PV was found to cooperate with all three agents in enhancing the overall fraction of treated cells undergoing apoptosis. The treatment with Irinotecan, 5-Fluorouracil and Cisplatin combined with H-1 PV infection more strongly inhibited the growth of the p53-negative HepG2 303 cells than treatment with chemotherapeutics alone. Therefore H-1 PV infection enhances cytostatic drug therapy in p53-negative tumors. Furthermore, irrespective of the p53 status, H-1 PV was able to induce programmed cell death in these human tumor cells, as it was also shown for other PVs<sup>[71]</sup>. Chemotherapeutic treatment alone did not induce such a high apoptosis rate compared to combined treatment with H-1 PV. Comparable data have also been published for other oncolytic viruses<sup>[72-75]</sup>. Thus, our data show a beneficial interaction between chemotherapy and oncolytic viral therapy and suggest that H-1 PV infection may enhance the effectiveness of chemotherapeutic agents in the treatment of HCC.

In summary, our results strongly suggest that p53-impaired tumors-which have a poor prognosis-may be particularly suitable to PV H-1-induced therapy<sup>[39,43,45]</sup>. Though p53 deficiency in tumors may induce resistance to chemotherapeutic agents, this will not affect the tumor cell susceptibility to H-1 PV-induced oncolytic infections<sup>[51]</sup>. As recombinant H-1 PV had a high capacity to transduce transgenes in these cells, the therapeutic potential of H-1 PV-based recombinant vectors carrying suicide genes or cytokines should be further assessed in p53-negative tumors. The PV H-1 may then also overcome other tumor resistance mechanisms against autocrine and paracrine apoptotic triggers developed in these tumor entities<sup>[50,51]</sup>. We conclude that our strategy using H-1 PV infection in combination with chemotherapeutic treatment can enhance the cytotoxic effect of anti-cancer agents. Furthermore, H-1 PV induced the expression of PML, thus increased the susceptibility to cell death in H-1 PV-infected tumor cells. So PML may operate as a positive element which controls in a direct or indirect way the susceptibility of hepatoma cells to apoptosis-activity of H-1 PV.

## ACKNOWLEDGMENTS

The authors wish to thank the lab assistants Petra Schaefer and Sandra Weyer for excellent technical assistance. The manuscript is based on at least in part of the data from the PhD thesis of Maike Sieben and of the MD thesis of Vera Heinrichs.

## COMMENTS

### Background

Oncolytic parvoviruses (PVs) are endowed with oncolytic properties and also increase the host immune response against the tumor by priming effector cells.

### Research frontiers

Authors evaluated the synergistic targeting and killing of human hepatocellular carcinoma (HCC) cells lacking p53 by PV H-1 and chemotherapeutic agents.

### Innovations and breakthroughs

Analysing the regulating the cell killing pathways and gene transfer mediated by PV H-1 in pairs of human hepatocellular cell lines with different p53 status, H-1 PV is quite a suitable agent to circumvent the resistance of p53-negative HCC to genotoxic agents, and enhances the apoptotic process which is dependent on functional PML.

### Applications

Especially for p53-negative human tumors authors consider PV H-1 as therapeutic option for human HCC.

### Peer review

This manuscript described that H-1 PV is a novel agent for treating p53 negative HCC via the induction of PML and apoptosis. This study is a well designed, well exerted, and well written manuscript.

and immunohistochemistry. Bcl-x<sub>L</sub> and Mcl-1 protein expression was knocked down or increased in CRC cell lines by applying specific siRNAs or expression plasmids, respectively. After modulation of protein expression, CRC cells were treated with chemotherapeutic agents, an antagonistic epidermal growth factor receptor (EGFR1) antibody, an EGFR1 tyrosine kinase inhibitor, or with the death receptor ligand TRAIL. Apoptosis induction and cell viability were analyzed.

**RESULTS:** Here we show that in human CRC tissue and various CRC cell lines both Bcl-x<sub>L</sub> and Mcl-1 are expressed. Bcl-x<sub>L</sub> expression was higher in CRC tissue than in surrounding non-malignant tissue, both on protein and mRNA level. *Mcl-1* mRNA expression was significantly lower in malignant tissues. However, protein expression was slightly higher. Viability rates of CRC cells were significantly decreased after knock down of Bcl-x<sub>L</sub> expression, and, to a lower extent, after knock down of Mcl-1 expression. Furthermore, cells with reduced Bcl-x<sub>L</sub> or Mcl-1 expression was more sensitive towards oxaliplatin- and irinotecan-induced apoptosis, and in the case of Bcl-x<sub>L</sub> also towards 5-FU-induced apoptosis. On the other hand, upregulation of Bcl-x<sub>L</sub> by transfection of an expression plasmid decreased chemotherapeutic drug-induced apoptosis. EGF treatment clearly induced Bcl-x<sub>L</sub> and Mcl-1 expression in CRC cells. Apoptosis induction upon EGFR1 blockage by cetuximab or PD168393 was increased by inhibiting Mcl-1 and Bcl-x<sub>L</sub> expression. More strikingly, CD95- and TRAIL-induced apoptosis was increased by Bcl-x<sub>L</sub> knock down.

**CONCLUSION:** Our data suggest that Bcl-x<sub>L</sub> and, to a lower extent, Mcl-1, are important anti-apoptotic factors in CRC. Specific downregulation of Bcl-x<sub>L</sub> is a promising approach to sensitize CRC cells towards chemotherapy and targeted therapy.

### Abstract

**AIM:** To explore the role of Bcl-x<sub>L</sub> and Myeloid cell leukaemia (Mcl)-1 for the apoptosis resistance of colorectal carcinoma (CRC) cells towards current treatment modalities.

**METHODS:** Bcl-x<sub>L</sub> and Mcl-1 mRNA and protein expression were analyzed in CRC cell lines as well as human CRC tissue by Western blot, quantitative PCR

**Key words:** Colorectal carcinoma; Bcl-x<sub>L</sub>; Myeloid cell leukaemia-1; Epidermal growth factor receptor 1; Apoptosis; 5-fluorouracil; Irinotecan; Oxaliplatin

## INTRODUCTION

Colorectal carcinoma (CRC) is one of the most common malignancies in the Western world. In palliative care, novel treatment approaches including combination of chemotherapy and targeted therapies, such as epidermal growth factor receptor (EGFR) 1 blockage, have improved survival of cancer patients<sup>[1]</sup>. However, 5-year survival of patients with metastatic CRC remains < 5%. Current established systemic therapy options include 5-fluorouracil (5-FU), oxaliplatin, irinotecan, the EGFR1 antibody cetuximab and the vascular endothelial growth factor (VEGF)-A antibody bevacizumab.

Apoptosis is a genetically programmed process of controlled suicide, which is critical for multicellular organisms during development and for tissue homeostasis. However, in cancer, tumor cells acquire resistance to apoptosis. Thus, the ratio of apoptosis and cell division is altered, resulting in a net gain of malignant tissue. Additionally, defects in apoptosis signalling in cancer cells impair response to therapy and contribute to the limited efficacy of different therapy regimens in metastatic disease<sup>[2]</sup>.

Stabilization of mitochondrial integrity is a key mechanism for the survival of a malignant cell and its resistance to therapy<sup>[3]</sup>. Mitochondrial integrity is regulated by pro- and anti-apoptotic members of the Bcl-2 family, such as Bcl-x<sub>L</sub> and Mcl-1 (Myeloid cell leukaemia-1, anti-apoptotic) and Bid, Bad and Bax (pro-apoptotic). Mcl-1 is essential for development, differentiation and survival in a variety of cell types<sup>[4,5]</sup>. It is involved in important interactions of Bcl-2 family members and thereby regulates mitochondrial activation<sup>[6]</sup>. Mcl-1 protein levels are elevated in various human tumors, such as hepatocellular carcinoma<sup>[7]</sup> and non-small cell lung cancer<sup>[8]</sup>. Importantly, it contributes to the resistance of cancer cells towards apoptosis induction<sup>[6,9]</sup>. Downregulation of Mcl-1 has been shown to sensitize cancer cells towards apoptosis induction, e.g. after treatment with the death receptor ligand TRAIL [tumor necrosis factor (TNF)-related apoptosis-inducing ligand]<sup>[10,11]</sup>. In addition, Mcl-1 degradation is necessary for mitochondrial activation after genotoxic stress<sup>[12]</sup>. Like Mcl-1, Bcl-x<sub>L</sub> is known to promote cell survival by

counteracting pro-apoptotic Bcl-2 family members, such as Bim, Bax and Bid. In cancer, overexpression of Bcl-x<sub>L</sub> is associated with tumor progression, poor prognosis and resistance to chemotherapy. In CRC, Bcl-x<sub>L</sub> expression is correlated with an advanced disease stage<sup>[13]</sup>. A role of Bcl-x<sub>L</sub> in cancer was first suggested when it was found that expression of Her-2/Neu in breast cancer cells increased Bcl-x<sub>L</sub> expression and rendered cells resistant to tamoxifen-induced apoptosis<sup>[14]</sup>. Ectopic expression of Bcl-x<sub>L</sub> in CRC blocks curcumin-induced apoptosis<sup>[15]</sup>. On the other hand, downregulation of Bcl-x<sub>L</sub> by antisense technique induces cell death, e.g. after treatment with chemotherapeutic drugs<sup>[16,17]</sup>. An important trigger for Bcl-x<sub>L</sub> expression in CRC is NF-κB<sup>[18]</sup>. CRC cells frequently harbor genetic aberrations that promote NF-κB-mediated induction of Bcl-x<sub>L</sub>.

The last decade has ushered in new advances for the treatment of patients with CRC. The older cytotoxic chemotherapy drug 5-FU underwent new formulation, and two new drugs, oxaliplatin and irinotecan, were investigated as adjunctive therapies. Finally, targeted therapies, including monoclonal antibodies against VEGF-A (bevacizumab) and EGFR1 (cetuximab), are now standard treatment for metastatic CRC. For patients with metastatic disease, the survival rate has doubled. Among others, a promising approach to overcome apoptosis resistance of CRC cells is the engagement of the death receptors belonging to the tumor necrosis factor receptor gene superfamily with the death ligand TRAIL (Apo2L)<sup>[19]</sup>.

In our study, we investigated the role of the anti-apoptotic Bcl-2 family members Bcl-x<sub>L</sub> and Mcl-1 for the apoptosis sensitivity of CRC. Both Bcl-2 family proteins were specifically modulated in CRC cells by RNA interference and overexpression, respectively, and the impact on apoptosis sensitivity towards chemotherapy and targeted therapy including TRAIL and EGFR1 blockage was explored.

## MATERIALS AND METHODS

### Reagents and cell lines

SW480, HT29, Caco-2 (all isolated from primary tumor tissue) and SW620 (derived from lymph node metastasis), all human CRC cell lines (adenocarcinomas), were purchased from ATCC. Cell lines were cultured in RPMI 1640 (Invitrogen, Karlsruhe, Germany), supplemented with 10% fetal calf serum (FCS, Biochrom, Berlin, Germany), Pen/Strep (1%) (PAA Laboratories, Pasching, Austria), HEPES (1%) (Cambrex, Verviers, Belgium) and L-Glutamin (1%) (Cambrex). Cells were cultivated in reduced medium (FCS concentration decreased to 0.5%) in all experiments. Reagents were purchased from the following suppliers: chemotherapeutic agents from Sigma (Deisenhofen, Germany); TRAIL (with enhancer, applied in a concentration of 1 ng/mL) from Alexis Biochemicals (San Diego, CA, USA); PD168393 from Calbiochem (Schwalbach, Germany); Protein A (for co-treatment with anti-APO-1, in a concentration of 10 ng/mL) and EGF

from Sigma. Cetuximab was supplied by Merck Pharma (Darmstadt, Germany). Anti-APO-1 was kindly provided by Peter H. Krammer (German Cancer Research Center).

### Tissue samples

CRC tissue samples as well as non-neoplastic colorectal tissues were obtained from patients undergoing elective surgery for colorectal cancer at the University of Mainz. Analysis of CRC samples was approved by the local ethics committee. The morphological classification of the carcinomas was conducted according to WHO specifications. Tissues samples were used for immunohistochemical staining as well as for mRNA extraction.

### Immunohistochemical staining

Paraffin-embedded tissue sections (which all included carcinoma as well as normal epithelial cells in one section) were subjected to immunostaining, using a biotin/streptavidin-peroxidase technique (Vector Laboratories Inc., Burlingame, CA). They were deparaffinized in xylene and dehydrated in ethanol, and dried in a steamer with 10 mmol Na-citrate buffer (pH 6.0). Endogenous peroxidase activity was blocked by incubating the slices for 5 min with 3.0% hydrogen peroxide at room temperature, followed by washing in TPBS (0.5% TWEEN in PBS). The sections were then incubated for 30 min at room temperature with TNB (1% BSA, 0.5% protein-blocking reagent in TBS) prior to an overnight incubation at 4°C with polyclonal rabbit Bcl-xS/L (clone S-18, Santa Cruz Biotechnology Inc., Santa Cruz, California) or polyclonal rabbit Mcl-1 (S-19, Santa Cruz). Both were diluted 1:160 in TNB. Bound antibody was detected using biotinylated anti-rabbit IgG secondary antibody (Vector) and streptavidin-peroxidase complex (Vector), followed by incubating with diaminobenzidine as substrate. Sections were counterstained with Mayer's haematoxylin. As negative controls, sections were incubated in the presence of nonimmunized rabbit IgG as first antibody.

### Viability test

Cell viability was determined by a colorimetric 3-(4,5-dimethylthiazole-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay. CRC cell lines were seeded onto 12-well plates. On day 1 after seeding, cells were treated as indicated. 100 µL MTT (5 mg/mL) was added to each well. After 4 h incubation at 37°C the supernatant was discarded and cells were washed with PBS. For cell lysis 0.5 mL 1-propanol was added for another 20 min. After transfer of 100 µL of each sample to a flat-bottomed 96-well microtiter plate; the optical density was determined at 550 nm. The viability of "1" was defined as the absorbance obtained from mock transfected cells or untreated cells, respectively.

### Detection of apoptosis

CRC cell lines were seeded onto 12-well plates. On day 1 after seeding, cells were treated as indicated. Cells were then collected, washed, and resuspended in lysis buffer containing 0.1% (w/v) sodium citrate, 0.1% (v/v) Triton

X-100 and 50 µg/mL propidium iodide (Sigma). After overnight incubation at 4°C, nuclei from apoptotic cells were quantified by flow cytometry according to the method of Nicoletti *et al.*<sup>[20]</sup>.

### Cell lysis and Western blotting

Cell lysis and Western blotting were performed as described before<sup>[7]</sup>. Immunodetection was performed using the indicated primary antibodies: anti-Mcl-1 (S19) (Santa Cruz Biotechnology, Heidelberg, Germany), anti-Bcl-x<sub>L</sub> (Labvision/NeoMarkers, Warm Springs Blvd. Fremont, Canada), and mouse anti-α-Tubulin clone B-5-1-2 (Sigma).

### RNAi and transfection

For small interfering RNA (siRNA)-mediated knock down of *Mcl-1* and *Bcl-x<sub>L</sub>*, the following siRNA sequences were applied (MWG Biotech, Ebersberg, Germany): *Mcl-1*, 5'-aagaucaacagacguucucTT-3' (sense) and 5'-gagaacgucugugauacuuTT-3' (antisense). *Bcl-x<sub>L</sub>*, 5'-gcu ug-ggaaagaaugcaaTT-3' (sense) and 5'-uugcauuuuau cccaag-cAG-3' (antisense). As a non-silencing control, siRNA specific for green fluorescent protein (GFP) was used: 5'-ggcuacguccaggagcgaccTT-3' (sense) and 5'-ggg ggcuc-cuggacguagccTT-3' (antisense), where capitals represent deoxyribonucleotides and lower case letters represent ribonucleotides. SW480 cells were transiently transfected with Lipofectamin RNAiMAX (Invitrogen, Karlsruhe, Germany) according to the manufacturer's protocol and analyzed 24 h after transfection. For Mcl-1 and Bcl-x<sub>L</sub> expression, we applied specific expression vectors (pEF4<sub>Mcl-1</sub> or pcDNA3<sub>Bcl-xL</sub>) or the corresponding empty vectors (pEF4<sub>empty</sub> or pcDNA3<sub>empty</sub>, respectively), all kindly provided by Peter H. Krammer, German Cancer Research Center (Heidelberg, Germany). SW480 cells were transfected with plasmids using Transfectin (Biorad, München, Germany) according to the manufacturer's protocol.

### Real-time quantitative polymerase chain reaction (RT-QPCR)

To analyze RNAi efficiency, total RNA from CRC cells was extracted using RNeasy Mini Kit (Qiagen) 24 h after transfection of siRNA. One µg of total RNA was reverse transcribed using an oligo-dT primer with the Omniscript RT kit (Qiagen) and afterwards analyzed for specific mRNA expression by RT-QPCR using the QuantiTect SYBR Green PCR Kit (Qiagen) and the following primers: *Actin* forward: 5'-GGACTTCGAGCAAGAGAT GG-3', *Actin* reverse: 5'-AGCACTGTGTTGGCGTAC AG-3', *Mcl-1* forward: 5'-TAAGGACAAAACGGGACT GG-3', *Mcl-1* reverse: 5'-ACCAGCTCCTACTCCAGC AA-3'. *Bcl-x<sub>L</sub>* forward: 5'-GTAAACTGGGGTTCGC ATTGT-3', *Bcl-x<sub>L</sub>* reverse: 5'-TGCTGCATTGTTCCC ATAGA-3'. The relative increase in reporter fluorescent dye emission was monitored. The level of *Mcl-1* or *Bcl-x<sub>L</sub>* (gene of interest, GOI) mRNA, respectively, relative to actin, was calculated using the formula: Relative GOI mRNA expression =  $2 [C_t (GOI_{control}) - C_t (GOI_{treated}) + C_t (Actin_{treated}) - C_t (Actin_{control})]$ , where  $C_t$

is defined as the number of the cycle in which emission exceeds an arbitrarily defined threshold. For evaluation of *Bcl-x<sub>L</sub>* and *Mcl-1* mRNA expression in tumor as well as non-neoplastic colon tissues, *RP II* instead of actin was measured as housekeeping gene: *RP II* forward: 5'-GCACCACGTCCAATGACAT-3', *RP II* reverse: 5'-GTGCGGCTGCTTCATAA-3'.

### Statistical analysis

All results are expressed as mean  $\pm$  SD. Data were analyzed by Student's *t*-test (paired, two sided). *P* < 0.05 was considered significant.

## RESULTS

### Expression of the anti-apoptotic Bcl-2 family members Bcl-x<sub>L</sub> and Mcl-1 in CRC

Apoptosis resistance is a well-known phenomenon which counteracts chemotherapeutic drug-induced cell death of CRC cells. Anti-apoptotic Bcl-2 family members such as Bcl-x<sub>L</sub> and Mcl-1 contribute to the apoptosis resistance in different tumor entities. First, we analyzed expression of Bcl-x<sub>L</sub> and Mcl-1 in various CRC cell lines. All cell lines tested showed a profound expression of Mcl-1 on protein level (Figure 1A). Bcl-x<sub>L</sub> expression was rather low in HT29 and Caco-2 and high in SW480 cells (Figure 1A).

Next, we analyzed expression of *Bcl-x<sub>L</sub>* and *Mcl-1* mRNA in human CRC tissues by quantitative PCR. Bcl-x<sub>L</sub> levels were higher in CRC tissues compared to non-malignant, adjacent tissue (Median of relative expression: 1.2, *n* = 9, *P* < 0.2, not significant, Figure 1B). Six of 9 patients showed a higher *Bcl-x<sub>L</sub>* expression, 2 patients showed a lower expression, and in 1 patient, expression was virtually equal. *Mcl-1* mRNA expression was significantly lower in carcinoma tissue compared to non-malignant tissue (Median of relative expression: 0.41, *n* = 9, *P* < 0.01). In addition, we performed immunohistochemical analysis of Bcl-x<sub>L</sub> and Mcl-1 in CRC. In all tissues tested (*n* = 6), expression of Bcl-x<sub>L</sub> was profoundly higher in carcinoma cells compared to surrounding epithelial cells (Figure 1C). Furthermore, Mcl-1 expression was also (slightly) higher compared to surrounding epithelial cells in all probes tested (*n* = 4).

### Sensitivity of Bcl-x<sub>L</sub> and Mcl-1 expressing CRC cells towards chemotherapeutic drug-induced apoptosis and EGFR1 inhibition

Subsequently, we tested the sensitivity of CRC cell lines towards chemotherapeutic drug-induced apoptosis. We treated SW480 cells with different agents frequently applied for the treatment of patients with CRC: the chemotherapeutic agents irinotecan, oxaliplatin and 5-FU (Figure 2). After 48 h, oxaliplatin (10  $\mu$ g/mL) and irinotecan (40  $\mu$ g/mL) induced apoptosis in more than 50% of the cells. 5-FU (10  $\mu$ g/mL) induced apoptosis in nearly 45% of CRC cells. Treatment with the antagonistic EGFR1 antibody cetuximab induced apoptosis in 18% of cells after 48 h (compared to 13% of apoptosis

**Figure 1** Mcl-1 and Bcl-x<sub>L</sub> expression in CRC. **A:** The CRC cell lines, HT29, SW620, SW480, and Caco-2, were analyzed for the basal expression of the Bcl-2 family members Bcl-x<sub>L</sub> and Mcl-1. Whole cell lysates were prepared, separated, and immunoblotted with antibodies against Bcl-x<sub>L</sub>, Mcl-1 and  $\alpha$ -tubulin; **B:** CRC tissues and normal colorectal tissues were tested for mRNA expression (*n* = 9 patients). mRNA expression levels of *Bcl-x<sub>L</sub>*, *Mcl-1* and *RP II* were measured in all tissue samples by quantitative real-time PCR. mRNA expression levels of *Bcl-x<sub>L</sub>* or *Mcl-1* were normalized to *RP II* in each sample. Each PCR reaction was run in triplicates. Median is added; **C:** Immunohistochemical analysis of human CRC tissues was performed as described in the Methods section. All sections included carcinoma as well as normal epithelial tissues to directly compare Bcl-x<sub>L</sub> as well as Mcl-1 expression in neoplastic and non-malignant tissues. Representative analysis of immunoperoxidase detection of Bcl-x<sub>L</sub> and Mcl-1 in paraffin embedded carcinoma tissue (T) and adjacent non-tumor tissue (N) is presented.

in control cells, *P* = 0.07, Figure 2). Apoptosis induction in cells treated with the EGFR1 tyrosine kinase inhibitor PD168393 was not significant (16% vs 13%, *P* = 0.15).

**Figure 2** Drug-induced apoptosis in CRC cells. SW480 cells were treated with the chemotherapeutic agents 5-FU, oxaliplatin ("oxali") and irinotecan ("irino") for 48 h (concentrations as indicated, upper panel). In addition, cells were treated with the EGFR1 antibody cetuximab ("cetux", 20 µg/mL) or the EGFR1 tyrosine kinase inhibitor PD168393 (7 µmol/L, lower panel) in FCS reduced medium. Cells were then harvested and analyzed for apoptosis induction by flow cytometry. Assays were performed in triplicates. Values are mean  $\pm$  SD.

### Modulation of Bcl-x<sub>L</sub> and Mcl-1 expression and its impact on chemotherapeutic drug-induced apoptosis

In order to analyze the functional contribution of Bcl-x<sub>L</sub> and Mcl-1 on apoptosis sensitivity of CRC cells, we specifically modulated their expression. Transfection of specific siRNA sequences effectively knocked down expression of Bcl-x<sub>L</sub> and Mcl-1 mRNA and protein in SW480 cells (Figures 3A and 4A). For example, 24 h after transfecting 20 nmol/L of specific siRNAs, mRNA expressions were reduced by 75% or 74%, respectively. For 10, 20 and 40 nmol/L of siRNA concentration, an efficient knock down of Bcl-x<sub>L</sub> and Mcl-1 was observed after 24 h (data not shown). As could be detected in Western blot assays, Bcl-x<sub>L</sub> and Mcl-1 protein expression were also drastically reduced 24 h after siRNA transfection. On the other hand, transfection of expression plasmids for Bcl-x<sub>L</sub> increased protein expression (Figure 3C). Next, we tested the effect of specific knock down of Mcl-1 *vs* Bcl-x<sub>L</sub> on apoptosis sensitivity of SW480 cells. Knock down of Bcl-x<sub>L</sub> significantly enhanced apoptosis induction in untreated cells compared to control transfected cells (21% to 38%,  $P < 0.05$ , Figure 3B). These results were confirmed in viability assays: Viability was decreased by 33% (Figure 3B). In contrast, Mcl-1 knock down only moderately enhanced spontaneous apoptosis rates (20% to 25%,  $P < 0.05$ , Figure 4B). Correspondingly, viability was not decreased in CRC cells after Mcl-1 knock down (Figure 4B).

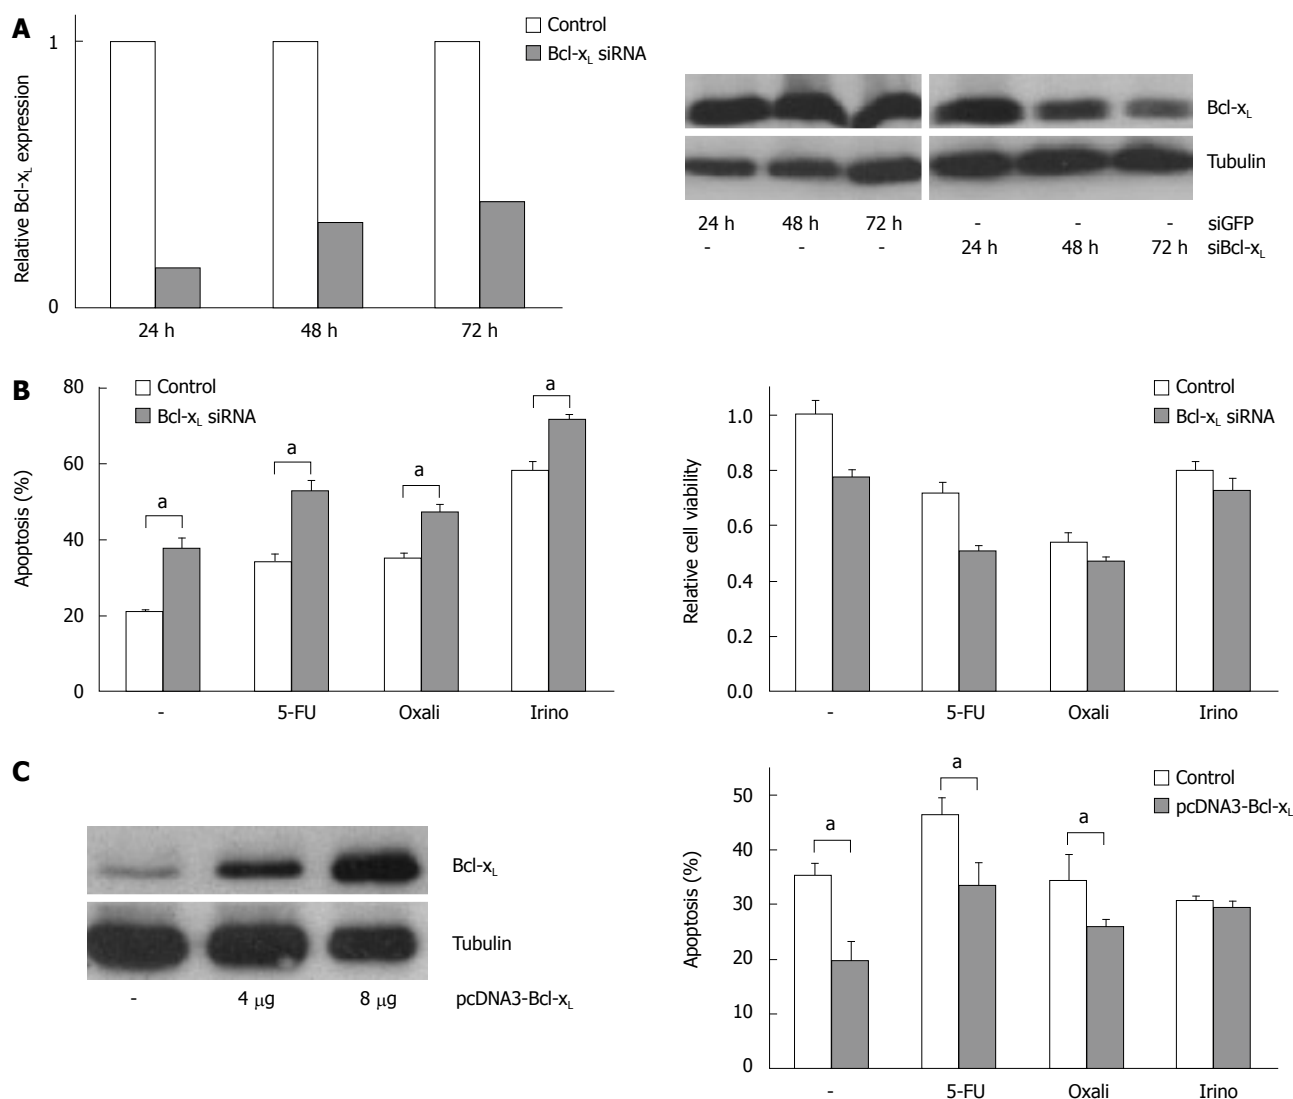

Subsequently, we treated CRC cells with the chemotherapeutic agents 5-FU, oxaliplatin and irinotecan. Knock down of Bcl-x<sub>L</sub> in combination with chemotherapy resulted in an increase of apoptosis induction (5-FU: 34% (chemotherapy alone) to 53% (chemotherapy plus Bcl-x<sub>L</sub> knock down); oxaliplatin: 35% to 47% and irinotecan: 58% to 72%,  $P < 0.05$ , Figure 3B). Silencing of Mcl-1 expression led to a slight enhancement of irinotecan-induced apoptosis (33% to 35%, not significant, Figure 4B) and to a moderate, but significant increase of oxaliplatin-induced apoptosis (27% to 33%,  $P < 0.05$ ). Surprisingly, 5-FU-induced apoptosis was decreased in cells with lower Mcl-1 expression (32% to 28%, not significant, Figure 4B). Transfection of the Bcl-x<sub>L</sub> expression plasmid enhanced viability of CRC cells: spontaneous apoptosis rates were 20% instead of 36% in control transfected cells ( $P < 0.05$ , Figure 3C). Moreover, 5-FU (33% *vs* 46%,  $P < 0.05$ ), and irinotecan (26% *vs* 34%,  $P < 0.05$ )-induced apoptosis, but not oxaliplatin-induced apoptosis (29% *vs* 30%, n.s.), was reduced by transfecting Bcl-x<sub>L</sub> (Figure 3C). After transfection of Mcl-1 expression plasmids, no significant impact on chemotherapeutic-drug-induced apoptosis was observed (data not shown).

### Modulation of Bcl-x<sub>L</sub> and Mcl-1 expression and its impact on EGFR1 blockage

We next analyzed apoptosis induction in CRC cells after targeted therapy approaches. Inhibition of EGFR1 signalling has already entered clinical routine in the treatment of patients with CRC. Cetuximab, a monoclonal antibody against EGFR1, demonstrates anti-tumor efficacy both as a single agent and in combination with irinotecan- and oxaliplatin-based chemotherapy. EGF is known to contribute to an apoptosis resistant phenotype of carcinoma cells. First, we tested the influence of EGF treatment on Bcl-x<sub>L</sub> and Mcl-1 expression *in vitro*. EGF treatment of CRC cells induced expression of Bcl-x<sub>L</sub> and Mcl-1 after 1.5 and 2.5 h, respectively (Figure 5A). We next analyzed the role of Mcl-1 and Bcl-x<sub>L</sub> for the resistance towards targeted therapy. First, we treated CRC cells with cetuximab. Treatment with cetuximab alone (100 µg/mL) did not induce apoptosis SW480 cells after 24 h (Figure 5B). However, in cells with reduced Bcl-x<sub>L</sub>, a significant increase in apoptosis induction after treatment with cetuximab (44% *vs* 37%,  $P < 0.05$ , Figure 5B) or the EGFR1 tyrosine kinase inhibitor PD168393 (0.7 µmol/L; 41% *vs* 29%,  $P < 0.01$ , Figure 5B) was observed. Moreover, knock down of Mcl-1 also resulted in a moderate, but significant sensitization towards cetuximab (28% *vs* 23%; Figure 5B,  $P < 0.01$ ) and PD168393 (32% *vs* 24%, Figure 5B,  $P < 0.05$ ).

### Modulation of Bcl-x<sub>L</sub> and Mcl-1 expression and its impact on TRAIL- and CD95-mediated apoptosis

The death receptor ligand TRAIL is a promising anti-cancer agent (for recent review<sup>[21]</sup>) and already has been tested in clinical studies in CRC patients. Thus, we analyzed the impact of Bcl-x<sub>L</sub> and Mcl-1 modulation

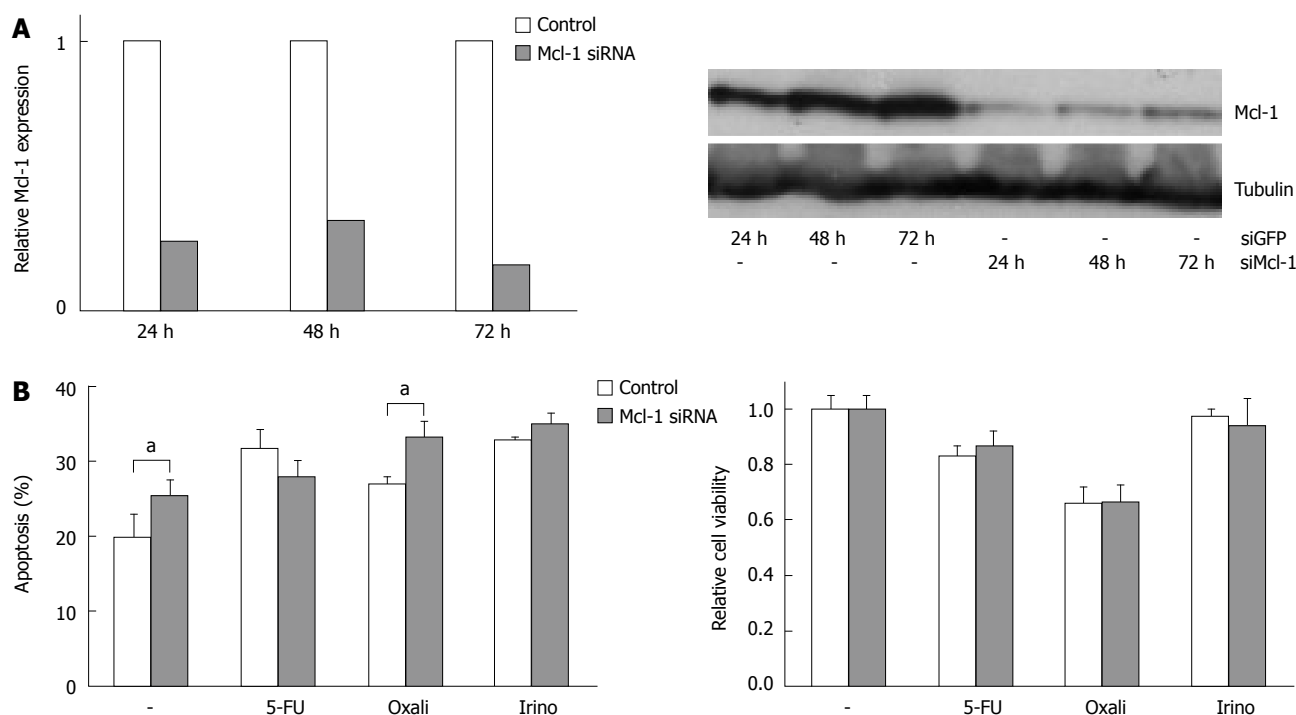

**Figure 3** Modulation of Bcl-x<sub>L</sub> expression alters chemotherapeutic drug-induced apoptosis. **A:** SW480 cells were transfected with siRNA specific for Bcl-x<sub>L</sub> or transfected with siRNA specific for GFP as control (20 nmol/L). After the indicated time post transfection, total RNA was extracted and analyzed for Bcl-x<sub>L</sub> expression by quantitative real-time PCR (left panel). Relative expression was calculated as described in the materials and methods section. In addition, after the indicated time post transfection, cells were lysed and analyzed for Bcl-x<sub>L</sub> expression by Western blot (right panel).  $\alpha$ -Tubulin expression was used to control equal loading; **B:** SW480 cells were transfected with siRNA specific for Bcl-x<sub>L</sub> or transfected with siRNA specific for GFP as control. 24 h post transfection, cells were treated with 5-FU (10  $\mu$ g/mL), oxaliplatin (16  $\mu$ g/mL) and irinotecan (60  $\mu$ g/mL) for further 24 h. Cells were then harvested and analyzed for apoptosis induction (left panel). In addition, cell viability was measured by MTT assay and is shown relative to mock treated controls (right panel); **C:** SW480 cells were transfected with pcDNA3 Bcl-x<sub>L</sub> or pcDNA3 empty vector as control. 24 h post transfection, cells were analyzed for Bcl-x<sub>L</sub> expression using Western blotting (left panel). In addition, 24 h post transfection, cells were treated with 5-FU (15  $\mu$ g/mL), oxaliplatin (10  $\mu$ g/mL) and irinotecan (40  $\mu$ g/mL) for further 24 h. Cells were then harvested and analyzed for apoptosis induction by flow cytometry. (B) and (C) assays were performed in triplicates. Values are means  $\pm$  SD, \* $P$  < 0.05.

on TRAIL-induced apoptosis of CRC cells. TRAIL efficiently induced apoptosis in SW480 cells (22% *vs* 3% apoptosis in control cells,  $P$  < 0.05, Figure 6A). Importantly, Bcl-x<sub>L</sub> downregulation enhanced TRAIL-induced apoptosis more than two-fold (46% *vs* 22%,  $P$  < 0.001, Figure 6A). To further evaluate the sensitizing effect of Bcl-x<sub>L</sub> knock down for TRAIL efficacy, we included another CRC cell line, SW620, in our study. After Bcl-x<sub>L</sub> knock down, TRAIL-induced apoptosis was increased from 16% to 27% ( $P$  < 0.05, Figure 6A). Mcl-1 knock down sensitized SW480 cells to TRAIL (17% *vs* 11%,  $P$  < 0.05, Figure 6B). Upregulation of Bcl-x<sub>L</sub> by transfection of expression plasmids decreased TRAIL-induced cell death ( $P$  < 0.05, Figure 6C). Subsequently, we tested the effect of Bcl-x<sub>L</sub> and Mcl-1 knock down on CD95-

induced apoptosis of CRC cells (Figure 6D). SW480 cells were highly susceptible to CD95 stimulation by the agonistic CD95 antibody anti-APO-1 (65% *vs* 3% after 24 h of anti-APO-1 treatment, Figure 6D). Bcl-x<sub>L</sub> knock down further increased anti-APO-1 induced apoptosis from 65% to 80% ( $P$  < 0.001). Mcl-1 knock down did not further enhance CD95-triggered apoptosis of CRC cells (Figure 6D).

## DISCUSSION

In the present study we demonstrate an important role of the anti-apoptotic Bcl-2 family members Bcl-x<sub>L</sub> and, to a lower extent, Mcl-1, for the apoptosis sensitivity of CRC cells. Bcl-x<sub>L</sub> expression is considerably enhanced in

**Figure 4** Modulation of Mcl-1 expression alters chemotherapeutic drug-induced apoptosis. **A:** SW480 cells were transfected with siRNA specific for Mcl-1, or transfected with siRNA specific for GFP as control (20 nmol/L). After the indicated time post transfection, total RNA was extracted and analyzed for Mcl-1 expression by quantitative real-time PCR (left panel). Relative expression was calculated as described in the materials and methods section. In addition, after the indicated time post transfection, cells were lysed and analyzed for Mcl-1 expression by Western blot (right panel).  $\alpha$ -Tubulin expression was used to control equal loading; **B:** SW480 cells were transfected with siRNA specific for Mcl-1 or transfected with control siRNA. 24 h post transfection cells were treated with 5-FU (10  $\mu$ g/mL), oxaliplatin (16  $\mu$ g/mL) and irinotecan (60  $\mu$ g/mL) for further 24 h. CRC tissue compared to adjacent non-malignant tissue. After knock down of Bcl-x<sub>L</sub> by RNA interference, CRC cells prove to be more sensitive towards chemotherapy, EGFR1 blockage, CD95 triggering and treatment with the death receptor ligand TRAIL. The sensitizing effect of Mcl-1 knock down is comparatively moderate. Our data suggest, that Bcl-2 family members, such as Bcl-x<sub>L</sub>, are promising targets to improve treatment of patients with CRC. Since strategies to inhibit Bcl-x<sub>L</sub> activity have already been applied in preclinical studies, our data are of particular interest<sup>[22]</sup>.

In the past two decades, substantial progress has been made in the treatment of colon cancer, the second most common cancer in western countries. However, therapy resistance of CRC remains a common clinical problem, so that recurrence and metastasis of CRC remain major obstacles in oncology. Thus, new strategies to overcome resistance to current treatment options are needed.

Numerous defects in apoptosis signalling have been described in CRC. These defects appear to be involved in colorectal tumorigenesis, by facilitating tumor cell progression<sup>[23]</sup>. In addition, defects in apoptosis signalling represent principle mechanisms through which cancer cells are enabled to survive therapy, since chemotherapy and irradiation induce cell death mainly by apoptosis induction<sup>[24]</sup>. These defects include, among others, stabilization of mitochondria, inactivation of death receptor signalling and overexpression of EGFR1<sup>[2]</sup>.

Anti-apoptotic proteins of the Bcl-2 family, such as Bcl-2, Bcl-x<sub>L</sub> and Mcl-1 critically regulate mitochondrial integrity. Increased expression of anti-apoptotic Bcl-2 proteins counteracts chemotherapeutic drug-induced apoptosis in cancer cells. In our study, human CRC tissues revealed enhanced Bcl-x<sub>L</sub> expression both on mRNA and protein levels. In line with our study, previous studies also observed enhanced Bcl-x<sub>L</sub> expression in CRC tissues<sup>[13,25]</sup>. In contrary, Northern blot as well as immunohistochemical analysis failed to detect Bcl-2 expression in CRC<sup>[25]</sup>. The reason for increased Bcl-x<sub>L</sub> expression in CRC remains elusive. However, a consistent finding is that oncogenic tyrosine kinases induce expression of Bcl-x<sub>L</sub> and enhance protein stability. Among these tyrosine kinases is EGFR1, which has been described to up-regulate Bcl-x<sub>L</sub> in other tumor models<sup>[26]</sup>. In line with this observation, we show a significant upregulation of Bcl-x<sub>L</sub> in CRC cells upon treatment with EGF in this study. Since overexpression of EGFR1 is a frequent finding in CRC cells, EGFR1 signalling may represent a major cause for the induction of Bcl-x<sub>L</sub> expression in CRC. Another mechanism which triggers Bcl-x<sub>L</sub> activity in tumor cells is suppression of deamidation<sup>[27]</sup>. In a recent immunohistochemical evaluation of human CRC tissues, hypoxia-inducible factor-1 has been discussed to induce expression of Bcl-x<sub>L</sub><sup>[28]</sup>.

We also explored expression of the anti-apoptotic protein Mcl-1 in CRC. In other cancer entities, e.g. in hepatocellular carcinoma, a significant correlation of

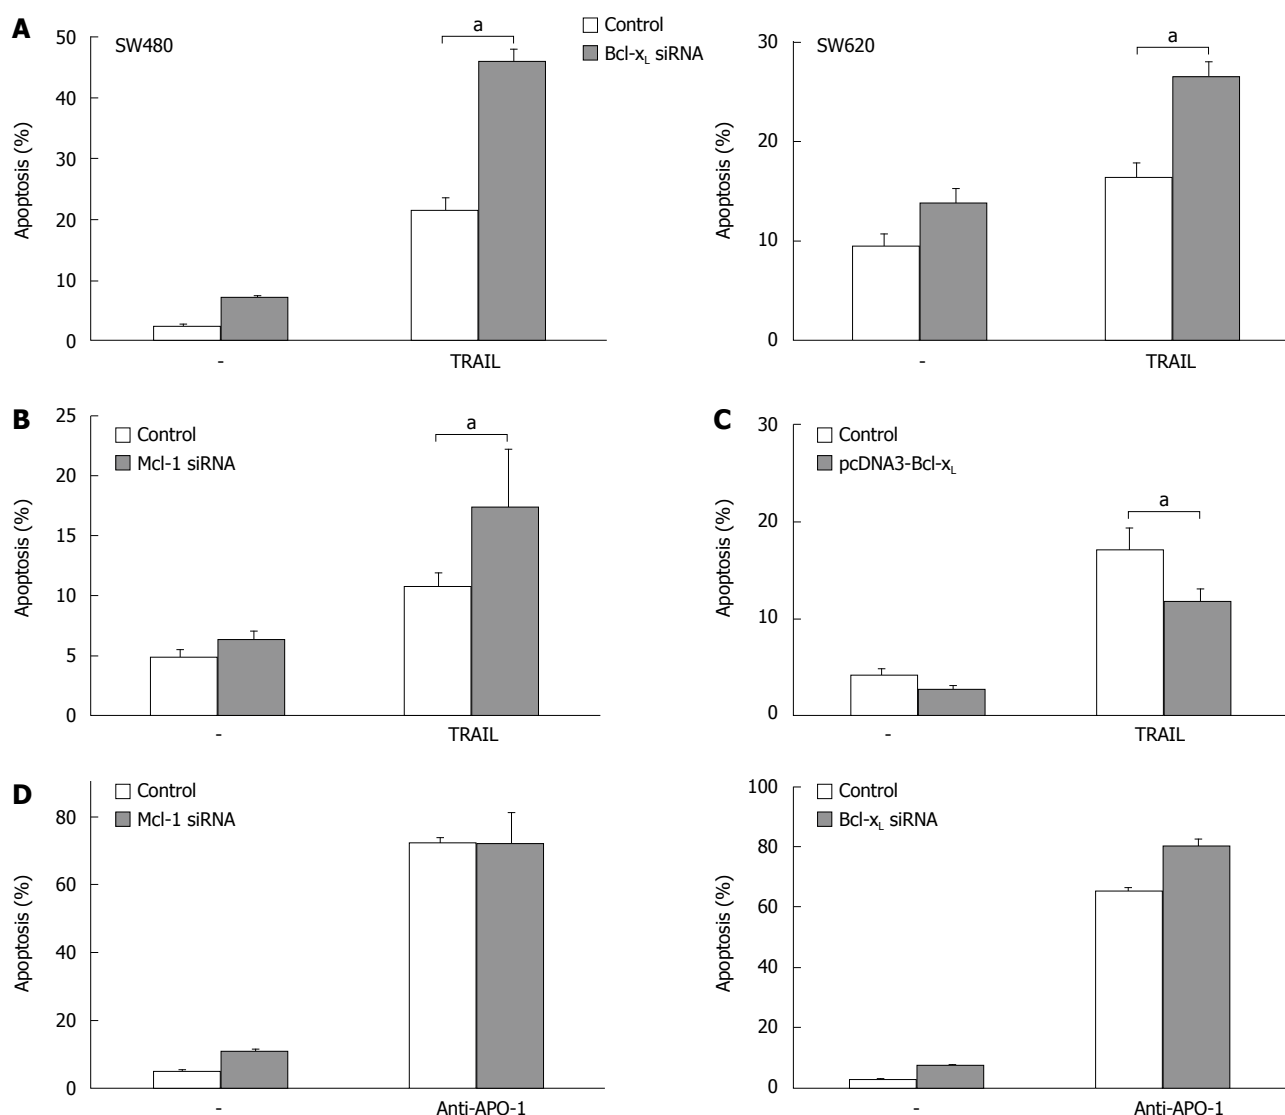

**Figure 5** Bcl-x<sub>L</sub> and Mcl-1 knock down enhances apoptosis induction after EGFR1 inhibition. **A:** SW480 and HT29 cells were treated with EGF (100 ng/mL) for the time indicated. Whole cell lysates were prepared, separated, and immunoblotted with antibodies against Bcl-x<sub>L</sub>, Mcl-1 and  $\alpha$ -tubulin; **B:** SW480 cells were transfected with siRNA specific for Bcl-x<sub>L</sub> (upper panel), or Mcl-1 (lower panel), respectively, or transfected with siRNA specific for GFP as control. 24 h post transfection cells were treated with cetuximab (100  $\mu$ g/mL) or PD168393 (0.7  $\mu$ mol/L) for further 24 h. Cells were then harvested and analyzed for apoptosis induction by flow cytometry. Assays were performed in triplicates and are representative for at least two independent experiments. Values are means  $\pm$  SD, <sup>a</sup> $P < 0.05$ .

Bcl-x<sub>L</sub> and Mcl-1 with apoptosis resistance was observed<sup>[29]</sup>. In our study, *Mcl-1* mRNA expression was significantly lower in CRC tissue compared to non-neoplastic cells. In contrast, no profound difference was observed on protein level in immunohistochemistry. Previous studies, however, observed decreased Mcl-1 expression relative to normal mucosa and adenomas, also in immunohistochemistry<sup>[13]</sup>. At the same time, decrease in Mcl-1 expression has been discussed as a later event in the progression of colorectal tumors, since adenomas show no decreased Mcl-1 expression<sup>[13]</sup>. The significant difference in *Mcl-1* expression we observed on mRNA level, is in line with these previously published data. Another important aspect about Mcl-1 expression is the staining pattern: in contrast to normal mucosa cells, Mcl-1 has been described to be diffusely expressed in tumour samples in previous studies<sup>[30]</sup>. Such a diffuse expression could also be detected in our study.

Next, we confirmed that Mcl-1 has a relatively short

half-life in CRC cells. Inhibition of translational events in different CRC cell lines resulted in a much more rapid decrease in Mcl-1 compared to Bcl-x<sub>L</sub> expression. This is in line with the well-known fact that Mcl-1 provides short-term cell viability protection against cell death during critical transitions in the cell fate<sup>[6]</sup>. The rapid decrease of Mcl-1 expression can be explained mainly by efficient proteasomal degradation. In addition, we could show that Mcl-1 expression is induced upon treatment with EGF. This might be mediated at least in part by activation of the MEK/ERK-pathway. In lung cancer, it has been shown that EGF enhanced Mcl-1 protein level in an ERK-dependent manner<sup>[8]</sup>. In our study, EGF also induced expression of Bcl-x<sub>L</sub> and ERK might also be involved in this context. Chemotherapeutic agents such as oxaliplatin have been shown to decrease anti-apoptotic proteins like Bcl-x<sub>L</sub> in SW480 cells<sup>[31]</sup>. This effect at least in part explains the apoptosis-inducing capacity of oxaliplatin. However, other chemotherapeutic agents such as

**Figure 6** TRAIL- and CD95-induced apoptosis after modulation of Mcl-1 and Bcl-x<sub>L</sub> expression. **A:** SW480 or SW620 cells were transfected with siRNA specific for Bcl-x<sub>L</sub> or GFP as control. 24 h post transfection cells were treated with TRAIL (0.1 µg/mL) for further 24 h. Cells were then harvested and analyzed for apoptosis induction by flow cytometry; **B:** SW480 cells were transfected with siRNA specific for Mcl-1 or GFP as control. 24 h post transfection cells were treated with TRAIL (0.01 µg/mL) for further 24 h. Cells were then harvested and analyzed for apoptosis induction by flow cytometry; **C:** SW480 cells were transfected with pcDNA3 Bcl-x<sub>L</sub> or pcDNA3 empty vector as control. 24 h post transfection, cells were treated with TRAIL (0.1 µg/mL) for further 12 h. Cells were then harvested and analyzed for apoptosis induction by flow cytometry; **D:** SW480 cells were transfected with siRNA specific for Mcl-1 (left panel) or Bcl-x<sub>L</sub> (right panel) or with control siRNA. 24 h post transfection cells were treated with anti-APO-1 (0.1 µg/mL) for further 24 h. Cells were then harvested and analyzed for apoptosis induction by flow cytometry. All assays were performed in triplicates and are representative for at least three independent experiments. Values are mean ± SD, <sup>a</sup>*P* < 0.05.

5-FU and paclitaxel did not downregulate Bcl-x<sub>L</sub> in CRC cells in previous studies<sup>[32]</sup>.

Our results demonstrate that a specific knock down of Bcl-x<sub>L</sub> and, to a lower extent, knock down of Mcl-1 by RNAi sensitize CRC cells to chemotherapeutic drugs frequently applied in CRC therapy (5-FU, oxaliplatin and irinotecan). Notably, Bcl-x<sub>L</sub> knock down alone already significantly induces apoptosis in untreated cells. Thus, Bcl-x<sub>L</sub> expression is important for the survival of CRC cells. Our results extend studies which have already shown that knock down of Bcl-x<sub>L</sub> effectively blocks proliferation of CRC cells<sup>[33]</sup>. On the other hand, overexpression of Bcl-x<sub>L</sub> counteracts chemotherapeutic drug-induced apoptosis. In previous studies, overexpression of Bcl-x<sub>L</sub> has been reported to enhance resistance to various chemotherapeutic agents in leukaemia cells<sup>[34]</sup>.

However, in a previous study, resistance of CRC cells was not observed in Bcl-x<sub>L</sub> overexpressing cells treated with 5-FU or TRAIL<sup>[33]</sup>. In our study, Bcl-x<sub>L</sub> overexpression only reduced apoptosis rates in CRC cells treated with 5-FU, irinotecan and oxaliplatin.

Bcl-x<sub>L</sub> exerts anti-apoptotic effects in cancer cells mainly by its interaction with pro-apoptotic Bcl-2 family members, e.g. Bax and Bak. Activation of Bax and Bak commit the cell to apoptosis by permeabilizing the outer mitochondrial membrane. However, interaction with Bcl-2 proteins such as Bcl-x<sub>L</sub> and Mcl-1 ablates pro-survival functions of Bax and Bak<sup>[35]</sup>. Bax expression is not reduced in CRC tissues<sup>[25]</sup>. Thus, Bcl-x<sub>L</sub> silencing might induce apoptosis *via* release of Bax and concomitant mitochondrial permeabilization. However, more studies are required to fully understand the roles of the

Bcl-2 proteins and how they cooperate to regulate CRC cell survival.

The apoptosis-sensitizing effect of Mcl-1 modulation was less pronounced (e.g. for oxaliplatin and irinotecan-induced apoptosis) or not significant (e.g. for 5-FU-induced apoptosis), respectively. The reason might be the relatively low expression of Mcl-1 in CRC cells, which may at least in part be compensated by a higher Bcl-x<sub>L</sub> expression. Nevertheless, Mcl-1 knock down has sensitizing effects in our study. This effect may also be explained by the fact that Mcl-1, like Bcl-x<sub>L</sub>, guards Bax and Bak and thereby prevents them to activate mitochondria.

Notably, Bcl-x<sub>L</sub> knock down by siRNA also enhances death receptor-mediated apoptosis in CRC cells. CD95-mediated apoptosis was increased by Bcl-x<sub>L</sub> knock down in SW480 cells. However, this effect is supposed to be less relevant for the *in vivo* situation, since no CD95 expression has been detected in CRC tissues in previous studies<sup>[30]</sup>. Remarkably, Bcl-x<sub>L</sub> knock down considerably enhanced tumor necrosis factor alpha (TNF-alpha)-related apoptosis-inducing ligand (TRAIL)-induced apoptosis of SW480 as well as SW620 cells. TRAIL is a member of the TNF family, which has been reported to induce apoptosis in various tumor cells, but not in normal cells, thus representing a promising anticancer agent<sup>[36]</sup>. Agonistic TRAIL receptor antibodies have already entered clinical trials<sup>[37]</sup>. Recently, we have shown that treatment with TRAIL alone or in combination with chemotherapeutic drugs (with the exception of cisplatin) is not toxic for human hepatocytes<sup>[38]</sup>. In our study, treatment of CRC cells with TRAIL resulted in relatively low apoptosis rates. This is in line with previous studies on CRC cells, e.g. on SW620 cells<sup>[39]</sup> or HT29 cells<sup>[40]</sup>. The reason for restricted apoptosis induction is that TRAIL signalling also involves activation of anti-apoptotic pathways including PI3K/Akt, NF-κB and MEK/ERK<sup>[41]</sup>. NF-κB activation, for example, induces anti-apoptotic proteins such as Mcl-1 in HT29 cells, contributing to TRAIL resistance<sup>[39]</sup>. Bcl-x<sub>L</sub> has also been shown to be upregulated by NF-κB activity<sup>[42]</sup>.

Several approaches have been exploited to sensitize cancer cells towards TRAIL. An important strategy, also pursued in this study, is downregulation of anti-apoptotic Bcl-2 proteins. In the present study, Bcl-x<sub>L</sub> knock down by siRNA efficiently sensitized CRC cells towards TRAIL-induced apoptosis. In contrary, Mcl-1 knock down only slightly sensitized CRC cells to TRAIL. These data correspond to previous studies of our group and others on hepatocellular carcinoma, where Mcl-1 knock down did not sensitize towards TRAIL<sup>[9]</sup>. However, in cholangiocellular carcinoma, where high Mcl-1 expression is frequently found, Mcl-1 knock down renders cancer cells susceptible to TRAIL<sup>[11]</sup>. Since TRAIL-induced apoptosis in cancer cells is hampered by NF-κB activation, inhibition of NF-κB is likely to augment TRAIL-induced death of CRC cells. Approaches to block NF-κB are, among others, peptidomimetic compounds that disrupt the IKK complex or multikinase inhibitors, such as sorafenib<sup>[43]</sup>.

The epidermal growth factor receptor (EGFR1) is

a receptor tyrosine kinase of the ErbB family that is abnormally activated in many epithelial tumors, such as CRC. EGFR1 is involved in survival signalling, cell migration, metastasis formation, angiogenesis, and reduced responses to chemotherapy. Clinical and survival benefits with anti-EGFR1 agents have been demonstrated in tumor patients (for review<sup>[44]</sup>). Monoclonal antibodies to EGFR1 are among promising novel targeted therapies being explored in CRC. One such agent that inhibits EGFR1 signalling by interfering with ligand-binding is cetuximab. Cetuximab is a human-mouse chimeric therapeutic monoclonal antibody that competitively binds to the extracellular domain of EGFR1. EGFR1 tyrosine kinase inhibitors, such as PD168393, also block EGFR1 signalling. In this study, knock down of Mcl-1 slightly sensitized CRC cells towards cetuximab and PD168393. Moreover, knock down of Bcl-x<sub>L</sub> sensitized CRC cells towards cetuximab as well as PD168393. These findings suggest that combining EGFR1 blockage with agents that directly destabilize or disable Bcl-x<sub>L</sub> and Mcl-1 will have therapeutic benefits.

The development of siRNA technology has made it possible to suppress the function of specific molecules and helps to develop new treatment strategies for cancer<sup>[45]</sup>. Our study suggests that Bcl-x<sub>L</sub> and Mcl-1 are suitable targets to sensitize CRC cells to death. The delivery of siRNA *in vivo* including specific uptake in tumor cells remains a challenging issue<sup>[46]</sup>. Many approaches use plasmid and viral vectors for transcription of short-hairpin RNAs, both *in vitro* and *in vivo*. However, human trials are still on the way to optimize delivery techniques. Another approach to specifically knock down Bcl-x<sub>L</sub> expression is by antisense oligonucleotides. Bispecific antisense oligonucleotides inhibiting both Bcl-2 and Bcl-x<sub>L</sub> may be useful to induce apoptosis of tumor cells<sup>[47]</sup>. Other promising strategies to downregulate Bcl-x<sub>L</sub> or Mcl-1 are application of small-molecule inhibitors. ABT-737 is an example of one of the first small-molecule inhibitors of Bcl-2/Bcl-x<sub>L</sub> shown to be efficacious *in vivo*, causing complete regression in small-cell lung carcinoma tumour xenografts in mice<sup>[22]</sup>. TW-37 has recently been described to simultaneously inhibit Bcl-2, Bcl-x<sub>L</sub> and Mcl-1 in lymphoma cells by targeting the BH3-binding groove of these Bcl-2 proteins<sup>[48]</sup>. Apart from direct suppression of Bcl-x<sub>L</sub> by siRNA or small-molecule inhibitors, suppression of oncogenic tyrosine kinases, such as Src kinases, which trigger Bcl-x<sub>L</sub> expression<sup>[26]</sup>, is another promising approach to induce killing of CRC cells.

In conclusion, our findings clearly implicate the anti-apoptotic activity of Bcl-2 family members, such as Bcl-x<sub>L</sub> and, to a lower extent, Mcl-1, as important components of the treatment resistance of CRC cells. Efficacy of chemotherapy, EGFR1 blockage and treatment with TRAIL, might be substantially improved by co-suppression of the anti-apoptotic protein Bcl-x<sub>L</sub>.

## COMMENTS

### Background

Colorectal carcinoma (CRC) is a very common malignancy with an increasing

incidence in recent decades. Defects in apoptosis signalling contribute to the resistance of CRC cells towards different treatment regimens. Thus, one of the main goals for oncologic treatment of patients suffering from CRC is to overcome resistance of tumor cells towards apoptosis.

### Research frontiers

Decreased sensitivity of mitochondria towards apoptosis stimuli, such as chemotherapy, is a key mechanism for apoptosis resistance of CRC cells. Mitochondrial activation is determined by the interaction of pro- and anti-apoptotic Bcl-2 family proteins, such as Bcl-x<sub>L</sub> and Mcl-1. In CRC, anti-apoptotic Bcl-2 family proteins are highly expressed, thus contributing to apoptosis resistance.

### Innovations and breakthroughs

In previous articles, the interaction of anti- and pro-apoptotic members of the Bcl-2 protein family and their role for the apoptosis sensitivity of carcinoma cells has been extensively studied. It has been shown that anti-apoptotic Bcl-2 family members are capable of blocking pro-apoptotic members of the family. Approaches to block the activity of anti-apoptotic Bcl-2 proteins, e.g. by RNA interference, have been evaluated and proven to be likely effective for the treatment of cancer patients.

### Applications

In this article, authors show an important role of Bcl-x<sub>L</sub> and Mcl-1 for the apoptosis resistance of CRC cells. Thus, downregulation of these anti-apoptotic proteins is a promising approach for the treatment of patients with CRC. Here authors show that the use of RNA interference can effectively downregulate Bcl-x<sub>L</sub> and Mcl-1 expression in CRC cells. After downregulation, CRC cells are sensitized to chemotherapy and target therapy approaches. Other ways to downregulate these proteins is application of so called "BH3-only mimetics". These drugs can interact with Bcl-x<sub>L</sub> and Mcl-1 and thereby induce the release of pro-apoptotic Bcl-2 proteins. "BH3-only mimetics" have already entered clinical trials in cancer patients.

### Terminology

Apoptosis is also depicted as programmed cell death. It is characterized by typical morphological alterations, e.g. the condensation of chromatin in the nucleus. Bcl-2 proteins are a large family of proteins, which can be sub-divided in anti-apoptotic members, multidomain pro-apoptotic members and BH3-only pro-apoptotic members. Bcl-x<sub>L</sub> and Mcl-1 are both anti-apoptotic members of the Bcl-2 family. Receptors for epidermal growth factor (EGF) contribute to the growth of cancer cells. Therapeutic approaches in patients with CRC target this receptor (e.g. antibodies binding to the EGF receptor as well as small molecules which inhibit the kinase domain of the receptor) and have been proven to be effective anti-cancer reagents in clinical studies.

### Peer review

This study shows that Mcl-1 and Bcl-x<sub>L</sub> are important anti-apoptotic factors in CRC. Downregulation of Bcl-x<sub>L</sub> is proven to be a promising approach to sensitize CRC towards chemotherapy and targeted therapy. Thus, a translational idea for the treatment of CRC is provided. This is a well written paper and the results are important.

lation time between right heart and liver (RHLT). LTT for each lobe was used to evaluate the early portal hypertension. RHLT is useful in cirrhosis to detect liver areas missing portal inflow. We calculated the classical per-rectal portal shunt index (PRSI) at PRPS and the hepatic perfusion index (HPI) at LAS.

**RESULTS:** The normal LTT value was  $24 \pm 1$  s. Abnormal LTT had PPV = 100% for CLD. Twenty-seven non-cirrhotic patients had LTT increased up to 35 s (median 27 s). RHLT ( $42 \pm 1$  s) was not related to liver disease. Cirrhosis could be excluded in all patients with PRSI < 5% ( $P < 0.01$ ). PRSI > 30% had PPV = 100% for cirrhosis. Based on PRPS and LAS we propose the classification of CLD in 5 hemodynamic stages. Stage 0 is normal (LTT = 24 s, PRSI < 5%). In stage 1, LTT is increased, while PRSI remains normal. In stage 2, LTT is decreased between 16 s and 23 s, whereas PRSI is increased between 5% and 10%. In stage 3, PRSI is increased to 10%-30%, and LTT becomes undetectable by PRPS due to the portosystemic shunts. Stage 4 includes the patients with PRSI > 30%. RHLT and HPI were used to subtype stage 4. In our study stage 0 had NPV = 100% for CLD, stage 1 had PPV = 100% for non-cirrhotic CLD, stages 2 and 3 represented the transition from chronic hepatitis to cirrhosis, stage 4 had PPV = 100% for cirrhosis.

**CONCLUSION:** LTT allows the detection of early portal hypertension and of opening of transhepatic shunts. PRSI is useful in CLD with extrahepatic portosystemic shunts. Our hemodynamic model stages the evolution of portal hypertension and portosystemic shunts. It may be of use in the selection of patients for interferon therapy.

### Abstract

**AIM:** To explore portal hypertension and portosystemic shunts and to stage chronic liver disease (CLD) based on the pathophysiology of portal hemodynamics.

**METHODS:** Per-rectal portal scintigraphy (PRPS) was performed on 312 patients with CLD and liver angioscintigraphy (LAS) on 231 of them. The control group included 25 healthy subjects. We developed a new model of PRPS interpretation by introducing two new parameters, the liver transit time (LTT) and the circu-

## INTRODUCTION

The most frequent causes of chronic liver disease (CLD) are viral infections, ethanol, autoimmune, enzymatic and metabolic disorders<sup>[1,2]</sup>. Cirrhosis is the final stage of CLD<sup>[3]</sup>. Liver biopsy is still an important diagnostic tool in CLD<sup>[4]</sup>.

Portal hypertension is a major complication which appears during CLD evolution. It is defined as an increase of portal blood pressure over 5-10 mmHg. Portosystemic shunts open when the venous portal-liver gradient becomes higher than 10-12 mmHg<sup>[5,6]</sup>.

There are inferior, superior, anterior and posterior portosystemic shunts which could communicate with either inferior or superior vena cava territories. The existence of shunts as well as their blood flow is correlated to the severity and prognosis of CLD<sup>[7-9]</sup>.

Investigation of portal pressure and portosystemic shunts may be performed by invasive and non-invasive methods. Invasive techniques offer the most correct data because of the direct measure of portal pressure. They have however a limited clinical use because of risks and costs<sup>[10]</sup>.

Among the non-invasive methods, ultrasonography and upper digestive endoscopy are those currently used. The main parameters measured by ultrasonography to evaluate the effects of increased blood pressure in the portal territory are the diameters of portal, splenic and superior mesenteric veins, together with spleen size and portal flow velocity. However, dilation of portal territory veins can be seen in only 50% of cases<sup>[11,12]</sup> and only 35%-80% of cirrhotic patients present esophageal varices at upper digestive endoscopy.

Nuclear medicine offers noninvasive static and dynamic procedures to investigate portal hypertension in CLD and to estimate the existence of portosystemic shunts<sup>[13]</sup>.

A classic method is the liver scintigraphy using labeled colloid (planar and SPECT), which offers data regarding portal hypertension by calculating the capture ratio between liver and spleen, respectively between the right and left liver lobes<sup>[14,15]</sup>. Increased colloid capture in the bone marrow is characteristic for advanced stages of portal hypertension.

Per-rectal portal scintigraphy (PRPS) investigates the hemodynamic importance of portosystemic shunts. Radio-tracer absorbed from rectum passes through inferior mesenteric vein into portal vein-liver-right heart<sup>[16-18]</sup>. The per-rectal portal shunt index (PRSI) was introduced by the classic works of Shiomi and co-authors as the main parameter calculated at PRPS by analyzing the dynamic curves raised on liver and heart areas<sup>[19,20]</sup>.

Liver angioscintigraphy (LAS) uses the hepatic per-

fusion index (HPI) to estimate the ratio between the hepatic artery inflow and total liver perfusion, arterial plus portal. Increased HPI (> 40%) in CLD shows the decrease of portal inflow with reactive increase of the flow through the hepatic artery by activation of the buffer response firstly described by Lautt<sup>[21,22]</sup>. The decrease of portal inflow in advanced CLD is mainly determined by the quantity of blood deviated through portosystemic shunts<sup>[23-25]</sup>. In cirrhosis, HPI > 100% highlights the reversion of portal flow.

In this study we improved the interpretation of classical PRPS technique allowing a better characterization and staging of portal hypertension and portosystemic shunts.

## MATERIALS AND METHODS

PRPS with <sup>99m</sup>Tc-pertechnetate was performed in 312 consecutive patients there were 116 females and 196 males between 18 years and 80 years old. Their CLD diagnosis was based on clinical, laboratory, imaging and morphological data. The final diagnoses of the study population are shown in Table 1. The etiology of CLD in 291 patients is presented in Table 2.

LAS was performed on 231 patients with CLD, randomly selected from the 312 explored by PRPS. There were 141 males and 90 females, between 22 years and 77 years old.

Two hundred and four of the 312 patients who underwent PRPS were also investigated by upper digestive endoscopy: 175 of them had cirrhosis. One hundred and eleven of the cirrhotic patients who presented with esophageal varices at upper digestive endoscopy were followed up for 6 mo after investigation.

The control group for PRPS included 25 healthy subjects, 11 females and 14 males, between 18 years and 80 years old. The control group for LAS was composed of 25 healthy subjects, 10 females and 15 males, between 20 years and 78 years old.

PRPS was also performed on one group of 12 patients with complete thrombosis of portal vein in order to calculate RHLT and to compare its values with those in healthy subjects. This group included 6 females and 6 males, between 34 years and 73 years old.

All the patients were fasted for at least 12 h before LAS and PRSI.

Nuclear medicine investigations were made by using a SPECT Orbiter Siemens gamma-camera with high-resolution, low-energy, parallel collimator connected to a Power Macintosh computer, using ICON dedicated software.

For PRPS we used <sup>99m</sup>Tc-pertechnetate eluted from Drygen generators (General Electric-Amersham, UK). The colloid used for LAS was Hepatate (General Electric-Amersham, UK) labeled with <sup>99m</sup>Tc.

Two enemas were performed in each patient for PRPS: the first on the evening before the exam, and the second two hours prior to the examination.

The patients were positioned at PRPS with the camera detector in the anterior view including the liver

and heart areas. A solution containing 2 milliliters of  $^{99m}\text{Tc}$ -pertechnetate (296-370 MBq) was introduced into the upper part of the rectum, followed by 15 milliliters of air under pressure. Serial scintigrams were recorded every 2 s for 3 min. Radioactivity curves were built on liver and heart areas to show the dynamics of radio-tracer absorbed from the rectum.

LAS was performed after antecubital i.v. bolus injection of 370-440 MBq of  $^{99m}\text{Tc}$  radio-colloid, with the patients lying down, in anterior-posterior view. Collimator area included abdomen and lower part of thorax. Sequential images were recorded 1/s for 1 min. Right kidney, right liver lobe and spleen dynamic curves were built. HPI was calculated using the Sarper's method<sup>[26]</sup>.

The results were compared with clinical diagnosis, liver biopsy and upper digestive endoscopy. For statistical evaluation of PRSI we used the Kruskal-Wallis and Mann-Withney non-parametric tests.

### New approach to the per-rectal portal scintigraphy

At the beginning of the research we used for the first 100 patients the classic interpretation of PRPS, based on the calculation of PRSI for the global area of the liver<sup>[16]</sup>. All information was stored in the computer.

In the second stage we considered the possibility of acquiring more useful data in PRPS, by developing a new model of interpretation. Pertechnetate is not significantly captured by liver or heart, so that at PRPS the first-passage histograms built for these organs represent transit curves, not accumulation curves. This suggests the importance of time-related parameters. Transit type of PRPS liver and heart curves is highlighted by dynamic curves built on the inferior mesenteric vein area. These curves have the same ascending aspect as the histograms on liver and heart thereafter produced at first passage by the same radiotracer flow absorbed from the upper rectum.

We introduced LTT as a new parameter useful for the early phases of CLD where PRSI offers not enough information. LTT is the time interval between entrance into the liver and subsequent entrance into the right heart of the radiotracer absorbed from the upper rectum, after passing through the mesenteric and portal veins. LTT was separately measured for each liver lobe as the time interval between the liver and heart dynamic histograms. The normal value is  $24 \pm 1$  s. This parameter is useful for patients without extra-hepatic shunts. In patients with portosystemic extrahepatic shunts, LTT cannot be correctly determined by PRPS because the tracer absorbed from the rectum may arrive at the right heart faster by passing through shunts than following the physiological pathway.

PRSI equal to 10% corresponds to LTT equal to  $16 \pm 1$  s. LTT decreased between 16 s and 23 s corresponds to a PRSI increased up to 10% and approximates the interval in which only the transhepatic shunts are open. A PRSI equal to 30% corresponds to a mean time of 8 s between the liver and heart curves, but this interval does not have the significance of LTT because of the flow passing through the extra-hepatic portosystemic shunts, which arrives at the heart faster than the tracer passing through the liver.

Liver areas perfused only through the hepatic artery may be seen in cirrhosis. One lobe or both have, in such cases, abolished or insignificant portal inflow and the time between PRPS curves on the heart and on the area(s) without portal inflow has a maximum value, equal to RHLT. This is a constant time interval (not related to CLD) between the entrance of the tracer into the right heart and its subsequent arrival to the liver following the route: right heart-lungs-left heart-aorta-hepatic artery. We measured RHLT in the patients with complete portal thrombosis as the time interval between heart and liver curves. In healthy controls, RHLT was measured as the time interval between the arrival of tracer into the right heart and the ascending inflexion on the liver histogram determined by the subsequent arrival of tracer through the hepatic artery. The value of RHLT was  $42 \pm 1$  s for both methods.

We performed separate PRPS analyses of the two liver lobes, which are autonomous in relation to the blood inflow (Figure 1). No differences between the two lobes could be found in the control group. We compared PRPS curves for the two lobes in order to distinguish subtypes, respectively stages of portal hypertension evolution. Figure 1 shows the case of a cirrhotic patient in which time intervals between the heart histogram and the curves on the two liver lobes are different.

Our PRPS model is based on the two new time parameters, the classic calculation of PRSI and the separate evaluation of the two liver lobes.

## RESULTS

The distribution for the 312 patients of the PRSI calculated using Shiomi's formula is presented in Table 3.

**Figure 1** Per-rectal portal scintigraphy dynamic curves. Separate analyses of the two liver lobes for a cirrhotic patient (stage 4b).

There were no correlations of PRPS and LAS parameters with sex or age ( $P < 0.01$ ).

As many as 202 of 312 patients investigated with the PRPS were diagnosed as having a cirrhosis. One hundred and seventy-five of these underwent upper digestive endoscopy. Twenty seven patients with advanced cirrhosis (all of them with PRSI  $> 30\%$  at PRPS) could not be explored by endoscopy as deemed too risky. Using Child-Pugh classification, the 175 cirrhotic patients investigated by upper digestive endoscopy were classified as follows: 99 in class A, 38 in class B and 38 in class C.

Only 16 patients from the 93 with PRSI between 5% and 30% had esophageal varices. Thirty two additional patients with PRSI  $< 30\%$  but without varices were also diagnosed with cirrhosis. As a result, we had a total number of 48 cirrhotic patients with PRSI  $< 30\%$ . Five patients with cirrhosis had discordant low PRSI values ranging from 5% to 10%, but no cirrhotic patient had normal PRSI ( $< 5\%$ ). All the patients with PRSI  $> 30\%$  had cirrhosis, so we used PRSI = 30% as an upper limit value for chronic hepatitis.

The PRSI was significantly higher in cirrhotic patients than in chronic hepatitis ( $P < 0.01$ ). The median value for PRSI was 5% for the control group, 5% for the patients with steatosis, 6% for the patients with chronic hepatitis and 73.5% for the cirrhotic patients. The sums of ranks for the PRSI values based on Kruskal-Wallis test for the healthy subjects and stages of CLD are shown in Table 4 ( $P = 0.000$ ). Using the Mann-Whitney test we showed that there was a significant statistical difference between PRSI for patients with chronic hepatitis and the controls ( $P = 0.0003$ ), between patients with cirrhosis and those with chronic hepatitis ( $P = 0.0000$ ) and respectively between patients with cirrhosis and controls ( $P = 0.0000$ ).

**Table 3** Distribution of all the patients and of those with cirrhosis according to the per-rectal portal shunt index and to our classification in 5 stages

Per-rectal portal shunt index (%)	Number of patients (n)	Cirrhosis	Stage in our classification
0-5	65	0	Stages 0 & 1
5-10	13	5	Stage 2
10-20	42	43	Stage 3
20-30	38		
30-40	17	154	Stage 4
40-50	10		
50-60	11		
60-70	10		
70-80	18		
80-90	40		
90-100	48		
Total	312	202	

**Table 4** Statistical analysis of the per-rectal portal shunt index for healthy subjects and for the different stages of chronic liver disease using Kruskal-Wallis test

Disease	Number of patients (n)	Sum of ranks
CLD infirmed	21	759.5
Steatosis	17	1201.5
Chronic hepatitis	69	5004.5
Cirrhosis	202	40929.5

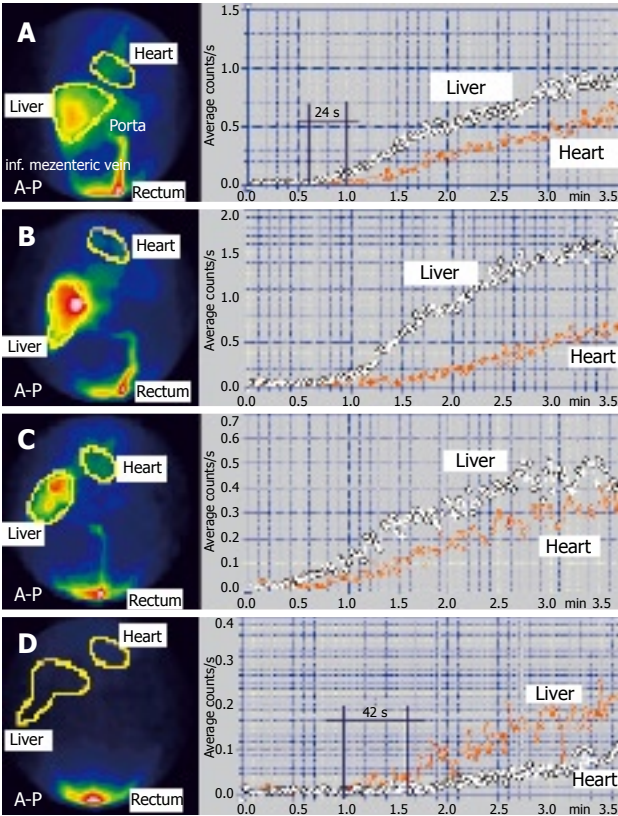

Kruskal-Wallis test:  $H(3, n = 309) = 169.5024, P = 0.000$ .

One hundred and eleven patients with esophageal varices and PRSI  $> 30\%$  were followed up for 6 mo; 51 of these had experienced previous upper digestive bleeding. During the follow up, 17 of these patients had an episode of upper digestive bleeding (11 as first time, 6 as recurrence). All our patients with upper digestive bleeding had PRSI  $> 70\%$  (mean of 88%). The 94 patients from the group of 111 with esophageal varices who had not upper digestive bleeding during the follow up had a mean value of PRSI equal to 46.75%. We had no patients with upper digestive bleeding among those with PRSI  $< 30\%$ , even if they had esophageal varices at upper digestive endoscopy.

These results show the diagnostic value of the classic parameter PRSI. A PRSI  $< 5\%$  had a NPV = 100% for cirrhosis, while a PRSI  $> 30\%$  had PPV = 100% for cirrhosis. A PRSI  $> 70\%$  was associated with a high risk of upper digestive bleeding ( $P < 0.01$ ), while with a PRSI  $< 30\%$  no variceal bleeding was encountered. However, using only PRSI is not always possible to make the differential diagnosis between chronic hepatitis and cirrhosis or between chronic hepatitis and healthy subjects.

Using LTT parameter originally introduced by us at PRPS we were able to find more data about the early stages of portal hypertension, when PRSI cannot offer enough information. In healthy subjects, LTT was  $24 \pm 1$  s. The distribution of LTT in patients with PRSI smaller than 10% (LTT  $> 16$  s) is shown in Table 5. For the 27 non-cirrhotic CLD patients who had prolonged LTT

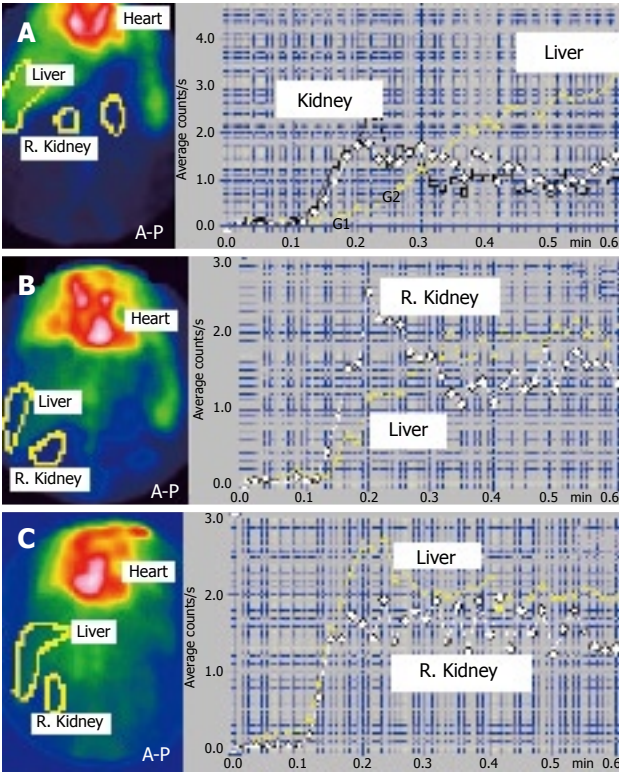

**Figure 2** Per-rectal portal scintigraphy. **A:** Stage 0, normal aspect. LTT = 24 s, PRSI < 5%; **B:** Stage 1. LTT increased (33 s). PRSI < 5%; **C:** Stage 2. Decreased LTT (18 s), PRSI slightly increased (8%); **D:** Stage 4c. Time between heart and liver curves is equal to RHTL = 42 s. Cirrhosis with undetectable portal inflow to the both lobes.

Table 5 Liver transit time and distribution in stages of the patients with the per-rectal portal shunt index lower than 10%					
Per-rectal shunt index	Mean value of liver transit time (s)		Etiology	Number of patients (n)	Stage in our classification
	Right lobe	Left lobe			
< 5%	24		-	38	Stage 0
	25	28	viral	10	Stage 1a
	31	24	alcoholic	6	Stage 1b
	31.5	29	viral + alcoholic	7	Stage 1c
5%-10%	19.5			13	Stage 2

(> 25 s), the median value was 27 s. LTT determined at PRPS has hemodynamic significance as it shows the time required at first-passage by the main part of portal inflow of radio-tracer to arrive to right heart through the liver.

RHLT measured in the control group and in patients with complete portal thrombosis is 42 ± 1 s. We used it to identify cirrhotic patients with undetectable portal inflow to one liver lobe or both. Other causes of portal flow interruption (thromboses, compressions) were excluded by ultrasonography.

HPI was used in our study to show the reactive increase of arterial flow due to the decreasing of portal

**Figure 3** Liver angioscintigraphy. **A:** Normal aspect. HPI = 30%. G1 = arterial inflow segment; G2 = portal inflow segment; **B:** Cirrhotic patient. HPI = 60%; **C:** Cirrhosis with reversed portal flow. HPI = 130%.

inflow (HPI > 40%) and to identify those cirrhotic patients with reversed portal flow (HPI > 100%).

**Staging of portal hypertension and portosystemic shunts**

Using the above shown data we propose a hemodynamic model in 5 steps to stage the evolution of portal hypertension and portosystemic shunts on physiopathological basis using nuclear medicine dynamic investigations (PRPS and LAS).

The 5 stages of portal hypertension and portosystemic shunts proposed by us are the following: (1) Stage 0 is normal: PRSI < 5%, LTT = 24 ± 1 s (Figure 2A), HPI < 40% (Figure 3A); (2) Stage 1 is characterized by PRSI < 5% (normal), but LTT is increased over 25 s at least on one lobe (Figure 2B). HPI is normal. For stage 1 we found 3 subtypes according to the liver lobe(s) with prolonged LTT: (a) Subtype 1a, with increased LTT for the left lobe, but with normal or slightly decreased LTT for the right lobe; (b) Subtype 1b, with increased LTT for the right lobe and with normal or slightly decreased LTT for the left lobe; (c) Subtype 1c, with increased LTT for the both lobes; (3) Stage 2 is characterized by decreased LTT for both lobes, between 16 s and 23 s. PRSI is slightly increased, between 5% and 10% (Figure 2C). HPI calculated at LAS is currently at the upper normal limit or slightly increased, up to 45%; (4) Stage 3 is characterized by a moderately increased PRSI, between 10%-30%. Time interval between the hepatic and heart curves is decreased between 8 s and 16 s, but it is no more equal to LTT due

to the shunts. HPI is moderately increased, usually up to 50%-55%; (5) Stage 4 is characterized by PRSI > 30%. HPI is increased over 60%-70%. Liver curve precedes heart curve with less than 8 s or heart curve precedes liver curve (when PRSI > 50%). We found 4 subtypes of stage 4, according to the lobe(s) with undetectable or reversed portal flow: (a) Subtype 4a: heart curve precedes the hepatic histograms on both lobes with less than 42 s. Both lobes have portal inflow; (b) Subtype 4b: Cardiac curve precedes right liver lobe histogram with 42 s and the left liver lobe histogram with less than 42 s. There is still a portal flow to the left lobe, but the portal inflow to the right lobe is undetectable (Figure 1); (c) Subtype 4c: PRSI > 95%. Time between heart and both liver lobes curves is equal to RHLT = 42 s (Figure 2D). PRPS cannot detect portal inflow to any of the hepatic lobes. For subtypes 4a, 4b and 4c, the HPI is increased over 60%, but smaller than 100% (Figure 3B); (d) Subtype 4d: HPI at LAS is higher than 100% (Figure 3C). The time between PRPS heart curve and both liver lobes histograms is 42 s. Portal flow is reversed.

## DISCUSSION

Stage 0 includes the subjects without CLD. There are no portal flow changes. In our study, stage 0 had NPV = 100% for CLD. The tracer absorbed at PRPS from the rectum reaches the liver through the physiological pathway (inferior mesenteric and portal veins).

In stage 1, it is possible to detect the earliest changes that affect either one lobe or both, determined by the increased resistance opposed by liver to portal inflow. Portal flow velocity decreases and LTT is consequently increased. In our study stage 1 had PPV = 100% for non-cirrhotic CLD. In this stage the transhepatic and extrahepatic shunts are not open and the arterial inflow is normal. We encountered subtype 1a in patients with chronic viral hepatitis, subtype 1b in alcoholic etiology and subtype 1c in viral and mix (viral + alcohol) etiologies.

Stage 2 theoretically corresponds to the dilation of part of transhepatic pathways between portal and hepatic veins as a result of the portal pressure which is increased at higher values than in stage 1. The blood passes faster through these dilated transhepatic shunts than through sinusoids<sup>[27,28]</sup>. LTT is consequently decreased. Our threshold PRSI = 10% between stage 2 and stage 3 was selected based on the correspondence of this PRSI value with LTT =  $16 \pm 1$  s. Extrahepatic shunts are not open and arterial inflow remains normal (hepatic artery buffer response is not activated). Stage 2 theoretically appears when the increased resistance opposed by liver to the portal inflow produces a higher portal pressure which is able to enlarge transhepatic pathways, but is not high enough to open extrahepatic shunts. As stage 1, stage 2 has PPV = 100% for CLD, but stage 2 includes not only chronic hepatitis, but also cirrhotic patients, showing a more advanced stage of portal hypertension than stage 1. 38.46% of our 13 patients in stage 2 had cirrhosis, the other 61.54% had chronic hepatitis.

A steady state between stage 1 and stage 2 may

appear in cases with the resistance (and LTT) increased on one more affected liver lobe and with redirecting of an increased percentage of the portal inflow through the other lobe. In such cases, the lobe less affected may encounter opening of transhepatic shunts due to its higher portal inflow (with consequently slightly decreased LTT, like in stage 2), while the more affected lobe has prolonged LTT (characteristic for stage 1).

Stage 3 is theoretically characterized by the opening of extrahepatic shunts, added to the transhepatic dilated pathways already present from stage 2. Low flow extrahepatic shunts appear when the transhepatic shunts are no more able to compensate the higher values of portal pressure. The inferior per-rectal portosystemic shunts are in most cases the first extrahepatic shunts which open. The cause is the pressure gradient between inferior mesenteric vein and inferior vena cava territories, which is lower than the pressure gradient between portal vein and superior vena cava. The portal inflow to the liver decreases due to shunted flow and PRSI increases over 10%. A reactive increase of the arterial liver inflow due to the activation of the buffer mechanism of the hepatic artery is reflected at LAS by HPI > 40%. 53.75% of our 80 patients in stage 3 had cirrhosis, the other 46.25% had chronic hepatitis.

Stage 4 in our study had PPV = 100% for cirrhosis. Theoretically, stage 4 involves shunts open to the territory of superior vena cava, which has a higher diameter and increased flow<sup>[29]</sup>. PRPS shows diminished or abolished portal inflow to one or both liver lobes, with PRSI > 30%. In stage 4, the tracer absorbed at PRPS from the rectum usually arrives faster to the right heart (through the portosystemic shunts and caval veins) than to the liver through the physiological pathway. Inverted order of heart and liver curves may be thus seen in advanced cases, corresponding to PRSI > 50%. In patients with undetectable portal inflow to one or both lobes (subtypes 4b, 4c, 4d), the tracer absorbed from the rectum reaches those liver areas only through the hepatic artery and time interval between the heart and liver curves is equal to RHLT = 42 s. Subtype 4b appeared more frequently in alcoholic CLD. In our study, we did not have patients with abolished inflow to the left lobe and maintaining portal inflow to the right lobe, but such cases may theoretically exist.

Figure 1 shows a case where the interval between heart and left liver lobe curves was equal to 20 s (left lobe maintained a low portal inflow) while the time interval between heart and right liver lobe histograms was equal to RHLT = 42 s (the right lobe received tracer only through hepatic artery).

In our group, the number of patients in early stages (1 and 2) was lower than in advanced stages (3 and 4). This could be explained by the fact that few patients in early CLD stages were hospitalized and/or proposed for nuclear medicine dynamic liver investigations. Moreover, stage 2 is theoretically an intermediate stage in the natural history of CLD and of the portal hypertension, so it lasts a short time compared to the evolution of the disease.

Our experience confirmed that at PRSI > 70% the risk of upper digestive hemorrhage is increased<sup>[17,30]</sup>.

The classical parameter PRSI allows only a rough characterization of non-cirrhotic patients. PRSI gives no information about early increased resistance opposed by liver to the portal inflow or about the existence of transhepatic shunts, the first that open due to the portal hypertension. Another diagnostic limitation in using PRSI alone is the fact that there are patients with chronic hepatitis but who have normal PRSI, lower than 5%.

Our model using LTT besides PRSI allows a very early diagnosis of portal hypertension, represented by stages 1 and 2. Changes of liver dynamic resistance opposed to portal inflow could be shown in these early stages, at a moment when morphological effects on the portohepatic circulation are not detectable. The diagnosis of early hemodynamic changes determined by portal hypertension could be the basis for an appropriate therapy in a stage when the disease is reversible. Thus, we propose LTT as the main parameter of PRPS in the evaluation of early stages of portal hypertension. PRSI remains a very useful parameter for portal hypertension and portosystemic shunts in advanced stages of CLD.

Staging of portal hypertension has implications in the selection of patients for the treatment. Hemodynamic pathophysiology information offered by nuclear medicine dynamic investigations may improve also the selection of patients for interferon therapy.

## ACKNOWLEDGMENTS

We are grateful to our colleagues from the 3rd Medical Clinic, Cluj-Napoca, Romania, for their professional cooperation. Many thanks to the staff of our hospital for supporting the costs of publication. We are grateful to professor dr Monica Acalovschi for the final revision of the manuscript and to Ms Sally Wood-Lamont for the English language checking.

## COMMENTS

### Background

Portal hypertension and portosystemic shunts are severe complications of chronic liver disease (CLD). Their evaluation could be considered a dynamic marker of the progression of the disease. Ultrasonography and upper digestive endoscopy are usually performed to evaluate their existence and hemodynamic importance. Nuclear medicine techniques like per-rectal portal scintigraphy (PRPS) and liver angioscintigraphy (LAS) can offer valuable supplementary information.

### Research frontiers

Doppler ultrasonography and MRI are continuously increasing their accuracy in exploring portal hypertension and portosystemic shunts. PRPS is usually performed to investigate the advanced stages of CLD. The classical PRPS parameter per-rectal portal shunt index (PRSI) is useful in cases with open portosystemic shunts. Our research improves the diagnosis possibilities of PRPS especially in early stages of CLD by introducing two new time parameters. The early diagnosis of CLD and the therapy (including the selection of patients for interferon therapy) may be improved using dynamic scintigraphy data.

### Innovations and breakthroughs

We introduced two new parameters at PRPS, respectively liver transit time (LTT) and right heart to liver transit time (RHLT). LTT is useful in early stages of portal hypertension, before the opening of extrahepatic portosystemic shunts. LTT allows the diagnosis of early increase of liver resistance opposed to portal inflow and of the opening of transhepatic shunts. RHLT is useful in advanced CLD

stages to detect liver areas missing portal inflow. We propose the classification of portal hypertension and portosystemic shunts in 5 hemodynamic stages, characteristic for the progression of the disease. We introduce the separate evaluation of the two liver lobes at PRPS, used to subtype the stages 1 and 4.

### Applications

Using LTT as a basic parameter, PRSI allows the detection of early stages of portal hypertension, which are reversible under proper therapy. Our method can also distinguish between the 1<sup>st</sup> stage of portal hypertension, with increased resistance opposed by liver to portal inflow, without shunts, and the 2<sup>nd</sup> stage, characterized by the opening of transhepatic shunts. The new parameter RHLT and the hepatic perfusion index (HPI) calculated at LAS allow a better characterization of liver hemodynamics in advanced cirrhosis. We confirm the results of other studies showing that at PRSI > 70% the risk for upper digestive bleeding increases. The classification of portal hypertension and portosystemic shunts in 5 hemodynamic stages is useful for clinicians, in order to have a more accurate view of the patients with CLD. A better understanding of hemodynamic status of border-line cases between chronic hepatitis and cirrhosis may also improve the selection of patients for interferon therapy. Patients with PRSI between 5%-30% (stages 2 and 3 in our classification) require a precise evaluation in order to choose an adequate therapy. Correlation of dynamic nuclear medicine techniques with other non-invasive methods makes it possible to avoid liver biopsy for guiding the treatment in border-line patients between chronic hepatitis and cirrhosis. Dynamic follow-up of patients under interferon-treatment may be useful to adjust the therapy. Based on calculation of LTT, PRPS may be used to determine whether the early portal pressure reducing effect of anti-viral therapy is maintained in the long term, especially in sustained viral responders. It can be also helpful to evaluate whether long-term use of anti-viral therapy may delay the appearance and decrease the severity of portal hypertension manifestations.

### Terminology

*Per-rectal portal scintigraphy (PRPS)* is a dynamic nuclear medicine technique which investigates the existence and hemodynamic importance of portal hypertension and portosystemic shunts. A radiotracer introduced in the upper rectum is absorbed and follows the next pathway: inferior mesenteric vein-portal vein-liver-right heart. Dynamic curves built on liver and heart allow the calculation of specific parameters. *Liver transit time (LTT)* determined at PRPS is the time interval between entrance into the liver and subsequent entrance into the right heart of the radiotracer absorbed from the rectum, after passing through mesenteric and portal veins. *Right heart to liver transit time (RHLT)* represents at PRPS a constant time interval (not related to liver disease) between the entrance of the tracer into the right heart and its subsequent arrival to the liver following the next route: right heart-lungs-left heart-aorta-hepatic artery. *Per-rectal portal shunt index (PRSI)* is a parameter calculated at PRPS by analysis of dynamic curves built on liver and heart areas. *Liver angioscintigraphy (LAS)* is a dynamic nuclear medicine method based on i.v. antecubital administration of a radio-tracer and subsequent analyses of the liver dynamic curve which is determined at first passage by both hepatic artery and portal inflows of tracer. *Hepatic perfusion index (HPI)* is a parameter calculated at LAS which estimates the ratio between hepatic artery inflow and total liver perfusion, arterial plus portal.

### Peer review

This is a well done study probably not completely well presented where Dragoteanu and coworkers used per-rectal portal scintigraphy and liver angioscintigraphy in 312 and 231 CLD patients and 25 controls to calculate hepatic perfusion index (HPI) and other new hemodynamic parameters and classify portal hypertension and porto-caval shunts in 5 hemodynamic stages, which are specifically for the progression of CLD.

### Abstract

**AIM:** To observe the inhibition of hepatitis B virus (HBV) replication and expression in HepG2.2.15 cells by combination of small interfering RNAs (siRNAs).

**METHODS:** Recombinant plasmid psil-HBV was constructed and transfected into HepG2.2.15 cells. At 48 h, 72 h and 96 h after transfection, culture media were collected and cells were harvested for HBV replication assay. HBsAg and HBeAg in the cell culture medium were detected by enzyme-linked immunosorbent assay (ELISA). Intracellular viral DNA and covalently closed circular DNA (cccDNA) were quantified by real-time polymerase chain reaction (PCR). HBV viral mRNA was reverse transcribed and quantified by reverse-transcript PCR (RT-PCR).

**RESULTS:** siRNAs showed marked anti-HBV effects. siRNAs could specifically inhibit the expression of HBsAg and the replication of HBV DNA in a dose-dependent manner. Furthermore, combination of siRNAs, compared with individual use of each siRNA, exerted a stronger inhibition on antigen expression and viral replication. More importantly, combination of siRNAs significantly suppressed HBV cccDNA amplification.

**CONCLUSION:** Combination of siRNAs mediates a stronger inhibition on viral replication and antigen

Xin XM, Li GQ, Jin YY, Zhuang M, Li D. Combination of small interfering RNAs mediates greater suppression on hepatitis B virus cccDNA in HepG2.2.15 cells. *World J Gastroenterol* 2008; 14(24): 3849-3854 Available from: URL: <http://www.wjgnet.com/1007-9327/14/3849.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.3849>

### INTRODUCTION

Hepatitis B virus (HBV) is a major cause for acute and chronic hepatitis in humans. Although recombinant vaccines are widely available, about 400 million people have chronic HBV infection worldwide. Chronic infection may also have serious consequences, and nearly 25% people with chronic HBV infection would die due to untreatable liver cancer<sup>[1]</sup>. The deaths of liver cancer patients resulting from chronic HBV infection exceeds one million per year worldwide<sup>[2]</sup>. Therefore, it is important to develop effective strategies for the treatment of HBV-infected patients.

Nucleotide analogues, such as lamivudine, can effectively inhibit HBV DNA synthesis<sup>[3,4]</sup> and are widely used in the treatment of HBV-infected patients. However, analysis of viral kinetics during lamivudine therapy revealed that a prolonged treatment is required since

lamivudine does not completely inhibit viral replication and the rate of clearance for infected hepatocytes is slow<sup>[5]</sup>. HBV is not a cytopathogenic virus and hepatocytes are normally long-lived and their half-life is estimated to be 6-12 mo or longer, explaining the requirement for a long-term antiviral treatment course, which is associated with the selection of drug-resistant mutants<sup>[6]</sup>.

During HBV replication, viral covalently closed circular DNA (cccDNA) serves as the template for viral transcription and its production is regulated and amplified by an intra-cellular pathway in which newly synthesized genomic DNA is recycled to the nuclei<sup>[7,8]</sup>. This process establishes a steady pool of nuclear cccDNA, which is maintained during the life of infected hepatocytes. It is likely that cccDNA may reactivate synthesis of viral transcript and protein, leading to a rebound of active viral replication. Thus, elimination of cccDNA from infected hepatocytes still remains a challenge in therapy for HBV-infected patients. A potent agent used in anti-HBV therapy should be evaluated with special emphasis on its inhibitory effect against the amplification of cccDNA.

Small interfering RNAs (siRNA) are double-stranded RNA molecules, approximately 21 nucleotides in length that hybridize to a homologous mRNA target and result in degradation of mRNA<sup>[9]</sup>. This posttranscriptional gene silencing process, called RNA interference (RNAi), is evolutionarily conserved in both plants and eukaryotic cells<sup>[10,11]</sup>. Due to the high sequence specificity and efficiency, RNAi can be used in functional genomic studies such as human immunodeficiency virus (HIV), hepatitis C virus (HCV), and influenza virus, *etc*<sup>[12-14]</sup>. HBV is one of the major candidates for RNAi, as its pregenomic RNA is a key intermediate for maintaining DNA replication *via* reverse transcription in the viral life cycle. Many studies have demonstrated that siRNA targeting different regions of the HBV genome can block viral replication and antigen expression<sup>[15-19]</sup>. Our previous study showed that siRNA targeting HBV nuclear localization signal (NLS) can inhibit viral DNA synthesis and cccDNA amplification<sup>[20]</sup>. As HBV infection is a cellular infection involving multiple genes, we hypothesize that combination of siRNAs targeting different sequences along the HBV NLS mediates a greater inhibitory efficacy on cccDNA amplification. If this is the case, it would be of significance in the treatment of HBV infection. In this study, we analyzed the kinetics of HBV genome replication during siRNA therapy and tested the antiviral capacity of combination therapy in comparison to monotherapy in HepG2.2.15 cells, showing that combination of siRNAs exhibits better effects on the inhibition of HBV replication, especially at viral cccDNA level.

## MATERIALS AND METHODS

### Materials

Dulbecco's modified Eagle's medium (DMEM) and G418 were purchased from GIBCO BRL (USA). HepG2.2.15 cells were maintained in our laboratory.

Plasmid psi/U6 was supplied by Wuhan JS Biotech (China). All polymerase chain reaction (PCR) primers were synthesized by Shanghai Boya Biological Company (China). Trizol, M-MLV reverse transcriptase, Lipofection 2000 reagent were purchased from Invitrogen Company (USA). Restriction enzymes were purchased from New England Bio-laboratory (Beijing, China).

### Construction of siRNA express vector

siRNA expression plasmid was generated as previously described<sup>[21]</sup>. Briefly, 21-nucleotide long inverted sequences were cloned into the plasmid pGenesil/U6. Five thymidines were inserted into the downstream anti-sense strand to provide a stop signal for the polymerase III RNA polymerase. The sense strand of hairpin was homologous to the target mRNA (NLS region) as analyzed by BLAST in the NCBI database. Oligonucleotides used to code for the sense strand of siRNA included siRNA1 (5'-AAG ATCTCAATCTCGGGAATC-3'), siRNA2 (5'-CAGGT CCCCTAGAAGAAGAAC-3'), and control siRNAHK (5'-ACTACCGTTGTATAGGTG-3'). All the plasmids constructed were confirmed by endonuclease digestion and DNA sequencing.

### Cell culture and transfection

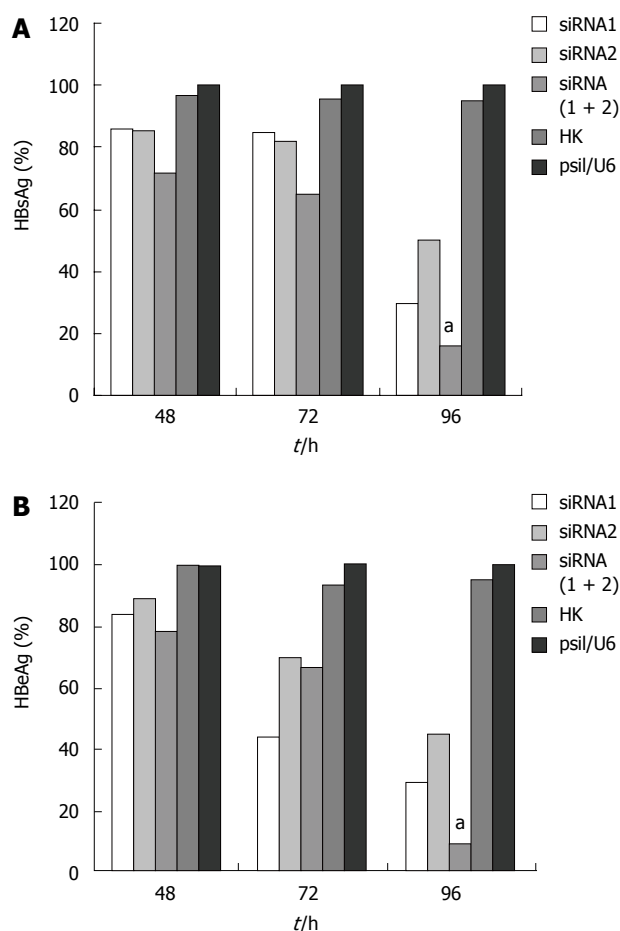

The human hepatoma cell line, HepG2.2.15, was maintained in Dubecco's modified Eagle's medium (DMEM) with 10% fetal bovine serum and 200 µg/mL G418 in 5% CO<sub>2</sub>-humidified air as previously described<sup>[22]</sup>. Cells were cultured at a density of  $3 \times 10^5$  cells per well in 6-well plates. Twenty-four hours after incubation, the cells were transfected with 4 µg siRNA-expressed plasmid using the Lipofection 2000 reagent. We removed the medium, washed the cells with warmed PBS, and added fresh medium every 24 h. At 48, 72 and 96 h after transfection, culture media were collected and cells were harvested for HBV replication assay. All experiments were performed in triplicate and divided into five groups.

### Detection of HBsAg and HBeAg

To assess the effects of RNAi on viral antigen expression, HBsAg and HBeAg levels in culture medium were measured with an enzyme-linked immunosorbent assay (ELISA) kit following its manufacture's instructions.

### Assay of HBV mRNA

Antiviral activities were evaluated by reverse-transcript PCR (RT-PCR). Total RNA was extracted directly from the transfected cells using Trizol reagent. Then, RNA was denatured for 5 min at 70°C, immediately cooled in ice water, reverse transcribed using M-MLV reverse transcriptase. A RT-PCR experiment targeting β-actin gene was run as an internal control. The primer sequences used are HBV forward (5'-ACCTC TGCCTAATCATCTC-3') and reverse (5'-GTAAG ACAGGAAATGTGAAAC-3'), β-actin forward (5'-GTCGGTGTGAACGGATT-3') and reverse (5'-ACTCCACGACGTACTCAGC-3'). The PCR

**Figure 1** Relative expression of HBsAg (A) and HBeAg (B). <sup>a</sup> $P < 0.05$  vs siRNA1 or siRNA2.

amplification product was analyzed by 1.2% agarose gel electrophoresis.

### Quantitative real-time PCR

Real-time PCR was performed to quantify the HBV DNA or cccDNA using a HBV fluorescence detection kit following its manufacturer's protocol. For measurement of viral DNA, DNA was extracted from the culture supernatant using a QIAamp DNA mini kit. cccDNA was isolated from the transfection cells to quantify its level and examined every 24 h post-transfection according to its manufacture's protocol. Reactions with no reverse transcriptase enzyme added were performed in parallel. The inhibition ratio of HBV DNA was calculated according to the formula:  $1 - \log(\text{treated sample fluorescent intensity}) / \log(\text{control fluorescent intensity}) \times 100\%$ .

### Dose-dependent inhibitory effect of single siRNA

To evaluate the dose-dependent effects of siRNA on HBV gene expression, a series of experiments were conducted in HepG2.2.15 cells transfected with different plasmids at the concentration of 2  $\mu\text{g}$ , 3  $\mu\text{g}$  and 4  $\mu\text{g}$ , respectively. The transfection cells were harvested and cell culture supernatant was collected 96 h post-transfection for further examination. Several parameters

**Figure 2** Reduction in HBV mRNA level after treatment with siRNA. M: marker, lane 1: HK, lane 2: psil/U6, lane 3: siRNAs 1 and 2, lane 4: siRNA2, lane 5: siRNA1.

of HBV were measured including HBsAg, HBV DNA as described above.

### Statistical analysis

Statistical analysis was performed using the SPSS 12.0 software. The results were expressed as mean  $\pm$  SD and compared using *F*-test and one-way ANOVA.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Inhibition of the expression of HBsAg and HBeAg

To test whether siRNA could effectively inhibit the expression of viral proteins in HepG2.2.15 cells, HBsAg and HBeAg in culture media were detected by ELISA. For HBsAg, cells transfected with the control siRNA produced an equal secretion with those treated with empty vector ( $P < 0.05$ ) as expected in the absence of any specific silencing response, whereas cells expressing HBV siRNA gave a very different result. The HBsAg level in all the cells integrated with three siRNAs was significantly reduced compared with those transfected with empty vector, and the greatest reduction rate was 83.89% in the combined therapy group 96 h post-transfection (Figure 1A). HBeAg was also reduced in the selected siRNA-transfected cells, and the greatest reduction rate was 91.07% in the combined therapy group 96 h post-transfection (Figure 1B). For both HBsAg and HBeAg, combination therapy for siRNAs was more potent than any individual therapy.

### Reduction of HBV mRNA level

To determine whether viral mRNA is efficiently degraded by siRNA, RT-PCR was performed 48 h, 72 h and 96 h after transfection. The results demonstrated that the mRNA level of each tested siRNA was markedly reduced, whereas the empty plasmid had no effect on mRNA level (Figure 2). Combination therapy with all the siRNAs produced a stronger inhibition on viral transcripts compared with the therapy with one siRNA. The HepG2.2.15 cells treated with combined siRNAs for 96 h did not contain any detectable mRNA, whereas mRNA was abundant in cells treated with empty vector.

### Reduction of copies of viral DNA and cccDNA

The effect of siRNA silencing on HBV DNA was investigated by quantitative real-time PCR, which can detect  $10^4$ - $10^8$  copies of HBV DNA. The level of viral

**Figure 3** Inhibition of HBV DNA (A) and cccDNA (B) amplification after treatment with siRNA. <sup>a</sup> $P < 0.05$  vs siRNA1 or siRNA2.

DNA in cells transfected with combined siRNAs was significantly lower than that in cells treated with empty vector. Treatment with irrelevant control siRNA slightly decreased the level of viral DNA in cells transfected with siRNA (Figure 3A). Furthermore, combined siRNA1 and siRNA2 showed a greater inhibitory effect (88.6%) on viral DNA replication than siRNA1 or siRNA2 alone ( $P < 0.05$ ).

HBV cccDNA is an important parameter in the therapy for chronic HBV infection. To evaluate if combination of siRNAs can effectively inhibit viral cccDNA, we isolated viral cccDNA from the transfected cells every 24 h post-transfection. Quantitative assay revealed that HBV cccDNA levels were decreased by 50.4%, 22.31%, and 69.83% in the cells transfected with siRNA1, siRNA2 and siRNA (1 + 2), respectively, compared to the level of cells treated with empty plasmid 96 h post-transfection. Meanwhile, HBV cccDNA levels did not significantly change in cells treated with control siRNA and empty vector. As expected, the use of siRNA1 and siRNA2 synergistically suppressed the viral cccDNA activities compared with siRNA1 or siRNA2 alone ( $P < 0.05$ , Figure 3B). These results were reproducibly observed in three independent experiments.

#### Dose-dependent effect of siRNA

As shown in Figure 4, siRNA had an obvious dose-

**Figure 4** Dose-dependent inhibitory effects of siRNA on HBV antigen HBsAg expression (A) and HBV replication (B). <sup>a</sup> $P < 0.05$  vs 2 μg or 3 μg.

dependent effect on HBV replication and antigen expression 96 h post-transfection. When the cells were transfected with a low concentration of siRNA, siRNA had almost no effect on HBV replication and antigen expression. However, a more significant inhibition of HBsAg and DNA in the cells treated at the concentration of 4 μg was observed. The level of HBsAg was decreased by 29%, 43% or 70% after siRNA1 treatment, and 9%, 30% or 50% after siRNA2 treatment, respectively, at the concentrations of 2 μg, 3 μg, 4 μg (Figure 4A). The level of HBV DNA was reduced by 17%, 39% or 65% after siRNA1 treatment, and 9%, 29% or 51% after siRNA2 treatment, respectively, at the concentrations of 2 μg, 3 μg, 4 μg (Figure 4B).

## DISCUSSION

Chronic HBV infection is one of the most serious diseases threatening human health. RNAi technology provides an alternative strategy to combat HBV infection<sup>[23,24]</sup>. It was reported that viral mutations could escape single synthetic siRNA treatments, such as HBV, HCV and HIV<sup>[25-27]</sup>. One strategy to address the problem is to generate multiple siRNA molecules that can target different sites on the viral genome. The other is to choose target sequences in the relatively conserved region. Recently, combination therapy has emerged as a new approach to the treatment of chronic HBV infection with the objective to decrease the viral load

to the lowest possible levels<sup>[28,29]</sup>. This is then followed by a continued chemotherapy with another nucleotide analog or IFN- $\alpha$  in order to eliminate the remained viral load. Following the same strategy, we also investigated the effect of combination of siRNAs in comparison to monotherapy in HepG2.2.15 cells. As HBV infection is a pathological process involving multiple genes, it will be ideal to develop a combination strategy for siRNAs that can knock down the expression of multiple pathogenic viral antigens as well as inhibit viral replication. During the progress of combination therapy, several siRNAs may block multiple sites in viral genome and make it difficult to repair immediately, thus achieving greater suppression on HBV infection than a single siRNA.

The HepG2.2.15 cell line, a derivative of human HepG2 hepatoma cells, has been used as an *in vitro* stable HBV-producing model<sup>[22]</sup>. The cell line can be transformed with a head-tail dimer of HBV DNA. Using this method, we could simulate the natural condition in which cells can still stably produce mRNA, antigen and viral particles. Specific siRNA targeting different sites on HBV NLS region were transfected and monitored in HepG2.2.15 cells. As a result, the load of HBsAg, HBeAg, and mRNA was inhibited to some extent. Meanwhile, real-time PCR revealed that the number of viral DNA and cccDNA copies was markedly decreased. This inhibition was highly selective, sequence-specific and dose-dependent since control siRNA had almost no inhibitory effect on the expression or replication of HBV.

The selected siRNAs showed marked anti-HBV effects. Surprisingly, combination of siRNAs, compared with a single siRNA, exerted a stronger inhibition on antigen expression and viral replication, even though the final concentration of siRNA used in the therapy was the same. More importantly, combination therapy significantly suppressed HBV cccDNA amplification.

In summary, combination of siRNAs targeting various regions of HBV NLS inhibits viral replication and suppresses cccDNA amplification and can be used in the treatment of HBV infection.

## COMMENTS

### Background

Hepatitis B virus (HBV) is a major cause for acute and chronic hepatitis in humans. The development of an effective therapy for HBV infection is still a challenge. As HBV infection is a cellular infection involving multiple genes, progress in RNA interference (RNAi) has shed light on developing a new anti-HBV strategy.

### Research frontiers

siRNA targeting HBV nuclear localization signal (NLS) can inhibit viral DNA synthesis and cccDNA amplification. In this study, the authors hypothesize that combination of siRNAs targeting different sequences along HBV NLS mediates greater inhibitory effects on cccDNA. If this is the case, it would be of significance in the treatment of HBV infection.

### Innovations and breakthroughs

In this study, the selected siRNA showed marked anti-HBV effects. Surprisingly, combination of siRNAs, compared with a single siRNA, exerted a stronger inhibition on antigen expression and viral replication, even though the final concentration of siRNA used in the therapy was the same. More importantly, combination therapy significantly suppressed HBV cccDNA amplification.

## Applications

Combination of siRNAs targeting various regions of HBV NLS not only inhibits viral replication, but also suppresses cccDNA amplification, indicating that it can be used in the treatment of HBV infection.

## Peer review

The effect of combination of siRNAs on suppressing HBsAg and HBeAg expression, and levels of HBV mRNA, DNA and cccDNA *in vitro* was studied in this study. This manuscript provides some important information about the treatment of chronic HBV infection. It is very interesting paper and has certain value.

## Abstract

**AIM:** To compare a lansoprazole-based triple versus quadruple therapy for *Helicobacter pylori* (*H. pylori*) eradication with emphasis on side effect profile, patient compliance and eradication rate at a rural district general hospital in Wales, United Kingdom.

**METHODS:** One hundred one patients with *H. pylori* infection were included in the study. Patients were randomised to receive triple therapy comprising of lansoprazole 30 mg, amoxycillin 1 g, clarithromycin 500 mg, all *b.d.* (LAC), or quadruple therapy comprising of lansoprazole 30 mg *b.d.*, metronidazole 500 mg *t.d.s.*, bismuth subcitrate 240 mg *b.d.*, and tetracycline chloride 500 mg *q.d.s.* (LMBT). Cure was defined as a negative <sup>13</sup>C urea breath test 2 mo after treatment.

**RESULTS:** Seven patients were withdrawn after randomisation. Fifty patients were assigned to LAC group and 44 to LMBT group. The intention-to-treat cure rates were 92% and 91%, whereas the per-protocol cure rates were 92% and 97%, respectively. Side effects were common, with 56% experiencing

moderate to severe symptoms in the LAC group and 59% in the LMBT group. Symptoms of vomiting, diarrhoea and black stools were significantly more common in the LMBT group. Patient compliance was 100% for triple therapy and 86% for quadruple therapy ( $P < 0.01$ ). One-third of patients in both groups were still taking acid-reducing medications at six-month follow-up.

**CONCLUSION:** One-week triple and quadruple therapies have similar intention-to-treat eradication rates. Certain side effects are more common with quadruple therapy, which can compromise patient compliance. Patient education or modifications to the regimen are alternative options to improve compliance of the quadruple regimen.

## INTRODUCTION

European studies have shown that quadruple therapy, even though more effective with a cure rate of over 95% by per protocol analysis<sup>[1-3]</sup>, is less popular compared to a standard triple therapy for eradication of *Helicobacter pylori* (*H. pylori*) infection. The reasons for this are the complexity of the regimen and also its side effects. Scheduling drugs four or more times a day reduces compliance<sup>[4,5]</sup>. However, some studies have suggested that quadruple therapy has a similar magnitude of

adherence and adverse effects compared to triple therapies<sup>[6,7]</sup>.

Triple therapies are the mainstay of current treatment but resistance to clarithromycin is reducing its effectiveness. In the presence of resistance to clarithromycin, some studies have shown eradication rate below 80% and even as low as 25%-61% with standard triple therapy containing clarithromycin, amoxycillin and a proton-pump inhibitor<sup>[7-11]</sup>. Clarithromycin resistance is also increasing in our region<sup>[12,13]</sup>.

Quadruple therapy is used mainly as a second-line therapy after failed eradication with triple therapy<sup>[14-18]</sup>. Earlier consensus meeting reports including the Maastricht II Consensus Report on the management of *H pylori* infection have recommended the use of quadruple therapy for 1 wk as second-line therapy for *H pylori* infection<sup>[19-21]</sup>. However, updated reports have now recommended quadruple therapy as an alternative first-line eradication therapy<sup>[22-24]</sup>.

The objective of the study was to compare a standard lansoprazole-based triple therapy (HeliClear®) to a lansoprazole-based quadruple therapy as first-line therapy in a surgical practice in a predominantly Caucasian population in North Wales.

## MATERIALS AND METHODS

We conducted a prospective randomised trial of patients under the care of an upper gastrointestinal surgeon at Ysbyty Gwynedd, a rural District General Hospital in North Wales. The population served by Ysbyty Gwynedd is predominantly (98.8%) white and there are about 120 new cases of *H pylori* each year from a population of around 180 000. Twenty-four percent of strains were resistant to metronidazole, 7% to clarithromycin and 4% to both. There was resistance to tetracycline in 1 out of 363 isolates and none to amoxycillin<sup>[12]</sup>.

The Local Ethics Committee of the participating hospitals approved the study. From June 2001 to November 2005, 101 patients with diagnosis of *H pylori* infection proven by gastric histology or urease test or culture were included in the study. Two positive tests were required for inclusion. The inclusion and exclusion criteria are shown in Table 1.

Patients were recruited into the trial once they had met the criteria and given fully informed written consent. Patients were recruited from the outpatient departments at one district general hospital and a satellite hospital served by the same team of doctors. The patients received a 7-d course of either a triple regimen (LAC) or a quadruple regimen (LMBT) (Table 2).

Randomisation took place at the hospital pharmacies when the patients collected their medications with a note from the recruiting doctor. The pharmacists dispensed the medications adhering to the order on a random list of therapy regimens.

A printed chart showing the names of the drugs, the number of pills to take and the time schedule was given to all participants to improve understanding and

Table 1 Inclusion criteria and exclusion criteria

Criteria	
Inclusion criteria	Dyspeptic symptoms Has recent OGD (duodenal ulcer; gastric ulcer; gastritis or non-ulcer dyspepsia) Positive for <i>H pylori</i> on histology and culture or CLO test or <sup>13</sup> C-urea breath test
Exclusion criteria	Age less than 18 or above 75 yr Symptomatic gallstones Treated with antibiotic or bismuth-containing drugs during the month prior to inclusion Treated with proton pump inhibitor during the week prior to inclusion Disturbed gastrointestinal physiology (gastric surgery; vagotomy; Zollinger-Ellison syndrome; chronic ingestion of NSAIDs) Concomitant serious disease Concomitant medications that may adversely interact with the study drugs (e.g. warfarin, anti-epileptics) Pregnancy and breast-feeding Childbearing age without adequate contraception Allergy to drugs used in the study Mental illness Heavy drinking or abuse of drugs

Table 2 Regimens used in the trial

Triple therapy regimen (LAC)	Quadruple therapy regimen (LMBT)
Lansoprazole (30 mg b.d.)	Lansoprazole (30 mg b.d.)
Amoxycillin (1 g b.d.)	Metronidazole (400 mg t.d.s.)
Clarithromycin (500 mg b.d.)	Bismuth subcitrate (240 mg b.d.) Tetracycline chloride (500 mg q.d.s.)

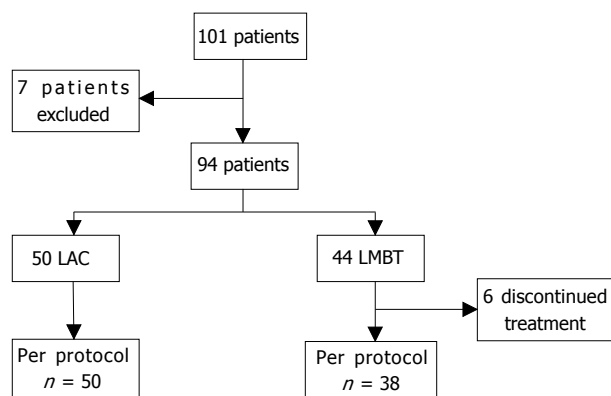

compliance with treatment.

Compliance was evaluated by patient's record of each dosage taken onto the chart during the week of therapy. Any tablet that was not consumed needed to be brought back to the clinic for pill count. The patients were asked to record the reasons for missed dosages. They were also asked to record any side effects and their severity during the therapy. Proton pump inhibitors and other acid-reducing medications were not allowed after treatment. The patients returned for interview at 6 wk after therapy. The efficacy of treatment was evaluated by means of the <sup>13</sup>C-urea breath test performed following the standard European protocol at 8 wk following the start of therapy<sup>[12]</sup>. Patients were reviewed again at 6 mo after therapy to assess symptoms and use of any medications after determining their post therapy *H pylori* status. Patients who tested positive were offered the alternate regimen and retested after a gap of 2 mo.

## Statistical analysis

Proportions were compared using Fisher's Exact Test. Quantitative variables were compared using *t*-test and non-parametric variables were compared using Mann-Whitney *U* test. Non-categorical values are given as the mean ± SD. Calculations were performed using the SPSS for Windows statistical package.

**Figure 1** CONSORT flow diagram showing entries and withdrawals from the study.

**Table 3** Patient characteristics

	Therapy	
	LAC (n = 50)	LMBT (n = 44)
Age	55.2 ± 10.9	53.7 ± 11.4
Gender (male: female)	26:24	27:17
Active smoking	10 (20%)	16 (36%)
NSAID use	4 (8%)	3 (7%)
Ethanol abuse (> 14 U/wk)	4 (8%)	3 (7%)
Previous therapy with antacids	4 (8%)	8 (18%)
Time between treatment and UBT (mo)	2.2 ± 0.7	2.1 ± 0.5
Gastric ulcer	1	1
Duodenal ulcer	3	1
Gastritis	36	33
Duodenitis	6	8
Diagnosis of <i>H pylori</i> infection (Urease: Culture: Biopsy)	42:29:45	37:27:44

NSAID: Non-steroidal anti-inflammatory drug; UBT: Urea breath test.

## RESULTS

One hundred one patients were randomized into the trial but seven patients were withdrawn from the study after randomization (one because of diagnosis of bronchial carcinoma, one because of diagnosis of gallstones, two withdrew from the study and three were non-compliant to study protocol) (Figure 1).

Fifty patients were assigned to the LAC group and 44 to the LMBT group. The demographic and clinical characteristics of the groups were comparable (Table 3).

### Compliance and side-effects

Compliance was excellent in the LAC group with all the patients completing the 7-d therapy. In contrast, 6 patients (14%) in the LMBT group failed to complete the treatment ( $P < 0.01$ ). In spite of this three had a negative breath test.

Four out of the six patients had attributed moderate/severe nausea as the reason for discontinuing treatment. One had severe diarrhoea and another had nausea, vomiting and diarrhoea.

Side effects were reported by vast majority of patients in both groups, 45 patients (90%) in the LAC group and 42 patients (95%) in the LMBT group.

**Table 4** Incidence of side effects n (%)

	Therapy		P-value
	LAC (n = 50)	LMBT (n = 44)	
Nausea	11 (22)	20 (45)	< 0.05
Vomiting	0 (0)	9 (20)	< 0.01
Diarrhoea	14 (28)	25 (57)	< 0.01
Headache	12 (24)	19 (44)	
Dizziness	9 (18)	11 (25)	
Blurred vision	5 (10)	6 (14)	
Itching	5 (10)	5 (11)	
Rash	1 (2)	2 (5)	
Dry mouth	27 (54)	19 (43)	
Sore mouth	4 (8)	0 (0)	
Glossitis	2 (4)	1 (2)	
Black tongue	6 (12)	6 (14)	
Black stool	5 (10)	35 (80)	< 0.01
Taste disturbance	23 (46)	14 (32)	
Arthralgia	3 (6)	1 (2)	

**Table 5** Severity of side-effects (n)

Severity	Therapy	
	LAC	LMBT
None	5	2
Mild	17	19
Moderate	25	13
Severe	3	10
Total	50	44

Severity score: 1 = mild, does not cause any concern; 2 = moderate, but not bad enough to discontinue treatment; 3 = severe or incapacitating, forced to discontinue treatment.

The most frequent symptoms in the LAC group were dry mouth (54%) and taste disturbance (46%). Patients in the LMBT group experienced significantly more nausea (45%), vomiting (20%), diarrhoea (57%) and black stool (80%) (Table 4).

Each symptom was graded as mild, moderate or severe. In the LAC group, mild symptoms were observed in 17 patients (34%), moderate symptoms observed in 25 patients (50%) and severe symptoms observed in 3 patients (6%). In the LMBT group, mild symptoms were observed in 19 patients (43%), moderate symptoms observed in 13 patients (30%) and severe symptoms observed in 10 patients (23%) (Table 5,  $P < 0.05$ ). Despite most of the patients experiencing some side effects, none were severe enough to require hospitalization.

### <sup>13</sup>C-urea breath test

All 94 patients returned for a <sup>13</sup>C-urea breath test 2 mo after eradication therapy. Four patients (8%) from the LAC group and four patients from LMBT (9%) had positive results indicating failure of *H pylori* eradication. Three of the four patients had an incomplete quadruple therapy (Table 6).

All the eight patients who tested positive with <sup>13</sup>C-urea breath test had the alternate regimen. Three of four patients, who had initially LAC and then LMBT therapy, were negative on the second breath test.

Table 6 <sup>13</sup>C-urea breath test results *n* (%)

	Therapy		P-value
	LAC ( <i>n</i> = 50)	LBMT ( <i>n</i> = 44)	
Returned for UBT	50 (100)	44 (100)	-
Completed therapy	50 (100)	38 (86)	< 0.01
UBT result	46 negative, 4 positive	37 negative, 1 positive	
Not completed therapy	0 (0%)	6 (14)	< 0.01
UBT result	-	3 positive, 3 negative	-
Intention-to-treat cure rate	92% (46/50)	91% (40/44)	
Per-protocol cure rate	92% (46/50)	97% (37/38)	

UBT: Urea breath test.

Table 7 Symptomatic outcome at 6-mo follow-up *n* (%)

	Therapy	
	LAC ( <i>n</i> = 50)	LBMT ( <i>n</i> = 44)
Follow-up at 6 mo	46 (92)	40 (91)
Persistent symptoms	4 (8)	7 (16)
Recurrent symptoms	17 (34)	9 (20)
Repeat eradication therapy	1 (2)	1 (2)
Long-term acid-reduction therapy	17 (34)	14 (32)

### Six-month follow-up

Eighty-six patients (91.5%) returned for a 6-mo follow-up. Over one-third of patients had recurrent or persistent symptoms and remained on long-term acid-reduction therapy (with proton-pump inhibitors, H<sub>2</sub>-antagonist or other antacids) even after successful eradication (Table 7).

## DISCUSSION

This study has shown that a lansoprazole-based quadruple therapy is as effective as triple therapy in a predominantly white population in the UK (intention-to-treat rate: 91% *vs* 92% respectively). The resistance to clarithromycin (7%) is beginning to diminish the effectiveness of the triple therapy (92% per protocol eradication) whereas metronidazole resistance (24%) did not affect quadruple therapy (97% per protocol eradication)<sup>[25]</sup>.

Side effects are common in both regimens occurring in around 90% of patients. However, severe side effects occurred more frequently with quadruple therapy (23% *vs* 6%) and this reduced compliance.

Four out of the six patients taking quadruple therapy stopped because of nausea and vomiting, which was probably due to metronidazole. Replacing metronidazole with amoxicillin should reduce these side effects and increase compliance<sup>[26]</sup>. Interestingly, dry mouth was noticed more in the triple therapy group even though lansoprazole was the most likely cause.

The intention-to-treat cure rate of quadruple therapy (LBMT) was comparable to triple therapy (LAC) in spite of lower compliance. Educating patients about the possible common side effects and the importance of

complete eradication should provide a very high cure rate as the per protocol cure rate was 97% for quadruple therapy.

Quadruple therapy is very cost effective and should be considered as a first-line therapy especially when there are economic constraints. Lansoprazole-based quadruple therapy costs £17 as against £38 for the triple therapy for a one-week course<sup>[27]</sup>. The difference of £21 per treatment can be relieved from economic burden for the health service to treat this common condition.

Patients have to be warned that about one sixth of them will have persistent symptoms and about third of them will develop recurrent symptoms with a similar proportion needing long-term treatment with a proton-pump inhibitor, H<sub>2</sub>-antagonist or other antacids.

Modified seven-day quadruple therapy, by reducing the frequency of tetracycline chloride and bismuth subcitrate from four times to three times daily, has also been tried successfully as a first-line treatment with cure rate and compliance rate of over 90%<sup>[2]</sup>. Bateson has shown that a twice-daily quadruple therapy using lansoprazole, tetracycline, clarithromycin and metronidazole is effective (95.5% eradication rate) in UK patients with duodenal ulcer but this pre-dated resistance to clarithromycin and metronidazole<sup>[28]</sup>. Amoxicillin has been shown to improve eradication in resistant patients and perhaps a trial of a twice-daily quadruple therapy substituting amoxicillin for metronidazole should be considered<sup>[26]</sup>. Other approaches to the problem of antibiotic resistance include a sequential therapy that substituted amoxicillin with tinidazole during the first 5 d of a 10-d triple therapy with pantoprazole, amoxicillin and clarithromycin, which has been shown to achieve a significantly higher eradication rate<sup>[29]</sup>. Pretreatment sensitivity testing has been confirmed to be cost effective by significantly improved eradication in a study that used omeprazole and two antibiotics chosen based on susceptibility testing, compared to omeprazole, clarithromycin and metronidazole standard triple therapy<sup>[30]</sup>.

Recent randomised studies that compared triple therapy with quadruple therapy as a first-line treatment option for *H. pylori* and some reports showed superior eradication rates with the quadruple therapy<sup>[6,31,32]</sup> whereas others have shown no difference<sup>[33,34]</sup>. Quadruple therapy is becoming the standard treatment as resistance to clarithromycin, and to a lesser extent metronidazole, is reducing the efficacy of triple therapies. The side effects may be reduced by replacing metronidazole with amoxicillin but patients should be better educated about the side effects in order to improve compliance and cure rates.

## ACKNOWLEDGMENT

We are indebted to Ms Meinir Williams for her dedicated secretarial assistance.

## COMMENTS

### Background

The treatment for *Helicobacter pylori* (*H. pylori*) is becoming less effective as the organism is becoming resistant to the commonly used antibiotics in triple

therapies. Quadruple therapies were less popular because of their side effects but still have good eradication rates.

### Research frontiers

This study compares lansoprazole-based triple and quadruple therapy for *H pylori* infection in white Caucasians in rural Wales, an area with low resistance to Clarithromycin and moderate resistance to metronidazole.

### Innovations and breakthroughs

Both regimens had high eradication rates (> 90%) showing that resistance has not yet significantly affected this UK population. Even better rates (97%) can be achieved with quadruple therapy if patients are able to complete the full course. Patients need to be educated about the side effects and importance of completing the course to achieve the higher eradication rates.

### Applications

Quadruple therapies provide a cost effective and highly successful treatment for *H pylori*. The side effects and compliance may be improved by substituting amoxicillin for metronidazole-an area for future research.

### Terminology

Triple therapy is a regimen of a proton pump inhibitor and two antibiotics. Quadruple therapy is a regimen of a proton pump inhibitor, a bismuth compound and two antibiotics.

### Peer review

The authors compared lansoprazole-based triple and quadruple therapy in the eradication of *H pylori*. They found that both regimens were equally effective and that quadruple therapy was less costly even though 6 patients had to discontinue treatment because of side effects. This is an important study.

S- Editor Li DL L- Editor Li M E- Editor Lin YP

liver unit, we selected retrospectively those fulfilling the following criteria: detectable HCV RNA, Knodell score  $\leq 3$  at the first pathological evaluation<sup>[10]</sup>, at least 2 sequential liver biopsies in the absence of antiviral therapy or HIV and HBV co-infection. Kidney transplant recipients or hemodialyzed patients were excluded as well as patients with other causes of chronic liver disease (hepatotoxic drugs, autoimmune chronic hepatitis, hemochromatosis, Wilson's disease and alpha 1 anti-trypsin deficiency). In our center we usually perform a liver biopsy in all HCV-RNA chronic carriers, whatever the transaminase levels. In the case of low pathological lesions, we usually propose therapeutic abstention, a biochemical follow-up twice a year, an abdominal ultrasonography (US) yearly and a pathological follow-up with a liver biopsy every three to five years. In patients infected by blood transfusion or intravenous drug use, duration of HCV infection was estimated as the time elapsed from the year of transfusion or intravenous drug use (IVDU) onset to that of the first liver biopsy. Gender, route of infection, HCV viral genotype and serum viral load, body mass index (BMI), alcohol consumption before the first biopsy, serum ALT and serum glutamyl-transferase (GGT) levels were recorded for each patient.

### Histological analysis

Liver biopsy specimens were fixed, paraffin-embedded, and routinely stained with haematoxylin-eosin and Masson's trichrome and picosirius red for collagen. For each liver biopsy specimen, stage of fibrosis (from 0 to 4) and grade of necro-inflammation including portal inflammation (from 0 to 4), periportal piecemeal necrosis (from 0 to 10) and intralobular inflammation (from 0 to 4) were established according to the Knodell score criteria. Worsening of the necro-inflammation (sum of portal inflammation, periportal piecemeal necrosis and intralobular inflammation scores) and fibrosis were defined by an increase of at least 2 and 1 points, respectively.

### RNA quantification and procedure for HCV genotyping

Serum HCV RNA quantitative detection was performed using the RT-PCR method with a sensitivity limit of 100 copies/mL (Amplicor® Roche, Switzerland). Genotypes were identified using the INNO-LIPA HCV procedure (Innogenetics, Belgium).

### Statistical analysis

SPSS software version 10.0 (SPSS Inc, Chicago, Illinois, USA) was used for statistical analysis. Quantitative variables were compared using Student's *t*-test or non-parametric Mann-Whitney variance analysis (ANOVA). Qualitative variables were compared using the  $\chi^2$  test or the Fischer test when necessary. Multivariate analysis was done using robust logistic regression. A two-tailed *P* value less than 0.05 was considered as significant.

## RESULTS

Among our HCV-infected patient group, 410 patients

**Table 1** Demographic and clinical features of HCV patients with initially normal liver

Demographic and clinical features	Data
Number of patients	76
Sex (M/F)	34/42
Age at the first biopsy (mean, yr)	38 $\pm$ 9
Age at Infection (mean, yr)	25 $\pm$ 9
BMI (M/F)	23.5 $\pm$ 3.1/22 $\pm$ 5.1
Route of infection:Transfusion	28 (36.8%)
IVDU	33 (43.4%)
Other or unknown	15 (20%)
Genotype 1/2/3/4/5	40/9/15/6/2
Infection duration, median (95% CI)	13 (1-28)
Times between 2 biopsies, median (95% CI)	4 (2-16)
Alcohol consumption (g/d, mean $\pm$ SD)	22.2 $\pm$ 44
ALT level between 2 biopsies	
Constantly normal	42 (55.3%)
Normal or $< 2$ N	31 (40.8%)
$> 2$ N	3 (3.9%)
Viral load:	
Low (under 350 000 UI/mL)	33 (55%)
Medium	14 (23.3%)
High (more than 700 000 UI/mL)	13 (21.7%)
Knodell score at the first liver biopsy	
Necroinflammatory index (mean $\pm$ SD)	1.7 $\pm$ 0.7
Fibrosis score (mean $\pm$ SD)	0.6 $\pm$ 0.5

had a first liver biopsy with a Knodell score  $\leq 3$ . Only 76 patients, 34 males and 42 females, had at least a second liver biopsy and fulfilled the selection criteria. Their main characteristics are given in Table 1. Mean age at infection and at the first biopsy were 25  $\pm$  9 years and 38  $\pm$  9 years, respectively. Thirty-three patients (43.4%) had been contaminated by intravenous drug use and 28 (36.8%) by transfusions. Forty patients (55.6%) were infected with genotype 1 and 15 (20.8%) with genotype 3. The median duration of infection before the first biopsy was 13 (95% CI: 1-28) years and the median time between paired biopsies was 4 (95% CI: 2-16) years. The mean number of ALT level available between the 2 biopsies was 6  $\pm$  3. During the follow-up period, 33 patients (43.4%) had normal serum ALT activity, 33 (43.4%) patients displayed occasional mild ALT increases (less than 2 times the upper normal limit) and 10 patients (13.2%) had constantly elevated ALT ( $> 3$ N). The mean daily alcohol consumption was 22.2 g/d (95% CI: 0-250). Mean BMI was 23.5  $\pm$  3.1 for males and 22.0  $\pm$  5.1 for females, without significant difference. Forty patients (55.6%) were infected with genotype 1; 9 (12.5%) with genotype 2; 15 (20.8%) with genotype 3; 6 (8.3%) with genotype 4 and 2 (2.8%) with genotype 5. Genotype was unknown for 4 patients. Viral load was low (under 350 000 UI/mL) for 33 patients (55%), medium (350 000 to 700 000 UI/mL) for 14 patients (23.3%) and high (more than 700 000 UI/mL) for 13 patients (21.7%). At the first biopsy, mean values for necro-inflammation and fibrosis were 1.75  $\pm$  0.68 and 0.57  $\pm$  0.5 respectively.

At the last biopsy, a significant increase in necro-inflammation ( $\geq 2$  points) and fibrosis score ( $\geq 1$  point) was observed in 38 (50%) and 26 patients (34%) respectively; 3 patients having a fibrosis equal to 3 and one equal to 4 (Figure 1). The mean difference in the necro-

**Figure 1** Pathological evolution. 38 patients (50%) had progression of necroinflammatory activity (progression  $\geq 2$ ) and 26 (34%) had progression of fibrosis (progression  $\geq 1$ ; 3 patients having a fibrosis score at 3 and one at 4).

inflammation and fibrosis scores between the 2 biopsies was low:  $1.79 \pm 2.23$  and  $0.42 \pm 0.77$ , respectively. Univariate analysis showed there was no difference between activity and fibrosis evolution according to the genotype, viral load or the infection duration. A higher fibrosis progression ( $1.00 \pm 1.3$ ) was observed in patients with BMI  $> 25$  as compared to patients with BMI  $< 25$  ( $0.28 \pm 0.53$ ) ( $P = 0.03$ ). A significant progression in activity (mean =  $1.7 \pm 0.8$  *vs*  $0.4 \pm 0.5$ ) ( $P < 0.05$ ) or fibrosis (mean =  $0.9 \pm 0.3$  *vs*  $0.0 \pm 0.2$ ) ( $P < 0.01$ ) was observed in patients with elevated ALT as compared to patients with normal ALT. There was also a significant correlation between activity progression and fibrosis progression ( $P = 0.003$ ).

By multivariate analysis, factors independently associated with liver fibrosis progression were an elevated ALT (RR = 7.5, CI = 1.4) ( $P = 0.02$ ), BMI  $> 25$  (RR = 4.9, CI = 1.2) ( $P = 0.03$ ) and the interval between the 2 biopsies (RR = 1.8, CI = 1.3) ( $P = 0.001$ ).

## DISCUSSION

The long-term natural history of the so-called healthy carriers of HCV is not clear. Although ALT levels do not reflect the severity of the liver damage<sup>[11]</sup>, patients with persistently normal ALT levels usually have a less severe disease, corresponding to a lower progression of fibrosis<sup>[8,12-15]</sup>. Nevertheless, some reports suggest the presence of significant fibrosis or cirrhosis in some of them<sup>[8,13,16,17]</sup>. Other reports underline the relationship between excess weight and hepatitis C-related fibrosis progression<sup>[18,19]</sup>. This study was designed to evaluate whether HCV-infected subjects with pathologically normal liver had any progression of liver damage after 4 years of follow-up. This might allow the screening of patients for which antiviral treatment would be helpful.

In our study, fibrosis progression only concerns one third of the patients. The short time between two biopsies cannot exclude a later worsening of liver fibrosis, which is probably slow, with a low risk of evolution to cirrhosis. Although ALT levels do not reflect the sever-

ity of the liver disease, elevated ALT was associated with liver fibrosis progression in this population with initially normal liver. Overweight, accordingly to the recent literature was also associated with fibrosis worsening<sup>[19]</sup>. Patients with elevated ALT or BMI may have more necro-inflammatory activity resulting in more pronounced fibrosis progression<sup>[19,21]</sup>.

Our results suggest that ALT level follow-up is necessary whatever the histopathological results. In the subgroup of patients with elevated ALT or BMI, pathological follow-up seems to be useful and weight loss should be proposed. Our study suggests that liver fibrosis progression is correlated with time between biopsies, which probably make histopathological controls necessary. In patients with normal liver, normal ALT level and without co-morbidities such as excess weight, the time between biopsies should be longer than 5 years.

In our study, alcohol consumption was not correlated with fibrosis progression. We recorded the alcohol consumption before the first biopsy. We can suggest as a major hypothesis for this unusual result, that patients reduced their alcohol consumption after knowledge of their HCV status during follow up<sup>[22]</sup>.

Antiviral therapy is usually not used in the so-called “asymptomatic HCV-carriers”<sup>[23,24]</sup>. We can differentiate in these “asymptomatic carriers” a sub-group which is at risk of fibrosis progression. The question is whether and when pegylated interferon and ribavirin should be a therapeutic option? Theoretically, if patients with normal liver tests do not really need treatment, therapy still can be proposed to interested patients with the same response rate as patients with elevated transaminases<sup>[25-29]</sup>. In addition, patients with a higher risk of liver fibrosis progression should be treated, particularly in case of genotype 2 or 3 infection<sup>[30]</sup>.

In conclusion, this study confirms that the “HCV-healthy carrier” state does exist. Fibrosis does not worsen in two thirds of HCV-carriers without histopathological features after 4 years, supporting the concept that the natural history of chronic hepatitis in this group of subjects is characterized by a very slow or no progression. Antiviral therapy is not recommended in these patients with normal ALT or BMI under 25. Overweight, HCV-infected patient should be informed of the risk of liver fibrosis progression and the need of dietetic councils.

## COMMENTS

### Background

Chronic hepatitis C virus (HCV) infection cause liver damage, with a fibrotic scarring, which can progress to cirrhosis. The natural history of the infection varies among patients. For instance, in 10% of the case, the liver appears pathologically normal. Altogether, 10% to 40% of HCV infected patients harbor normal liver tests and the disease progresses very slowly as compared with patients with elevated liver tests. Until now, studies usually differentiate patients with or without liver test abnormalities but rarely patients with or without liver biopsy abnormalities.

### Research frontiers

The goal of this work was to evaluate and differentiate patients for whom treatment will offer a better management of the disease. Among HCV infected

patients without significant liver damage, one-third progress toward fibrosis. This work focuses on early detection of these patients with a view to treatment before fibrosis onset.

### Innovations and breakthroughs

In two thirds of HCV infected patients without significant liver damage, there is no fibrosis progression. In these patients, fibrosis progression is associated with abnormal liver tests and elevated BMI.

### Applications

These observations may be helpful to suggest if a patient should receive an antiviral therapy. A treatment should be counselled to the patients with abnormal liver test and elevated BMI.

### Terminology

Liver fibrosis is the excessive accumulation of a scarred tissue that occurs in most types of chronic liver diseases. This fibrosis can progress to cirrhosis. The transaminases are a group of liver enzymes including alanine aminotransferase (ALT). Elevated transaminases can be an indicator of liver damage.

### Peer review

Sobesky *et al* present an interesting study describing the features and development of individuals with chronic hepatitis C infection and almost normal histological findings. The paper is properly written.

Nuclear  $\beta$ -catenin expression as a prognostic factor in advanced colorectal carcinoma. *World J Gastroenterol* 2008; 14(24): 3866-3871 Available from: URL: <http://www.wjgnet.com/1007-9327/14/3866.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.3866>

### Abstract

**AIM:** To investigate the changing pattern of  $\beta$ -catenin expression and its prognostic value in advanced colorectal cancer (CRC).

**METHODS:** Archival tumor samples were analyzed for  $\beta$ -catenin using immunohistochemistry (IHC) in 95 patients with advanced CRC.

**RESULTS:** Membranous  $\beta$ -catenin expression was found in the normal colorectal epithelium. Almost 100% of CRC cases showed membranous and cytoplasmic expression, and 55 (58%) cases showed nuclear expression. In univariate (Kaplan-Meier) survival analysis, only the nuclear index (NI) was a significant predictor of disease-free survival (DFS) ( $P = 0.023$ ;  $n = 35$ ), with a NI above the median associated with longer DFS (34.2 mo) than those with a NI below the median (15.5 mo) ( $P = 0.045$ , ANOVA). The other indices were not significant predictors of DFS, and none of the three tested indices (for membranous, cytoplasmic, or nuclear expression) predicted disease-specific survival (DSS). However, when dichotomized as positive or negative nuclear expression, the former was a significant predictor of more favorable DFS ( $P = 0.041$ ) and DSS ( $P = 0.046$ ).

**CONCLUSION:** Nuclear  $\beta$ -catenin expression provides additional information in predicting patient outcome in advanced CRC.

### INTRODUCTION

$\beta$ -catenin is a 92-kDa multifunctional protein that, in its membrane location, links the intracellular part of the E-cadherin complex to actin cytoskeleton, which is a critical step in morphogenesis and maintenance of tissue integrity<sup>[1]</sup>. Alternatively, through Wnt signaling-mediated stabilization,  $\beta$ -catenin may act as a down-stream transcriptional trans-activator of several target genes<sup>[2]</sup>. Alterations in  $\beta$ -catenin protein expression levels and genetic rearrangement located in  $\beta$ -catenin exon 3 have been shown to contribute to the malignant character of various carcinomas and are likely to affect both intercellular adhesion and signal transduction, which are believed to be two independent functions of  $\beta$ -catenin protein<sup>[3]</sup>.

The rare occurrence of mutations in  $\beta$ -catenin exon 3 has been previously documented in ulcerative colitis-related neoplastic progression<sup>[4]</sup> and in colorectal cancer (CRC) as well<sup>[5]</sup>. Immunohistochemical studies suggest that the observed accumulation in  $\beta$ -catenin protein is probably due to genomic alterations in  $\beta$ -catenin coding regions, particularly in exon 3.

The impact of aberrations in  $\beta$ -catenin expression on the clinical outcome of CRC is controversial. Some studies reported prognostic value for cytoplasmic rather than nuclear expression<sup>[6]</sup>, whereas others showed that nuclear accumulation of  $\beta$ -catenin may be an independent marker of unfavorable prognosis<sup>[7,8]</sup>. The aim of this study was to evaluate the possible role of  $\beta$ -catenin expression as a predictor of clinical outcome in advanced CRC patients.

## MATERIALS AND METHODS

### Study material

Ninety-five patients with advanced colorectal carcinoma (CRC), enrolled consecutively from CRC patients attending our clinic for therapeutic procedures during the late 1990s, were included in our study. Of these 95 patients, 60 had metastases at diagnosis (Stage IV disease), while the remaining 35 patients (with stage II and III disease at baseline) subsequently developed a metastatic disease during the mean follow-up (FU) time of  $25.1 \pm 27.8$  (SD) mo. All patients were treated at the Department of Oncology and Radiotherapy, Turku University Hospital, according to the protocols in routine use for the treatment of CRC patients with stage II, III or IV disease at that time. The 95 patients included in the present study were enrolled into the study cohort between October 1998 and August 2003. All patients were prospectively followed-up until death or until their last clinical visit (March 2007), with the median FU-time of 27.6 (range 3-150) mo. The study was approved by the TUH Ethics Committee and was conducted in accordance with the Declaration of Helsinki. Samples were collected with the endorsement of the National Authority for Medico-legal Affairs.

Key clinical data for these patients are shown in Table 1. Of the 95 cases, 38 were women and 57 were men. The mean age was 61.5 (range 24-78) years. The majority ( $n = 39$ ) of the tumors were localized in the left colon, followed in the order of frequency by the right colon ( $n = 24$ ), rectum ( $n = 24$ ), and colon transversum ( $n = 7$ ). At the time of diagnosis, 15 patients were Stage II, 20 were Stage III and 60 patients were Stage IV. Accordingly, the majority ( $n = 63$ , 66.3%) had T3 tumors, and almost half of the patients had lymph node involvement at the time of diagnosis ( $n = 46$ ). The patients were selected for the cohort on the basis of both the diagnosis and treatment they received, and each patient was assigned to one of two treatment arms: (1) 20 were treated with irinotecan alone, and (2) 75 received a combination of irinotecan and 5-fluorouracil (5-FU). The chemotherapy regimen the patients received was included in a previous study investigating irinotecan combined with bolus 5-fluorouracil and folinic acid<sup>[9]</sup>.

### $\beta$ -catenin immunostaining

Formalin-fixed, paraffin-embedded primary colorectal tumor tissue was obtained from 95 patients. Sections were cut serially at 5  $\mu$ m for routine haematoxylin and eosin staining and for immunohistochemical (IHC) analysis. An experienced pathologist confirmed all histological diagnoses. IHC analysis was done using an automatic system (BenchMark XT, Ventana Medical Systems, Inc. Tucson, Arizona, USA). This fully automated processing of bar code labeled slides included baking of the slides, solvent free deparaffinization, antigen retrieval in a cell conditioning buffer CC2 (Mild: 36 min conditioning, and standard: 60 min conditioning), and incubation with the monoclonal mouse  $\beta$ -catenin antibody (clone CAT-5H10, isotype IgG1-kappa, Zymed

Laboratories, San Francisco, CA) at a dilution 1:200 (32 min, 37°C). The dilution of the primary antibody was based on previous dilution experiments. UltraView™ Universal DAB (a biotin-free, Multimer-based detection system for the specific and sensitive detection of mouse IgG, mouse IgM, and rabbit IgG primary antibodies) was used. UltraView DAB includes: ultraView Universal HRP, ultraView Universal DAB Inhibitor, ultraView Universal DAB Chromogen, ultraView Universal DAB H<sub>2</sub>O<sub>2</sub>, and ultraView Universal DAB Copper. Counterstaining with haematoxylin (2021) was done for 4 min, and post-counterstaining with a blueing reagent (2037) was done for 4 min as well. After staining, the sections were dehydrated in ethanol, cleared in xylene, and covered with Mountex and cover slips.

### Evaluation of $\beta$ -catenin staining

$\beta$ -catenin staining was evaluated using regular light microscopy by an observer who was blind to the clinical data (AB). All membranous, cytoplasmic, and nuclear staining were evaluated separately. For cell membrane staining, four categories were used (+++, ++, +, -), starting from equivalent to normal to entirely negative<sup>[10]</sup>. The cytoplasmic staining was also graded into four categories: (0) Negative, no detectable staining, (1) Weak, but still detectable staining, (2) Moderate, clearly positive but still weak, (3) Heavy staining, intense<sup>[11]</sup>.

**Figure 1** Different immunohistochemical (IHC) staining patterns for  $\beta$ -catenin in colorectal carcinomas. **A:** In normal colonic epithelium,  $\beta$ -catenin is predominantly expressed in the cell membrane; **B:** A medium-powered view of a colonic adenocarcinoma showing membranous and cytoplasmic expression of  $\beta$ -catenin; **C:** This case shows intense nuclear expression of  $\beta$ -catenin.

The nuclear staining index (NI) was also graded to into four categories (+++, ++, +, -): (0) Negative, only blue staining seen, (1) Weak, blue staining clearly seen through brown staining, (2) Moderate, blue scarcely seen through brown staining, nuclei appear darker than the cytoplasm, (3) Heavy staining, no blue seen through brown staining, nuclei appear darker than the cytoplasm. Three staining indexes were calculated: the membrane index (MI), cytoplasmic index (CI), and nuclear index (NI). These indices were calculated with both the intensity of staining and the fraction of positively-stained cells taken into account using the following formula:

$$I = 0 * f_0 + 1 * f_1 + 2 * f_2 + 3 * f_3$$

where I is the staining index and  $f_0$ - $f_3$  are the fractions of the cells showing a defined level of staining intensity (from 0 to 3). Theoretically, index scores could vary between 0 and 3<sup>[12]</sup>. The reproducibility of the evaluation of the  $\beta$ -catenin staining indices was tested by employing two observers (AE, AB), and the estimations showed good correlation and reproducibility (Pearson's r: MI, CI, and NI, were 0.77, 0.91, and 0.90, respectively).

### Statistical analysis

Statistical analyses were performed using SPSS® (SPSS, Inc., Chicago, USA) and STATA (Stata Corp., Texas, USA) software packages (SPSS for Windows, version 14.0.1 and STATA/SE 9.2). Frequency tables were analyzed using the Chi-square test, which included the likelihood ratio (LR) or Fischer's exact test to assess the significance of the correlation between the categorical variables. Odds ratios and their 95% confidence intervals (95% CI) were calculated where appropriate, using the exact method. Differences in the means of continuous variables were analyzed using non-parametric tests (Mann-Whitney or Kruskal-Wallis) for 2- and K-independent samples, respectively. ANOVA (analysis of variance) was only used for deriving the mean values (and their SD) for each individual category. Bivariate correlation (Spearman rho) and scatterplots were used to check the correlations between two continuous variables (MI, CI *vs* DFS, DSS), controlled by linear regression analysis (R and R<sup>2</sup>) for linearity. Univariate survival (life-table) analysis for the outcome measure (DSS, DFS) was based on Cox's method (indices treated as continuous

variables), and/or using Kaplan-Meier analysis (indices with Median as cut-off). Multivariate survival analysis was carried out using Cox's proportional hazards model in a backward stepwise manner with the log-likelihood ratio (L-R) significance test, using the default values for enter and exclusion criteria. The assumption of proportional hazards was controlled by log-minus-log (LML) survival plots. In all tests, the values  $P < 0.05$  were regarded statistically.

## RESULTS

$\beta$ -catenin expression patterns are illustrated in Figure 1. The expression pattern of  $\beta$ -catenin was predominantly membranous and weakly cytoplasmic in normal colonic epithelium but the pattern was cytoplasmic, membranous, or nuclear in the tumor tissue. Almost 100% of the cases showed membranous and cytoplasmic  $\beta$ -catenin expression, with nuclear expression being observed in 55 (58%) cases. The mean values of the three  $\beta$ -catenin staining indices (MI, CI, and NI) were 1.14, 1.26, and 0.80, respectively, and the median values were 1.20, 1.30, and 0.77, respectively.

We analyzed the three  $\beta$ -catenin staining indices in relation to all available clinical variables and tumor characteristics in univariate analyses. Using the median cut-off point, there was no correlation between  $\beta$ -catenin expression and most of the clinical variables (age, sex, stage, and grade). However,  $\beta$ -catenin expression (CI and NI) was borderline or significantly related ( $P = 0.06$ ,  $P = 0.04$ , respectively) to the localization of the primary tumor, with expression being more intense in descending colon and rectum carcinomas than in lesions of the ascending and transverse colon.

There was also a marginal relation ( $P = 0.086$ ) between NI and response to treatment in that the patients with a NI below the median had a response rate (24/48, 50%) better than those with a NI above the median (16/47, 34.0%). A direct relationship ( $P = 0.068$ ) was found between the MI and response to treatment when the 75th percentile was used; patients with a MI  $> 75\%$  had a higher response rate (9/16; 56.3%) than patients with a MI  $< 75\%$  (31/79, 39.2%).

In univariate (Kaplan-Meier) survival analysis

**Figure 2** Disease-specific survival predicted by the nuclear index (NI) of colorectal tumors. The stippled line: nuclear expression positive. The continuous line: nuclear expression negative. The Kaplan-Meier, log rank test;  $P = 0.046$ . One patient died of another cause and was excluded from analyses.

**Figure 3** Disease-free survival predicted by the nuclear index (NI) of colorectal tumors. The stippled line: nuclear expression positive. The continuous line: nuclear expression negative. The Kaplan-Meier, log rank test;  $P = 0.041$ .

(calculable for 35 patients with stage II or III disease) with the median as the cut-off, only the NI was a significant predictor of more favorable disease-free survival (DFS) ( $P = 0.023$ ). The patients with a NI above the median had longer DFS (34.2 mo) than those with a NI below the median (15.5 mo) ( $P = 0.045$ , ANOVA). The other indices were not significant predictors of DFS, and none of the three indices predicted disease-specific survival (DSS) in univariate analysis (Cox or Kaplan-Meier).

When the patients were stratified into two groups: nuclear expression positive ( $n = 55$ ) and nuclear expression negative ( $n = 39$ ), the former was a significant predictor of more favorable DSS ( $P = 0.046$ ) (Figure 2) and DFS ( $P = 0.041$ ) (Figure 3).

When  $\beta$ -catenin expression was analyzed jointly with E-cadherin expression<sup>[13]</sup> as a potential predictor of disease outcome, the combined (E-cadherin and  $\beta$ -catenin) cytoplasmic index did not provide any significant prognostic information.

We also reproduced the grading used by Ougolkov *et al*<sup>[7]</sup>, resulting in 6/46 cases with nuclear expression at the invasive front, 20/46 cases with a diffuse nuclear pattern, and 20/46 tumors with a mixed pattern. When correlated with the treatment response and disease outcome, this grading system did not produce any results with predictive or prognostic value.

## DISCUSSION

As compared with the sub-cellular distribution of  $\beta$ -catenin in normal colonic mucosa, neoplastic cells demonstrated a distinct shift from a membranous localization to a more widespread distribution (membranous, cytoplasmic, and nuclear) in cancer lesions. This is in line

with previous reports describing  $\beta$ -catenin expression in cancer cells with this type of altered pattern<sup>[14,15]</sup>. For example, Wong *et al*<sup>[16]</sup> observed no nuclear  $\beta$ -catenin accumulation in normal tissues, whereas it was present in 8% of polyps, 92% of adenomas, and 100% of carcinomas. In the present series, nuclear expression or accumulation was observed in 48% of the cancer samples, which is in line with several other reports<sup>[7,17]</sup>. Interestingly, in 13% of the cases with nuclear expression,  $\beta$ -catenin was expressed by the tumour cells at the invasion fronts, a figure very similar to the 9% reported by Ougolkov *et al*<sup>[7]</sup>.

We did not find significant correlations between the three  $\beta$ -catenin expression patterns (MI, CI, and NI) and most of the clinical variables recorded (age, sex, grade, and stage), except for tumor localization. Accordingly,  $\beta$ -catenin expression, both CI and NI, was more intense in carcinomas of the descending colon and rectum as compared with lesions localized in the ascending and transverse colon. Similar observations have been reported by previous studies<sup>[18-20]</sup>. There is increasing evidence to suggest that molecular mechanisms and molecular phenotypes differ in carcinomas arising in the proximal and distal segments of the large bowel<sup>[21]</sup>. The involvement of different molecular pathways in colorectal carcinogenesis is exemplified by the fact that cancers of “mutator” phenotypes preferentially occur in the proximal (right side) colon, whereas the adenoma-carcinoma sequence phenotype is characteristic of carcinomas in the distal (left side) colon and rectum<sup>[22,23]</sup>. Corresponding differences have also been shown in association with other potential prognosticators<sup>[24]</sup>.

Interestingly, a marginally significant relation was observed between the NI and MI and response to treatment. Accordingly, the patients who did not respond to treatment had a NI above the median, whereas patients

who had a high MI responded better to treatment. The significance of these observations remains to be elucidated in a larger study. There is an obvious need to identify novel molecular targets for cancer therapeutics, and in this respect, the recent data showing that suppression of  $\beta$ -catenin can inhibit the neoplastic growth of APC-mutant colorectal cancer are of interest<sup>[25]</sup>.

The correlation between  $\beta$ -catenin expression pattern and clinical outcome is a controversial subject. Some studies reported that cytoplasmic rather than nuclear accumulation of  $\beta$ -catenin is significantly related to metastasis-free survival in CRC<sup>[6]</sup>. The same was reported regarding the potential prognostic value of nuclear expression. There are studies reporting that positive nuclear expression at the invasive front of the tumor predicts shorter survival<sup>[7,19]</sup>. However, other workers failed to find any correlation between nuclear expression and survival in CRC<sup>[17,26]</sup>. In contrast, our data show that nuclear expression is a significant predictor of more favorable DSS and DFS (Figures 2 and 3). We also analyzed our samples using the same system as originally described by Ougolkov *et al*<sup>[7]</sup>. In our study, however, this special grading system did not confirm the original observation that nuclear expression at the invasive front of the tumor predicts a shorter survival<sup>[7]</sup>.

There are multiple explanations for the inconsistent and, in part, discrepant results reported in different studies<sup>[6,7,17,19,26]</sup>. Such potential confounding factors might include the size of tissue samples, intrinsic tumor heterogeneity, lack of standardization in the evaluation of positive and negative results, and different immunohistochemical staining and grading methods with varying degree of sensitivity. In addition, our patients represent advanced CRC, with the majority of patients having stage IV disease, as compared with the Ougolkov study, where the majority of patients had stage II CRC. Also, the type of treatment may have played a role in the detected relationships.

Cell-cell adhesion molecules are believed to participate in the processes of invasion, migration and metastasis<sup>[27-29]</sup>. In this regard, the E-cadherin and  $\beta$ -catenin complex plays a critical role in cell-cell adhesion. E-cadherin is a member of the cadherin family that mediates calcium-dependent adhesion to ensure the maintenance of a normal phenotype of epithelial cells<sup>[1,30]</sup>.  $\beta$ -catenin binds directly to the cytoplasmic domain of E-cadherin and to the actin microfilament network of the cellular cytoskeleton. This binding is essential for stable cell-cell adhesion<sup>[31]</sup>.

It can be reasoned that altered expression of  $\beta$ -catenin (i.e., the shift from membranous to cytoplasmic and nuclear sites) might compromise the integrity of the E-cadherin/ $\beta$ -catenin complex and result in weaker cell-cell adhesion in cancer cells. Thus, it seems feasible to assess whether altered co-expression patterns of these two markers is of any predictive value in CRC. For that purpose, we combined both the membranous and cytoplasmic E-cadherin expression with membranous and cytoplasmic  $\beta$ -catenin expression to compare normal (MI/MI) and abnormal (CI/CI)

co-expression, respectively, of these two markers as previously analysed in CRC<sup>[13]</sup>. To our disappointment, however, neither the membranous nor the cytoplasmic E-cadherin/ $\beta$ -catenin index (analyzed in two different modes) provided any useful information as to DFS or DSS. Thus, no added value can be obtained with analyzing E-cadherin expression together with  $\beta$ -catenin expression as compared to the analysis of the latter alone (Figures 2 and 3).

Taken together, the present results confirm that  $\beta$ -catenin expression is markedly altered in the vast majority of colorectal cancers. This shift from normal membranous expression to the cytoplasmic (CI) and nuclear (NI) patterns seems to bear some association with the localization of the primary tumour, being most pronounced in lesions of the descending colon and rectum. Although the association of CI and NI to treatment response remains unclear, NI seems to provide some prognostic value in predicting more favourable DFS and also DSS, when dichotomized as NI+/NI-expression. Many of the issues still remain unanswered, however, and additional clinical and experimental studies are needed to fully elucidate the role of  $\beta$ -catenin in colorectal carcinogenesis and its potential usefulness as an independent predictor of disease outcome.

### Abstract

**AIM:** To determine the immunomodulatory effect of Shiitake (a mushroom extract), we tested its effect on liver-mediated immune regulation in a model of immune-mediated colitis.

**METHODS:** Four groups of mice were studied. Colitis was induced by intracolonic instillation of TNBS in groups A and B. Groups A and C were treated daily with Shiitake extract, while groups B and D received bovine serum albumin. Mice were evaluated for development of macroscopic and microscopic. The immune effects of Shiitake were determined by FACS analysis of intra-hepatic and intrasplenic lymphocytes and IFN- $\gamma$  ELISPOT assay.

**RESULTS:** Administration of Shiitake resulted in marked alleviation of colitis, manifested by significant improvement in the macroscopic and microscopic scores, and by reduction in IFN- $\gamma$ -producing colonies in group A, compared to group B mice (1.5 pfu/mL vs 3.7 pfu/mL, respectively). This beneficial effect was associated with a significant increase in the intra-hepatic CD8<sup>+</sup> lymphocyte trapping, demonstrated

by an increased intrasplenic/intrahepatic CD4/CD8 lymphocyte ratio. These effects were accompanied by a 17% increase in the number of intrahepatic natural killer T (NKT) cells. A similar effect was observed when Shiitake was administered to animals without disease induction.

**CONCLUSION:** Shiitake extract affected liver-mediated immune regulation by altering the NKT lymphocyte distribution and increasing intrahepatic CD8<sup>+</sup> T lymphocyte trapping, thereby leading to alleviation of immune-mediated colitis.

### INTRODUCTION

Mushrooms have been valued by humans throughout history as a food product and for medical purposes<sup>[1]</sup>. Mushrooms have been used as a medicine in the Far East since ancient times. Extracts and isolated metabolites from mushrooms are known to modulate immune responses<sup>[2]</sup>, resulting in enhanced innate and acquired disease resistance. The major immunomodulatory effects of the active substances derived from mushrooms include mitogenicity and activation of immune effector

cells, such as lymphocytes, macrophages, and natural killer cells. Activation of these cells can result in the production of cytokines, including interleukins (ILs), tumor necrosis factor alpha (TNF- $\alpha$ ), and interferon gamma (INF- $\gamma$ )<sup>[2]</sup>. The ability of select mushroom extracts to modulate the differentiation capacity of CD4<sup>+</sup> T cells into mature Th1 and/or Th2 subsets has been documented recently<sup>[3]</sup>.

Other recent studies have suggested that these extracts may have a profound effect on Th1- or Th2-immune mediated disorders<sup>[4]</sup>. A number of bioactive molecules, mostly polysaccharides with anti-tumor properties have been identified in mushroom-derived formulations<sup>[5]</sup>.

Lentian, a (1-3)- $\beta$ -glucan from *Lentinus edodes* (Shiitake), is licensed as an immunostimulatory drug<sup>[6]</sup>. Pre-treatment of mice with lentian results in increased concentrations of TNF- $\alpha$ , IL-12, and INF- $\gamma$ , as well as an increase in the number of *Listeria monocytogenes*-specific CD8 T cells in the spleen. The bacterial burden in the spleen and liver of mice was reduced significantly during primary and secondary listeria infection after lentian pre-treatment of mice. In addition, *Lentinus edodes* and its active component, the polysaccharide lentian, have been found to be effective against several tumors, including prostate and gastric tumors, and leukemia<sup>[7,8]</sup>. However, the mechanism of action of lentian is not clearly understood and there is currently no data on its effect on immune-mediated diseases.

The role of liver in the pathogenesis of various immune-mediated disorders is well known<sup>[9]</sup>. Liver contains a mixture of lymphocytes including both conventional T and B cells, as well as a distinct population of resident liver lymphocytes. Furthermore, liver is involved in the trapping and destruction of activated T cells<sup>[10]</sup>. As of this writing, the precise role of the liver in immune cell trapping and destruction is not fully understood, although one theory suggests that cells already in the process of apoptosis are sequestered in the liver<sup>[11,12]</sup>. A second theory suggests that the liver plays an active role by destroying activated T cells through a local tolerance mechanism that causes clonal deletion<sup>[13,14]</sup>.

The goal of the present study was to determine the effect of Shiitake on colonic inflammation in a murine model of immune-mediated colitis and to examine the role of liver in systemic tolerance induction in this setting.

## MATERIALS AND METHODS

### Animals

Normal inbred 2-4 mo old C57BL male mice were obtained from Harlan, Israel, and maintained in the Animal Core of the Hadassah-Hebrew University Medical School. Mice were maintained on standard laboratory feed and kept in 12-h light/dark cycles. All of the experiments were performed in accordance with the institute's ethical committee for animal handling.

### Experimental design

Four groups of mice consisting of 10 animals each

were studied. Mice in experimental group A were fed Shiitake extract (50 g/mouse), starting 2 d before (day 2), until 9 d after induction of colitis by intra-rectal administration of trinitrobenzene sulfonic acid (TNBS, day 9) as described previously<sup>[15]</sup>. Mice in group B were fed bovine serum albumin (BSA, 50 g/mouse). Group C was fed with Shiitake extract (50 g/mouse) from day 0 of experiment until day 9. Mice in control group D were fed with BSA, 50 g/mouse from day 0 to day 9. Mice were sacrificed on day 10.

### Preparation and administration of the mushrooms

**Source:** Mushroom spawn (*Lentinus edodes* 4087) used in this study was purchased from Sylvan (France).

**Mushroom culture:** Mushrooms were grown on a 1:1 mixture of cotton and wheat straws. The straws were oven dried at 60°C for 24 h and milled to 1-3 cm particle size. The straw mixture was wetted to 70% water content and packed into 4 kg polypropylene bags containing a microporous filter. The bags were steam sterilized at 100°C for 2 h, then cooled to 25°C for inoculation with 2% spawn w/w. The culture was incubated at 25°C for 30 d. For fruiting, the temperature was reduced to 16°C with a relative humidity of 90%, 12 h daily light and CO<sub>2</sub> concentration of 600-800 ppm. The fruiting bodies were then oven dried at 60°C for 24 h and milled to 1 mm particle size.

**Experimental colitis:** Colitis was induced by a single enema of TNBS (Sigma, USA)<sup>[16]</sup>. Fifty milligrams of TNBS was dissolved in 20% ethanol (total volume 1 mL) and instilled through a rubber catheter 10 cm into the colon *via* the anus, without any bowel preparation. The animals were kept fasting for 24 h prior to the procedure and were anesthetized with Ketalar. After instillation, the mice were maintained in the supine position until recovery from the anesthesia to prevent immediate leakage of the instillate.

**Assessment of colonic damage:** Assessment of colonic damage was performed 10 d following induction of colitis<sup>[15]</sup>. Ten centimeters of the distal colonic tissue was removed and opened by a longitudinal incision and gently washed with saline. The freshly opened colonic segments were examined by an independent observer blinded to the treatment. The extent of the mucosal damage was assessed. Four macroscopic parameters were determined: degree of colonic ulceration, intestinal and peritoneal adhesions, wall thickness, and degree of mucosal edema. Each parameter was graded on a scale from 0 (completely normal) to 4 (most severe).

**Colonic histology:** For each animal, 6 specimens of colonic tissue from the distal 10 cm were removed for histological analysis. The tissues were fixed in formaldehyde, then sliced into 4 to 6 mm pieces, dehydrated in ethanol, embedded in paraffin wax, sectioned, and stained with hematoxylin and eosin. The degree of inflammation on microscopic sections of the colon was graded semi-quantitatively from 0 to 4.

Grade 0: Normal with no signs of inflammation; Grade 1: very low level of leukocyte infiltration; Grade 2: Low level of leukocyte infiltration; and Grade 3: High level of infiltration with high vascular density and bowel wall thickening; Grade 4: Transmural infiltration, with loss of goblet cells, high vascular density, wall thickening, and disruption of normal bowel architecture. Two experienced examiners who were blinded to the study group performed the grading.

#### **Evaluation of the role of natural killer T (NKT) lymphocytes and the liver in CD4 trapping**

**Liver and spleen lymphocyte isolation:** Splenocytes and liver lymphocytes were isolated as described previously with the following modifications<sup>[17]</sup>. The inferior vena cava was cut above the diaphragm and the liver was flushed with 5 mL cold PBS until it became pale in color. The connective tissue and the gallbladder were removed, and the liver was placed in a 10 mL dish containing cold sterile PBS. Splenocytes and liver lymphocytes were isolated by crushing the spleen and liver through a stainless mesh (size 60, Sigma Chemical Co., St. Louis MO)<sup>[16]</sup>. The resulting cell suspension was placed in a 50 mL tube for 3 min, washed twice with cold PBS (1250 r/min for 10 min), and all insoluble debris was removed. Cells were re-suspended in PBS, and passed through a nylon mesh pre-soaked in PBS. Unbound cells were collected and washed twice in 45 mL PBS. For liver and spleen lymphocyte isolation, the cells were suspended in a 50 mL tube containing 7 mL PBS, and underlaid with 20 mL Histopaque 1077 (Sigma Diagnostics, St. Louis, MO). The tube was centrifuged at 1640 r/min for 15 min at room temperature. Cells at the density interface were collected, diluted in a 50 mL tube, and washed twice with ice-cold PBS (pelleting at 1250 r/min for 10 min). Approximately  $1 \times 10^6$  cells per mouse liver were recovered. The cell viability, assessed by Trypan blue staining was > 95%. Both splenocytes and liver-associated lymphocytes were isolated from every animal in all the experimental groups.

**Flow cytometry analysis for determination of CD4<sup>+</sup>, CD8<sup>+</sup> and NKT lymphocyte subsets:** Following lymphocyte isolation, triplicate samples of  $2 \times 10^5$  to  $5 \times 10^5$  cells/500  $\mu$ L PBS were placed in Falcon 2052 tubes, incubated with 4 mL 1% BSA for 10 min, and centrifuged at 1400 r/min for 5 min. The cells were resuspended in 10  $\mu$ L FCS with 1:20 FITC-anti mouse CD3 antibody, 1:20 PE-anti mouse CD4 antibody, 1:20 APC-anti mouse CD8 antibody, or 1:20 FITC-anti mouse NK1.1 antibody (NKR-P1C, Pharmingen, USA), and mixed every 10 min for 30 min. The cells were washed twice in 1% BSA, and kept at 4°C until reading. In the control group, only 5  $\mu$ L of 1% BSA was added. Analytical cell sorting was performed on  $1 \times 10^4$  cells from each group with a fluorescence-activated cell sorter (FACSTAR plus, Becton Dickinson). Only live cells were counted, and background fluorescence from non-antibody-treated lymphocytes was subtracted. Gates were set by forward- and side-scatter to exclude dead cells and red blood cells. Data

was analyzed by the Consort 30 two-color contour plot (Becton Dickinson, Oxnard, CA) or Cellquest program.

**Antigen specific IFN ELISPOT assays:** IFN spot forming cells (SFC), were identified using a modified subject-specific, antigen-directed ELISPOT assay (Mabtech, Nacka, Sweden)<sup>[18]</sup>. Filtration plates (96 well), coated with high protein binding hydrophobic PVDF membrane were used (Millipore Corp., Bedford, MA, USA). The plates were coated with 1-D1K anti-IFN coating antibody (15 mg/mL, Mabtech, Nacka, Sweden) for 24 h at 4°C. Peripheral blood mononuclear cells (PBMC) were isolated by Ficoll gradient separation of 2 mL whole blood samples, collected in acid citrate dextrose tubes, and processed within 1 h. The PBMC were washed twice in RPMI 1640 with 10% fetal bovine serum. The cells were cultured in 96 well plates ( $1 \times 10^5$  cells/well) with RPMI 1640 and 10% FBS. Triplicate samples were prepared with 2 doses of the study drug from each subject (5 and 10 g/mL) or phytohemagglutinin (PHA, 2.5 g/mL) without antigen. Plates were incubated for 48 h at 37°C under 5% CO<sub>2</sub>. The plates were then washed and 100  $\mu$ L biotinylated antibody (7-B6-1-biotin, Mabtech, Nacka, Sweden) at a concentration of 1  $\mu$ g/mL in filtered PBS with 0.5% FBS. Plates were incubated for 3 h at room temperature. Following washing, 100  $\mu$ L of streptavidin-alkaline phosphatase was added, and the plates were incubated for 90 min at room temperature. The plates were washed and substrate (BioRad, Richmond, CA) was added for 30 min, until reddish-purple spots appeared. Using a dissection microscope, dark spots, reflecting IFN- $\gamma$ -secreting clones, were counted. The results were expressed as mean IFN- $\gamma$ -secreting cells per  $10^5$  PBMC (in triplicate), after subtraction of the mean spots from wells without the study drug.

#### **Statistical analysis**

Statistical analysis was performed using the student's *t* test. *P* < 0.05 was considered significant.

## **RESULTS**

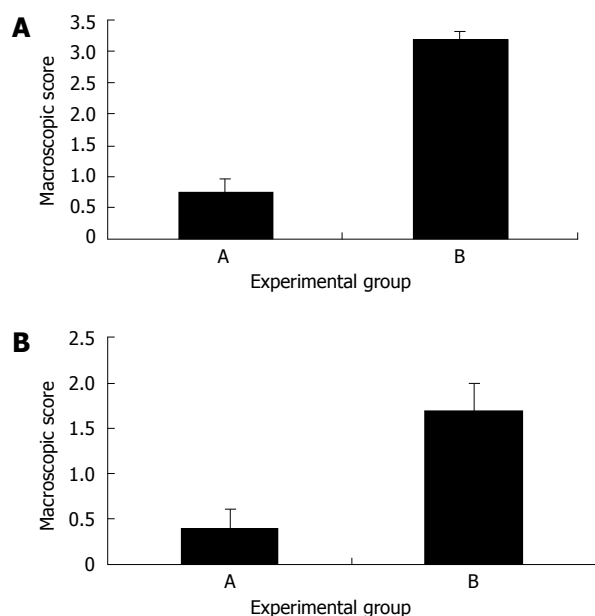

#### **Effect of Shiitake on survival**

Shiitake administration was associated with significant improvement in the survival of animals in group A, compared with the control group B (BSA control). Of the mice in group A, 100% survived *vs* 44% in group B. All mice in control groups C and D survived.

#### **Effect of Shiitake on severity of experimental colitis**

**Macroscopic scoring of colitis:** The severity of colitis in mice treated with Shiitake mushroom showed marked improvement compared with mice in group B, that were fed BSA (mean macroscopic score  $0.75 \pm 0.2$  and  $3.2 \pm 0.1$  for groups A and B, respectively, *P* < 0.005, Figure 1A). No significant signs of colitis were observed in mice in groups C and D.

**Histological assessment of colitis:** Similar results

**Figure 1** A: Effect of Shiitake administration on the macroscopic score of experimental colitis: Shiitake administration significantly alleviated the severity of colitis in group A mice compared with mice in control group B; B: Effect of Shiitake administration on the microscopic score of colitis: Shiitake administration alleviated the severity of colitis in group A mice compared with mice in control group B.

were obtained in the total microscopic score of colitis. The mean microscopic score was  $0.4 \pm 0.2$  in group A *vs*  $1.7 \pm 0.3$  in group B (Figure 1B). Histological evaluation of colonic tissues showed a marked reduction in the inflammatory response in Shiitake fed mice (Figure 2A). By contrast, mice in group B showed severe colitis, manifested by inflammatory infiltration of the mucosa, and patchy necrosis of the mucosa and submucosa with purulent and fibrinoid material extending up to the muscle layer. The muscle and serosal layers showed infiltration by acute and chronic inflammatory cells (Figure 2B).

#### Effect of Shiitake on NKT lymphocyte distribution

The number of intra-hepatic NKT cells was determined in all experimental groups. The number of liver NKT cells was increased in group A, compared to group B (29.1% *vs* 18.6%, Figure 3A). Liver NKT cells were also increased in group C compared with group D (32.1% *vs* 24.1%). The intrasplenic NKT cell counts, reflecting the total systemic pools of NKT cells, were also determined. A decrease in NKT cell number was observed in group A compared with group B, and in group C compared with group D (1.1 *vs* 2.4 and 1.6 *vs* 3.3, respectively). To determine whether the intra-hepatic NKT increase was part of a systemic increase in NKT cells, the intrasplenic/intrahepatic NKT cell ratio was calculated. This ratio was significantly reduced in the Shiitake fed mice (groups A and C *vs* groups B and D, Figure 3B).

#### Effect of Shiitake on the intrahepatic and systemic CD4/CD8 ratios

The intra-hepatic CD4/CD8 ratio was reduced signifi-

**Figure 2** Histological evaluation of colonic tissues showed a marked reduction in the inflammatory response in Shiitake fed mice (A). By contrast, severe colitis was observed in mice in group B, manifested by inflammatory infiltration of the mucosa, and patchy necrosis of the mucosa and submucosa, with purulent and fibrinoid material extending to the muscle layer (B).

cantly in mice that were fed Shiitake compared with those fed BSA (1.5 for group A *vs* 2.4 in group B,  $P < 0.005$ , Figure 4). A marked decrease in the intra-hepatic CD4/CD8 ratio was also noted in group C compared with the naïve group D (1.5 *vs* 2,  $P < 0.005$ , Figure 4). Interestingly, an opposite effect was noted when the intrasplenic CD4/CD8 ratios were calculated. Intra-hepatic CD8 trapping in Shiitake fed mice was associated with an increase in the peripheral (intrasplenic) CD4/CD8 ratio compared with BSA fed mice (4 and 2.1 for groups A and B, respectively;  $P < 0.005$ ; Figure 4). However, even in mice without colitis, feeding Shiitake caused the peripheral CD4/CD8 ratio to decrease compared with naïve mice (2.3 in group C *vs* 3.9 in group D,  $P < 0.005$ , Figure 4). The intrasplenic/intrahepatic CD4/CD8 ratio was also calculated. This ratio was increased in groups A, C, D, while it was reduced significantly in group B (2.6, 1.5, 1.80 *vs* 0.9, respectively;  $P < 0.005$  for all; Figure 5). The increased peripheral/liver CD4/CD8 ratio suggests CD8 lymphocyte trapping in the liver during systemic tolerance induction.

#### Effect of Shiitake on antigen-directed IFN ELISPOT

The number of antigen specific T-cell colonies secreting IFN- $\gamma$  was reduced significantly in group A compared with group B (1.5 pfu/mL *vs* 3.7 pfu/mL,  $P < 0.005$ ), suggesting a specific effect of Shiitake on T cells involved in Th1-mediated immune colitis.

**Figure 3** A: The effect of Shiitake administration on intrahepatic NKT cells. Liver NKT cell numbers were increased in groups A and C (which received Shiitake), compared with mice in group B and in control group D; B: The effect of Shiitake administration on the intrasplenic/ intrahepatic NKT cell ratio.

## DISCUSSION

Previous studies have shown that Lentinan, a (1-3)- $\beta$ -glucan obtained from *Lentinus edodes*, has anti-tumor activity, but the purported immunomodulatory effect has not yet been tested in immune-mediated disorders<sup>[19-21]</sup>. The present study indicates that a Shiitake-derived formulation has a beneficial effect in an animal model of TNBS-induced colitis. Administration of this formulation significantly improved the survival rate, and alleviated the macroscopic and microscopic evidence (scores) of colitis. These results were associated with a dramatic reduction in the number of antigen-specific IFN- $\gamma$ -producing colonies. The present study has shown that the liver has a role in mediating systemic induction of tolerance in the setting of our experimental model. This role comprises of sequestering and possibly destroying potentially harmful effector cells, resulting in disease amelioration. The systemic effect of Shiitake in reducing TNBS-induced colitis, was mediated by the trapping of CD8 T cells in the liver. Altered NKT lymphocyte distribution was also associated with the protective effect of Shiitake.

Shiitake and its active component, the polysaccharide lentinan, have previously been shown to be effective against different tumors<sup>[20,21]</sup>. Several studies have shown that these compounds are effective against gastrointestinal tumors, gynecologic tumors, as well as against leukemia and lymphoma<sup>[22,23]</sup>. In most of these studies Shiitake was used to augment the effect of other drugs<sup>[24]</sup>. It has been suggested that mushroom-derived factors do not attack the cancer cells directly, but rather produce their anti-tumor effects by activating different

**Figure 4** Effect of Shiitake administration on the intra-hepatic (open bars) and intrasplenic (black bars) CD4/CD8 ratio.

**Figure 5** The effect of Shiitake administration on the intrasplenic/intrahepatic CD4/CD8 ratio: The peripheral (spleen)/intrahepatic (liver) CD4/CD8 ratio was markedly increased in groups A, C, and D. By contrast, the ratio was markedly reduced in group B.

immune responses in the host<sup>[7,25]</sup>.

Mushroom derivatives can affect different parts of the immune system, including macrophage activation by induction of TNF- $\alpha$ , IL-6, and IL-1, dendritic cell activation, and various effects on T cells<sup>[5]</sup>. *Lentinus edodes* has been described as a T-cell adjuvant, skewing the Th1/Th2 balance towards Th1 through the specific induction of IL-12 from activated macrophages<sup>[26-28]</sup>.

In addition to the protective effects against cancer, Shiitake has also been shown to be hepatoprotective as well as an anti-fibrotic agent. In dimethylnitrosamine-induced hepatitis, Shiitake decreased the serum aminotransferase levels by inhibiting the over-accumulation of collagen fibrils and suppressing the over-expression of genes for smooth muscle  $\alpha$ -actin and heat shock protein-47<sup>[29]</sup>. Shiitake also inhibited, in a dose-dependent manner and without cytotoxicity, the morphologic changes and proliferation of isolated rat hepatic stellate cells (HSCs), which play a central role in liver fibrosis<sup>[29]</sup>. Interestingly, the hepatoprotective effects of Shiitake were also observed after oral administration<sup>[30]</sup>. In another model, the D-galactosamine (GalN)-induced liver injury in mice, oral administration of Shiitake decreased the release of aminotransferases and reduced the degree of histological injury<sup>[30]</sup>.

Inflammatory bowel disease (IBD) is a chronic, relapsing and remitting condition of unknown etiology that exhibits a variety of autoimmune features<sup>[31,32]</sup>. Studies in animal models and in humans implicate an abnormal intestinal epithelial cell barrier function, excessive production of Th1 or Th2 cytokines, and the

unrestrained activation of CD4<sup>+</sup> TCRαβ<sup>+</sup> T cells in the pathogenesis of this disorder<sup>[32]</sup>. Induction of systemic tolerance towards disease-associated antigens has been validated as a method to alter the immune response and alleviate colitis in both animals and humans<sup>[17,18]</sup>.

Rectal administration of TNBS in mice induces chronic intestinal inflammation similar to that seen in Crohn's disease in humans. Stimulated cells in the inflamed mucosa produce increased amounts of IFN-γ, IL-2, and IL-12, along with reduced IL-4 expression<sup>[33]</sup>. Administration of low dose colitis-extracted protein has been shown to inhibit the host colonic inflammatory response and to alleviate colitis in this model<sup>[17]</sup>. Tolerance induction led to an immunological shift from a pro-inflammatory Th1 type response to an anti-inflammatory Th2 type.

NKT regulatory lymphocytes differentiate through thymic and extrathymic pathways<sup>[34]</sup>. These cells are characterized as CD4<sup>+</sup> or CD4<sup>+</sup>CD8<sup>-</sup> and CD16<sup>-</sup>, express αβ TCRint, and share the surface molecules with NK cells, including NK1.1 and CD122<sup>[35]</sup>. NKT cells exist in low numbers in the peripheral blood as well as in most other tissues, but are abundant in the liver<sup>[35]</sup>. The expression of NK1.1-CD1 ligand in the liver is likely responsible for this phenomenon. Upon stimulation, these cells produce significant quantities of IL-4 and IFN-γ, and exhibit enhanced cytolytic activity<sup>[36]</sup>. Our group and others have recently shown that this subset of lymphocytes may play an important role in the induction of peripheral tolerance<sup>[33,37]</sup>. Induction of peripheral tolerance *via* oral administration of an antigen or FK506 treatment, have both been associated with a significant increase in NKT LAL production and cytotoxic activity<sup>[15]</sup>. Relevant to this study, NKT lymphocytes have also been shown to play an active role in the immune modulation of experimental colitis. Adoptive transfer of tolerized NKT cells mediate the transfer of tolerance to recipient mice and prevent the induction of disease<sup>[15]</sup>.

In the present study, the beneficial effect of Shiitake was associated with increased number of liver NKT cells irrespective of the induction of colitis. This change was accompanied by a systemic decrease in NKT cell number in treated animals. To determine whether the intra-hepatic NKT increase was part of a systemic increase in NKT cells or retention of these cells in the liver, the intrahepatic/intrasplenic NKT cell ratio was calculated. While no overall increase in the number of systemic NKT cells was found, this ratio was increased significantly in Shiitake treated mice. Thus, NKT residency in the liver was increased. Taken together, these data suggest that the Shiitake-derived formulation used in the present study has a substantial effect on NKT regulatory lymphocytes. As such, such formulations may carry the potential to alleviate similar NKT-dependent disorders.

In addition to the observed changes in NKT cells, the beneficial effect of Shiitake was associated with increased intrasplenic/intrahepatic ratio of CD4/CD8, suggesting a preferential trapping of CD8 lymphocytes in the liver during systemic tolerance induction. This

effect was similar to that observed in other previously described methods of tolerance induction, where the liver was shown to play an active role<sup>[9,10]</sup>. Similar to its effect on NKT regulatory cell distribution, the effect of Shiitake on intrahepatic lymphocyte sequestration was observed in treated animals whether or not colitis was induced. This finding suggests that Shiitake acts as a genuine immune modulator in both healthy and disease conditions, although a more pronounced effect was noted in disease states.

In summary, the Shiitake-derived formulation had a favorable effect on immune mediated colitis. This effect was associated with alterations in the NKT lymphocyte distribution, and on intra-hepatic CD8 lymphocyte trapping during tolerance induction. Further identification of the specific effects caused by several mushroom derived compounds may facilitate the development of oral administration of these products for the treatment of immune-mediated disorders, including IBD.

## COMMENTS

### Background

Natural killer T (NKT) lymphocytes play a regulatory role in various immune-mediated disorders. To determine the immunomodulatory impact of Shiitake we tested its effect on liver-mediated immune regulation in a model of immune-mediated colitis. Shiitake extract affected liver-mediated immune regulation by altering NKT lymphocyte distribution and increasing intra-hepatic CD8<sup>+</sup> T lymphocyte trapping, thereby leading to alleviation of immune-mediated colitis.

### Research frontiers

The liver is a site for lymphocyte clearance, and plays an important role in determining the CD4<sup>+</sup>/CD8<sup>+</sup> balance during tolerance induction.

### Innovations and breakthroughs

Shiitake extract altered NKT lymphocyte distribution and increased intra-hepatic CD8<sup>+</sup> T lymphocyte trapping.

### Applications

Shiitake extracts can serve as immune modulatory tools in various immune mediated disorders.

### Peer review

The present study looked at the role of mushroom extract on tolerance induction, using an established model of TNBS colitis. It was observed that there was alleviation of microscopic and macroscopic colitis and better survival with Shiitake treatment, accompanied with changes in intra-hepatic NKT, CD4, CD8 populations with reduced IFN secreting colonies in the peripheral blood. The authors concluded that Shiitake modulates the immune response in the liver to a more tolerogenic state, and results in improvement of the colitis.

tumor differentiation and survival. VEGFR-2 levels were associated with poor tumor differentiation. There was no significant prognostic value for any of the VEGF family members or their receptors except for VEGFR-1 where high levels were associated with a poor overall survival.

**CONCLUSION:** Serum VEGF levels vary significantly in the same cohort of patients with variable clinico-pathological features and prognostic values. The simultaneous measurement of VEGF receptors levels in sera may overcome the limitations of a single biomarker assay.

### Abstract

**AIM:** To analyze the serum levels and prognostic significance of vascular endothelial growth factor (VEGF) -A, -C, and -D, and their receptors, VEGFR-1 and -2 in gastric adenocarcinomas.

**METHODS:** The serum levels of VEGF family members were measured in 76 control subjects and 76 patients with gastric adenocarcinoma using an enzyme-linked immunosorbent assay (ELISA). These measurements were correlated with clinico-pathological features and survival rates.

**RESULTS:** The serum levels of VEGF-A and its receptor, VEGFR-1, were significantly higher in patients with gastric cancer than in healthy donors ( $t = 2.3$ ,  $P = 0.02$  and  $t = 4.2$ ,  $P < 0.0001$ , respectively). In contrast, the serum levels of VEGF-D were significantly higher in control subjects than in patients ( $t = 2.9$ ,  $P = 0.004$ ). There was no significant difference in serum levels of VEGF-C and VEGFR-2 between patients and controls. VEGF-C was associated with advanced tumor stage and presence of metastasis. VEGFR-1 was associated with metastasis, advanced overall stage,

### INTRODUCTION

Gastric cancer is the second most common cancer worldwide and remains a global health burden<sup>[1]</sup>. The prognosis of patients with gastric cancer has been shown to be influenced by established surgical-pathological features, such as pathological stage, location of the tumor, and histological type and grade of the tumor<sup>[2-4]</sup>. In comparison, the intense search for predictive molecular biomarkers has not yet translated into clinical use<sup>[5-7]</sup>.

There is growing recognition of the central role that the vascular endothelial growth factor (VEGF) family plays in angiogenesis in which the formation of new blood vessels is necessary for the growth and spread of tumors<sup>[8]</sup>. The VEGF family consists of seven members- VEGF-A, VEGF-B, VEGF-C, VEGF-D, VEGF-E,

VEGF-F, and placental growth factor (PlGF)-which share eight cysteine residues in a VEGF homology domain<sup>[9,10]</sup>. The members act through specific tyrosine kinase receptors, VEGFR-1, -2 and -3. VEGF-A acts through VEGFR-1 and -2 receptors, VEGF-C and -D act through VEGFR-2 and -3<sup>[9,11]</sup>.

Studies have shown an association between intratumoral microvessel density and tumor aggressiveness in gastric cancer<sup>[12,13]</sup>. Among angiogenic stimulators, VEGF-A plays an essential role in both vasculogenesis and angiogenesis<sup>[14]</sup>. Serum concentrations of VEGF-A have been examined in patients with gastric cancer and a relationship between the serum concentration of VEGF and metastasis and/or poor outcome has been demonstrated<sup>[15,16]</sup>. However, the significance of other VEGF family members (VEGF-B, -C, and -D) in tumor angiogenesis and metastasis are not fully demonstrated<sup>[17]</sup>. Recently, the prognostic importance of serum concentrations of other VEGF family members (VEGF-C and -D and their receptors) in gastric cancer has been reported<sup>[18,19]</sup>. Overall, these studies were limited to one or two VEGF family members and their receptors and did not examine the full profile of expression of these proteins in the same patient<sup>[14,15,18]</sup>.

In the current study, we evaluated the serum levels of VEGF-A, -C, and -D, and their receptors, VEGFR-1 and -2 in both healthy controls and gastric cancer patients. We then correlated these serum levels with clinico-pathological features and patient survival rates.

## MATERIALS AND METHODS

### Study subjects

The study population consisted of a series of unrelated patients diagnosed with gastric cancer in three main hospitals in the Sultanate of Oman (Sultan Qaboos University Hospital, Royal Hospital, and Sohar Hospital). The control group was composed of subjects of the same ethnic and geographical origin as the patients. The Medical Research and Ethics Committee of the College of Medicine of Sultan Qaboos University approved the study design. The study subjects gave an informed consent prior to participation in the study.

### Serum VEGF family level assay

Peripheral venous blood samples were obtained prior to any treatment and allowed to clot at room temperature and centrifuged at 2000 g for 10 min. Sera were separated, aliquoted, and stored at -70°C until assay. Serum VEGF concentrations were determined using a commercially available enzyme-linked immunoassay (ELISA) designed to measure VEGF-A (VEGF 165), VEGF-C, VEGF-D, VEGFR-1, and VEGFR-2 levels (Quantikine, R&D Systems Europe, Abingdon, UK). Assays employed the quantitative sandwich enzyme immunoassay and were performed according to the manufacturer's procedure.

### Statistical analysis

The significance of differences in the levels of various

**Table 1** Serum concentrations (pg/mL) of VEGF-A, -C, and -D, and VEGFR-1 and -2 in patients with gastric adenocarcinoma and control subjects (*n* = 76)

	Patients	Control	<i>P</i>
VEGF-A	585.7 ± 408.4; 469.3 <sup>1</sup> (44.1-1927.7)	444.9 ± 328.9; 346.9 (31.1-630.6)	0.02
VEGF-C	6141.0 ± 2456.1; 5858.4 <sup>1</sup> (970.4-12158.9)	6067.8 ± 2219.3; 5872.3 (711.7-12158.9)	0.88
VEGF-D	483.0 ± 259.3; 428.9 <sup>1</sup> (205.7-1355.2)	671.1 ± 501.8; 605.9 (205.7-3859.7)	0.004
VEGFR-1	873.7 ± 360.8; 1026.4 <sup>1</sup> (279.4-1767.6)	645.3 ± 297.9; 475.4 (224.1-1333.6)	0.0001
VEGFR-2	9266.5 ± 2111.1; 9382.3 <sup>1</sup> (4726.1-15427.3)	9420.3 ± 1840.7; 9386.2 (5727.9-15433.3)	0.45

<sup>1</sup>Refers to mean ± SD; median (range).

VEGF molecules between patients and controls was studied using the unpaired *t* test and further confirmed with Mann-Whitney *U* test. The significance of the correlations between the expression of various VEGF proteins and clinico-pathological features was evaluated by the Spearman's correlation test.

Overall survival rates were determined from the time of biopsy-proven diagnosis until either the time of death or last known follow-up examination. The dates of death were obtained from either medical records or phone contact. The Kaplan-Meier method was used to estimate overall survival time, and the statistical significance was determined by log-rank test. Backward conditional Cox proportional hazards regression model was utilized for multivariate analyses where age ( $\leq 40$  years,  $> 40$  years), gender, proximal or distal location, histological classification (intestinal *vs* non-intestinal), T stage (1 + 2 *vs* 3 + 4), presence or absence of lymph node metastasis, overall all stage (I + II *vs* III + IV), tumor differentiation (well *vs* moderate + poor), all the VEGF factors were included. *P* values less than 0.05 were considered statistically significant. Analysis of data was performed using SPSS 10.0 software.

## RESULTS

A total of 76 gastric cancer patients and 76 unrelated controls were included. The age range for the participants included in the study was 21-82 years; the mean and standard deviation of ages for the patients and controls were 55.7 ± 11.3 and 38.5 ± 10.2 years, respectively. The proportion of males (*n* = 41) and females (*n* = 35) were equal in both groups. Fifty four patients received either chemotherapy alone or chemoradiotherapy.

### The serum values of VEGF-A, -C, -D, and VEGFR-1 and -2 in patients and controls

Table 1 shows the mean, standard deviation, median, and ranges of serum levels of VEGF-A, -C, and -D, and VEGFR-1 and -2 in patients with gastric cancer and controls. The serum VEGF-A and VEGFR-1 levels were significantly higher in patients with gastric cancer than

<sup>a</sup> $P < 0.05$  and <sup>b</sup> $P < 0.01$  vs determined in patients who had surgical resections ( $n = 58$ ).

**Figure 1** Kaplan-Meier survival curves in relation to serum VEGFR-1 levels in 76 patients with gastric adenocarcinoma. <sup>1</sup>Elevated serum VEGFR-1 levels were defined as greater than the 95th percentile in the healthy control group.

in healthy donors ( $P = 0.02$  and  $0.0001$ , respectively). Interestingly, the serum levels of VEGF-D were higher in controls than in patients with gastric cancer. There was no significant difference in serum levels of VEGF-C and VEGFR-2 between patients and controls.

#### **The association between serum values of VEGF-A, -C, -D, and VEGFR-1 and -2 and clinico-pathological features**

Table 2 shows the association between serum values of VEGF-A, -C, -D and VEGFR-1 and -2 and clinico-pathological features. VEGF-C was associated with advanced tumor stage and presence of metastasis. VEGFR-1 was associated with metastasis, advanced overall tumor stage, and tumor differentiation. VEGFR-2 levels were associated with poor tumor differentiation.

#### **Correlation between circulating VEGF levels and patient survival**

Elevated serum VEGF levels were defined as greater than the 95th percentile in the healthy control group as previously described<sup>[15]</sup>. There was no significant predictive value for any of the VEGFs or their receptors (data not shown) except for VEGFR-1 as shown in Figure 1. The median survival time for patients with high and low levels of VEGFR-1 was 5 mo (95% CI 2.6-7.4) and 13 mo (95% CI 1.4-24.6), respectively. The 5-year survival rates were 20% and 36%, respectively ( $P = 0.02$ ). Multivariate regression analysis showed that only advanced stage III and IV (Hazard ratio 6.7; 95% CI, 2.2-20.0;  $P = 0.001$ ) to be a significant independent factor.

## **DISCUSSION**

Studies on the role of the VEGF family in gastric cancer have focused on individual VEGF members and their respective receptors<sup>[14,15,18]</sup>. The evaluation of the simultaneous expression of VEGF family members and their receptors may provide more accurate prognostic information<sup>[17]</sup>. Therefore, we have investigated the serum levels of VEGF-A, -C, -D, and VEGFR-1 and -2 and studied their predictive and prognostic significance in the same group of patients.

In the present study, the VEGF-A and VEGFR-1 levels are higher in patients with gastric cancer than in healthy controls, which is consistent with results from other studies<sup>[15,20,21]</sup>. However, we found that serum VEGF-D levels were higher in the control group than in patients with gastric cancer. George *et al*<sup>[12]</sup> studied VEGF-A, -C, and -D mRNA tissue expression in colorectal cancer progression, demonstrating that VEGF-D mRNA remained at persistently low levels in carcinomas compared with adenomas, and that

both VEGFR-2 and VEGFR-3 mRNA expression levels remained constant. This result suggested that VEGF-D acts as a competitive agonist with VEGF-A and VEGF-C; a decrease in VEGF-D levels may allow increased access of VEGF-A and VEGF-C, which are more potent angiogenic cytokines than VEGF-D, to the two VEGF receptors<sup>[22]</sup>. It has been previously shown that tissue expression of certain VEGF family members correlates with their serum levels<sup>[18]</sup>. Therefore, the advanced tumor stage presentation that predominated in the current cohort of patients may have led to the differential expression of the VEGF family members, further emphasizing the importance of the simultaneous measurement of these factors.

The correlation of markers of angiogenesis and clinico-pathological features further highlights the complex interaction between various factors and their respective receptors<sup>[16,23]</sup>. Whereas VEGF-A and -D did not correlate with any of the clinico-pathological features studied, it is interesting to note the strong association between VEGFR-1 and advanced stage cancer, the presence of metastasis, and poor tumor differentiation. VEGF-C was a serum biomarker for advanced tumor stage and poor differentiation, whereas VEGFR-2 correlated with poor tumor differentiation. It is interesting that serum VEGF-C and -D levels did not correlate with lymph node metastasis, a result that has been shown previously<sup>[18]</sup>. This finding is most likely due to the fact that most patients included had lymph node metastasis and, therefore, such differences could not be found (Table 2).

The available data on the prognostic significance of serum VEGF levels in malignancies is controversial<sup>[24-26]</sup>. The prognostic significance of VEGF (in particular, of VEGF-A), as determined by ELISA, has been commonly studied in various tumors<sup>[24-27]</sup>. It has been shown that high serum VEGF levels correlate with poor prognosis in certain hematological malignancies<sup>[28,29]</sup>. In gastric cancer, it has been shown that serum VEGF-A levels correlated with local tumor extent, disease stage, and the presence of distant metastases, and is an independent prognostic factor for patient survival<sup>[14,15,20]</sup>. Recently, Wang *et al*<sup>[9]</sup> reported that serum VEGF-C levels might be a useful biomarker to determine the presence of lymph node metastasis in patients with gastric cancer as well as correlate with VEGF-C tissue expression<sup>[18]</sup>. Juttner *et al*<sup>[8]</sup> showed that both VEGF-D and VEGFR-3 are independent prognostic biomarkers to identify patients with poor prognosis after curative resection of gastric adenocarcinomas; when combined with an analysis of VEGF-C, patients with shorter survival times could be predicted<sup>[17]</sup>. In the current study, a significant correlation between VEGFR-1 and advanced tumor stage, presence of metastasis, and poor tumor differentiation in turn reflects poor survival outcome as shown in Figure 1. To our knowledge, this is the first study to report on the prognostic significance of serum VEGFR-1 levels in patients with gastric cancer. It has been suggested that the VEGFR-1/VEGF ratio in sera may be of greater prognostic value than VEGF

levels alone<sup>[28]</sup>, hence, overcoming the limitations of a single biomarker assay<sup>[27,30]</sup>.

In conclusion, we have demonstrated that there are significant variations in VEGF serum concentrations when measured simultaneously that correlate with important variations in clinico-pathological features and prognostic significance. Future work will address the application of this concept on a larger cohort of patients to generate a predictive profile that examines the simultaneous expression of these proteins at the tissue level.

## COMMENTS

### Background

The prognostic importance of serum concentrations of vascular endothelial growth factor (VEGF) family members in gastric cancer has been reported. Overall, these studies were limited to one or two VEGF family members and their receptors and did not examine the full profile of expression of these proteins in the same patient. In the current study, authors evaluated the serum levels of VEGF-A, -C, and -D, and their receptors, VEGFR-1 and -2 in both healthy controls and gastric cancer patients. They then correlated these serum levels with clinico-pathological features and patient survival rates.

### Research frontiers

To date, the prognostic value of simultaneous measurement of serum concentration several VEGF family proteins in gastric cancer remains unclear. The variation of serum concentration of various VEGF family members in the same patient may provide useful predictive and prognostic tool.

### Innovations and breakthroughs

In the present study, the authors measured the serum levels of VEGF-A, -C, and -D, and their receptors, VEGFR-1 and -2. This is the first study that measures serum level of VEGF family members simultaneously. The serum levels of VEGF-A and its receptor, VEGFR-1, were significantly higher in patients with gastric cancer than in healthy donors. In contrast, the serum levels of VEGF-D were significantly higher in control subjects than in patients. VEGFR-1 was associated with metastasis, advanced overall stage, tumor differentiation and survival. The result suggests that levels of VEGF family members may vary significantly and that simultaneous pre-operative measurement may provide a more accurate prognostic tool.

### Applications

The results of the present study demonstrate the variation in VEGF family members when measured simultaneously. The measurement of all these proteins may provide more accurate predictive and prognostic information.

### Terminology

Angiogenesis is a physiological process in the body that involves the formation of new blood vessels. VEGF family plays an important role in angiogenesis. The VEGF family consists of seven members-VEGF-A, VEGF-B, VEGF-C, VEGF-D, VEGF-E, VEGF-F, and placental growth factor. The members act through specific tyrosine kinase receptors-VEGFR-1, -2 and -3. VEGF-A acts through VEGFR-1 and -2 receptors; VEGF-C and -D act through VEGFR-2 and -3.

### Peer review

This is an interesting paper. Authors analyzed the serum levels and prognostic significance of VEGF-A, -C, and -D, and their receptors, VEGFR-1 and -2 in gastric adenocarcinomas.

significantly higher in patients with LC with ascites than in healthy control subjects or patients with LC without ascites ( $0.88 \pm 0.12$  vs  $0.52 \pm 0.05$  or  $0.53 \pm 0.03$ ,  $P < 0.05$ ) and correlated with urine nitrite excretion ( $r = 0.98$ ). Interestingly, the serum TNF- $\alpha$  concentration was significantly higher in LC without ascites than in control subjects or in LC with ascites ( $198.9 \pm 55.8$  pg/mL vs  $40.9 \pm 12.3$  pg/mL or  $32.1 \pm 13.3$  pg/mL,  $P < 0.05$ ). Urine nitrite excretion was significantly higher in LC with ascites than in the control subjects or in LC without ascites ( $1170.9 \pm 28.7$   $\mu$ mol/L vs  $903.1 \pm 55.1$   $\mu$ mol/L or  $956.7 \pm 47.7$   $\mu$ mol/L,  $P < 0.05$ ).

**CONCLUSION:** Increased intestinal macromolecular permeability and NO is probably of importance in the pathophysiology and progression of LC with ascites, but the serum TNF- $\alpha$  concentration was not related to LC with ascites.

Increased intestinal macromolecular permeability and urine nitrite excretion associated with liver cirrhosis with ascites. *World J Gastroenterol* 2008; 14(24): 3884-3890 Available from: URL: <http://www.wjgnet.com/1007-9327/14/3884.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.3884>

### Abstract

**AIM:** To determine intestinal permeability, the serum tumor necrosis factor (TNF)- $\alpha$  level and urine nitric oxide (NO) metabolites are altered in liver cirrhosis (LC) with or without ascites.

**METHODS:** Fifty-three patients with LC and 26 healthy control subjects were enrolled in the study. The intestinal permeability value is expressed as the percentage of polyethylene glycol (PEG) 400 and 3350 retrieval in 8-h urine samples as determined by high performance liquid chromatography. Serum TNF- $\alpha$  concentrations and urine NO metabolites were determined using an enzyme-linked immunosorbent assay (ELISA) and Greiss reaction method, respectively.

**RESULTS:** The intestinal permeability index was

### INTRODUCTION

It has been shown that the gut, as a reservoir of enteric bacteria in the body, plays a protective role as mucosal barrier function, immunoglobulin secretion, and local and systemic macrophage system, but under liver cirrhosis (LC) with portal hypertension a correlative connection between liver damage and the functional activity of the intestine with mucosal abnormalities exist<sup>[1-3]</sup>. Increased intestinal permeability (IPI) with bacterial translocation and endotoxemia have been implicated

in the pathogenesis of chronic liver injury and as contributory factors in the development of dangerous complications, such as encephalopathy and bacterial infections in LC<sup>[4]</sup>. However, other investigators have suggested that intestinal permeability is probably of limited importance in the pathophysiology of bacterial infections in patients with LC<sup>[5]</sup>. Intestinal permeability in LC has been reported as being increased or normal<sup>[6-10]</sup>. The development of systemic endotoxemia may in turn act through the release of cytokines, to further increase intestinal permeability, impair host immunity and promote bacterial translocation from the gut, thus resulting in a vicious circle<sup>[11,12]</sup>. It has been proposed that some of these cytokines play a role in several known cirrhosis-related complications, such as hyperdynamic circulation, susceptibility to infection, and hepatic encephalopathy<sup>[13]</sup>. Tumor necrosis factor (TNF)- $\alpha$  is a 17 kDa cytotoxic protein produced by mononuclear cells on activation by bacterial endotoxin and tissue injury<sup>[13]</sup>. However, the TNF- $\alpha$  level in LC has been reported with controversial findings, as it may or may not correlate with an advanced stage of disease and a worse outcome<sup>[14-18]</sup>.

Nitric oxide (NO) has a role in cirrhosis. Endotoxemia, possibly from gut-derived bacterial translocation, causes induction of NO synthase leading to increase vascular NO production, which is the primary stimulus for the development of vasodilatation in cirrhosis and its accompanying clinical manifestations<sup>[19]</sup>. While NO is an unstable molecule, one means of investigating NO formation is to measure nitrite (NO<sub>2</sub>), which is one of two primary stable non-volatile breakdown products of NO. A dose dependent increase in nitrite has been demonstrated to occur when macrophages are activated with lipopolysaccharide (LPS) both *in vitro* and *in vivo*<sup>[20]</sup>. Therefore, we speculated that endotoxin mediated increases in the NO metabolite nitrite in urine are related to the magnitude of intestinal macromolecular permeability and hence to LC related complications.

Limited data exists on the state of intestinal macromolecular permeability using polyethylene glycol (PEG) (400 and 3350) in cirrhotic patients with or without ascites. To clarify the role of intestinal macromolecular permeability, the serum TNF- $\alpha$  level and nitrite level in urine to the development of LC with ascites, we investigated whether intestinal macromolecular permeability is altered in patients LC with or without ascites, and its relationship with the serum TNF- $\alpha$  level and NO metabolite level in urine.

## MATERIALS AND METHODS

### *Patients and healthy control subjects*

Participating patients and healthy control subjects were comprised of 26 patients with LC with ascites, 27 patients with LC without ascites and 26 age and sex-matched healthy individuals with a normal medical history, physical examination and blood chemistry.

Subjects with known infection, gastrointestinal or renal disease or diabetes mellitus were excluded from the study. Also excluded were patients that received substances known to affect intestinal permeability test results such as lactulose, non-steroidal anti-inflammatory drugs, or alcohol, in the previous 2 wk. The Institutional Review Board of the Seonam University Health Sciences Center (Namwon, Korea) approved the study. All subjects in this study gave informed consent. The diagnosis of LC was based on the typical findings of hepatic cirrhotic appearance, splenomegaly, esophageal varices, and ascites by ultrasonography and an upper gastrointestinal endoscopy, and laboratory results (prolonged prothrombin time, hypoalbuminemia with or without elevated liver enzymes). The severity of liver disease was determined according to Child-Pugh criteria.

### *Measurement of intestinal macromolecular permeability*

Urine samples used in this study were collected during 8 h from subjects that fasted overnight (last meal before 8 PM the day before). Subjects ingested a 100 mL test solution containing 1 g of PEG 400 and 10 g of PEG 3350 in water. Each subject ingested the PEG solution 1 h before a breakfast meal. Urine samples were been kept frozen (-20°C) until processing for analysis. In this study, we attempted to detect PEG 400 as a low molecular weight (MW) marker and 3350 as a higher MW marker simultaneously in urine samples by high performance liquid chromatography (HPLC) using evaporative light scattering detection. About 2 mL of urine was filtered through a 0.45  $\mu$ m syringe filter (Nylon membrane) and stored at 4°C until analysis. All of the 1 mL-vial urine samples for analysis were directly placed into a Waters 717+ autosampler with refrigerator (10°C). The HPLC column was a 5  $\mu$ m PLRP-S 100 A column (150 mm  $\times$  4.6 mm, Polymer Laboratories, Amherst, MA USA) packed with PS/DVB polymeric beads. To remove particles in the urine sample, a disposable Security Guard kit (Phenomenex, Torrance, CA USA) was used with the HPLC column. A gradient mobile phase (acetonitrile/H<sub>2</sub>O) for an elution of 40-60 min was used to separate efficiently all hydrophilic and hydrophobic compounds. As the HPLC eluents were controlled by a gradient controller program, we tried to set the program to allow the impurities elute first while the marker compounds (PEG 400 and PEG 3350) eluted later without peak overlap. The eluted components were analyzed by an evaporative light scattering detector (PL-ELSD 2100 under conditions of evaporation -85°C, nebulizer 85°C and gas flow 1.0; Polymer Laboratories). Calibration curves were obtained in the range of 200-1500 mg/L for PEG 400 and 10-200 mg/L for PEG 3350, respectively. The intestinal permeability was calculated by the concentration of the PEG marker compound and total urine volume. The calculated intestinal permeability index (IPI, in %), PEG retrieval ratio, is an expression of the PEG 3350 intestinal permeability, relative to PEG 400.

### Measurement of serum TNF- $\alpha$

With in a 12 h period after oral administration of the PEG solution, 10 milliliters of a blood sample was taken from a forearm vein of each individual. All blood samples were anticoagulated with EDTA and then plasma was separated by centrifugation at 1600 *g* for 15 min. Plasma samples were stored at -70°C until analysis. The serum TNF- $\alpha$  concentration was determined by the enzyme-linked immunosorbent assay (ELISA) technique (Quantikine® human TNF- $\alpha$ , R & D Systems, Minneapolis, MN USA), according to the manufacturer instructions.

### Measurement of urinary nitrite excretion

About 2 mL of urine was filtered through a 10000 MW filter (Millipore Microcon YM-10) and was assayed for the NO metabolite nitrite by the Greiss reaction using Parameter TM Total NO/Nitrite/Nitrate kit (R & D Systems). The total concentration of nitrite was determined by absorbance at 540 nm after urine nitrate (NO<sub>3</sub><sup>-</sup>) was converted to nitrite (NO<sub>2</sub><sup>-</sup>) by the NADPH-dependent nitrate reductase.

### Statistical analysis

Data are reported as mean values and standard errors (mean  $\pm$  SE) or percentage according to variables. Differences among the three groups were analyzed by ANOVA. When a significant effect occurred, Scheffe post hoc comparisons were used to test differences among the means. An independent samples *t*-test was used to compare test results between two groups. A nonparametric test, the Mann-Whitney test, was used to compare independently two groups that had fewer than 10 samples. We calculated Pearson's correlation

**Figure 1** Polyethylene glycol retrieval ratio (PEG 3350/400) in the healthy control subjects and the cirrhotic patients. <sup>a</sup> $P < 0.05$ .

coefficient for associations between two variables. SPSS statistical software (version 11.0) was used for the statistical analysis. A two-tailed significant level of 5% was chosen as a type I error.

## RESULTS

### Characteristics of the participating patients

There were no significant differences regarding age and gender between the cirrhotic patients with or without ascites and healthy control subjects. The distribution of causes of LC were alcohol ( $n = 31$ ), viral infection (HBV 14, HCV 7;  $n = 21$ ) and alcohol combined with HBV infection ( $n = 1$ ). Renal function as assessed based on blood urea and creatinine levels was normal in all patients and control subjects. Details of the demographics, etiology, severity, complications of the LC and concurrent infections are outlined in Table 1.

### Intestinal macromolecular permeability

Mean values for PEG 400 and 3350 retrieval were  $46.5 \pm 3.22$  and  $0.24 \pm 0.03$  in control subjects,  $44.1 \pm 5.17$  and  $0.21 \pm 0.02$  in patients with LC without ascites and  $37.4 \pm 3.55$  and  $0.31 \pm 0.04$  in patients with LC with ascites, respectively. The mean values for the IPI were different in patients from the healthy control subjects and patients with LC without ascites reflected the expected low diffusion of PEG 3350, being significantly higher in patients with LC with ascites ( $0.52 \pm 0.05$  and  $0.53 \pm 0.03$  vs  $0.88 \pm 0.12$ ,  $P < 0.05$ ) (Figure 1). However, there was no significant difference between the healthy control subjects and patients with LC without ascites (Table 2).

A sub-analysis relating intestinal permeability to the severity of LC for all patients as indicated by the Child-Pugh class showed significant differences between class A, B and C for PEG 3350 ( $0.20 \pm 0.02$ ,  $0.25 \pm 0.03$  vs  $0.42 \pm 0.08$ ,  $P < 0.05$ ) and IPI ( $0.52 \pm 0.04$ ,  $0.72 \pm 0.07$  vs  $1.12 \pm 0.27$ ,  $P < 0.05$ ). According to sub-analysis relating IPI to the presence of complications of LC for patients as indicated by encephalopathy and hypoalbuminemia, there were significant differences ( $P < 0.05$ ), but not for

**Figure 2** Tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) levels in the healthy control subjects and the cirrhotic patients. <sup>a</sup> $P < 0.05$ .

**Table 2** Intestinal permeability, serum TNF- $\alpha$  and urine nitrite levels in the healthy control subjects and cirrhotic patients (mean  $\pm$  SE)

	Cirrhotics with ascites (n = 26)	Cirrhotics without ascites (n = 27)	Healthy controls (n = 26)
PEG400	37.4 $\pm$ 3.55	44.1 $\pm$ 5.17	46.5 $\pm$ 3.22
PEG3350	0.31 $\pm$ 0.04	0.21 $\pm$ 0.02	0.24 $\pm$ 0.03
IPI	0.88 $\pm$ 0.12 <sup>a</sup>	0.53 $\pm$ 0.03	0.52 $\pm$ 0.05
Nitrite	1170.9 $\pm$ 28.7 <sup>a</sup>	956.7 $\pm$ 47.7	903.1 $\pm$ 55.1
TNF- $\alpha$	32.1 $\pm$ 13.3	198.9 $\pm$ 55.8 <sup>a</sup>	40.9 $\pm$ 12.3

PEG: Polyethylene glycol; IPI: Intestinal permeability index. <sup>a</sup> $P < 0.05$ .

patients as indicated by a prolonged prothrombin time, esophageal varix or hyperbilirubinemia.

### Serum TNF- $\alpha$ level

The concentration of serum TNF- $\alpha$  was 198.9  $\pm$  55.8 pg/mL in patients with LC without ascites, 32.1  $\pm$  13.3 pg/mL in LC with ascites and 40.9  $\pm$  12.3 pg/mL in the control subjects (Figure 2). A group comparison by the Mann-Whitney test showed that the serum TNF- $\alpha$  level was significantly higher in patients with LC without ascites than in the control subjects and in patients with LC with ascites ( $P < 0.05$ ) (Table 2). According to the sub-analysis relating the TNF- $\alpha$  level to the severity of LC for all patients as indicated by the Child-Pugh class, class A was higher than class B and C (218.8  $\pm$  43.4 *vs* 78.9  $\pm$  26.3 and 17.7  $\pm$  3.1, respectively) and class B was higher than class C, and there were significant differences between them ( $P < 0.05$ ). According to the sub-analysis relating the TNF- $\alpha$  level to the presence of complications of LC for patients as indicated by the presence of hypoalbuminemia, there were significant differences ( $P < 0.05$ ), but not for patients as indicated by encephalopathy, prolonged prothrombin time, esophageal varix and hyperbilirubinemia (Table 3).

### Urinary nitrite excretion

Urinary nitrite excretion was significantly increased in patients with LC with ascites as compared to patients with LC without ascites or the healthy control subjects (1170.9  $\pm$  28.7  $\mu$ mol/L *vs* 956.7  $\pm$  47.7  $\mu$ mol/L or 903.1  $\pm$

**Figure 3** Urinary nitrite excretion in the healthy control subjects and the cirrhotic patients. <sup>a</sup> $P < 0.05$ .

55.1  $\mu$ mol/L,  $P < 0.05$ ) (Figure 3 and Table 2). According to a sub-analysis relating urinary nitrite excretion to the severity of LC as measured by the Child-Pugh class and to the presence of complications of LC for patients as indicated by the presence of encephalopathy, hypoalbuminemia, prolonged prothrombin time, esophageal varix and hyperbilirubinemia, there were no significant differences (Table 3).

### Correlation and statistical analysis

Patients with alcoholic *versus* non-alcoholic cirrhosis did not differ significantly ( $P > 0.05$ ) in the intestinal macromolecular permeability (PEG 400, 3350 retrieval and IPI), serum TNF- $\alpha$  level and urine nitrite level. There was a positive correlation between the Child-Pugh score and increasing intestinal macromolecular permeability ( $r = 0.494$  for PEG 3350 and  $r = 0.447$  for IPI,  $P < 0.01$ ), but no significant correlation between the Child-Pugh score and the TNF- $\alpha$  level or urinary nitrite level among patients with LC with or without ascites. No significant correlation was observed between PEG 400, 3350 percentage retrieval, IPI and the serum TNF- $\alpha$  level, between the TNF- $\alpha$  level, and urine nitrite level but there was a significant correlation between IPI and urine nitrite excretion ( $r = 0.98$ ,  $P < 0.05$ ) among patients with LC with or without ascites.

## DISCUSSION

The concept of altered intestinal permeability is important and has been implicated in a number of pathological situations, including celiac disease associated with antigen permeability, allergic intestinal diseases such as digestive hypersensitivity, inflammatory diseases such as Crohn's disease, ulcerative colitis, acute pancreatitis, alcoholic liver disease and LC associated with substance permeability during inflammation<sup>[5,21,22]</sup>.

The pathogenic mechanisms implicated in the failure of intestinal barrier in cirrhosis have not been fully elucidated as yet and remains to be investigated.

PEG: Polyethylene glycol; IPI: Intestinal permeability index. <sup>a</sup>*P* < 0.05.

Toxic metabolites of alcohol are known to induce alterations of enterocyte tight junctions, which may increase paracellular permeability<sup>[23]</sup>. However, other inflammatory conditions may alter barrier integrity, as measured by increased gut permeation. An alternative mechanism may be the proinflammatory cytokines, which can be produced locally by epithelial cells or may reach the intestinal mucosa from an inflammatory focus distant from the bowel<sup>[24]</sup>. Interestingly, *in vitro* studies in cell monolayers suggest that cytokines may mediate these permeation effects by changes in the production of NO<sup>[25]</sup>. The mechanism for this effect is not known, but may involve relaxation of the cytoskeleton or oxidation/nitration of cytoskeleton proteins<sup>[26]</sup>.

In the current study, PEG with different molecular masses was used to assess gut permeability, as it combines unique attributes in its chemical structure. It is non-toxic, water-soluble, as is endotoxin, and not metabolized either by the host or by intestinal bacteria<sup>[27]</sup>. After transmigration into the blood, the polar PEG-molecule is excreted with the urine. Because of its homogeneous chemical properties, its appropriately adaptable molecular mass and its linear, chain-like shape (mimicking the comparable structure of endotoxin)<sup>[28]</sup>, PEG seems to be an appropriate probe for the assessment of LPS translocation through the intestine. All of these demands cannot be met by other commonly used permeability marker compounds such as mono- or disaccharides, sugar alcohols, complexes with radioactive nuclides (51Cr-EDTA, 99mTc-DTPA), proteins, or even combinations of these compounds<sup>[29]</sup>.

The simultaneous use of two test marker compounds allows the expression of global intestinal permeability as an index reflecting the transfer value of the less permeable test marker (PEG 3350) relative to the most diffusible probe (PEG 400). Since pre-absorption factors

such as gastric emptying, dilution by digestive secretions and post-absorption factors such as systemic distribution and renal clearance are assumed to affect both molecules equally, the value of this index should then be directly comparable from one individual to another<sup>[30]</sup>.

It has been suggested that intestinal permeability markers pass through either a transcellular or a paracellular pathway. However, it is difficult to determine that endotoxins or other bacterial toxins from the gut lumen into the portal system pass paracellularly or transcellularly in cirrhotic patients, as there was no significant difference of PEG 400 and 3350 retrieval between the control subjects and cirrhotic patients with or without ascites in this study. To address this issue, further studies are needed for morphological or molecular changes of intestinal mucosa in LC during the PEG test. Distribution of PEG in ascites might have caused a lower urinary excretion rate and thus underestimated possible permeability changes in patients with ascites. However, Kalaitzakis *et al* assessing intestinal permeability with 51Cr-EDTA concluded that a loss of 51Cr-EDTA into the ascitic compartment was unlikely and paracentesis had no significant effect on the urinary 51Cr-EDTA excretion, which suggests that ascites in itself does not unduly affect the test results<sup>[5]</sup>. In the present study, ascitic fluid from three cirrhotic patients was tested for PEG and it was not detected; therefore, the possibility of lower urinary excretion rates due to distribution of PEG in ascites can be ruled out.

Previous studies have shown an association between IPI and severity of LC assessed according to the Child-Pugh classification<sup>[8,9]</sup>, but other studies have failed to reproduce these results<sup>[6]</sup>. In the present study, we observed significantly higher PEG 3350 retrieval and IPI in Child-Pugh class C patients as compared with that in class A and B patients. Methodological and/or patient selection differences should be taken into account when

interpreting the results of this study.

In this study, there were no concomitant infections and a significantly higher TNF- $\alpha$  level in cirrhotic patients without ascites than healthy control subjects or patients with LC with ascites was seen; thus, there was a tendency for a negative correlation between the TNF- $\alpha$  level and Child-Pugh class in the advanced stage of LC. In advanced cirrhosis, hepatic damage and inflammation are reduced due to a decreased liver reserve and marked fibrosis, and consequently, ALT levels decrease. Additionally, diminished amounts of cytokine-producing cells such as hepatocytes and Kupffer cells may lead to a decrease of TNF- $\alpha$  production<sup>[15]</sup>. In LC, several inflammatory states and commonly occurring infections may be another source of TNF- $\alpha$  production and could explain contradicting results. Increased production of TNF- $\alpha$  associated with inflammation and tissue necrosis is seen not only in hepatitis, but also in other inflammatory conditions. In the present study, IPI and urinary nitrite excretion were significantly higher in patients with LC with ascites as compared to patients with LC without ascites or healthy control subjects, with a significant correlation. Since NO is thought to have a wide range of biological functions other than vasodilatation, it is likely to affect both the progress and the clinical features of LC as well as the hemodynamics in cirrhotic patients. For example, NO is a potent inducer of increased membrane permeability in the vascular endothelium and intestinal mucosa, possibly contributing to the accumulation of ascites and to bacterial translocation<sup>[31]</sup>. In the current study, although TNF- $\alpha$  was thought to induce NO synthesis (NOS) through the inducible NOS and endothelial NOS<sup>[32,33]</sup>, there was no significant correlation between TNF- $\alpha$  level and NO level in LC. This is the same to some studies, where such a relation could not be observed<sup>[34,35]</sup>. It has been suggested that some other factors including TNF- $\alpha$  contribute to elevation of NO in LC.

A simple comparison of the published data with the findings of the present study is not easy to make. There were differences between the reported results of intestinal permeability, which means differences in the methods of assessment, including the composition of the probe solution and analytic techniques employed, as well as differences in the patient populations and in the causes and severity of LC. In conclusion, our results suggest that increased intestinal macromolecular permeability and NO are probably of importance in the pathophysiology and progression of LC with ascites, and furthermore, IPI may be a contributory factor in the development of encephalopathy in LC.

## ACKNOWLEDGMENTS

We express our gratitude to Ho Young Na and Gun Young Hong for assisting with the sample collection and Cheol Hyun Kim for assistance with the statistical analysis.

## COMMENTS

### Background

Increased intestinal permeability (IPI) with bacterial translocation and endotoxemia have been implicated in the pathogenesis of chronic liver injury and as contributory factors in the development of dangerous complications, such as encephalopathy and bacterial infections in liver cirrhosis (LC). However, limited data exists on the state of intestinal macromolecular permeability using PEG (400 and 3350) in cirrhotic patients with or without ascites. To clarify the role of intestinal macromolecular permeability, the serum tumor necrosis factor (TNF)- $\alpha$  level and nitrite level in urine to the development of LC with ascites, the authors investigated whether intestinal macromolecular permeability is altered in patients LC with or without ascites, and its relationship with the serum TNF- $\alpha$  level and NO metabolite level in urine.

### Innovations and breakthroughs

The authors investigated the relation between intestinal permeability in compensated and decompensated cirrhosis in relation to TNF- $\alpha$  and urine nitrite oxide levels. Their results suggest that increased intestinal macromolecular permeability and NO are probably of importance in the pathophysiology and progression of LC with ascites, and furthermore, IPI may be a contributory factor in the development of encephalopathy in LC.

### Applications

All the findings of the current study will provide useful information for the understanding and the treatment of LC.

### Peer review

This is an interesting study on a relevant topic. The main results of the study are that the increased permeability and nitrite oxide is of importance in the pathophysiology of decompensated cirrhosis.

### Abstract

**AIM:** To study liver cell apoptosis caused by the toxicity of selenium and observe the alteration of choline compounds using *in vitro* 9.4T high resolution magnetic resonance spectroscopy.

**METHODS:** Twenty male Wistar rats were randomly divided into two groups. The rats in the treatment group were intraperitoneally injected with sodium selenite and the control group with distilled water. All rats were sacrificed and the livers were dissected.  $^1\text{H}$ -MRS data were collected using *in vitro* 9.4T high resolution magnetic resonance spectrometer. Spectra were processed using XWINNMR and MestRe-c 4.3. HE and TUNEL staining was employed to detect and confirm the change of liver cells.

**RESULTS:** Good  $^1\text{H}$ -MR spectra of perchloric acid extract from liver tissue of rats were obtained. The conventional metabolites were detected and assigned. Concentrations of different ingredient choline compounds in treatment group *vs* control group were as follows: total choline compounds,  $5.08 \pm 0.97$  mmol/L *vs*  $3.81 \pm 1.16$  mmol/L ( $P = 0.05$ ); and free choline,  $1.07 \pm 0.23$  mmol/L *vs*  $0.65 \pm 0.20$  mmol/L ( $P = 0.00$ ). However, there was no statistical significance between the two groups. The hepatic sinus and cellular structure of hepatic cells in treatment

### INTRODUCTION

Apoptosis is a programmed, active, highly selective mechanism of cell death. Multicellular organisms' apoptosis is an essential component of cellular regulation. Abnormal regulation of apoptosis can lead to disorders such as cancer<sup>[1,2]</sup>.

The field of cell death research has undergone an explosion of new knowledge over the past decade. The methods to evaluate death of cells, especially in intact tissues, have led to the development of several techniques. However, the properties revealed in these assays are not always applicable to study of diversified metabolite of apoptosis at one time<sup>[3]</sup>.

Nuclear magnetic resonance spectroscopy is a non-destructive and non-invasive technique that can provide complete structural analysis of a wide range of organic molecules in complex mixtures. It generates

quantitative information, as the peak intensities can be proportional to analyze concentrations<sup>[4]</sup>. Because of their low sensitivity and small magnet gaps, the early spectrometers had limited applications, primarily to synthetic chemistry<sup>[5]</sup>. Over the past three decades, however, sensitivity has increased by orders of magnitude so that this technique can be used to detect the metabolite alteration of apoptosis<sup>[6-8]</sup>.

Choline compounds are one kind of biologically interesting metabolites that can be detected by <sup>1</sup>H-MRS. Declining of choline compounds is considered as a <sup>1</sup>H-NMR metabolite marker of advanced stage of apoptosis<sup>[9]</sup>. Lehtimäki *et al*<sup>[10]</sup> consider that choline compounds stay unchanged despite reduced cell density. However, how the intensity choline compounds change when apoptosis occurs is still confused.

Our hypothesis was that there is no reason for choline compounds to stay unchanged when apoptosis of liver cell occurs. The alteration of choline compounds could be observed through detailed quantitative analysis by high-resolution <sup>1</sup>H-MR spectroscopy. Therefore, the purpose of this study was to observe the liver cell apoptosis caused by the toxicity of selenium and the alteration of choline compounds using *in vitro* 9.4T high resolution magnetic resonance spectroscopy.

## MATERIALS AND METHODS

### Animal

Twenty male Wistar rats, weighing 280-320 g, were randomly divided into two groups (*n* = 10). The rats in the treatment group were intraperitoneally injected with sodium selenite liquor (Na<sub>2</sub>SeO<sub>3</sub>) at a dose of 20 μmol/kg and the control group with distilled water at a dose of 1 ml/kg. The rats of both groups were fasted for 12 h but with free access to water. All the rats were sacrificed after 24 h. The livers of all rats were immediately dissected. Parts of livers were frozen in liquid nitrogen and then stored at -70°C until measured. The rest parts of livers were fixed in formalin. All animal experiments were performed according to the guidelines approved by the Ethical Committee of the Medical College of Shantou University.

### *In vitro* <sup>1</sup>H-MR spectroscopy

Frozen liver tissue was pulverized with a pestle and mixed with a volume of 2 mmol/mL ice-cold perchloric acid. The mixture was transferred to a homogenizer and homogenized for 20 min at 4°C. The mixture was neutralized with ice-cold 3mmol/mL and 2 mmol/mL KOH and then centrifuged at 10 000 *g* for 30 min in order to eliminate perchlorate salts. The resulting supernatant was lyophilized and the precipitate discarded. The powder of extracts was transferred into a 5-mm NMR tube and redissolved in 500 μL D<sub>2</sub>O containing 1 mmol/L 2,2'-3,3'-tetra deuterio-trimethyl-silylpropionate (TMSP). D<sub>2</sub>O was added for locking signal. TMSP was used as an internal chemical shift reference at 0.00 ppm. Each sample was collected using *in vitro* 9.4T high resolution magnetic resonance spectrometer (Bruker

Avance 400 MHz). Spectra of extracts were acquired with a pulse sequence with water suppression from the Bruker zgpr pulse program. Data were obtained over a 5000 Hz sweep width and digitized with 4096 data points. The number of scans was 128. Total acquisition time was 6 min. Spectra were primarily processed in the frequency domain using XWINNMR (Bruker GmbH), including fourier-transformation, phased correction and baseline correction. The chemical shift was assigned according to the internal standard TMSP and advanced analysis was then performed using MestRe-c 4.3.

### Statistical analysis

The peak areas which were assigned as metabolites containing choline and TMSP and integral values were calculated separately by MestRe-c 4.3. The concentration of choline was calculated following the amended formula<sup>[11]</sup>.

$$(\text{metabolite}) = \frac{\text{square}(\text{metabolite})}{\text{square}(\text{TMSP})} \times \frac{\text{number of protons of metabolite}}{9} \times (\text{TMSP})$$

Square (metabolite) and square (TMSP) stand for the area of peaks of choline compounds and TMSP; 9 correspond to the number of protons giving rise to the TMSP peak; (TMSP) and (metabolite) represent the concentration of TMSP and metabolite.

The concentration data were put into computer and analyzed using SPSS 13.0 software. A two-sample *t* test was used for comparison of choline concentration of the samples in both groups. Significance level was set at *P* < 0.05.

### Histopathology

Parts of livers presenting no necrosis by visual inspection underwent histopathological examination during follow-up. Formalin fixed samples were embedded in paraffin and 4-mm sections were cut. Samples were stained with hematoxylin and eosin and examined under light microscopy.

The terminal deoxynucleotidyl transferase-mediated dUTP nick end labeling (TUNEL) assay was performed using the *in situ* cell death detection kit according to Schrum LW<sup>[12]</sup>. Briefly, DNA ends were tagged with fluorescein-labeled dUTP using terminal deoxynucleotidyl transferase by incubating the samples at 37°C in a humidified chamber. Liver sections were then incubated with anti-fluorescein-alkaline phosphatase conjugate for 30 min in a humidified chamber. Slides were incubated with 5-bromo-4-chloro-3-indolyl phosphate/nitro blue tetrazolium for 20 min at room temperature and were counterstained with hematoxylin. The sections were observed under light microscopy.

## RESULTS

<sup>1</sup>H-MRS spectra of perchloric acid extract from rat liver tissues are shown in Figure 1. The conventional metabolites were detected and assigned. The assignments of spectra were performed following the

**Figure 1** High-resolution proton spectra of liver tissue of a rat in control group and internal standard (TMS). The field 0.0-5.0 ppm is shown.

**Table 1** Assignments of liver metabolites from male Wistar rats

Metabolite	Chemical shift (ppm)
TMS	0
Isoleucine and Leucine	0.87
Valine	0.96
Lactate	1.32
Lysine	1.47
Alanine	1.48
Acetate	1.92
Glutamate	2.07-2.34
Succinate	2.41
Glutamine	2.13-2.45
Asparagine	2.95
Creatinine	3.05
Tyrosine	3.11
Choline compounds	3.20-3.23
TMAO	3.27
Region A	3.41-4.0
β-glucose	4.67
Water (residual)	4.75

TMS: 2,2'-3,3'-tetra deuterio-trimethyl-silylpropionate; TMAO: Trimethylamine-N-oxide methyl; Region A: Glucose and amino acid CH resonances.

previous studies<sup>[13-16]</sup> and presented in Table 1. The resonances of partially megascopic region 3.20-3.27 ppm were well resolved, where N(CH<sub>3</sub>)<sub>3</sub> signals from the compounds choline, phosphorylcholine and glycerophosphorylcholine can be separated. Following the formula, the total choline compounds and free choline concentrations were calculated. The mean concentration of total choline compounds was 5.08 ± 0.97 mmol/L in control group and 3.81 ± 1.16 in treatment group and the mean concentration of free choline was 1.07 ± 0.23 mmol/L in control group and 0.65 ± 0.20 in treatment group. The differences of the two groups were statistically significant (*P* = 0.05 and *P* = 0.00, respectively). However, there were no statistical significances if we compared the concentrations of synthetical choline, including phosphorylcholine and glycerophosphorylcholin (3.71 ± 0.74 mmol/L *vs* 3.01 ±

0.94 mmol/L, *P* = 0.46) between the two groups.

Although the structure of liver lobules was normal in both groups in the view of 100 times magnification, the hepatic sinus was wider in treatment group than in the control group. Cell shape was then inspected in 400 times magnification under light microscopy. The normal hepatic cells were like short shuttle while hepatic cells in treatment group were irregular and verge was not clear. Some of the cells were slightly bigger than the normal ones, but smaller ones were more often observed. We found that the cytoplasm was dyed redder than normal ones. Simultaneously, the condensed or diffuse chromatin remained randomly distributed, and the nuclear pores disappeared (Figure 2). No obviously inflamed cells could be detected under light microscope. Apoptosis of hepatic cells in both groups was confirmed by TUNEL assay. The brown ones in TUNEL assay were the apoptosis positive (Figure 3).

Although positive cells were detected in both groups, the number of positive cells was conspicuously more in treatment group than in control group. The positive cells were spread around in the control group but relatively assembled in the treatment group. Some of the apoptosis positive hepatocytes were vacuolated in treatment group. We found a very interesting phenomenon in our results: Few of apoptosis positive cells were detected in a rat of the treatment group. The <sup>1</sup>H-MRS data showed that choline concentrations were also much higher than the mean concentration of the treatment group, the concentration of total choline, free choline and synthetical choline of this rat was 5.67, 0.87 and 4.04 mmol/L, respectively.

**DISCUSSION**

Selenium is an essential trace element for human health. The cellular effects of selenite appear quite complex and are concentration-dependent. It is demonstrated that the serum level of selenite affects cell proliferation<sup>[17]</sup>. At intermediate concentrations, selenite appears to exert its chemopreventive activity. At higher concentrations,

**Figure 2** Light microscopy of HE stained livers. **A:** Specimen from control group (x 100); **B:** Specimen from treatment group (x 100); **C:** Specimen from control group (x 400); **D:** Specimen from treatment group (x 400). Arrowhead indicates vacuolated hepatocytes.

**Figure 3** The brown hepatocytes showing the cell apoptosis (TUNEL staining). **A:** Specimen from control group (x 400); **B:** Specimen from treatment group (x 400).

selenite induces oxidative stress and may become toxic<sup>[18]</sup>. Many researchers focused on the induction of apoptosis by toxic concentrations of selenite. Selenocompounds have been reported to induce apoptosis in non-malignant cell lines, such as the Chang liver cells<sup>[19]</sup>. The results of our experiments also intensively suggested that high-concentration selenium was able to cause lesions in rat livers and induce apoptosis *in vivo*. However, we also observed that one rat liver in treatment group did not present obvious cell apoptosis. We think that this phenomenon might be related to the individual diversity. Some of the rats are not sensitive towards this remedy. Bollard *et al* pointed out that various intrinsic physiological factors were known to affect the metabolic composition of biological samples from healthy experimental animals. These included well-being, genetic drift, strain, hormonal differences, rate of metabolism, age, and gender<sup>[20]</sup>. It is still unclear how selenocompounds might induce apoptosis. Many potential mechanisms have been proposed, including protection against oxidative damage, modulation of metabolism of carcinogens, cytotoxicity of selenium metabolites, induction of apoptosis secondary to production of ROS, regulation of the thioredoxin redox system, regulation of the cell cycle, and inhibition of angiogenesis<sup>[21]</sup>.

It has been reported that, with Se supplementation, the liver Se concentration increases disproportionately<sup>[22]</sup>. How to predict the liver lesion and inspect the efficiency and toxicity of selenocompounds is an important issue. <sup>1</sup>H-MRS is one of suitable, low-cost, and accurate methods for this study.

MR spectroscopy possesses the sensitivity required to measure subtle biochemical changes<sup>[23]</sup>. Although MR spectroscopy detects only a fairly small number of metabolites, it can still be used to monitor the activity of many cellular activities, because so many metabolic pathways are connected<sup>[24]</sup>. Choline compounds are one group of metabolites that can be detected by <sup>1</sup>H-MRS.

Choline is a nutrient essential for normal function of all cells<sup>[25]</sup>. It is a precursor not only for acetylcholine but also for phospholipids that are found in intracellular membranes and in the cell membrane<sup>[26]</sup>. The total choline peaks consist of glycerophosphorylcholine, phosphorylcholine and free choline, but the low resolution of *in vivo* spectroscopy can not identify the individual peaks from these compounds<sup>[27]</sup>. Because of the high resolution of the spectrometer which we used in this experiment, free choline is detached among the choline compounds so that we can further find out how free choline changes are when apoptosis of cells takes place separately. In our research, we found that the total choline declined when apoptosis occurred in the liver cells. This result is quite conformable with the result of Blankenberg FG and the conventional idea, but different from the results of Lehtimäki<sup>[10]</sup>. In our opinion, there are three reasons for this phenomenon: firstly, it is related to the inspected organ, which is liver but not brain. As it is known, all ingested choline and free choline generated by phospholipid metabolism enter the hepatic circulation, making the liver, where there are very active biochemical pathways for choline metabolism, a significant “sink” for choline<sup>[28]</sup>. But when a lesion arises in the liver, the liver loses the function of absorbing choline and causes choline declining. Secondly, the method used to induce liver cell apoptosis could cause this difference. One of the reasons why the selenocompounds cause cell apoptosis is that it is capable of inducing rapid superoxide generation and p53 phosphorylation<sup>[29]</sup>. This activation can initiate mitochondrial dysfunction and result in energy insufficiency. Ultimately, it may affect the exchange of the cell containing substance, including choline compounds. This is testified by Luck *et al*<sup>[30]</sup>. Finally, cell apoptosis period is also one of the influencing factors towards the result. In our study, the apoptosis was in its early phase. At the beginning of cell apoptosis, the total choline compounds declined because free choline decreased. This was supported by our spectroscopic and light microscopic data. It is also very interesting that the total concentration of synthetic choline, including phosphorylcholine and glycerophosphorylcholine did not have statistical difference between the two groups. Energy insufficiency and activity decline may originally cause the concentration decrease of synthetic choline when apoptosis takes place in liver cells. Because of the synthetic choline supplement by membrane dilatation

and release when the samples were mashed, the total concentration of synthetical choline finally remained fairly constant. This process of membrane perturbations is mainly the function of phospholipase A<sub>2</sub> activity *in vivo*<sup>[31]</sup>.

In summary, high dose selenium compounds can cause lesion of rat liver and induce cell apoptosis *in vivo*. *In vitro* high resolution <sup>1</sup>H-MRS can detect diversified metabolism that can resolve in water. The data of the spectroscopy include quantitative and qualitative information. Moreover, it can repetitively and accurately evaluate the lesion of the organ at early stage. Thus, this method has a potential role in oncology, including detection of malignancy, grading of tumor, predicting and monitoring the treatment response, and identifying persistent or recurrent diseases<sup>[32,33]</sup>. In our study, we found that the changing trend for different ingredient of choline compounds is not completely the same at early period of apoptosis. Further studies are needed to know how choline compounds change at the advanced and final stage of apoptosis.

## COMMENTS

### Background

The field of cell death research has undergone an explosion of new knowledge over the past decade. The methods to evaluate death of cells have led to the development of several techniques. However, the properties revealed in these assays are not always applicable to study of diversified metabolite of apoptosis at one time. Magnetic resonance spectroscopy is a non-destructive and non-invasive technique that can provide complete structural analysis of a wide range of organic molecules in complex mixtures. This technique used to detect the metabolite alteration of apoptosis has been reported. Choline compounds are one kind of biologically interesting metabolites that can be detected by <sup>1</sup>H-MRS. However, how the intensity of choline compounds changes when apoptosis occurs is still confused.

### Research frontiers

The alteration of different ingredient of choline compounds could be quantitatively analyzed by *in vitro* 9.4T high-resolution <sup>1</sup>H-MR spectroscopy when apoptosis of liver cell takes place because of the toxicity of selenium. The results of present article will be helpful for further studies concerning metabolism of apoptosis.

### Innovations and breakthroughs

When apoptosis of liver cell takes place, the concentrations of total choline and free choline decline, whereas the total concentration of synthetical choline, including phosphorylcholine and glycerophosphorylcholine, stays unchanged.

### Applications

This study is useful to explain how apoptosis of liver cell occurs. It may also play an important role in guiding the clinical diagnosis and treatment of tumors.

### Peer review

This is an interesting study, where the advanced technique of <sup>1</sup>H-NMR to detect the effect of choline compounds is paralleled to TUNEL staining of liver tissues of rats injected with selenium.

## Abstract

**AIM:** To study the immunoregulatory effect of 1,25-dihydroxyvitamin-D<sub>3</sub> on dominant Th1 response in rats.

**METHODS:** Sixty adult Lewis rats were randomized into three groups. Rats in group 1 ( $n=25$ ) were treated with 1,25-(OH)<sub>2</sub>D<sub>3</sub> first and then challenged with LPS, rats in group 2 ( $n=25$ ) were treated with vehicle first and then challenged with LPS. Ten animals in groups 1 and 2 were preserved for mortality observation. The remaining animals were injected (i.p) with endotoxin, 24 h after the last administration of 1,25-(OH)<sub>2</sub>D<sub>3</sub> and vehicle. Rats in group 3 ( $n=10$ ) were treated with 1,25-(OH)<sub>2</sub>D<sub>3</sub> only. Serum IL-12, IFN- $\gamma$ , IL-2 and IL-4 levels were measured and target gene of 1,25-(OH)<sub>2</sub>D<sub>3</sub> on Th cells was studied after 6 h. Gene abundance was verified by real-time quantitative PCR.

**RESULTS:** No death occurred in rats pretreated with 1,25-(OH)<sub>2</sub>D<sub>3</sub> after LPS injection. Death occurred 9 h after LPS injection in rats pretreated with the vehicle, and the number of deaths was 5 within 24 h, with a mortality rate of 50%. There was no change in the number of deaths within 96 h. Six hours after endotoxin stimulation, serum IL-12 and IFN- $\gamma$  levels decreased significantly in rats pretreated with 1,25-(OH)<sub>2</sub>D<sub>3</sub> as compared with those in rats pretreated with the vehicle. The serum content of these two cytokines was very low in rats not challenged by endotoxin, and there was a significant difference as compared with the previous two groups.

**CONCLUSION:** 1,25-(OH)<sub>2</sub>D<sub>3</sub> attenuates injury

induced by the lethal dose of LPS, regulates Th1 and Th2 cells at the transcription level, and dominantly responds to cytokine production in rats.

## INTRODUCTION

1,25-dihydroxyvitamin D<sub>3</sub> [1,25-(OH)<sub>2</sub>D<sub>3</sub>] is an active form of vitamin D, which not only regulates the dynamic balance of calcium and phosphorus metabolism but also participates in differentiation and regulation of the immune system<sup>[1,2]</sup>. *In vitro* study<sup>[3]</sup> showed that both antigen-presenting cells (APCs) and activated lymphocytes express vitamin D receptor (VDR), and that 1,25-(OH)<sub>2</sub>D<sub>3</sub> acts on APCs (mainly dendritic cells) and helper T cells (Th) through VDR mediation<sup>[4]</sup>, inhibits proliferation and differentiation of Th1 and cytokine production, and induces differentiation of Th2. The status of Th1/Th2 differentiation determines the type of immune response and the final outcome of body response<sup>[5]</sup>. Cytokine environment is the key factor for initiating Th1/Th2 differentiation<sup>[6,7]</sup>.

Th1 immune response is not only associated with a variety of acute inflammatory responses but also plays a leading role in the development and progression of many autoimmune diseases and transplantation rejection<sup>[1,8-12]</sup>. Few *in vivo* studies reporting the influence of 1,25-(OH)<sub>2</sub>D<sub>3</sub> on Th1 immune response are available, and the experimental results about cytokine regulation are conflicting or completely different<sup>[5,13-17]</sup>. The target gene in Th cells

remains almost unknown<sup>[10,17]</sup>. *E.coli* endotoxin is a potent bacterial mitogen, able to promote maturity of immature dendritic cells (DC), directly activates T cells and induces Th1 immune response<sup>[18]</sup>. We established a Th1 dominant response animal model and pre-treated it with 1,25-(OH)<sub>2</sub>D<sub>3</sub>. The results of our study showed that 1,25-(OH)<sub>2</sub>D<sub>3</sub> was able to regulate the production of IL-12, IFN- $\gamma$  and IL-4 in dendritic, Th1 and Th2 cells. The effector target point of regulation was at the gene transcription level. It is the regulation of 1,25-(OH)<sub>2</sub>D<sub>3</sub> on T cell polarization that attenuates injury induced by the lethal dose of LPS in rats and significantly reduces the mortality of rats.

## MATERIALS AND METHODS

### Animals

Inbred line Lewis rats (at the age of 3.5-4.5 mo, weighing 242  $\pm$  14 g) were provided by Experimental Animal Center of the Chinese Academy of Medical Sciences (Beijing, China) and fed with normal chow containing 1.6% calcium, 0.9% phosphorus and 0.3% vitamin D (Nanjing Animal Technology Co., Ltd, Nanjing, China) with free access to water. The experiment protocol followed the institutional regulations of the Ministry of Health of the People's Republic of China concerning animal experimentation.

### Experiment protocol

Sixty rats were randomized into three groups. Rats in group 1 ( $n = 25$ ) as the study group, were administered 1,25-(OH)<sub>2</sub>D<sub>3</sub> by gavage (GmbHcd&Go, Swiss) at 1  $\mu$ g/animal for 14 d<sup>[19]</sup>, rats in group 2 ( $n = 25$ ) as the positive control group were administered the same dose of the vehicle for 14 d by gavage. Animals in groups 1 and 2 were injected intraperitoneally with *E.coli* 0111, B4 (Sigma, USA). Rats in group 3 ( $n = 10$ ) as the negative control group were administered 1,25-(OH)<sub>2</sub>D<sub>3</sub> only by gavage at the dose of 1  $\mu$ g/animal for 14 d, and injected (i.p) with the same volume of normal saline (Sigma Chemical CO., St Louis, MO, USA).

Ten animals in groups 1 and 2 were preserved for mortality observation. The remaining animals were injected (i.p) with endotoxin (10 mg/kg), 24 h after the last administration of 1,25-(OH)<sub>2</sub>D<sub>3</sub> and vehicle. Six hours after the injection, they were anesthetized with 50 mg/kg (i.p) pentobarbital (Sigma-Aldrich, USA) and used for drawing 5mL blood from the abdominal major artery. The blood was centrifuged at 4°C for 15 min, and the serum was stored at -80°C for test. The spleen was removed aseptically, washed with PBS and stored in liquid nitrogen.

### Enzyme-linked immunosorbent assay (ELISA)

Serum IL-12, IL-2, IFN- $\gamma$  and IL-4 levels were measured with commercially available ELISA kits (Biosource CO., Camarillo, CA, USA) according to the manufacturer's instructions, and the quality control serum values were calculated.

### Ca<sup>2+</sup>/NF-AT signaling pathway gene array

Three spleen tissue samples were chosen randomly from rats in groups 1 and 2 for RNA extraction. UV absorption precipitation method and denaturing gel electrophoresis were used to test the quantity, quality and completion of RNA. The probe was synthesized by RT-PCR. Five  $\mu$ g RNA was used to prepare annealing solution and mixed with RT solution to undergo reverse transcription reaction under the action of reverse transcriptase (M1701, Promega, USA).

Chip hybridization was conducted by using Ca<sup>2+</sup>/NF-AT signaling pathway gene array chip (Super Array Bioscience CO., Cat.NO.HS-022 USA) and chemiluminescent assay kit (Super Array Bioscience CO., NO.D-01) according to the manufacturer's instructions. The chip was scanned with the ArtixScan 120tf scanner (Micro TEK CO., USA) and the original data were analyzed using the attached software GEArray analyzer. Each chip had 10 positive controls (2 for GAPDH, 4 for Ppia, 2 for RP113 and 2 for Actinb), three negative controls (PUC18DNA) and 3 blank controls. The original data were deduced by the background minimum value and then corrected by the content of home-keeping gene. The corrected data were analyzed for abundance of gene transcription between the two groups. The ratio  $\geq 2$  was considered up-regulation of the gene and  $\leq 0.5$  down-regulation<sup>[20]</sup>.

### Verification of IL-2 gene expression by RT-PCR

RNA extraction was done as previously described. The sample was RNA reverse transcribed to synthesized cDNA. The target gene and home-keeping gene of the sample were reacted by RT-PCR. A standard curve was plotted by measurement of the standard sample gradient to calculate the content of gene in the sample, which was corrected by the content of home-keeping gene to obtain the content of the related gene. All reagents used in the experiment were provided by Promega CO., USA. The sequences of  $\beta$ -actin (211 bp) and IL-2 (190 bp) are 5'-CCTGTACGCCAACACAGTGC-3' and 5'-ATACTCC TGCTTGCTGATCC-3', and 5'-CACTGACGCTTGTC CTCCTT-3' and 5'-TTCAATTCTGTGGCCTGCTT-3', respectively.

### Statistical analysis

Data were represented as mean  $\pm$  SD. SPSS 10.0 was used to perform *t*-test and *F*-test.  $P < 0.05$  was considered statistically significant.

## RESULTS

### Mortality of rats after LPS injection and protective effect of 1,25-(OH)<sub>2</sub>D<sub>3</sub>

No death occurred in rats pretreated with 1,25-(OH)<sub>2</sub>D<sub>3</sub> after LPS injection. Death occurred 9 h after LPS injection in rats pretreated with the vehicle, and the number of deaths was 5 within 24 h, with a mortality rate of 50%. There was no change in the number of deaths within 96 h.

**Table 1** 1,25-(OH)<sub>2</sub>D<sub>3</sub>-regulated LPS-induced cytokine production in rats (pg/mL, mean ± SD)

	1,25-(OH) <sub>2</sub> D <sub>3</sub> + LPS (n = 15)	Vehicle + LPS (n = 15)	1,25-(OH) <sub>2</sub> D <sub>3</sub> (n = 10)
IL-12	3986 ± 328 <sup>a</sup>	4160 ± 289	69.99 ± 3.99 <sup>b</sup>
IFN-γ	4840 ± 802 <sup>a</sup>	5264 ± 524	5.42 ± 0.12 <sup>b</sup>
IL-4	5.57 ± 1.75 <sup>a</sup>	3.72 ± 1.60	

<sup>a</sup>P < 0.05 *vs* vehicle + LPS; <sup>b</sup>P < 0.01 *vs* 1,25-(OH)<sub>2</sub>D<sub>3</sub> + LPS and vehicle + LPS.

### 1,25-(OH)<sub>2</sub>D<sub>3</sub> inhibited LPS-stimulated production of IL-12 and IFN-γ in rats

Six hours after endotoxin stimulation, serum IL-12 and IFN-γ levels decreased significantly in rats pretreated with 1,25-(OH)<sub>2</sub>D<sub>3</sub> as compared with those in rats pretreated with the vehicle. The serum level of these two cytokines was very low in rats not challenged by endotoxin, and there was a significant difference as compared with the previous two groups. As the serum IL-2 was below the limit of measurement in most rats 3 and 6 h after LPS attack, measurement was not done.

### 1,25-(OH)<sub>2</sub>D<sub>3</sub> promoted IL-4 production in LPS-challenged rats

Six hours after endotoxin stimulation, serum IL-4 level elevated significantly in rats pretreated with 1,25-(OH)<sub>2</sub>D<sub>3</sub> as compared with that in rats pre-treated with the vehicle. As the serum IL-4 was below the limit of measurement in most rats that are not attacked by LPS, measurement was not done (Table 1).

### Quality control of RNA extraction

Electrophoresis showed that RNA extracted from the rat spleen displayed two clear bands (18S and 28S), and the absorbance at 260 nm and 280 nm was between 1.8 and 2.0, indicating that no RNA degradation occurred and the extract outcome was good.

### 1,25-(OH)<sub>2</sub>D<sub>3</sub> regulated expression of Th1 and Th2 cytokines and related transcription factors

The gene chip used in the present experiment contains 95 target genes and other positive and negative controls. Expression difference was found in 39 genes between groups 1 and 2, accounting for 41% of the total number of the chip genes. These 39 genes include 10 up-regulated genes and 29 down-regulated genes (Table 2). The chip results showed that 1,25-(OH)<sub>2</sub>D<sub>3</sub> down-regulated gene expression of Th1 and up-regulated gene expression of Th2, and the gene expression level in related transcription factors (Table 3).

### Verification of down-regulation of IL-2 gene expression by RT-PCR

The results of the experiment showed that gene expression level in rats pretreated with 1,25-(OH)<sub>2</sub>D<sub>3</sub> was significantly lower than that in rats pre-treated with the vehicle (0.476 ± 0.023 *vs* 0.678 ± 0.038, P < 0.01).

## DISCUSSION

The purpose of the present experiment was to clarify the immune regulatory effect of 1,25-(OH)<sub>2</sub>D<sub>3</sub> on Th1 dominant response *in vivo*. The results showed that 1,25-(OH)<sub>2</sub>D<sub>3</sub> inhibited IFN-γ production of IL-12 and Th1 cytokines, suggesting that this inhibitory effect occurs at the transcription level. What implies in the results of the present experiment is the therapeutic effect of 1,25-(OH)<sub>2</sub>D<sub>3</sub> on diseases mainly characterized by Th1 immune response (including autoimmune diseases) and transplantation rejection<sup>[16]</sup>. At the same time, as 1,25-(OH)<sub>2</sub>D<sub>3</sub> affects the secretary profile of Th1 and Th2 cytokines<sup>[21,22]</sup>, it inhibited the acute inflammatory reaction in the rats of group 1, indicating that 1,25-(OH)<sub>2</sub>D<sub>3</sub> attenuates LPS lethal dose-induced injury in rats. The fact that all rats survived in group 1 suggests that 1,25-(OH)<sub>2</sub>D<sub>3</sub> may also play a role in inhibiting the development and progression of acute inflammatory reaction.

IL-12 is a cytokine secreted by APCs and plays a central role in the growth of Th1 cells<sup>[23]</sup>. IL-12 has a potent biological function of inducing T cells to secrete IFN-γ<sup>[24]</sup>. IFN-γ is a pleiotropic cytokine, promoting inflammatory reaction and inducing expression of main tissue surface compatible complex of multiple cells<sup>[25]</sup>. Most recent studies found that this cytokine promotes vascular disease of the transplanted organ at the late stage of transplantation<sup>[26]</sup>. The present experiment confirmed that 1,25-(OH)<sub>2</sub>D<sub>3</sub> could inhibited IL-12 production in rats, suggesting that it is able to inhibit strong Th1 immune response *via* its action on APCs, thus reducing IFN-γ production. At the same time, 1,25-(OH)<sub>2</sub>D<sub>3</sub> may also directly inhibit the differentiation and proliferation of Th1 cells, as the cytokines mainly secreted by Th1 cells are reduced, especially transcription of NF-κB is inhibited. NF-κB is a key mediator of gene expression in immune and inflammatory responses. We also found that 1,25-(OH)<sub>2</sub>D<sub>3</sub> inhibited proliferation of splenic lymphocytes in rats challenged with LPS. We, therefore, think that the results of the above experiment suggest that differentiation and proliferation of 1,25-(OH)<sub>2</sub>D<sub>3</sub> on Th1 may also have an inhibitory effect on proliferation of splenic lymphocytes and is able to selectively inhibit Th1 immune response.

IL-4 is a main factor influencing the development of T cells into Th2 cells<sup>[13,27]</sup>. Once IL-4 level is able to resist activation of IL-12 on Th cells and IFN-γ on IL-4, it promotes differentiation of juvenile T cells to Th2 cells<sup>[28]</sup>. It is controversial over the regulatory effect of 1,25-(OH)<sub>2</sub>D<sub>3</sub> on IL-4. It was reported that the effect of 1,25-(OH)<sub>2</sub>D<sub>3</sub> is mediated through IL-4<sup>[5]</sup>, and that it is the up-regulation of IL-4 and TGF-β by 1,25-(OH)<sub>2</sub>D<sub>3</sub> that inhibits the inflammatory reaction rather than by the reduction of Th1 cytokines IFN-γ and TNF-α<sup>[29]</sup>. It was also reported that 1,25-(OH)<sub>2</sub>D<sub>3</sub> has no influence on the production of IL-4, or down-regulates IL-4<sup>[16,17]</sup>. We detected serum IL-4 levels in four batches of rats pretreated with 1,25-(OH)<sub>2</sub>D<sub>3</sub> and

Table 2 Genes down-regulated by 1,25-(OH)<sub>2</sub>D<sub>3</sub> in rat spleens

those pretreated with the vehicle. Although we used inbred line Lewis rats with little individual variance in establishing the model, we still found a significant individual difference in serum IL-4 level of the same experiment group, where the IL-4 level was lower than the test baseline in some rats. Only when we expanded the sample capacity, were the statistically significant results obtained. The results of gene chip test also showed that there was a great difference in IL-4 expression level between the rats 6 h after LPS stimulation. Only in one of the three rats in the study group, was IL-4 mRNA expression up-regulated by more than two times. However, as the capacity of the samples tested by gene chips was relatively small, and

as there was still a tendency to up-regulate the gene expression of IL-4, IL-5 and IL-10 mainly secreted by Th2 cells, we performed another experiment, which confirmed again that 1,25-(OH)<sub>2</sub>D<sub>3</sub> was able to up-regulate serum IL-10 level in rats challenged with LPS suggesting that 1,25-(OH)<sub>2</sub>D<sub>3</sub> is able to promote the production of Th2 type cytokines<sup>[5,30]</sup>, and at the same time inhibit the extent and progression of Th1 type immune response, forming the so-called “immune deviation” phenomenon<sup>[16]</sup>, which is believed to help establish peripheral tolerance and is of significance in inhibiting transplantation rejection<sup>[4,31]</sup>.

IL-12 is an allodiploid consisting of two subunits (P<sub>35</sub> and P<sub>40</sub>) encoded by two genes independently<sup>[32]</sup>.

It is known that the P<sub>40</sub> gene initiator region contains a NF- $\kappa$ B combining site<sup>[33]</sup>. The finding in the present experiment that 1,25-(OH)<sub>2</sub>D<sub>3</sub> down-regulated the important transcription factor NF- $\kappa$ B, suggests that 1,25-(OH)<sub>2</sub>D<sub>3</sub> reduces the expression of IL-12P40 subunit by inhibiting NF- $\kappa$ B, thus down-regulating assembly and secretion of IL-12 protein<sup>[33]</sup>. After activation of T cells, VDR is induced within 6 h, where IL-2 is the first expression-producing gene<sup>[34]</sup>, and 1,25-(OH)<sub>2</sub>D<sub>3</sub> inhibits the expression of IL-2 and IFN- $\gamma$  mRNA, reaching the peak in 6-12 h<sup>[35]</sup>. It has been recognized that NF- $\kappa$ B and NF-ATp/c are specific transcription factors on IL-2 initiators<sup>[36,37]</sup>. It is also known that IFN- $\gamma$ , GM-CSF, TNF- $\alpha$ , IL-4 and IL-5 initiators contain NF-AT element<sup>[34]</sup> and IL-4 enhancer contains 5 independent NF-AT sites, of which NF-ATp is a combining site of high affinity<sup>[34,38]</sup>. In the present experiment, increased IL-4 secretion by 1,25-(OH)<sub>2</sub>D<sub>3</sub> might be related to up-regulation of NF-ATp. Although we were unable to identify the respective action of individual members of the NF-AT family on the expression of the cytokines in this study, we may still draw the conclusion that 1,25-(OH)<sub>2</sub>D<sub>3</sub> influences the activity of NF- $\kappa$ B and NF-AT, two important transcription factors associated with cytokine regulation, by up-regulating NF-ATp gene expression and down-regulating NF-ATc gene expression. Both MAPK P38 and TNF pathways are mitogen-activated protein kinase pathways, not only closely associated with inflammatory reaction but also with cell growth, differentiation and apoptosis. 1,25-(OH)<sub>2</sub>D<sub>3</sub> down regulates gene transcription of these important regulatory proteins in the MAPK pathways, suggesting that its influence on T help cell differentiation is the result of regulation on multiple signal pathways, and that the effector target of 1,25-(OH)<sub>2</sub>D<sub>3</sub> regulating cytokines is at the gene transcription level.

## COMMENTS

### Background

1,25-dihydroxyvitamin D<sub>3</sub> (1,25-(OH)<sub>2</sub>D<sub>3</sub>) has many effects on the production of cytokines, the gene expression maps of related cytokines and the mortality of rats. 1,25-(OH)<sub>2</sub>D<sub>3</sub>, the activated form of vitamin D, has, in addition to its central function in calcium and bone metabolism, important effects on the growth and differentiation of many cell types, and pronounced immunoregulatory properties. In the present study, the immunoregulatory effect of 1,25-(OH)<sub>2</sub>D<sub>3</sub> in dominant Th1 response rats was investigated.

### Research frontiers

Th1-biased immune response is associated with acute inflammatory conditions, and also plays a major role in a variety of human autoimmune diseases and graft rejection. However, few studies on the selective immunosuppression *in vivo* of 1,25-(OH)<sub>2</sub>D<sub>3</sub> are available and the effect of 1,25-(OH)<sub>2</sub>D<sub>3</sub> on gene expression profiles in Th cells is still unclear.

### Innovations and breakthroughs

This is the first study to address the immunoregulatory effects of 1,25-(OH)<sub>2</sub>D<sub>3</sub> in a dominant Th1 response model. The results show that 1,25-(OH)<sub>2</sub>D<sub>3</sub> could regulate Th1-derived and Th2-derived cytokine production and protect rats from attacking of the LPS lethal dose.

### Applications

The immunoregulatory properties of 1,25-(OH)<sub>2</sub>D<sub>3</sub> were explored clinically for

the topical treatment of psoriasis, a Th1 cell-mediated autoimmune disease of the skin. Our findings suggest that 1,25-(OH)<sub>2</sub>D<sub>3</sub> may play an important role in Th1-inflammatory, autoimmune diseases and graft transplantation rejection.

### Peer review

The manuscript "1,25-(OH)<sub>2</sub>D<sub>3</sub> regulates LPS-induced cytokine production and reduces mortality in rats" by Qi XP *et al.* presents experimental data from rats. The authors claim by pretreating rats with 1,25-(OH)<sub>2</sub>D<sub>3</sub> that the LPS response is shifted towards a Th2-associated cytokine response with reduced Th1-associated cytokine response, so ensuring increased survival. The topic is of high interest.

### Abstract

**AIM:** To explore the method of isolation and biological analysis of tumor stem cells from pancreatic adenocarcinoma cell line PANC-1.

**METHODS:** The PANC-1 cells were cultured in Dulbecco modified eagle medium F12 (1:1 volume) (DMEM-F12) supplemented with 20% fetal bovine serum (FBS). Subpopulation cells with properties of tumor stem cells were isolated from pancreatic adenocarcinoma cell line PANC-1 according to the cell surface markers CD44 and CD24 by flow cytometry. The proliferative capability of these cells *in vitro* were estimated by 3-[4,5-dimethyl-2-thiazolyl]-2, 5-diphenyl-2H-tetrazolium bromide (MTT) method. And the tumor growth of different subpopulation cells which were injected into the hypodermis of right and left armpit of nude mice was studied, and expression of CD44 and CD24 of the CD44<sup>+</sup>CD24<sup>+</sup> cell-formed nodules and PANC-1 cells were detected by avidin-biotin-peroxidase complex (ABC) immunohistochemical staining.

**RESULTS:** The 5.1%-17.5% of sorted PANC-1 cells expressed the cell surface marker CD44, 57.8% -70.1% expressed CD24, only 2.1%-3.5% of cells were CD44<sup>+</sup>CD24<sup>+</sup>. Compared with CD44<sup>-</sup>CD24<sup>-</sup> cells, CD44<sup>+</sup>CD24<sup>+</sup> cells had a lower growth rate *in vitro*. Implantation of 10<sup>4</sup> CD44<sup>-</sup>CD24<sup>-</sup> cells in nude mice showed no evident

tumor growth at wk 12. In contrast, large tumors were found in nude mice implanted with 10<sup>3</sup> CD44<sup>+</sup>CD24<sup>+</sup> cells at wk 4 (2/8), a 20-fold increase in tumorigenic potential ( $P < 0.05$  or  $P < 0.01$ ). There was no obvious histological difference between the cells of the CD44<sup>+</sup>CD24<sup>+</sup> cell-formed nodules and PANC-1 cells.

**CONCLUSION:** CD44 and CD24 may be used as the cell surface markers for isolation of pancreatic cancer stem cells from pancreatic adenocarcinoma cell line PANC-1. Subpopulation cells CD44<sup>+</sup>CD24<sup>+</sup> have properties of tumor stem cells. Because cancer stem cells are thought to be responsible for tumor initiation and its recurrence after an initial response to chemotherapy, it may be a very promising target for new drug development.

### INTRODUCTION

Pancreatic carcinoma is an obstinate disease that is difficult to deal with. Though pancreatic cancer accounts for only 2%-3% of all cancers, it is the fourth most frequent cause of cancer death in industrialized countries<sup>[1]</sup>. It is estimated in the United States in 1998 that at least 29000 new cases of pancreatic cancer will be diagnosed<sup>[2]</sup>. Unfortunately, only 18% will survive one year after diagnosis, the five-year survival rate is 4%. This is because by the time a patient exhibits symptoms, and the cancer is diagnosed, it is no longer in its early stage<sup>[3-5]</sup>. The main conventional treatments for pancreatic cancer are surgery, radiation therapy and chemotherapy. Despite advances in surgical and

medical therapy, little effect has been made on the mortality rate of this disease. According to Bjerkvig *et al*<sup>[6]</sup>, the capacity of a tumor to grow and propagate is dependent on a small subset of cells (so-called tumor stem cells), tumor stem cells are immature cells that can replicate or self-renew, and are able to differentiate or grow into all the cells that an organism or particular organ system need. It has profound implications to understand how tumors evolve and how we treat tumors. If we can destroy these tumor stem cells, it will be possible to treat the patients successfully. However, it is difficult to purify tumor stem cells because of lack of specific cell surface markers in solid tumors. Recently, it was reported that cancer stem cells existed in some solid malignancies, including breast<sup>[7]</sup>, brain<sup>[8,9]</sup>, prostate<sup>[10]</sup>, and lung cancers<sup>[11]</sup>. Thus, we deduced that pancreatic cancer might contain its own stem cells responsible for its metastasis and recurrence. To prove this hypothesis, we isolated subpopulation cells that have characteristics of tumor stem cells according to markers CD44 and CD24 by flow cytometry from pancreatic adenocarcinoma cell line PANC-1, and explore their biological characteristics. This study was to identify the method of isolation of pancreatic tumor stem cells and the ability of propagation of the tumor stem cells *in vitro* and *in vivo*.

## MATERIALS AND METHODS

### Experimental materials

Male nude mice, aged 6-8 wk and weighing  $20 \pm 2$  g, were provided by the Experimental Animal Center, Hubei Center for Disease Control and Prevention, China. The nude mice were caged individually under specific pathogen free (SPF) conditions. Human pancreatic adenocarcinoma cell line PANC-1 was obtained from American Type Culture Collection, Manassas, Virginia, the Dulbecco modified eagle medium F12 (1:1 volume) (DMEM-F12) from Hyclone, Wuhan, China, the fetal bovine serum from Sijiqing, Hangzhou, China, trypsin from Sigma-Aldrich, Shanghai, China, the epidermal growth factor (EGF), basic fibroblast growth factor (b-FGF), insulin-transferrin-selenium solution (ITS) and trypsin from Sigma-Aldrich, Shanghai, China and PE anti-human CD44 and FITC anti-human CD24 were purchased from American Ancell.

### Cell culture

The cells were cultured in incubator filled with 5% CO<sub>2</sub> at 37°C. The PANC-1 cells were cultured in DMEM-F12 (1:1 volume) supplemented with 20% fetal bovine serum (FBS), penicillin ( $1 \times 10^5$  U/L) and streptomycin (100 mg/L).

### Flow cytometric analysis

Cells were dissociated by trypsin-EDTA solution (trypsin, 0.25%; EDTA, 0.02%) for 2-5 min at 37°C, transferred to a 5-mL tube, washed twice with PBS with 2% heat-inactivated calf serum (HICS; 5 min at 1000 r/min), resuspended in 100  $\mu$ L (per  $10^6$  cells) of PBS, then were counted. PE anti-human CD44 and (or) FITC anti-human CD24 (appropriate dilution per antibody) were added and incubated for 30 min

at 4°C, and then washed twice with PBS. Flow cytometry was performed on a FACS, and data were analyzed with the Cell Quest software (B.D., America). Using forward and side scatter profile, debris and dead cells were gated out. Cells were routinely sorted twice, and reanalyzed for purity. Then CD44<sup>+</sup>, CD44<sup>-</sup> cells, CD44<sup>+</sup>CD24<sup>+</sup> and CD44<sup>-</sup>CD24<sup>-</sup> and unsorted cells were obtained.

### Estimation of proliferative capability of cells in vitro

The CD44<sup>+</sup>CD24<sup>+</sup>, CD44<sup>-</sup>CD24<sup>-</sup> and unsorted cells were diluted to a density of about  $10^4$  cells/mL with serum-free medium (SFM), a mixture of DMEM-F12 containing 10 ng/mL fibroblast and 20 ng/mL epidermal growth factors, 5  $\mu$ g/mL insulin, 2.75 mg/mL transferrin, 2.75 ng/mL selenium (insulin-transferrin-selenium solution), penicillin ( $1 \times 10^5$  U/L) and streptomycin (100 mg/L). The 200- $\mu$ L/well diluted cell suspension was plated to 96-well culture dishes. The wells with  $2 \times 10^3$  cells were observed everyday under an Olympus CKX41 microscope; the images were captured using an Olympus C5050Z camera. Each group was set up with five duplicate holes. Their OD values were measured with spectrophotometer at 490 nm by 3-[4,5-dimethyl-2-thiazolyl]-2, 5-diphenyl-2H-tetrazolium bromide (MTT) method, and a 96-well plate was determined every 24h. The mean value was obtained and a growth curve was drawn.

### Transplantation of cells into nude mice

After resuspension, CD44<sup>+</sup>, CD44<sup>-</sup>, CD24<sup>+</sup>, CD24<sup>-</sup>, CD44<sup>+</sup>CD24<sup>+</sup>, CD44<sup>-</sup>CD24<sup>-</sup> and unsorted cells were diluted to a density of about  $5 \times 10^6$  to  $5 \times 10^3$  cells/mL with SCM. The cells (0.1 mL) were injected into the hypodermis of right and left armpit of nude mice. The mice were maintained in a specific pathogen-free room under constant temperature and humidity.

### Immunohistochemical staining of CD44 and CD24

All samples of the CD44<sup>+</sup>CD24<sup>+</sup> cell-formed nodules were placed into 10% formalin immediately, processed with routine histological procedures, and embedded in paraffin. Serial sections were cut 5  $\mu$ m thick, and parts of them were stained with hematoxylin and eosin for routine histological observation under light microscope. The others were used for immunohistochemical examination for the CD44 and CD24. After deparaffinization (hydration), sections were treated sequentially with normal goat serum, anti-human CD44 polyclonal antibody (1:200) or anti-human CD24 polyclonal antibody (1:200), biotin-labeled goat anti-mouse IgG, and avidin-biotin-peroxidase complex (ABC). The sites of peroxidase binding were demonstrated by the diaminobenzidine method. Sections were then counterstained with hematoxylin for microscopic examination. Similar procedures were done for the PANC-1 cells. The numbers and areas of CD44-positive and CD24-positive foci > 0.2 mm in diameter and the total areas of the examined sections were measured using a Olympus C5050Z digital camera, Adobe Photoshop version 7.0, and Image-Pro Plus version 6.0.

Figure 1 Analysis of Panc-1 pancreatic cancer cells by FACS.

### Statistical analysis

Data were expressed as means  $\pm$  SD, and were analyzed with SPSS 12.0,  $P < 0.05$  was considered significant in difference.

## RESULTS

### Presence of CD44 and CD24 on cell surface of pancreatic carcinoma cell lines

To determine the presence of CD44 and CD24 on the cell surface of the PANC-1 cells, flow cytometric analysis was made. The cell surface markers CD44 and CD24 were chosen as a starting point based on prior work on breast cancer stem cells, in which  $CD44^+CD24^{-/low}$  Lineage tumorigenic cells generated tumors histologically similar to primary breast tumors when as few as 100 cells were transplanted, whereas tens of thousands of bulk unsorted cancer cells were needed to form tumors in NOD/SCID mice<sup>[7]</sup>. CD44 and CD24 have been identified as the stem cell surface markers, which act as adhesive molecules with multiple signaling functions<sup>[12-14]</sup>. As shown in Figure 1, 5.1%-17.5% of sorted PANC-1 cells expressed the cell surface marker CD44, and 57.8%-70.1% expressed CD24. When expression of multiple surface markers was examined, only 2.1%-3.5% of cells were  $CD44^+CD24^+$  (Figure 1).

### Proliferation potential of cells *in vitro*

To evaluate the proliferation ability of cells *in vitro*, the  $CD44^+CD24^+$ ,  $CD44^+CD24^-$  and unsorted cells were cultured in SCM in 96-well culture dishes, their OD values were measured with spectrophotometer at 490nm by MTT method. Compared with  $CD44^+CD24^-$  cells,  $CD44^+CD24^+$  cells had a lower growth rate and longer doubling time *in vitro*. For the former, the index growth trend appeared at the 5th day, while the latter appeared at the day 7 (Figure 2).

### Establishment of xenografts

To test the capability of tumor initiation, we injected cells into the hypodermis of right and left armpit of nude mice. When unsorted PANC-1 cells ( $5 \times 10^3$ ) were injected, no tumor growth was found at wk 12 while  $10^4$  cells were

Figure 2 Growth curve of tumors cells *in vitro*.

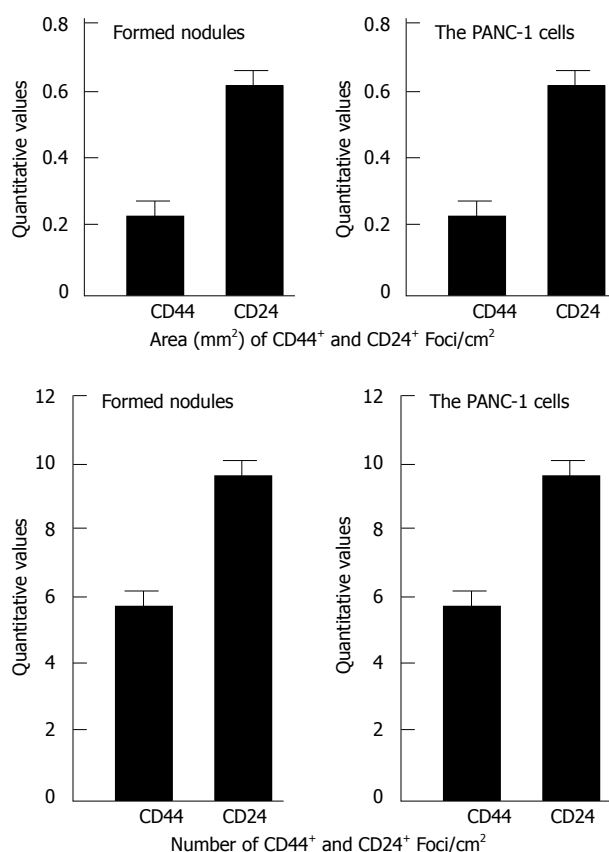

injected, one of six mice developed tumors. For cancer cells sorted for the markers CD44 and CD24, expression of individual markers identified cell populations with enhanced tumorigenic potential. For example, injection of  $5 \times 10^3$   $CD44^+$  cells would occasionally form a tumor (1 of 6 animals), whereas no tumor was observed with  $CD44^-$  cells until at least  $5 \times 10^4$  cells were injected (1 of 10 animals). Six of 10 animals developed tumors when injected with  $5 \times 10^4$   $CD44^+$  cells, representing a 10-fold increase in tumorigenic potential compared with marker negative cells ( $P = 0.029$ ). Similar results were obtained with  $CD24^+$ . Injection of  $CD44^+CD24^+$  cells resulted in an enhanced tumorigenic potential compared with single marker sorted cells. More tumors formed with injection of as few as  $10^3$  cells, and no tumor formed in marker-negative cells until at least  $5 \times 10^4$  cells were injected. The sorted cell population with the highest tumorigenic potential was those expressing CD44 and CD24. For example, injection of  $10^4$   $CD44^+CD24^-$  cells in nude mice found no tumor growth at wk 12. In contrast, nude mice injected with  $10^3$   $CD44^+CD24^+$  cells had large tumors at wk 4 (2 of 8), a 20-fold increase in tumorigenic potential ( $P < 0.05$  or  $P < 0.01$ ) (Table 1). There was no obvious histological difference between the  $CD44^+CD24^+$  cell-formed nodules and PANC-1 cells.

### CD44<sup>+</sup> and CD24<sup>+</sup> positive numbers and areas

For sections stained with hematoxylin and eosin, tumor cells with variable shape from polygon, spindle to irregular were seen under light microscope. The total  $CD44^+$  positive and  $CD24^+$  positive numbers and areas in the examined sections were measured using an Olympus C5050Z digital camera, Adobe Photoshop version 7.0, and Image-Pro Plus version 6.0. There was no significant difference in quantitative values of  $CD44^+$  and  $CD24^+$  cells between the formed nodules and the PANC-1 cells ( $P > 0.05$ ) (Figure 3).

## DISCUSSION

The theory of tumor stem cells<sup>[15,16]</sup> indicates that tumor cells have heterogeneity, i.e., the majority of cells in the

**Figure 3** Quantitative values of CD44<sup>+</sup> and CD24<sup>+</sup> cell foci in the formed nodules and PANC-1 cells. There was no significant difference between the formed nodules and PANC-1 cells.

tumor have lost the growth potential, only a small subset of cells have the capability of the infinite proliferation, the differentiation and the formation of cloning *in vitro*. The initial isolation and identification of tumor stem cells was first proved in hematological malignancies. The CD34<sup>+</sup>CD38<sup>-</sup> phenotype cells (5% of the cancer cells) with obvious proliferation, differentiation and self-renewal ability were purified from the blood of the patients with acute myeloid leukemia<sup>[17,18]</sup>. In 2003, researchers found that only a small subset of human breast cancer cells, with the phenotype CD44<sup>+</sup>CD24<sup>-</sup>, formed new tumors in NOD/SCID mice<sup>[7]</sup>. These breast cancer-initiating cells can be isolated and propagated *in vitro* as extensively proliferating, clonal, nonadherent spherical clusters are able to differentiate along different mammary epithelial lineages<sup>[19]</sup>. A small population of cancer-initiating cells (also called cancer stem cells) was later found in several malignancies, including brain<sup>[8]</sup>, prostate<sup>[10]</sup>, liver<sup>[20,21]</sup>, lung<sup>[22]</sup>, melanoma<sup>[23]</sup>, and colon tumors<sup>[24,25]</sup>.

Although there is increasing evidence that a rare population of undifferentiated cells is responsible for tumor formation and maintenance, little work has been done on the identification of pancreatic cancer special surface markers or on isolation of pancreatic tumor-initiating cells. Based on studies in breast cancer<sup>[7]</sup> and pancreatic adenocarcinoma<sup>[16]</sup>, we identified cells with the characteristics of tumor stem cells according to the cell surface markers CD44 and CD24 by flow cytometry from

**Table 1** Tumor formation ability of sorted pancreatic cancer cells using surface markers (number of tumors formed/number of injections)

Compared with results from marker-negative cells.

pancreatic adenocarcinoma cell line PANC-1. Tumor stem cells have the capability to maintain themselves in culture in an undifferentiated state, initiate tumor growth after xenotransplantation in mice, and differentiate into cancers that are phenotypically indistinguishable from the original tumor. We found that 5.1%-17.5% of sorted PANC-1 cells expressed the cell surface marker CD44, 57.8%-70.1% expressed CD24, and only 2.1%-3.5% of cells were CD44<sup>+</sup>CD24<sup>+</sup>. To take a small subset of cells and put it in the organism and see if it regenerates the original tissues is the classic definition of a stem cell. We injected cells into the hypodermis of the right and left armpit of nude mice to test the capability of tumor initiation. When  $5 \times 10^3$  unsorted PANC-1 cells were injected into nude mice, no tumor grew at wk 12 unless at least  $10^4$  cells were injected. For cancer cells sorted for the markers CD44 and CD24, injection of  $5 \times 10^3$  CD44<sup>+</sup> cells would form a tumor, whereas no tumor was observed with CD44<sup>-</sup> cells until at least  $5 \times 10^4$  cells were injected. Similar results were obtained with CD24<sup>+</sup>. The sorted cell population with the highest tumorigenic potential was those cells expressing CD44 and CD24. For instance, injection of  $10^4$  CD44<sup>+</sup>CD24<sup>-</sup> cells into nude mice, no tumor growth was evident at wk 12. In contrast, nude mice injected with  $10^3$  CD44<sup>+</sup>CD24<sup>+</sup> cells had large tumors at wk 4. Moreover, the CD44<sup>+</sup>CD24<sup>+</sup> cells maintained the ability to engraft and reproduce the same histological and antigenic pattern of the PANC-1. In addition, compared with CD44<sup>+</sup>CD24<sup>-</sup> cells *in vitro*, CD44<sup>+</sup>CD24<sup>+</sup> cells had a lower growth rate. The reason is that tumor stem cells are similar to stem cells, which is in relatively static group of cells, and besides other primates, the stem cell pool proliferates once a year<sup>[26]</sup>. For the CD44<sup>+</sup>CD24<sup>+</sup> cells, there were biological behaviors of the lower proliferative index and the faster tumor growth rate *in vivo*. It is self-contradictory. The reason awaits further studies. In addition, there was no obvious histological difference between the CD44<sup>+</sup>CD24<sup>+</sup> cell-formed nodules and PANC-1 cells.

The above results showed that CD44 and CD24 may be used as markers for isolation of pancreatic cancer stem cells from pancreatic adenocarcinoma cell line PANC-1, subpopulation cells CD44<sup>+</sup>CD24<sup>+</sup> have the characteristics of tumor stem cells. The purification and

other biological behaviors of pancreatic adenocarcinoma stem cells need to be further studied in the future.

## COMMENTS

### Background

Pancreatic carcinoma is an obstinate disease that is difficult to deal with. Though pancreatic cancer accounts for only 2%-3% of all cancers, it is the fourth most frequent cause of cancer deaths in industrialized countries. Unfortunately, only 18% will survive one year after diagnosis, the five-year survival rate is only 4%. Conventional main treatments for pancreatic cancer are surgery, radiation therapy and chemotherapy. Despite advances in surgical and medical therapy, little effect has been achieved on the mortality rate of this disease.

### Research frontiers

The initial isolation and identification of tumor stem cells was first proved in hematological malignancies. The CD34<sup>+</sup>CD38<sup>-</sup> phenotype cells (5% of the cancer cells) with obvious proliferation, differentiation and self-renewal ability had been purified from the blood of the patients with acute myeloid leukemia. Researchers have discovered a small population of cancer-initiating cells (also called cancer stem cells) in several malignancies, including brain, prostate, liver, lung, melanoma, and colon tumors.

### Innovations and breakthroughs

The authors isolated pancreatic adenocarcinoma cell line PANC-1 according to the cell surface markers CD44 and CD24 by flow cytometry, obtained subpopulation cells which have properties of tumor stem cells, and identified the ability of propagation of the tumor stem cells *in vitro* and *in vivo*.

### Applications

Because cancer stem cells are thought to be responsible for tumor initiation and its recurrence after an initial response to chemotherapy, it may be a very promising target for new drug development.

### Peer review

This study corroborates a recent publication in the pancreas reporting that a subpopulation of Panc1 cells can propagate to form spheres and that these cells express stem cell markers such as CD44. The study is very interesting.

## ACKNOWLEDGMENT

We thank our colleagues from the Research Laboratory of General Surgery, Union Hospital, Wuhan, for their technical assistance.

### Abstract

**AIM:** To evaluate the feasibility and efficacy of percutaneous transhepatic lymphosonography (PTL) as a novel method for the detection of tumor lymphangiogenesis in hepatic VX<sub>2</sub> of rabbits and to evaluate combined PTL and routine contrast-enhanced ultrasonographic imaging for the diagnosis of liver cancer.

**METHODS:** Ten rabbits with VX<sub>2</sub> tumor were included in this study. SonoVue (0.1 mL/kg) was injected into each rabbit *via* an ear vein for contrast-enhanced ultrasonographic imaging, and 0.5 mL SonoVue was injected into the normal liver parenchyma near the VX<sub>2</sub> tumor for PTL. Images and/or movie clips were stored for further analysis.

**RESULTS:** Ultrasonographic imaging showed VX<sub>2</sub> tumors ranging 5-19 mm in the liver of rabbits. The VX<sub>2</sub> tumor was hyperechoic and hypoechoic to liver parenchyma at the early and later phase, respectively. The hepatic lymph vessels were visualized immediately after injection of contrast medium and continuously visualized with SonoVue<sup>®</sup> during PTL. The boundaries of VX<sub>2</sub> tumors were hyperechoic to liver parenchyma and the tumors. There was a significant difference in the values for the boundaries of VX<sub>2</sub> tumors after injection compared with the liver normal parenchyma and the tumor parenchyma during PTL.

**CONCLUSION:** PTL is a novel method for the detection of tumor lymphangiogenesis in hepatic VX<sub>2</sub> of rabbits. Combined PTL and contrast-enhanced ultrasonographic imaging can improve the diagnosis of liver cancer.

### INTRODUCTION

The liver is the largest organ in the abdominal cavity and the main region of primary tumor and distant metastasis of malignant tumors. Detection of tumor nodules in the liver is of major importance for formulating therapeutic strategies and predicting the prognosis in malignant tumors<sup>[1]</sup>.

Non-ionizing radiation, portable and noninvasive real-time imaging<sup>[2,3]</sup>, ultrasonography (US) are the most commonly used imaging techniques. Introduction of microbubbles as contrast agents for ultrasound has improved the image quality and diagnostic value<sup>[4-8]</sup>. Contrast-enhanced ultrasonographic imaging enables noninvasive measurements of microvascular perfusion in the heart, brain, kidney, skeletal muscle, skin grafts and solid tumors<sup>[9]</sup> and provides functional images of angiogenesis in animals and humans.

At present, contrast-enhanced ultrasonographic imaging research has mainly focused on angiogenic blood vessels, blood vessel function and efficacy of

angiogenesis inhibitors. Recently, lymphangiogenesis has become a new research frontier<sup>[10]</sup>. Tumor lymphangiogenesis is the process of forming new lymph vessels in tumors and closely related to tumor development and progression. It is necessary to find noninvasive methods for evaluating lymphangiogenesis *in situ*. However, little is known about the contrast-enhanced ultrasonographic imaging used to detect tumor lymphangiogenesis. Recently, lymphosonography after interstitial injection of microbubble-based contrast agents can trace the lymphatic channels from the injection site up to the draining sentinel lymph nodes<sup>[11-15]</sup>. However, no report is available on lymphosonography for tumor lymphangiogenesis.

The aim of the present study was to evaluate the feasibility and efficacy of PTL with a small volume of SonoVue<sup>®</sup> as a novel method for the detection of tumor lymphangiogenesis of hepatic VX<sub>2</sub> in rabbits and to evaluate the combined PTL and contrast-enhanced ultrasonographic imaging in the diagnosis of liver cancer.

## MATERIALS AND METHODS

### Animal model

Ten male health New Zealand rabbits, weighing 2.5-3.0 kg, were included in this study and housed in an approved facility with free access to water and standard diet throughout the study. The study, approved by the Institutional Review Board for Animal Research, was performed following the Guidelines for the Care and Use of Laboratory Animals<sup>[16]</sup>.

An undifferentiated VX<sub>2</sub> carcinoma growing rapidly in rabbits served as the experimental tumor. Two VX<sub>2</sub> tumors were implanted into the right and left lobes of liver, respectively. In brief, rabbits were anesthetized with ketamine hydrochloride (40 mg/kg) and xylazine hydrochloride (5 mg/kg) intramuscularly. The rabbits were intermittently given small supplementary doses of sodium pentobarbital (ranging from 3.1 to 6.5 mg/kg) during the experiment to maintain adequate sedation, fixed in a supine position on a rigid board of paper. Hair on the abdominal skin was shaved after the animals became stable. Diagnostic US was performed to assess the implantation site. Cryoconserved tumor material, implanted in the lower leg muscles of an additional animal and harvested after it reached a size of 1.5 cm, was placed into a saline solution and cut into sections measuring 1 mm × 1 mm × 1 mm.

The implantation method used has been described elsewhere<sup>[17]</sup>. Only part of tumor tissue showing no macroscopic signs of necrosis was used. A 16-gauge intravenous cannula was placed into the left and right liver lobe respectively under US guidance, and the prepared tumor tissue sections were pushed through the cannula and placed at the preselected position. The same procedure was performed on each animal. The rabbits were permitted to recover and followed up sonographically (Sequia 512, Siemens, Germany) weekly until a localized, avascular carcinoma-like mass developed at the injection site after 10-15 d.

### Equipment

Sequia 512 US image system was purchased from Siemens, Germany, with a L15-8 probe equipped for Cadence CPS software. Its acoustic output was carefully controlled by the operator. MI was set at 0.1-0.3 in order to avoid considerable bubble destruction and reduction of the contrast effect. Cadence CPS is a real-time, non-linear imaging technique specific for the second echo-contrast agent examination. Cadence CPS processing utilizes all non-linear responses, fundamental and higher order harmonics, to produce high sensitivity contrast agent images with excellent agent-to-tissue specificity at a very low MI. Images and/or movie clips were stored during PTL and contrast-enhanced ultrasonographic imaging.

### Contrast agent

Contrast agent used in this study was SonoVue<sup>®</sup> (Bracco, Milan, Italy). Microbubbles are sulfur hexafluoride stabilized in a phospholipid shell, 1-10 µm in diameter, averaging about 2.5 µm. The SonoVue<sup>®</sup> preparation was reconstituted just before administration by adding 5 mL sterile saline to the freeze-dried powder, so that sulfur hexafluoride had a concentration of 45 µg/mL in the suspension.

### SonoVue<sup>®</sup> injection

SonoVue (0.1 mL/kg) was injected *via* an ear vein as a rapidly injected bolus, followed by a 1.5 mL saline flush for routinely contrast-enhanced ultrasonographic imaging.

SonoVue (0.5 mL) was injected into the normal liver parenchyma near the VX<sub>2</sub> tumors as a rapidly injected bolus using a tuberculin syringe and a 26-gauge needle for PTL. The absorption of the contrast agent and its flow were observed in lymphatic channels of the VX<sub>2</sub> tumors.

### Statistical analysis

For quantitative analysis, videodensities of the appropriate regions of interest (ROI), including perineoplastic liver parenchyma, boundaries of the tumor and tumor parenchyma were recorded during PTL. Respective evaluations were made for PTL. Data analysis was carried out using SPSS 16 statistical software. All videodensity data were expressed as mean ± SD. Parameters were tested using paired *t* test. Statistical analysis was performed using one-way analysis of variance and Dunnett's multiple comparison tests. *P* < 0.05 was considered statistically significant.

## RESULTS

The VX<sub>2</sub> tumor in liver of rabbits ranging 5-19 mm was found to be a low echoic mass. However, because the VX<sub>2</sub> tumor was almost isoechoic with the normal tissue and boundaries of the masses were unclear, detection and delineation of the lesion were difficult before SonoVue<sup>®</sup> injection (Figure 1A).

Since the typical enhancement pattern of VX<sub>2</sub> tumor detected by routine contrast-enhanced ultrasonographic imaging was hyperechoic and hypoechoic to liver

**Figure 1** Liver of a VX<sub>2</sub> tumor-bearing rabbit imaged in the conventional mode before (A), immediately after 18 s (B) and 96 s (C) of injection of 0.1 mL sonazoid microbubbles/kg. Arrows indicate VX<sub>2</sub> tumor.

**Figure 2** Hepatic lymph vessels visualized 36 s (A), 4 min (B), 7 min (C) 18 min (D) after injection of contrast agent and continuously visualized with SonoVue® during PTL with hyperechoic boundaries of VX<sub>2</sub> tumors to liver parenchyma and the tumor.

parenchyma during the early and later phase, respectively, a much more rapid wash-in and -out of ultrasonographic contrast agent was observed compared to the normal liver parenchyma (Figure 1B and C).

The enhancement pattern of VX<sub>2</sub> tumors detected by PTL was significantly different from the typical enhancement pattern of VX<sub>2</sub> tumors detected by routine contrast-enhanced ultrasonographic imaging. The hepatic lymph vessels were visualized immediately and continuously during PTL. SonoVue® was deposited in the parenchyma relatively quickly in winding channels. At the same time, the boundaries of VX<sub>2</sub> tumors were hyperechoic to liver parenchyma and the tumors. The hyperechoic boundaries clearly delineated VX<sub>2</sub> tumors compared with the normal liver and tumor parenchyma (Figure 2A-C). The difference in the videodensitometric measurements of the boundaries of VX<sub>2</sub> tumors was significantly higher than the baseline (Figure 3).

Conversely, videodensity in the normal liver and tumor parenchyma had no signal enhancement compared with the baseline (Figure 3). There was a significant difference in the boundaries of VX<sub>2</sub> tumors compared with the baseline as well as the normal liver and tumor parenchyma (Figure 3).

## DISCUSSION

Ultrasound is an important and useful imaging method for the detection of tumors. Ultrasound contrast agents containing encapsulated microbubbles are mainly used to increase the diagnostic imaging of tumors. McCarville *et al*<sup>[18]</sup> showed that gray-scale US measurements of microbubble contrast agent flow can be used to detect the functional consequences of antiangiogenic therapy for tumors and to assess angiogenesis inhibitors that act through different mechanisms<sup>[19-23]</sup>.

**Figure 3** Videodensitometric measurements of liver normal parenchyma (white), tumor parenchyma (gray) and tumor boundary (black) before and after percutaneous transhepatic injection of contrast agent SonoVue<sup>®</sup> into the normal liver parenchyma near the VX<sub>2</sub> tumors during PTL. \**P* < 0.05 vs respective pre-injection values (Dunnett).

Recently, lymphangiogenesis has become a new research frontier<sup>[10]</sup>. The important functions of the lymphatic system are to remove damaged cells from the body and to prevent the spread of infection and cancer for the maintenance of normal tissue fluid balance and immune surveillance. In spite of its important functions in physiological and pathological conditions, including tumor metastasis, lymphoedema and inflammation, lymphatic vessels have not received as much attention as blood vessels, and the mechanisms regulating their development and growth have been poorly understood<sup>[24]</sup>. Lymphangiogenesis is associated with increased tumor cells in lymphatics and lymph nodes, served as an independent prognostic factor and a potential target in the development of new therapies for hilar cholangiocarcinoma<sup>[25]</sup>. At present, neovessel formation, including lymphangiogenesis, represents the key event in tumor progression. Inhibition of metastatic spread may be achieved by restriction of lymphatic vessel growth with novel therapeutic strategies for anti-lymphangiogenic therapies<sup>[26]</sup>.

Currently, histologic determination of the mean intratumoral or peritumoral lymphatic vessels is the most commonly used method for assessing lymphangiogenesis. However, obtaining tissue for histologic evaluation may require an invasive procedure that cannot be normally accepted by patients. Furthermore, determination of the lymphatic microvessel density does not provide an accurate assessment of the functionality of tumor lymphatic vessels because many poorly functioning or collapsed lymphatic vessels have endothelial cells that are stained and counted. Therefore, the lymphatic microvessel density *in vivo* may be a potentially useful marker for assessing lymphangiogenesis in tumors at diagnosis, and accurately reflects the effectiveness of antitumor therapy.

Ultrasound lymphography with subcutaneous injection of ultrasound contrast material enables direct visualization of the lymphatic drainage pathways and sentinel lymph nodes of breast diseases, melanoma, *etc*<sup>[11-15]</sup>.

In the present study, the traditional percutaneous hepatic injection method was used to deliver SonoVue<sup>®</sup> microbubbles into the liver under US guidance to investigate tumor lymphangiogenesis. To the best of our knowledge, lymphosonography for the detection of tumor lymphangiogenesis has not been reported before. Hepatic lymph vessels were visualized immediately after injection of contrast agent and opacified with SonoVue<sup>®</sup> during PTL, whereas liver parenchyma was not enhanced by SonoVue<sup>®</sup>. SonoVue<sup>®</sup> was deposited in the parenchyma relatively quickly in winding lymph vessels. At the same time, the boundaries of VX<sub>2</sub> tumors were hyperechoic to liver parenchyma and the tumors, indicating that hyperechoic boundaries clearly delineate the peritumoral lymphatic vessels of VX<sub>2</sub> tumors. Compared with the hyperechoic boundaries of VX<sub>2</sub> tumors, the videodensity in the tumor parenchyma had no signal enhancement compared with the baseline. This is consistent with the findings in a previous study<sup>[27]</sup>. It was reported that three-dimensional changes of lymphatic architecture in rabbit VX<sub>2</sub> tongue cancer, dynamics of its adjacent lymphatic architecture, especially the increased number of capillaries in preexisting lymphatic vessels outside the tumor margin, are associated with lymph node metastasis<sup>[28,29]</sup>. The morphological features of lymphatic vessels during PTL may be important predictive markers for evaluating lymphatic metastasis and prognosis of tumors. The lymphatic drainage paths and lymphatic distribution pattern in hepatic tissue have been found to be very constant, showing that angiogenesis is a critical factor for tumor growth and metastasis<sup>[23]</sup>. In this study, the typical enhancement pattern of VX<sub>2</sub> tumors detected by routine contrast-enhanced ultrasonographic imaging was hyperechoic and hypoechoic to the liver parenchyma at the early and later phases, respectively, confirming that routine contrast-enhanced ultrasonographic imaging can assess tumor vascularity and reveal the microvascular perfusion and function<sup>[23,30,31]</sup>.

The specific mechanism by which the contrast agents used in this study enter the lymphatic system is unclear. SonoVue<sup>®</sup> microbubbles have a mean diameter of 2.5  $\mu\text{m}$  with 99% smaller than 11  $\mu\text{m}$ , allowing a free passage of capillaries, but keeping within the vascular lumen. This means that SonoVue<sup>®</sup> microbubbles in the hepatic inter-space cannot come into blood vessels. Although the optimal particle diameter for lymphatic uptake is 10-50 nm, particles up to hundreds of nanometers in diameter appear to be able to cross the lymphatic endothelium<sup>[32-34]</sup>. Due to the flexibility of microbubbles, phospholipidic shell and poor solubility and diffusivity of SF<sub>6</sub>, SonoVue<sup>®</sup> is highly resistant to pressure. This means the microbubbles may more easily distort and traverse lymphatic wall fenestrations into lymph capillaries.

Due to the different membranes, 99% of Sonazoid and Optison are phagocytosed by Kupffer cells, whereas only 7.3% of SonoVue<sup>®</sup> is phagocytosed by Kupffer cells<sup>[35]</sup>. This means that the SonoVue<sup>®</sup> microbubbles are

not easily phagocytosed by macrophages. Tracing the SonoVue<sup>®</sup> microbubble flowing in the lymph vessels can improve the pathologic staging of the disease and its treatment.

At the same time, microbubbles are used not only for contrast enhancement of ultrasound images and improvement of diagnosis, but also for delivery of drugs and genes<sup>[36-40]</sup>. The ability to localize lymphatic vessels in tumors may be of value for a new route to the administration of drugs, gene and immunotherapy, etc. Drugs/genes containing vesicles may be injected simultaneously with microbubbles or microbubbles in combination with microbubble-forming vesicle aggregates. Using microbubbles oscillation and cavitation under US guidance might assist in delivering drugs/genes from vesicles to the interstitial tissue, which may be an effective treatment for some diseases.

Since few studies about hepatic lymphography are available at present, it is difficult to find microbubbles in lymphatic vessels. Due to this reason, the study only limited to the ultrasound characteristic aspects of PTL, which were not compared with the histopathologically aspects of rabbit VX<sub>2</sub> tumors.

In conclusion, PTL with a small volume of SonoVue microbubbles is a novel method for the detection of tumor lymphangiogenesis of hepatic VX<sub>2</sub> in rabbits. Combined PTL and contrast-enhanced ultrasonographic imaging can improve the diagnosis of liver cancer. Additional research is needed to determine the potential advantages of PTL and to determine if PTL can be used in clinical practice.

## COMMENTS

### Background

Ultrasonography (US) is one of the most commonly used imaging techniques. Lymphangiogenesis has become a new research frontier. Tumor lymphangiogenesis is the process of generating new lymph vessels within and surrounding tumors, which is closely related to tumor development and progression. It is necessary to develop noninvasive methods for evaluating lymphangiogenesis *in situ*. However, to the best of our knowledge, lymphosonography showing tumor lymphangiogenesis with percutaneous hepatic injection of ultrasound contrast material has not been reported before.

### Research frontiers

This study investigated tumor angiogenesis and lymphangiogenesis with combined percutaneous transhepatic lymphosonography (PTL) and contrast-enhanced ultrasonographic imaging for hepatic VX<sub>2</sub> in rabbit liver.

### Innovations and breakthroughs

Contrast-enhanced ultrasonographic imaging enables noninvasive measurements of microvascular perfusion in the heart, brain, kidney, skeletal muscle, skin grafts and solid tumors in animals and humans. It was recently reported that lymphosonography after interstitial injection of microbubble-based contrast agents can trace lymphatic channels from the injection site up to the draining sentinel lymph nodes. This is the first study to evaluate the feasibility and efficacy of PTL with a small volume of SonoVue<sup>®</sup> as a novel method for the detection of tumor lymphangiogenesis of hepatic VX<sub>2</sub> in rabbits and to evaluate the role of combined PTL and contrast-enhanced ultrasonographic imaging in improving the diagnosis of liver cancer.

### Applications

PTL with a small volume of SonoVue microbubbles is a novel method for the detection of tumor lymph angiogenesis of hepatic VX<sub>2</sub> in rabbits. Combined PTL and contrast-enhanced ultrasonographic imaging can improve the diagnosis of liver cancer. Additional research is needed to determine the potential advantages of PTL and to determine if PTL can be used in clinical practice.

### Peer review

PTL is a new tool for the diagnosis of liver cancer. The study is well designed and interesting.

Tuberculosis *versus* non-Hodgkin's lymphomas involving small bowel mesentery: Evaluation with contrast-enhanced computed tomography. *World J Gastroenterol* 2008; 14(24): 3914-3918 Available from: URL: <http://www.wjgnet.com/1007-9327/14/3914.asp> DOI: <http://dx.doi.org/10.3748/wjg.14.3914>

### Abstract

**AIM:** To evaluate the specific computed tomography (CT) imaging criteria for differentiating tuberculosis involving the small bowel mesenteric lymph nodes from lymphomas.

**METHODS:** We retrospectively reviewed the anatomic distribution, CT enhancement patterns of lymphoma in 18 patients with mesenteric tuberculosis and 22 with untreated non-Hodgkin's lymphomas (NHL) involving small bowel mesentery (SBM). Of the 18 patients with tuberculosis, 9 had purely mesenteric tuberculous lymphadenopathy (TL), and 9 had mesenteric TL accompanied with tuberculous mesenteritis (TLM).

**RESULTS:** CT showed that tuberculosis and NHL mainly affected lymph nodes in the body and root of SBM. Homogeneously enhanced lymph nodes in the body and root of SBM were found more often in the NHL ( $P < 0.05$ ). Homogeneously mixed peripheral enhanced lymph nodes in the body of SBM were found more often in mesenteric TL and TLM ( $P < 0.05$ ). Peripheral enhanced lymph nodes in the root of SBM were found more often in mesenteric TL and TLM ( $P < 0.01$ ). "Sandwich sign" in the root of SBM was observed more often in NHL ( $P < 0.05$ ).

**CONCLUSION:** Anatomic lymph node distribution, sandwich sign and specific enhancement patterns of lymphadenopathy in SBM on CT images can be used in differentiating between tuberculosis and untreated NHL involving SBM.

### INTRODUCTION

The incidence of tuberculosis is increasing<sup>[1-4]</sup>. Abdominal tuberculosis can affect the gastrointestinal tract, peritoneum and lymph nodes. When the prevalence of abdominal tuberculosis is high, it is difficult to establish its diagnosis<sup>[5-7]</sup>. Lymphadenopathy is the most common manifestation of abdominal tuberculosis and may be easily confused with lymphomas involving abdominal lymph nodes in up to 55% of cases without other evidence of abdominal involvement<sup>[8]</sup>. Clinical and radiologic differentiation between the two can be challenging<sup>[6,8,9]</sup>. To our knowledge, a comparison of computed tomography (CT) findings in tuberculosis and lymphoma of the mesenteric lymph nodes has not been reported<sup>[10]</sup>. Lymphoma<sup>[11]</sup> is the most common malignant neoplasm affecting the mesentery and Hodgkin's Lymphoma can rarely involve the mesentery<sup>[10]</sup>, so we conducted a comparison of CT findings in tuberculosis and non-Hodgkin's lymphoma (NHL) involving the small bowel mesentery (SBM) to improve the physicians' ability to distinguish between these entities.

### MATERIALS AND METHODS

We retrospectively reviewed the medical records of 40 consecutive patients with documented tuberculosis [18 (45%) with mesenteric tuberculosis and 22 (55%) with untreated non-Hodgkin's lymphomas (NHL) involving small bowel mesentery (SBM)] who underwent contrast-

enhanced CT from October 1998 to May 2007 in our hospital. The patients with tuberculosis included 12 men and 6 women at the age ranging from 19 to 56 years (mean, 29 years) with no evidence of HIV infection, neoplastic disease, or opportunistic infection. Of the 18 patients with tuberculosis, 9 (50%) had purely mesenteric tuberculous lymphadenopathy (TL) [presented with a small quantity of ascites (*n* = 3), thickened peritoneum (*n* = 2), thickened small bowel wall (*n* = 1), "dirty" great omentum (*n* = 1), renal tuberculosis (*n* = 1), hepato-duodenum ligament tuberculosis (*n* = 1), omental bursa tuberculosis (*n* = 1), pleuritis (*n* = 2)], and 9 (50%) had mesenteric TL accompanied with tuberculous mesenteritis (TLM) [presented with ascites (*n* = 8), thickened peritoneum (*n* = 8), thickened small bowel wall (*n* = 5), "dirty" great omentum (*n* = 6), "caked" great omentum (*n* = 3), infra-bowel abscess (*n* = 1), renal tuberculosis (*n* = 1), pleuritis (*n* = 1)]. All the patients with tuberculosis had constitutional symptoms, such as weight loss, easy fatigability, night sweats, and obscure abdominal pains. Five of them had clinically palpable abdominal masses. Tuberculosis was diagnosed if lymphadenopathy was found through pathologic examination of specimens (*n* = 8) taken at laparotomy or microbiologic examination of abdominal tissues (*n* = 3). Tuberculosis was also diagnosed in patients for whom CT showed improvement in documented tuberculosis at extra-abdominal sites after anti-tuberculous chemotherapy (*n* = 7).

No evidence of HIV infection was found in the 22 patients (including 10 men and 12 women at the age ranging from 20 to 74 years, mean 49 years) with newly diagnosed and previously untreated NHL. The diagnosis was made by histologic examination of biopsy specimens of enlarged lymph nodes. Involvement of the left major psoas muscle in 2 patients and the adrenal gland in 1 patient was observed. Three patients had splenomegaly.

All patients giving their written informed consent were examined with a spiral CT scanner (Elscent HeliCAT Flash). Before undergoing CT, the patients drank 500 mL of a 1.5% diatrizoate solution. An 80-100 mL bolus of Ultravist (Schering Germany, 300 mgI/mL) at a rate of 2.5-3.0 mL/s was administered through veins. Contiguous axial images (5-8 mm thick) were obtained at 5-8 mm intervals from the dome of diaphragm to the symphysis pubis (120-140 KV, 212-250 Ma, pitch 1-1.5). Sixty seconds after injection of the contrast material, contrast-enhanced CT scan was performed.

Two observers unaware of the final diagnosis

independently reviewed each CT image and recorded a number of characteristics of enlarged lymph nodes in SBM, including anatomic location, enhancement patterns and "sandwich sign". Discrepancies in interpretation between observers were solved by consensus. Small bowel mesenteric lymph nodes were grouped anatomically into the following three sites: the root, margin (area including mesenteric marginal vessels and vasa rectas) and body of SBM (the area between the root and margin of SBM). The short-axis diameter of each node was measured. The CT images of enlarged lymph nodes were compared with those of normal lymph nodes as previously described<sup>[12]</sup>. The enhancement patterns of enlarged lymph nodes in the 40 patients were described as homogeneous, peripheral, and homogeneously mixed peripheral enhancement. Enhancement was considered peripheral when thick, irregular or thin rim was seen, and homogeneously mixed peripheral when some enlarged nodes showed homogeneous enhancement and other nodes at the same site showed peripheral enhancement. Additionally, we observed the extranodal sites of tuberculosis and NHL, including spleen and abdominal wall. Differences in anatomic distribution, enhancement patterns and presence of "sandwich sign" between the two groups were compared by statistical analysis. Because of the small number of cases, Fisher's exact test was used to compare tuberculosis with NHL involving SBM.

## RESULTS

The anatomic distribution and enhancement pattern findings are listed in Table 1 and the findings of "sandwich sign" are shown in Table 2.

CT revealed that TL and NHL affected mainly lymph nodes in the body and root of SBM (Figures 1 and 2). The margin of SBM was involved in NHL [5 patients (23%)], TL [1 patients (11%)], and TLM [0 patient (0%)].

Homogeneous enhancement (in the body of SBM) was found more often in NHL than in mesenteric TL and TLM (*P* < 0.01, *P* < 0.05). Homogeneously mixed peripheral enhancement (in the body of SBM) was observed more often in mesenteric TL and TLM than in NHL (*P* < 0.05). Homogeneous enhancement (in the root of SBM) was demonstrated more often in NHL than in TL (*P* < 0.05). Peripheral enhancement (in the root of SBM) was revealed more often in mesenteric TL and TLM than in NHL (*P* < 0.01). Enlarged lymph nodes

Table 2 Distribution of TL, TLM and NHL in mesenteric lymph nodes

	TL ( <i>n</i> = 9)			TLM ( <i>n</i> = 9)			NHL ( <i>n</i> = 22)

Disperse	1	6	7	0	9	9	5	14	10
Confluence	0	2	2	0	0	0	0	8	12
Sandwich sign	0	1	1	0	0	0	0	6	12

TL: Tuberculous lymphadenopathy; TLM: Tuberculous lymphadenopathy accompanied with mesenteritis; NHL: Non-Hodgkin's lymphoma.

**Figure 1** Contrast enhanced CT scan for a 25-year-old man with mesenteric TL showing enlarged lymph nodes in the body and root of SBM with peripheral enhancement (arrow) (A) and in the body of SBM with homogeneous enhancement (arrow) (B). The SBM was contracted and the wall of the small bowel was thickened.

**Figure 2** Contrast enhanced CT scan for a 56-year-old woman with NHL involving SBM showing enlarged lymph nodes in the root of SBM encasing the superior mesenteric artery (arrow), producing the "sandwich sign" (A) and homogeneously mixed peripheral enhancement of lymph nodes in the body of SBM encasing the small bowel mesenteric vessels (arrow), producing the "sandwich sign" (B).

(in the root of SBM) were dispersed in TLM, whereas confluence was found in NHL ( $P < 0.01$ ). "Sandwich sign" (in the root of SBM) was displayed more often in NHL than in mesenteric TL and TLM ( $P < 0.05$ ,  $P < 0.01$ ).

## DISCUSSION

TL is the most common manifestation of abdominal tuberculosis, and tuberculous infection may result in mesenteric lymphadenopathy<sup>[10,13]</sup>. It may be transmitted by three major routes. The first route is ingestion of materials infected with tubercle bacilli which are carried from a lesion in the intestinal submucosal layer to the lymph nodes draining the bowel segment. Drainage is usually from the lymphatics of the ileocecum, jejunum, ileum, and right side of colon to the peripancreatic and superior mesenteric lymph nodes. The second route is

hematogenous spread. Bacteria are disseminated from a distant site of infection, usually the lungs, to the abdominal lymphatic system. Because this process is systemic, it may cause infection of mesenteric lymph nodes. The third route is infection spreading directly to the abdominal lymph nodes from the serosa of adjacent infected structures. Literature *et al*<sup>[14]</sup> reported that most patients with a past history of TB come from areas with a high prevalence of active tuberculosis and have epigastric pain, fever and weight loss, and enlarged nodules with focal calcification sometimes.

SBM, in a series of fan-like ruffles, suspends the jejunum and ileum to the posterior abdominal wall consisting of two posterior peritoneal layers. It is composed of fatty, extraperitoneal connective tissue, blood vessels, nerves, lymph nodes, and peritoneal

investment. The attached border of SBM root extends obliquely from the distal duodenum at the lower border of pancreas on the left side of L2 to the cecum in the right iliac fossa. The line of attachment passes from the duodenojejunal junction over the third portion of the duodenum, then obliquely across the aorta, inferior vena cava, right ureter and psoas major muscle, to the right ilica region<sup>[15-17]</sup>.

The mesenteric lymph nodes can be divided into three subgroups: some lie close to the wall of small intestine, others occur in relation to primary branches of mesenteric vessels, and some consisting of central nodes along the main trunk of the superior mesenteric artery<sup>[18]</sup>.

In this study, 18 patients with tuberculosis and 22 patients with NHL mainly involved mesenteric lymph nodes in the body and root of SBM. Hence, distribution of enlarged lymph nodes in the diseases closely paralleled to the anatomic distribution.

Pathologic findings from surgical specimens of TL indicated that caseation or liquefactive substances at the center of enlarged lymph nodes had a low attenuation presumably resulting from insufficient blood supply, whereas peripheral inflammatory lymphatic tissue had a higher attenuation on enhanced CT resulting from the preserved blood supply<sup>[19]</sup>.

In most patients with untreated NHL, lymph nodes in the SBM increased homogeneously. In 9% of patients with NHL involving the body of SBM and 18% of patients with NHL involving the root of SBM, lymph nodes had a homogeneous and peripheral enhancement. Our findings on the morphology of lymph nodes are similar to those of previous reports, in which the enhancement patterns of untreated NHL are homogeneous or less frequently necrotic with central hypodensity in the neck and mediastinum<sup>[20-22]</sup>.

In this study, 25% of patients had mesenteric TL in the body of SBM, lymph nodes had peripheral enhancement. In 50% of patients with mesenteric TL and 44% of patients with TLM in the root of SBM, lymph nodes had a homogeneous and peripheral enhancement, more than that in NHL.

The focus of this study was to differentiate mesenteric tuberculosis from untreated NHL involving the SBM using contrast-enhanced CT. Anatomic distribution in patients with NHL involving SBM was similar to that in patients with mesenteric TL and TLM. Oliver *et al*<sup>[23]</sup> reported that enlarged lymph nodes have a decreased density and mesenteric stranding in 20% of patients with lymphoma after treatment. However, if relapse of the disease occurs, the lymph nodes appear homogeneous, suggesting that it is important to know if patients with NHL have undergone therapy that may have caused central low attenuation within nodes or mesenteric stranding in SBM, simulating TL involving the SBM.

Neoplastic involvement of the mesentery can be diagnosed in lymphoma on the basis of a characteristic appearance of “sandwich-sign” encasement of the superior mesenteric artery<sup>[18,24]</sup>. In our study, one patient with TL had “sandwich-sign” in the body and root of

SBM. However, it was detected in 27.3% of patients with NHL involving the body of SBM and in 54.5% of patients with NHL involving the root of SBM. When “sandwich-sign” is considered, mesenteric TL and TLM are rarely confused with NHL involving SBM in clinical practice.

One limitation of this study is the relatively small number of cases of tuberculosis involving SBM. Enlarged lymph nodes with a peripheral enhancement in SBM can also be seen in metastatic malignancy and other diseases. In general, if primary malignancy is known, most metastatic malignancies are easily diagnosed. Other causes for mesenteric lymphadenopathy that characteristically demonstrates central low attenuation on CT are Whipple disease<sup>[25]</sup> and cavitating mesenteric lymph node syndrome of celiac disease<sup>[26,27]</sup>. Mesenteric lymphadenopathy has also been reported in patients with familial Mediterranean fever during an acute abdominal attack, Castleman disease and Crohn's disease<sup>[28-31]</sup>.

In conclusion, contrast-enhanced CT can be used in differentiating mesenteric TL and TLM from NHL involving SBM on the basis of enhancement patterns of enlarged lymph nodes and presence of “sandwich-sign”. Mesenteric tuberculosis involves predominantly lymph nodes in the root and body of SBM. Lymph nodes at the margin of SBM are involved in only 5.5% of patients with mesenteric tuberculosis. In contrast, lymph nodes at the margin of SBM are involved in 22.7% of patients with NHL involving SBM. The presence of “sandwich sign” can be more frequently observed in NHL involving SBM than in mesenteric TL and TLM. A distinct difference in characteristic nodal enhancement patterns can also be observed.

## COMMENTS

### Background

The incidence of tuberculosis is increasing. When the prevalence of abdominal tuberculosis is high, it is difficult to establish its diagnosis. Lymphadenopathy is the most common manifestation of abdominal tuberculosis and may be easily confused with lymphoma involving abdominal lymph nodes. Lymphoma is the most common malignant neoplasm affecting mesentery, and Hodgkin's Lymphoma rarely involves mesentery. We conducted a comparison of CT findings in tuberculosis and non-Hodgkin's lymphoma (NHL) involving small bowel mesentery (SBM) to improve physicians' ability to distinguish between these entities.

### Research frontiers

The incidence of tuberculosis is increasing. Lymphadenopathy is the most common manifestation of abdominal tuberculosis. A comparison of CT findings in tuberculosis and lymphomas of retroperitoneal lymph nodes has been reported.

### Innovations and breakthroughs

SBM, in a series of fan-like ruffles, suspends the jejunum and ileum to the posterior abdominal wall consisting of two posterior peritoneal layers. NHL and tuberculous lymphadenopathy may involve SBM, and the correct diagnosis and

differential diagnosis are important for their clinical treatment. We compared CT findings in tuberculosis and NHL involving SBM to improve the physicians' ability to distinguish between these entities.

### Applications

This study may improve the physicians' ability to distinguish tuberculosis from NHL involving SBM, and specific CT imaging criteria may be used in the differential diagnosis of other malignant tumors involving SBM.

### Peer review

This study evaluated the specific CT imaging criteria for differentiating tuberculosis involving small bowel mesenteric lymph nodes from lymphomas, showing that distribution of anatomic lymph nodes, sandwich sign and specific enhancement patterns of lymphadenopathy in SBM on CT images can be used in differentiating tuberculosis from NHL involving SBM. The study is well designed and interesting.

## Abstract

The incidence of adenocarcinoma of the esophagogastric junction is constantly increasing. Curative treatment is no longer possible at the time of diagnosis in more than 50% of patients with esophageal carcinoma, and palliative treatment focusing on eliminating dysphagia is required. Endoscopic therapy with stent implantation is an established method of achieving this. It can be carried out quickly, with a low rate of early complications, and leads to fast symptomatic improvement, assessed using the dysphagia score. The relatively high rate of late complications such as stent migration, hemorrhage, and gastroesophageal mucosal prolapse has led to recent debate on the role of metal stents in palliative therapy. We present here a new type of stent design for transcatheter application, which is intended to prevent bleeding due to mechanical mucosal lesions caused by the distal end of the stent extending into the stomach. The further intention of this case report is to force the discussion on individually designed nitinol stents in special anatomic conditions.

## INTRODUCTION

The incidence of adenocarcinoma of the esophagogastric junction is constantly increasing<sup>[1,2]</sup>. Curative treatment is no longer possible at the time of diagnosis in more than 50% of patients with esophageal carcinoma, and palliative treatment<sup>[3]</sup> focusing on eliminating dysphagia is required. Endoscopic therapy with stent implantation is an established method of achieving this. It can be carried out quickly, with a low rate of early complications, and leads to fast symptomatic improvement, assessed using the dysphagia score<sup>[4-7]</sup>. The relatively high rate of late complications such as stent migration, hemorrhage, and gastroesophageal mucosal prolapse has led to recent debate on the role of metal stents in palliative therapy<sup>[8]</sup>. We present here a new type of stent design for transcatheter application, which is intended to prevent bleeding due to mechanical mucosal lesions caused by the distal end of the stent extending into the stomach. The further intention of this case report is to force the discussion on individually designed nitinol stents in special anatomic conditions.

## CASE REPORT

An 82-year-old patient presented at our department with 2-wk dysphagia, followed most recently by intermittent vomiting. He had a history of progressive prostate carcinoma (T3b Nx M0), which was treated with orchiectomy and antiandrogen therapy (bicalutamide). As there was local progression with infiltration of the urinary bladder, radiotherapy was planned. In addition, the patient had type 2 diabetes mellitus and arterial hypertension.

Gastroscopy showed a dilated esophagus, corresponding to the radiographic findings, with a high-grade stenosis 38 cm from the incisors, cranial to a 3-cm

**Figure 1** Radiographic image of the esophagus stenosis.

**Figure 4** Radiographic image of the stent.

**Figure 2** Endoscopic view of the hiatus hernia after passage through the tumor stenosis.

**Figure 5** Endoscopic view of the distal end of the stent in inversion, 2 mo after treatment.

**Figure 3** New stent design (Micro-Tech [Nanjing] Co. Ltd., Nanjing, China; distributed by Leufen Medizintechnik, Aachen, Germany).

long sliding hernia (Figures 1 and 2). The stenosis was diagnosed histologically as an adenocarcinoma of the esophagogastric junction, which already developed a hepatic metastasis. Reviewing the findings, we decided to carry out palliative stent implantation to treat the stenosis. As transcatheter positioned stents are associated with higher complication rates<sup>[9]</sup> and experience shows that bleeding often occurs due to stent-related mucosal lesions in the stomach, we requested individual production of an unusually shaped self-expanding nitinol stent (SEMS) (Figure 3). Decisive factors in developing this new designed SEMS included the special anatomic conditions in this patient, with a medium-sized esophageal hernia. The stent was woven from nitinol in accordance with our specifications and was 140 mm long and 24 mm wide. A 30-mm wide bulb was formed at the cranial end of the stent to prevent stent migration. The distal end of the stent was to bend cranially to ensure that the stent would

fit the cardia and not extend freely into the stomach. In addition, a circular ring-like widening was added 2 cm above the distal end of the stent to prevent migration. With the exception of the uncovered proximal bulb, the stent was completely covered.

After the patient's informed consent was obtained, the stent was placed on a carrier system with a diameter of 8 mm and released in the conventional way from the distal end by withdrawing an over tube. After the applicator with the stent was positioned fluoroscopically at the tumor level over a guide wire (Boston Scientific, Super Stiff Guidewire, 0.035 inch), the distal end of the stent was partially released. The proximally bent end of the stent was then pulled until the distal end fitted the cardia tightly. Finally, the stent was fully released by pulling and positioned without any special difficulties. The patient was able to take solid food 24 h later. A radiographic check showed that the stent was correctly positioned (Figure 4). No incidents of bleeding, vomiting as evidence of mucosal prolapse, or recurrent dysphagia occurred during a 4-mo follow-up period. An endoscopic check-up 2 mo after introduction of the stent showed that it was still correctly positioned, with no evidence of mucosal lesions (Figure 5).

## DISCUSSION

Although the use of self-expanding metal stents is now an established part of palliative treatment for esophageal carcinomas, late complications are frequent.

The complication rate is higher when the stent is in a transcatheter position. In our experience, however, stent migrations that are frequently reported occur much less often when a partially covered stent with a large diameter is used, and previous dilation of the tumor stenosis has not been carried out<sup>[10]</sup>. Nevertheless, bleeding, particularly due to mechanical lesions caused by the distal end of the stent which extends into the stomach, and mucosal prolapse with occlusion of the stent, still continue to be major problems. The aim in this case was therefore to take advantage of an individual stent design and provide an optimal solution in the palliative situation for this patient.

The stent described above was designed and manufactured in close collaboration with the producer and distributor of the nitinol stent within 10 d in order to avoid mechanical lesions of the mucosa in this special anatomic situation. The stent was positioned without any special difficulties in conventional way. The early clinical result was good after 24 h. The radiographic, clinical and endoscopic follow-up during a 4-mo period showed that the stent was still correctly positioned and none of usual complications occurred.

We believe that the stent design presented here is particularly suitable for palliative treatment of stenotic distal esophageal carcinomas. The advantage of this stent design is particularly clear when an axial hiatus hernia is present. Further optimization of the design and studies comparing it with conventional stents are required. We believe that individual stent designing could alleviate many of the late complications associated with stent treatment.

**Published online:** June 28, 2008

geal or chest trauma. It can also occur spontaneously in association with asthma, excessive coughing, or straining. Cervical emphysema occurs when air moves through tissue planes into subcutaneous areas of the face and neck. Subcutaneous neck emphysema, pneumomediastinum, and retroperitoneum have been reported infrequently following colonoscopic perforation. Iatrogenic colonic perforation is a serious but rare complication of colonoscopy. A perforation risk rate of 0.12% has been reported<sup>[1]</sup>.

Subcutaneous emphysema caused by non-traumatic perforations of the colon is extremely rare. However, it should be considered when no obvious case can be found for the origin of subcutaneous emphysema or a pneumomediastinum.

## Abstract

This case report describes a 69-year-old man presenting with an extensive subcutaneous emphysema in his neck and generalized peritonitis caused by a lower gastrointestinal tract perforation. This case emphasizes that subcutaneous emphysema patients with negative thoracic findings should be scrutinized for signs of retroperitoneal hollow viscus perforation.

## CASE REPORT

A 69-year-old man presented himself at the Accident and Emergency Department with a 6-h history of swelling in the neck, an altered voice and abdominal pain. He was treated for a painful fifth rib on the left which was caused by a metastasis of an unknown primary tumor. Analysis for the primary tumor was ongoing, but not yet concluded. Radiotherapy was started and prednisolone was prescribed.

Physical examination revealed signs of extensive subcutaneous emphysema in his neck and generalized peritonitis. Laboratory blood and urine tests were normal apart from an elevated white cell count of  $23 \times 10^9$  cells/L. A plain radiograph of the thorax showed free intraperitoneal air, pneumomediastinum and extensive subcutaneous emphysema, but no sign of pneumothorax (Figure 1).

An explorative laparotomy was performed, a perforation of the small bowel and the caecum was found, which were oversew. There were two perforations of the sigmoid but no palpable tumor. A sigmoid resection was performed with a permanent colostomy. The proximal end of the distal segment was oversew and left in place with a blind rectal pouch. The patient was admitted to the Intensive Care Unit after operation. Pathological examination showed diverticulitis with a perforation, and no tumor was found in the resected sigmoid.

After consultation with the patient and his family, the patient received no further surgical treatment. The patient died of respiratory arrest 12 d after surgery.

## INTRODUCTION

Pneumomediastinum usually occurs following esopha-

**Figure 1** Thorax X-ray examination of the patient showing free air in abdomen, pneumomediastinum and severe subcutaneous cervical emphysema.

## DISCUSSION

Non-traumatic subcutaneous emphysema is a rare presentation of lower gastrointestinal tract perforation due to colorectal cancer or diverticulitis<sup>[2-6]</sup>.

As the rectosigmoid is located in the retroperitoneum, injury can be present in the absence of peritonitis. Mediastinal and cervical emphysema may develop due to dissection of air *via* contiguous tissue planes, which occurs along the perivascular adventitia to the anterior pararenal space, through the diaphragmatic hiatus along the adventitia of great vessels to the mediastinum and pericardium/or pretracheal fascia to the neck<sup>[7,8]</sup>.

Subcutaneous emphysema patients with negative thoracic findings should be scrutinized for signs of retroperitoneal hollow viscus perforation to improve their outcome.

## INTRODUCTION

Double-balloon endoscope (DBE) is a new endoscopic device designed to examine the small intestine. Observation of the entire small intestine can be achieved through a combination of anal and oral approaches. Endoscopic interventions such as mucosal biopsy, clipping, argon plasma and polypectomy can also be performed. We often encounter patients with obscure gastrointestinal bleeding in which bleeding cause cannot be revealed by the usual methods of esophagogastroduodenoscopy (EGD) and colonoscopy. DBE is thus used to find the origin of small intestinal bleeding. Here we report a case in which the origin of the patient's gastrointestinal bleeding was found with DBE and diagnosed as a duplication cyst of the ileum after surgery.

## CASE REPORT

A 35-year-old man was admitted to a hospital with the complaint of right lower abdominal pain in April, 2003. Appendicitis was suspected and appendectomy was performed. However, he continued to suffer from occasional abdominal discomfort and symptoms of subileus. Early in August, bloody stools appeared. Iron deficiency anemia (hemoglobin level, 8.1 g/dL) was also noted. Although EGD, colonoscopy and

## Abstract

A 35-year-old man was admitted due to bloody stool and anemia. The bleeding source could not be detected by esophagogastroduodenoscopy or colonoscopy. Double balloon endoscopy (DBE) revealed a diverticulum-like hole in which coagula stuck in the ileum at 1 meter on the oral side from the ileocecal valve. The adjacent mucosa just to the oral side of the hole was elevated like a submucosal tumor. The lesion was considered the source of bleeding and removed surgically. It was determined to be a cyst with an ileal structure on the mesenteric aspect accompanying gastric mucosa. The diagnosis was a duplication cyst of the ileum, which is a rare entity that can cause gastrointestinal bleeding. In the present case, DBE was used to find the hemorrhagic duplication cyst in the ileum.

**Figure 1** Double-balloon endoscopy by a perianal approach revealing coagula in the ileum at 1 m on the oral side of the ileocecal valve (A) and a diverticulum-like hole (white arrow) after removal of the coagula with an elevation like a submucosal tumor on the oral side of the hole (black arrow) (B).

radiological enteroclysis were performed, the origin of the gastrointestinal bleeding remained unknown.

At the end of August 2003, the right lower abdomen pain appeared again after a meal. Inflammatory reactions were also elevated. Thus, he was referred to our hospital for further examination. Physical examination showed local peritonitis. Abdominal CT displayed ascites in the circumference of the liver and thickness of the distal small intestine wall in the pelvis. With appropriate medical treatment and antibiotic therapy, his condition and the inflammatory reaction improved. Colonoscopy and radiological enteroclysis failed to ascertain any lesions responsible for the symptoms. The patient was thus discharged from hospital.

His condition was good until bloody stool suddenly appeared again in July, 2005. He was admitted to our hospital the next day. Anemia gradually progressed. Scintigraphy for hemorrhage revealed a deposit in the ileum end. Colonoscopy, however, failed to detect the source of the bleeding. The patient was then referred to Kyushu University Hospital. DBE performed using a perianal approach revealed coagula adhered to the ileal wall about 1 m on the oral side from the ileocecal valve (Figure 1A). When the coagula were removed, a bleeding diverticulum-like hole appeared and the adjacent mucosa just on the oral side of the hole was elevated like a submucosal tumor (Figure 1B). We injected hypertonic saline with epinephrine and also injected India ink near it as a marker. However, intermittent bleeding continued after the procedure. The patient, therefore, underwent

**Figure 2** Macroscopic appearance of the resected specimen. The cyst was located on the mesenteric aspect and a diverticulum-like hole (arrow) was detected on the anal side.

**Figure 3** HE staining for the resected tissue showing an ileal structure with gastric mucosa and bleeding in the cyst.

an urgent operation. When the inside of the abdominal cavity was observed, a cyst was found on the mesenteric side of the ileum, about 1mm proximal to the ileocecal valve, and connected to the ileocecal valve by an adhesion band. The lesion was considered the bleeding source and thus resected. Histological examination revealed that the cyst was located on the mesenteric aspect and had an ileal structure with gastric mucosa (Figures 2 and 3). A diagnosis of duplication cyst of the ileum was thus made. The patient was discharged from hospital 10 d after surgery and has remained symptom-free since then.

## DISCUSSION

Duplication cysts are congenital malformations that can arise throughout the alimentary tract from the oral cavity to the anus. The majority are diagnosed in infancy and childhood. Duplication cysts of the small intestine constitute about 60% of those in alimentary tract and are located on the mesenteric aspect, in contrast to a Meckel's diverticulum that localizes on the antimesenteric aspect. Duplication cysts are classified into spherical and tubular types. The former is more commonly found in the small intestine<sup>[1]</sup>. The present case was considered a

spherical one.

Hoshi *et al*<sup>[2]</sup> reported that 34% of duplication cyst patients complain of stomachache, 24% vomiting, 17% an abdomen mass and 10.5% bloody stool. In our case, because of the right lower abdominal pain, appendectomy was performed 2 years ago. After the operation, the various symptoms continued. Though these symptoms seemed to be due to a duplication cyst, the relevant diagnosis was not made until 2 years later.

A preoperative diagnosis of duplication cyst is difficult. Indeed, only 11.2% have been correctly diagnosed before operation in Japan. Eighteen point two percent are diagnosed as intussusception, 15.1% as an abdominal mass, 14.4% as ileus, and 26.7% are not able to be diagnosed<sup>[2]</sup>. Cases diagnosed before operation have large lesions that are detectable by abdominal CT and US<sup>[3]</sup>.

Previously, it was relatively difficult to diagnose a small intestinal lesion. However, diagnostic strategy changes with the availability of DBE<sup>[4]</sup> and wireless capsule endoscopy (CE). In fact, Toth *et al*<sup>[5]</sup> reported that they could find a tubular type duplication cyst of the small intestine by CE, suggesting that CE can reveal circumferentially ulcerated stenosis in the ileum. There is no report on an image of a spherical type of duplication cyst in the small intestine detected by endoscopy. Here, for the first time, we showed an image of a spherical

type of duplication cyst obtained by DBE. The cyst was too small to be detected by other modalities such as CT, US and radiological enteroclysis.

Duplication cysts are rare in adults and there are few reports on a diagnosis made before operation. Thus ascertaining the existence of such a lesion is difficult. We presented a case of a duplication cyst of the small intestine found by DBE. We expect that duplication cysts may be more frequently found with the future spread of DBE and CE.

### INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common malignancies worldwide. It is usually manifested in the 6th and 7th decades of life. Extrahepatic metastases are seen in 64% of patients with HCC. The most frequent sites of extrahepatic metastases are lung, abdominal lymph node and bone, but peritoneal dissemination is unusual<sup>[1,2]</sup>. The incidence of spontaneous rupture of HCC is about 8%-26% in Asia<sup>[3-5]</sup> and the mortality rate of HCC patients is 10%<sup>[6]</sup>. However, peritoneal metastasis of HCC after spontaneous rupture is seldom noted. Here, we report a case of intraperitoneal metastasis of HCC after spontaneous rupture 10 mo ago, which was treated with transarterial embolization.

### Abstract

Rupture of hepatocellular carcinoma (HCC) is a life-threatening complication. Peritoneal metastasis of HCC after spontaneous rupture was seldom noted. We report a case of intraperitoneal metastasis of HCC after spontaneous rupture. A previously asymptomatic 72-year-old man was admitted due to dull abdominal pain with abdominal fullness. He had a history of HCC rupture 10 mo ago and transarterial embolization was performed at that time. Abdominal computer tomography (CT) scan showed a huge peritoneal mass over the right upper quadrant area. Surgical resection was arranged and subsequent microscopic examination confirmed a diagnosis of moderately-differentiated HCC.

### CASE REPORT

A previously asymptomatic 72-year-old man had a history of chronic hepatitis C-related liver cirrhosis without regular follow-up. Sudden nausea and vomiting with watery diarrhea were noted on January 2006. Then he was sent to Yun-Lin Branch of National Taiwan University Hospital for help. Abdominal computer tomography (CT) scan showed a huge HCC that was suspicious of rupture. Under the request of his family, he was transferred to our hospital and transarterial embolization was performed on January 31, 2006. After discharge, he was regularly followed up at our Gastrointestinal (GI) Outpatient Department (OPD). Dull abdominal pain over the right upper quadrant area, accompanied with fullness sensation, was noted in November 2006. Besides, he also had body weight loss of about ten kilograms in one year. So he visited our hospital again. Abdominal CT scan revealed a peritoneal mass in the right upper quadrant peritoneal area and hepatoma recurrence was considered (Figure 1). Transarterial embolization was arranged again, but failed. After consultation with the surgeon, he was admitted for surgical resection.

Surgical intervention was arranged on January 24, 2007. Operative methods were segmental hepatectomy (S6 and partial S5), excision of extrahepatic tumor, and cholecystectomy. The operation showed a huge tumor (12 cm × 8 cm × 6 cm) over the right upper quadrant area just below liver parenchyma (Figure 2) with its blood supplied from the omentum. Besides, two small mass lesions (3 cm × 2 cm and 2 cm × 1 cm) were found over

**Figure 1** A well-defined mass about 10 cm in diameter in RUQ peritoneal cavity anterior to liver parenchyma.

**Figure 2** A huge tumor (12 cm × 8 cm × 6 cm) over the right upper quadrant area just below liver (A), blood supply of tumor from the omentum (B), and intraperitoneal tumor (C, D).

S5 and S6, respectively (Figure 3). Microscopy showed that the huge extrahepatic tumor and two intrahepatic lesions were moderately differentiated.

## DISCUSSION

Intraperitoneal metastasis of non-ruptured HCC is rare, but the risk of such a metastasis of ruptured HCC increases<sup>[7]</sup>. The mechanism of spontaneous rupture of HCC is not exactly clear. Hypotheses include rapid expansion of the tumor and central necrosis, venous hypertension caused by venous obstruction due to direct tumor invasion, mild trauma or compression by the diaphragm associated with respiratory movement, coagulopathies such as thrombocytopenia and disturbed prothrombin synthesis, and vascular injury leading to hemorrhage and subsequent rupture<sup>[4,8-10]</sup>. Recently, Zhu *et al* postulated that the poor function of macrophage phagocytosis could result in cumulation of immune

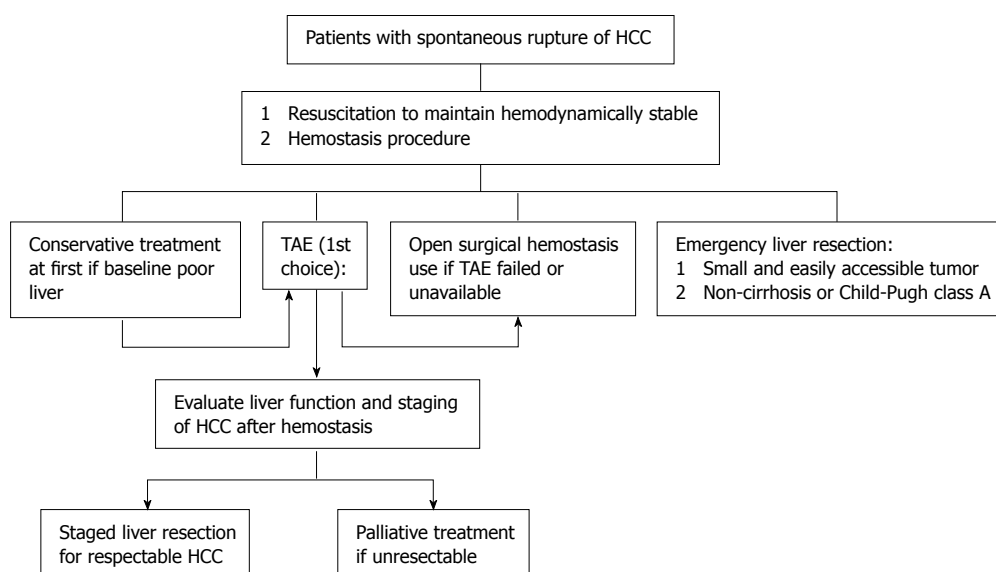

complex and deposition on vascular wall. Then vascular wall could become stiff and weak due to the proliferated fragment elastin and damaged collagen, which would make blood vessels more prone to splitting and result in hemorrhage and rupture of HCC<sup>[11,12]</sup>. Large tumor size, peripheral location and protruding contour are all associated with an increased risk for rupture of HCC<sup>[4,13,14]</sup>.

The diagnosis of HCC rupture is based on blood-stained ascites plus imaging studies and symptoms<sup>[2]</sup>. The most common symptom is sudden onset of abdominal pain (66%-100%)<sup>[6,15-17]</sup>. Yeh *et al* also found that the presence of sudden-onset abdominal pain is the only independent indicator of ruptured HCC<sup>[18]</sup>. Abdominal ultrasonography and computed tomography improve the rate of preoperative diagnosis<sup>[13,14,19,20]</sup>. Peripheral location, protruding contour, discontinuity of hepatic surface, surrounding hematoma and elevated ascitic CT number are helpful signs for the diagnosis of ruptured HCC. In addition, enucleation sign on helical CT could

**Figure 3** Two small mass lesions (3 cm × 2 cm and 2 cm × 1 cm) over S5 and S6, respectively.

**Figure 4** Logarithm about how to approach to the patient with spontaneously ruptured HCC.

be more specific<sup>[14,20,21]</sup>.

Treatment of ruptured HCC is primarily aimed at controlling hemorrhage and preserving the functional liver parenchyma as possible. Open surgical method was the mainstay of treatment during 1960s-1980s. It was reported that various surgical procedures, including perihepatic packing, suture plication of bleeding tumors, injection of alcohol, hepatic artery ligation (HAL), and liver resection, are effective against hemostasis<sup>[10,22-26]</sup>. Besides transarterial embolization (TAE) and transarterial chemoembolization (TACE) for palliative treatment in patients with unresectable HCC, TAE is also gradually used for hemostasis in spontaneous rupture of HCC. In addition, Ng *et al*<sup>[27]</sup> also reported that ruptured HCC could be treated with radiofrequency ablation as a salvage procedure. To our knowledge, no prospective randomized controlled trials have found the best method for hemostasis. There is evidence that TACE is the preferred method to arrest tumor bleeding<sup>[13,28-34]</sup>. Besides, two-stage hepatectomy is advisable because it can prolong the survival of selected patients<sup>[35-40]</sup>. Figure 4 is the logarithm about how to approach the patients with spontaneous ruptured HCC<sup>[35-40]</sup>.

Spontaneous rupture of HCC with intraperitoneal hemorrhage is a life-threatening complication with a high mortality rate. Prognosis is associated with poor liver reserve, advanced disease and severity of hemor-

rhage<sup>[41]</sup>. The median survival time is around 4-5 mo after HCC rupture, and only few patients can have a long-term survival<sup>[42,43]</sup>. Thus, implanted metastases usually do not become clinically apparent. Ong *et al*<sup>[44]</sup> reported the first case of peritoneal metastasis after HCC rupture in 1996 and then only sporadic case reports have been published. Most reported cases of peritoneal metastases are documented 8 mo after rupture<sup>[7,41,45-47]</sup>, but Ryu *et al*<sup>[48]</sup> and Lin *et al*<sup>[49]</sup> reported that peritoneal metastasis can be found 4 and 3 mo respectively after rupture episode. A single metastatic tumor is the most common presentation. Resection is the treatment of choice for peritoneal metastasis if possible and might offer long-term survival benefits<sup>[7,44-48]</sup>.

Peritoneal metastasis after spontaneous rupture of HCC is rare. This is our first experience with such a patient. Our patient developed peritoneal metastasis, which was documented 10 mo after spontaneous HCC rupture. The time from rupture to documentation of peritoneal metastasis is similar to other case reports. Because few cases of peritoneal metastasis after ruptured HCC have been reported, the association between metastatic tumor and viral infection (HBV or HCV), AFP level, or age is lacking. Lin *et al*<sup>[49]</sup> found that most reported cases are males, but the impact of gender is still unclear. The disease-free time is around 7-45 mo according to previous case reports<sup>[40-42,44]</sup>. Our patient had no peritoneal

recurrence until December, 2007 and is now regularly followed up at OPD.

## ACKNOWLEDGMENTS

# Acknowledgments to Reviewers of *World Journal of Gastroenterology*

Many reviewers have contributed their expertise and time to the peer review, a critical process to ensure the quality of *World Journal of Gastroenterology*. The editors and authors of the articles submitted to the journal are grateful to the following reviewers for evaluating the articles (including those published in this issue and those rejected for this issue) during the last editing time period.

### Dr. Philip Abraham, Professor

Consultant Gastroenterologist & Hepatologist, P. D. Hinduja National Hospital & Medical Research Centre, Veer Savarkar Marg, Mahim, Mumbai 400 016, India

### David Adams, Professor

Liver Research Laboratories, Institute for Biomedical Research, Queen Elizabeth Hospital, University of Birmingham, Birmingham B15 2TT, United Kingdom

### Rakesh Aggarwal Additional, Professor

Department of Gastroenterology, Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow 226014, India

### Rosemar Joyce Burnett, PhD

Department of Epidemiology National School of Public Health, University of Limpopo, Medunsa Campus PO Box 173, MEDUNSA, Pretoria 0204, South Africa

### Dr. Yogesh K Chawla, Professor

Department of Hepatology, Postgraduate Institute of Medical Education and Research, Chandigarh 160012, India

### Ramsey Chi-man Cheung, MD, Professor

Division of GI & Hepatology, VAPAHCS(154C), 3801 Miranda Ave, Stanford University School of Medicine, Palo Alto, CA 94304, United States

### Dario Conte, Professor

GI Unit-IRCCS Osp. Maggiore, Chair of Gastroenterology, Via F. Sforza, 35, Milano 20122, Italy

### Tsianos Epameinondas, MD, PhD, Professor

1st Division Of Internal Medicine & Hepato-Gastroenterology Unit, Medical school University of Ioannina, PO Box 1186 Ioannina 45110, Greece

### Ikolaus Gassler, Professor

Institute of Pathology, University Hospital RWTH Aachen, Pauwelsstrasse 30, 52074 Aachen, Germany

### Kazuhiro Hanazaki, MD, Professor and Chairman

Department of Surgery, Kochi Medical School, Kochi University, Kohasu, Okochi, Nankoku, Kochi 783-8505, Japan

### Frank Hoentjen, MD, PhD

Department of Gastroenterology, VU Medical Center, Sumatrastraat 16, 2022XL Haarlem, The Netherlands

### Toru Ishikawa, MD

Department of Gastroenterology, Saiseikai Niigata Second Hospital, Teraji 280-7, Niigata, Niigata 950-1104, Japan

### Tsuneo Kitamura, sociate Professor

Department of Gastroenterology, Juntendo University Urayasu Hospital, Juntendo University School of Medicine, 2-1-1 Tomioka, Urayasu-shi, Chiba 279-0021, Japan

### Robert J Korst, MD

Department of Cardiothoracic Surgery, Weill Medical College of Cornell University, Room M404, 525 East 68th Street, New York 10032, United States

### Shiu-Ming Kuo, MD

University at Buffalo, 15 Farber Hall, 3435 Main Street, Buffalo 14214, United States

### Peter L Lakatos, MD, PhD, Assistant Professor

1st Department of Medicine, Semmelweis University, Koranyi S 2A, Budapest H1083, Hungary

### Dr. Yun Ma, MD, PhD

Institute of Liver Studies, King's College Hospital, Denmark Hill, London SE5 9RS, United Kingdom

### Kevin McGrath, MD

Liver Research Group, 5th Floor, Institute of Biomedical Research, Wolfson Drive, The Medical School, Edgbaston, University of Birmingham, Birmingham B15 2TT, United Kingdom

### Gustav Paumgartner, Professor

University of Munich, Klinikum Grosshadern, Marchioninstr. 15, Munich, D-81377, Germany

### Dr. Bernardino Rampone

Department of General Surgery and Surgical Oncology, University of Siena, viale Bracci, Siena 53100, Italy

### Gerardo Rosati, MD

Medical Oncology Unit, "S. Carlo" Hospita, Via Potito Petrone, 1, Potenza 85100, Italy

### Damian Casadesus Rodriguez, MD, PhD

Calixto Garcia University Hospital, J and University, Vedado, Havana City, Cuba

### Mitsuo Shimada, Professor

Department of Digestive and Pediatric Surgery, Tokushima University, Kuramoto 3-18-15, Tokushima 770-8503, Japan

## Meetings

### Events Calendar 2008-2009

**FALK SYMPOSIA 2008**  
 January 24-25, Frankfurt, Germany  
 Falk Workshop: Perspectives in Liver Transplantation

International Gastroenterological Congresses 2008  
 February 14-16, Paris, France  
 EASL-AASLD-APASL-ALEH-IASL Conference Hepatitis B and C virus resistance to antiviral therapies  
[www.easl.ch/hepatitis-conference](http://www.easl.ch/hepatitis-conference)

February 14-17, Berlin, Germany  
 8<sup>th</sup> International Conference on New Trends in Immunosuppression and Immunotherapy  
[www.kenes.com/immuno](http://www.kenes.com/immuno)

February 28, Lyon, France  
 3<sup>rd</sup> Congress of ECCO - the European Crohn's and Colitis Organisation  
 Inflammatory Bowel Diseases 2008  
[www.ecco-ibd.eu](http://www.ecco-ibd.eu)

February 29, Québec, Canada  
 Canadian Association of Gastroenterology  
 E-mail: [general@cag-acg.org](mailto:general@cag-acg.org)

March 10-13, Birmingham, UK  
 British Society of Gastroenterology Annual Meeting  
 E-mail: [BSG@mailbox.ulcc.ac.uk](mailto:BSG@mailbox.ulcc.ac.uk)

March 14-15, HangZhou, China  
 Falk Symposium 163: Chronic Inflammation of Liver and Gut

March 23-26, Seoul, Korea  
 Asian Pacific Association for the Study of the Liver  
 18<sup>th</sup> Conference of APASL: New Horizons in Hepatology  
[www.apaslseoul2008.org](http://www.apaslseoul2008.org)

March 29-April 1, Shanghai, China  
 Shanghai-Hong Kong International Liver Congress  
[www.livercongress.org](http://www.livercongress.org)

April 05-09, Monte-Carlo (Grimaldi Forum), Monaco  
 OESO 9<sup>th</sup> World Congress, The Gastro-esophageal Reflux Disease: from Reflux to Mucosal Inflammation-Management of Adeno-carcinomas  
 E-mail: [robert.giuli@oeso.org](mailto:robert.giuli@oeso.org)

April 9-12, Los Angeles, USA  
 SAGES 2008 Annual Meeting - part of Surgical Spring Week  
[www.sages.org/08program/html/](http://www.sages.org/08program/html/)

April 18-22, Buenos Aires, Argentina  
 9<sup>th</sup> World Congress of the International Hepato-Pancreato Biliary Association  
 Association for the Study of the Liver  
[www.ca-ihpba.com.ar](http://www.ca-ihpba.com.ar)

April 23-27, Milan, Italy  
 43<sup>rd</sup> Annual Meeting of the European Association for the Study of the Liver  
[www.easl.ch](http://www.easl.ch)

May 2-3, Budapest, Hungary

Falk Symposium 164: Intestinal Disorders

May 18-21, San Diego, California, USA  
 Digestive Disease Week 2008

May 21-22, California, USA  
 ASGE Annual Postgraduate Course  
 Endoscopic Practice 2008: At the Interface of Evidence and Expert Opinion  
 E-mail: [education@asge.org](mailto:education@asge.org)

June 4-7, Helsinki, Finland  
 The 39<sup>th</sup> Nordic Meeting of Gastroenterology  
[www.congex.com/ngc2008](http://www.congex.com/ngc2008)

### Global Collaboration for Gastroenterology

For the first time in the history of gastroenterology, an international conference will take place which joins together the forces of four pre-eminent organisations: Gastro 2009, UEGW/WCOG London. The United European Gastroenterology Federation (UEGF) and the World Gastroenterology Organisation (WGO), together with the World Organisation of Digestive Endoscopy (OMED) and the British Society of Gastroenterology (BSG), are jointly organising a landmark meeting in London from November 21-25, 2009. This collaboration will ensure the perfect balance of basic science and clinical practice, will cover all disciplines in gastroenterology (endoscopy, digestive oncology, nutrition, digestive surgery, hepatology, gastroenterology) and ensure a truly global context; all presented in the exciting setting of the city of London. Attendance is expected to reach record heights as participants are provided with a compact "all-in-one" programme merging the best of several GI meetings. Faculty and participants from all corners of the earth will merge to provide a truly global environment conducive to the exchange of ideas and the forming of friendships and collaborations.

## Instructions to authors

### GENERAL INFORMATION

*World Journal of Gastroenterology* (*World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly open access peer-reviewed journal supported by an editorial board consisting of 1208 experts in gastroenterology and hepatology from 60 countries. The aim of the journal is to deliver the most clinically relevant original and commentary articles to readers, and to make the full text publicly available to all clinicians, scientists, patients and biomedical students on an unrestricted platform, so that they can access and learn about the most recent key advances in the field.

In addition to the open access nature, another key characteristic of *WJG* is its reading guidance for each article which includes background, research frontier, related reports, breakthroughs, applications, terminology, and comments of peer reviewers for the general readers.

*WJG* publishes articles on esophageal, gastrointestinal, hepatobiliary and pancreatic tumors, and other esophageal, gastrointestinal, hepatic-biliary and pancreatic diseases in relation to epidemiology, immunology, microbiology, motility & nerve-gut interaction, endocrinology, nutrition & obesity, endoscopy, imaging and advanced hi-technology.

The main goal of *WJG* is to publish high quality commentary articles contributed by leading experts in gastroenterology and hepatology and original articles that combine the clinical practice and advanced basic research, to provide an interactive platform for clinicians and researchers in internal medicine, surgery, infectious diseases, traditional Chinese medicine, oncology, integrated Chinese and Western medicine, imaging, endoscopy, interventional therapy, pathology and other basic medical specialties, and thus eventually improving the clinical practice and healthcare for patients.

### Indexed and abstracted in

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, Index Medicus, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology and Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

### Published by

The WJG Press

### SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the International Committee of Medical Journal Editors to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is <http://www.clinicaltrials.gov> sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

### Online submissions

Manuscripts should be submitted through the Online Submission System at: <http://wjg.wjgnet.com>. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (<http://www.wjgnet.com/wjg/help/instructions.jsp>) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to [submission@wjgnet.com](mailto:submission@wjgnet.com), or by telephone: +86-10-85381892. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

### MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

#### Title page

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was carried out; author contributions; disclosure of any financial support for the research; and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (remove all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s), and full family name.

**Author contributions:** The format of this section should be like this: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed research; Wang CL, Zou CC, Hong F and Wu XM performed research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed data; and Wang CL, Liang L and Fu JF wrote the paper.

**Peer reviewers:** All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

#### Abstract

An informative, structured abstract of no more than 350 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipment, and the experimental procedures should be included. RESULTS: The observed and experimental results, including data, effects, outcome, *etc.* should be included. Authors should present *P* value where necessary, and also include any significant data. CONCLUSION: Accurate view and the value of the results should be included.

The format for structured abstracts can be found at: <http://www.wjgnet.com/wjg/help/11.doc>.

#### Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

#### Text

For articles of these sections, original articles, rapid communication

and case reports, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, should be found at: <http://www.wjgnet.com/wjg/help/instructions.jsp>.

### Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: <http://www.wjgnet.com/1007-9327/13/4520.pdf>; <http://www.wjgnet.com/1007-9327/13/4554.pdf>; <http://www.wjgnet.com/1007-9327/13/4891.pdf>; <http://www.wjgnet.com/1007-9327/13/4986.pdf>; <http://www.wjgnet.com/1007-9327/13/4498.pdf>. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ... *etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

### Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### Notes in tables and illustrations

Data that are not statistically significant should not be noted. <sup>a</sup>*P* < 0.05, <sup>b</sup>*P* < 0.01 should be noted (*P* > 0.05 should not be noted). If there are other series of *P* values, <sup>c</sup>*P* < 0.05 and <sup>d</sup>*P* < 0.01 are used. A third series of *P* values can be expressed as <sup>e</sup>*P* < 0.05 and <sup>f</sup>*P* < 0.01. Other notes in tables or under illustrations should be expressed as <sup>1</sup>F, <sup>2</sup>F, <sup>3</sup>F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

### Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability<sup>[1,2]</sup>". If references are cited directly in the text, they should be put together within the text, for example, "From references<sup>[19,22-24]</sup>, we know that..."

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

### PMID requirement

PMID roots in the abstract serial number indexed by PubMed (<http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information for journal citations is very important. Using the reference testing system, the authors and editor should check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in an ASP file so that the readers can immediately access the abstract of the citations online.

### DOI requirement

A CrossRef DOI® (Digital Object Identifier) name is a unique string created to identify a piece of scholarly content in the online environment. The author should supply the DOIs for journal citation (doi:10.3748/wjg.13.6458). This link (<http://www.crossref.org/SimpleTextQuery/>) allows you to retrieve Digital Object Identifiers (DOIs) for journal articles, books, and chapters by simply cutting and pasting the reference list into the box. You may use the form with any reference style, although the tool works most reliably if references are formatted in a standard style such as shown in this example: Assimakopoulos SF, Scopa CD, Vagianos CE. Pathophysiology of increased intestinal permeability in obstructive jaundice. *World J Gastroenterol* 2007; 13(48): 6458-6464

The accuracy of the information of journal citations is very important. We will interlink all references with DOI in ASP file so that readers can access the abstracts of cited articles online immediately.

### Style for journal references

Authors: the name of the first author should be typed in bold-faced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

### Style for book references

Authors: the name of the first author should be typed in bold-faced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

## Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those linked with a hyphen when the difference between the two numbers is greater than five. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered inappropriate references. Authors should not cite their own unrelated published articles.

## Statistical data

Write as mean  $\pm$  SD or mean  $\pm$  SE.

## Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as  $\chi^2$  (in Greek), related coefficient as *r* (in italics), degree of freedom as *v* (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

## Units

Use SI units. For example: body mass, *m* (B) = 78 kg; blood pressure, *p* (B) = 16.2/12.3 kPa; incubation time, *t* (incubation) = 96 h, blood glucose concentration, *c* (glucose) 6.4  $\pm$  2.1 mmol/L; blood CEA mass concentration, *p* (CEA) = 8.6 24.5  $\mu$ g/L; CO<sub>2</sub> volume fraction, 50 mL/L CO<sub>2</sub>, not 5% CO<sub>2</sub>; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, etc. Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: <http://www.wjgnet.com/wjg/help/15.doc>.

## Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of

Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

## Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg 1*, *c myc*, *c fos*, etc.

Restriction enzymes: *EcoRI*, *HindIII*, *BamHI*, *KhoI*, *KpnI*, etc.

Biology: *H pylori*, *E coli*, etc.

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. The author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, and responses to the reviewers by courier (such as EMS/DHL).

## Editorial Office

### World Journal of Gastroenterology

Editorial Department: Room 903

Ocean International Center, Building D

No. 62 Dongsihuan Zhonglu

Chaoyang District, Beijing 100025, China

E-mail: [wjg@wjgnet.com](mailto:wjg@wjgnet.com)

<http://www.wjgnet.com>

Telephone: +86-10-59080039

Fax: +86-10-85381893

## Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; (4) Grade D: rejected. Revised articles should reach Grade A or B.

## Copyright assignment form

Please download a Copyright assignment form from <http://www.wjgnet.com/wjg/help/9.doc>.

## Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: <http://www.wjgnet.com/wjg/help/10.doc>.

## Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

## Links to documents related to the manuscript

*WJG* will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

## Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (<http://www.eurekalert.org>). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

## Publication fee

Authors of accepted articles must pay a publication fee.

EDITORIAL, TOPIC HIGHLIGHTS, BOOK REVIEWS and LETTERS TO THE EDITOR are published free of charge.
