Abstract

AIM: To investigate the association between single nucleotide polymorphisms (SNPs) in intercellular adhesion molecule-1 (ICAM-1) and the risk, biological behavior and prognosis of gastric cancer (GC) in Chinese population.

METHODS: The study group consisted of 332 GC patients and 380 healthy controls. Genotyping was performed using polymerase chain reaction and the results were confirmed by sequencing. The association of ICAM-1 K469E polymorphisms and the risk of GC were studied, and the correlation of ICAM-1 K469E polymorphisms with the clinicopathological parameters and prognosis of the patients with complete clinical and follow-up data was analyzed.

RESULTS: Carriers of AA genotype had a significantly increased risk of GC compared with carriers of AG and GG genotypes [odds ratios: 1.36; 95% confidence interval (CI): 1.01-1.84; P = 0.041]. GC patients with AA genotype were more prone to distant metastasis than those carrying AG and GG genotypes (18.9% *vs* 7.0%, respectively; P = 0.002). In addition, patients at stage Ⅳ had significantly more carriers of AA genotype than those of AG and GG genotype (27.4% *vs* 16.9%, respectively; P = 0.046). Follow-up study showed that the overall cumulative survival rate was 23.7% in AA genotype group and 42.9% in AG and GG genotypes group. In univariate analysis, AA genotype was correlated with the overall cumulative survival (P = 0.034). But in multivariate analysis, ICAM-1 polymorphism was not an independent prognostic factor for the overall survival (relative risk, 1.145; 95% CI: 0.851-1.540; P = 0.370).

CONCLUSION: Polymorphisms of ICAM-1 K469E can be a useful biomarker for identifying individuals with higher risk of GC, predicting disease progression, and guiding individualized treatment.

INTRODUCTION

Gastric cancer (GC) is the fourth most common cancer in the world and has the second highest mortality rate[1]. GC is a biologically and genetically heterogenous tumor and develops as a result of the interplay among genetic and environmental factors. Genetic polymorphism plays a role in determining how hosts respond to various environmental factors[2-4].

As a risk factor for GC, *Helicobacter pylori* (*H. pylori*) infection is closely correlated with the occurrence of GC. A number of studies have confirmed that many polymorphisms of inflammation-related genes are significantly associated with the risk of GC[5-8]. Intercellular adhesion molecule-1 (ICAM-1) is a cell adhesion molecule belonging to the immunoglobulin superfamily and is the ligand of β2 integrin (LFA-1 and Mac-1)[9]. *H. pylori* infection can induce increased expression of ICAM-1, possibly due to the stimulation of local mucosal inflammation and inflammatory cytokines. ICAM-1 is expressed in various cell types, including leukocytes, epithelial and endothelial cells, fibroblasts and keratinocytes[9,10]. ICAM-1 plays an important role in cell-to-cell, cell-to-extracellular matrix interaction and cell signaling. Two single-nucleotide polymorphisms (SNPs) in the ICAM1 gene have been recognized, the first at position +241 (+241G/A or G241R) located in exon 4 (GGG→AGG; Gly→Arg), and the second one at position +469 (+469 A/G or K469E) located in exon 6 and coding the Ig-like domain 5 (AAG→GAG; Lys→Glu)[11]. Some studies have shown that ICAM-1 plays an important role in the development and progression of human cancers. Overexpression of ICAM-1 in melanoma and renal cell carcinoma has been reported[12,13]. There is also a slightly increased expression of ICAM-1 in other tumors, such as gastric, breast, and colorectal cancers[14-16]. The soluble form of ICAM-1, sICAM-1, is partially detectable in the serum of healthy subjects, but its level is elevated in malignancies. It has been observed that sICAM-1 serum level was positively correlated with tumor size, lymph node and distant metastasis of cancers, such as breast cancer, pancreatic cancer, gastric cancer, lung cancer and hepatocellular carcinoma[17-22]. The SNP in ICAM1 gene was also found associated with the risk of cancers, including breast cancer, colorectal cancer and melanoma[23-28].

There has been no report on the relationship between ICAM1 gene polymorphisms and GC risk. The polymorphism of G241R is rare in Chinese populations[28,29]. In this study, we aimed to examine the frequency of the ICAM-1 K469E polymorphism in the Chinese population and its correlation with the risk of GC using a large case-control cohort from our hospital. We also analyzed the relationship between K469E polymorphism and the clinicopathological parameters and prognosis of GC patients with complete clinical and follow-up data.

MATERIALS AND METHODS

Patients and specimens

In this hospital-based case-control study, histologically normal tissue specimens of 332 patients (124 females and 208 males, median age 59 years, range 29-91 years) who underwent radical gastrectomy for GC without any adjuvant therapy prior to surgery in the Beijing Cancer Hospital from May 1999 to June 2004 were collected prospectively. Various clinicopathological data were evaluated or collected from patient files by a pathologist. Cancer staging followed the 7th edition of the TNM classification of the International Union Against Cancer (UICC)[30]. Of the 332 patients, 301 patients had complete follow-up records. The survival time was counted in months from the time of surgery to the date of death.

A total of 380 subjects (186 females and 194 males, median age 57 years, range 25-84 years) who received endoscopy in the Beijing Cancer Hospital from 2002 to 2005 with a pathological diagnosis of superficial gastritis served as controls. All patients and controls were of Chinese Han descent and lived in and around Beijing.

A total of 102 serum samples were provided by the Beijing Cancer Hospital tissue bank. *H. pylori* infection was detected by immunohistochemistry.

Experimental methods

Histologically normal tissues from patients and biopsied tissues from controls, fixed in formalin and embedded in paraffin, were used for extraction of genomic DNA. Tissues were dewaxed using xylene and ethanol and then dried. After addition of 1 mL lysis buffer and 10 μL proteinase K solution (20 mg/mL), the tissues were incubated at 37 ℃ overnight. The solution was extracted with equal volumes of saturated phenol, phenol : chloroform (1:1), and chloroform : isoamyl alcohol (24:1). After addition to the supernatant of 1/10 volume of NaOAc (3 mol/L) and 2.5 times the volume of ice-cold ethanol, the solution was precipitated at -20 ℃ overnight. The precipitate was washed with 70% ethanol to remove the salt. After the precipitate was dissolved in 1 × TE solution (pH 7.6), the DNA was stored at -20 ℃.

According to GenBank full-length sequence of human ICAM1 gene, we applied Primer 5.0 software to design 469K/E locus-specific primers. The primers used were 5'-GCTCAAGTGTCTAAAGGATGGC-3' (forward) and 5'-CTCACAGAGCACATTCACGG-3' (reverse). The annealing temperature was 60 ℃ and the length of polymerase chain reaction (PCR) products was 148 bp. The PCR products were sequenced using an ABI377 automatic sequencer (Applied Biosystems, Foster City, CA, United States).

sICAM-1 was measured using an enzyme linked immunosorbent assay (ELISA) kit. ICAM-1 expression in GC tissues was detected by immunohistochemistry using an ICAM-1 mouse monoclonal antibody (1:100, Santa Cruz Biotechnology, Santa Cruz, CA, United States). As a membrane protein, the positive staining for ICAM-1 was located in the cytoplasm and at the cell membrane. If > 10% cells were positively stained in each slice, the tissue was considered ICAM-1 positive[14]. *H. pylori* infection was detected by immunohistochemistry using an *H. pylori* rabbit monoclonal antibody (1:200; Zeta Corporation,

Sierra Madre, CA, United States).

Statistical analysis

All analyses were performed using SPSS statistical analysis software, version 10.0 (SPSS, Chicago, IL, United States). Differences in age, sex, *H. pylori* infection, tobacco smoking, alcohol consumption, and the distribution of the genetic polymorphism between cases and controls were calculated using Pearson's χ^2 test. It was also determined if the genotype distribution was consistent with Hardy-Weinberg equilibrium. $P < 0.05$ (both sides) was considered statistically significant.

The correlation between the polymorphism and clinicopathologic parameters of GC was also examined by Pearson's χ^2 test, and $P < 0.05$ (both sides) was considered statistically significant. The Kaplan-Meier method and log-rank test were used to evaluate the correlation between the polymorphism and patient survival. Odds ratios (OR) and confidence intervals (CI) (95%) were calculated by Cox regression model to examine the impact of the polymorphism on prognosis. P value < 0.05 was considered statistically significant.

RESULTS

Characteristics of GC patients and controls

Baseline characteristics of the 332 GC patients and 380 control subjects are summarized in Table 1. There were more males among the patients with GC (62.7%) compared with the control group (51.1%, $P = 0.002$). However, no significant difference was observed between the cases and controls in age, *H. pylori* infection, tobacco smoking, and alcohol consumption (Figure 1).

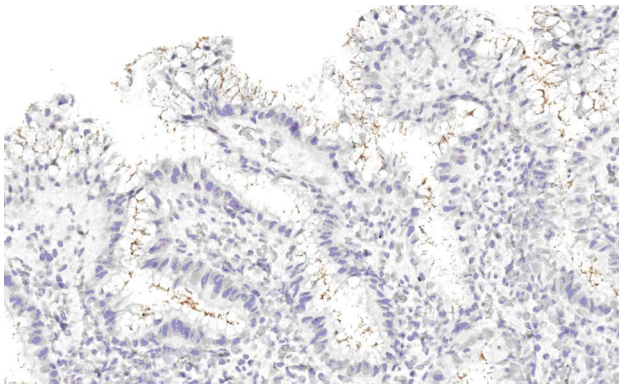

Figure 1 *Helicobacter pylori* infection was detected by immunohistochemistry.

ICAM-1 +469 A/G polymorphism and its relationship with GC risk

As is shown in Table 2, the frequency of the AA genotype was 57.2% and 49.2% in patients and controls, whereas the frequency of the AG genotype was 34.9% and 42.4% in patients and controls, respectively. On the other hand, the frequency of GG genotype was 7.8% and 8.4% in patients *vs* controls, respectively. The most common genotype was AA followed by AG. Significantly more AA carriers were found among the patients with GC compared with the controls ($P = 0.032$, Figure 2). It is noticeable that both patients and controls were in Hardy-Weinberg equilibrium.

Considering the low frequency of the GG genotype, we combined the GG and AG genotypes for use as the reference. After adjustment for age, sex, *H. pylori* infection, smoking, and alcohol consumption, subjects with AA genotype had a 1.36-fold increase in GC risk compared with those with AG + GG genotypes (OR = 1.36, 95% CI = 1.01-1.84, $P = 0.041$).

Association between ICAM-1 +469 A/G polymorphism and clinicopathological parameters of GC

The potential associations of the ICAM-1 +469 A/G polymorphism with tumor characteristics are presented in Table 3. Among the 332 patients with GC, the frequencies of the three genotypes were 57.2% (AA, 190/332), 34.9% (AG, 116/332), and 7.8% (GG, 26/332), respectively. No correlation was found between +469 A/G genotypes and tumor size, differentiation, presence of lymph node metastases and vascular invasion, or age and gender at diagnosis. However, AA genotype carriers had distant metastasis more frequently than AG and GG carriers (18.9% *vs* 7.0%, $P = 0.002$). In addition, there were more stage IV patients carrying the AA genotype compared with patients with the AG and GG genotypes

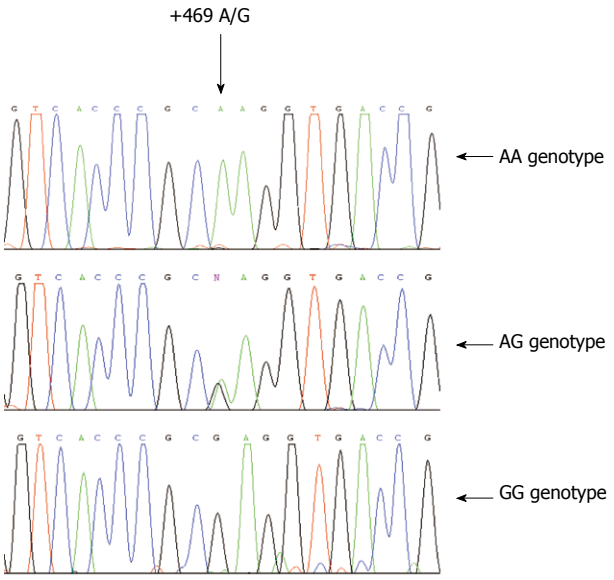

Figure 2 Sequence data of intercellular adhesion molecule-1 K469E genotype. These three graphs represent AA, AG and GG genotypes.

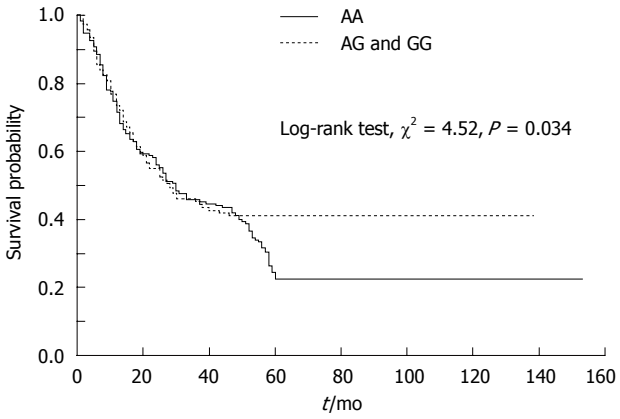

Figure 3 Kaplan-Meier survival analyses of gastric cancer patients.

(27.4% *vs* 16.9%, $P = 0.046$).

ICAM-1 +469 A/G polymorphism and GC prognosis

To evaluate whether the ICAM-1 +469 A/G polymorphism in GC correlates with a worse prognosis, Kaplan-Meier survival curves were constructed using overall cumulative survival to compare the patients with AA genotype to those with AG and GG genotypes. Our data revealed that AA genotype was correlated with overall cumulative survival ($P = 0.034$, log-rank test; Figure 3). The overall cumulative survival rate was 23.7% in AA genotype group and 42.9% in AG and GG genotypes group. In addition, we performed a multivariate analysis including ICAM-1 polymorphism, age, sex, tumor size, differentiation, depth of invasion, lymph node metastasis, distant metastasis, and TNM stage for GC, and found that ICAM-1 polymorphism is not an independent prognostic factor for the overall survival (relative risk, 1.145; 95% CI, 0.851-1.540; $P = 0.370$).

ICAM-1 +469 A/G polymorphism and sICAM-1 and ICAM-1 expression in GC

Among the 332 patients with GC, 102 had available serum samples. The serum sICAM-1 levels in these patients were measured using an ELISA kit. ICAM-1 immunohistochemical staining of paraffin sections from these patients showed that ICAM-1 was mainly expressed in the invasive front cells (Figure 4). Pearson's χ^2 test showed that the ICAM-1 +469 A/G polymorphism was not significantly associated with sICAM-1 or ICAM-1 expression in GC (Table 4).

DISCUSSION

In the present case-control study, we found that ICAM-1 K469E polymorphisms were associated with significantly increased risk of GC. Consistent with our results, Theodoropoulos *et al*[31] reported that this SNP in ICAM1 gene was associated with increased risk of colorectal carcinoma. Gastrointestinal carcinomas might largely be secondary to inflammation and immune response. Gastric carcinogenesis is closely related to chronic inflammatory lesion in gastric mucosa mainly caused by *H. polyri* infection. ICAM-1 plays a pivotal role in leucocyte migration across endothelial cells and facilitates leukocyte recruit-

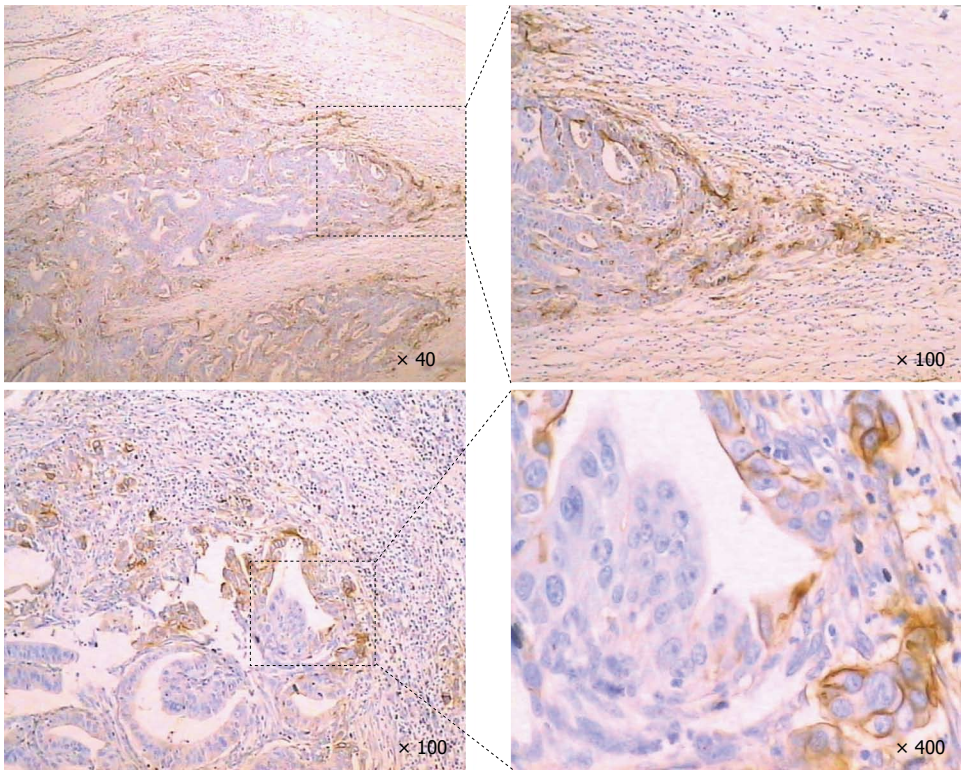

Figure 4 Intercellular adhesion molecule-1 expression in gastric cancer. Intercellular adhesion molecule-1 (ICAM-1) was mainly expressed in the invasive front cells.

ment into inflammatory sites. K469E amino acid changes in the ICAM1 gene may influence its functional role, as it is located at the Mac-1 binding domain and the immunoglobin-like domain 5. The ICAM-1 K469E polymorphism may result in the functional alteration of the gene product that facilitates the inflammation and immune response. The mixture of cytokine produced in inflammation and immune response contributes to the establishment of oncogenic microenvironment that plays a key role in initiation of gastric carcinogenesis by stimulating angiogenesis, damaging DNA and epithelial cell proliferation and subsequent malignant transformation[32,33]. For example, the pro-inflammatory and acid inhibiting properties of TNFα seem to enhance *H. pylori* oncogenic or other effects on gastric mucosa. In another study, we found that ICAM-1 K469E polymorphism was strongly associated with the progression of gastric lesions from gastritis to dysplasia (data not shown).

Since ICAM-1 K469E polymorphism could lead to the functional alteration of the gene product, it may influence its role in pathogenesis as well as in the progression and subsequent prognosis. This study revealed that K469E polymorphism was strongly associated with distant metastasis and advanced staging (stage Ⅳ) of GC. In addition, this polymorphism was correlated with poor survival of the patients, although there was no correlation between polymorphism and expression and soluble level of ICAM-1. Our results showed that ICAM-1 was mainly expressed in the invasive front cells. These findings are in agreement with previous reports on the involvement of ICAM-1 in tumor progression[34-37]. The possible mechanism of this phenomenon is that tumor cells with high ICAM-1 expression could bind to infiltrating lymphocytes through an ICAM-1/LFA-1 interaction. As a result, cancer cells could become detached from the tumor mass and migrate into the blood circulation. Additionally, cells would not be damaged when transiting through the blood vessels and could easily adhere to the capillaries or lymphatic sinus, leading to metastasis.

Our data analysis relied on extracted genomic DNA from tissue samples preserved in paraffin blocks. Rae *et al*[38] reported that the fixation process used for making paraffin blocks did not affect genotype detection. They found that the results of genotype detection with genomic DNA from paraffin blocks were consistent with the results of genotype detection using genomic DNA from peripheral

blood and suggested that accurate and reliable genotyping results with paraffin samples could be achieved.

To the best of our knowledge, this is the first evidence to indicate that individuals carrying the AA genotype of the ICAM-1 K469E polymorphism might be more susceptible to GC. In addition, patients with the AA genotype were more likely to develop distant metastasis and have a higher risk of death compared with other patients. These results suggested that the ICAM-1 K469E polymorphism could be used as a new molecular marker to screen for individuals with higher risk of GC, predict disease progression, and guide individualized treatment.

COMMENTS

Background

Gastric cancer (GC) is a biologically and genetically heterogenous tumor and develops as a result of the interplay among genetic and environmental factors. Genetic polymorphism plays a role in determining how hosts respond to various environmental factors. A number of studies have confirmed that polymorphisms of many inflammation-related genes are significantly associated with the risk of GC.

Research frontiers

According to the authors of this paper, there has been no report on the relationship between intercellular adhesion molecule-1 (ICAM-1) gene polymorphisms and the risk, biological behavior and prognosis of GC.

Innovations and breakthroughs

In this study, the authors investigated the association between single nucleotide polymorphisms in ICAM-1 and the risk, biological behavior and prognosis of GC in Chinese population. This is the first evidence to indicate that individuals carrying the AA genotype of the ICAM-1 K469E polymorphism might be more susceptible to GC. In addition, patients with AA genotype were more likely to develop distant metastasis and have a higher risk of death compared with other patients.

Applications

The ICAM-1 K469E polymorphism could be used as a new molecular marker to screen for individuals with higher risk of GC, predict disease progression, and guide individualized treatment.

Terminology

ICAM-1 is a cell adhesion molecule belonging to the immunoglobulin superfamily and is the ligand of β2 integrin (LFA-1 and Mac-1). ICAM-1 plays an important role in cell-to-cell, cell-to-extracellular matrix interaction and cell signaling.

Peer review

The authors investigated K469E polymorphism of ICAM-1 in patients with gastric cancer. The number of cases enrolled in this study is enough and the results are very important.

Abstract

AIM: To explore the DNA image cytometry (DNA-ICM) technique as a primary screening method for esophageal squamous precancerous lesions.

METHODS: This study was designed as a population-based screening study. A total of 582 local residents aged 40 years-69 years were recruited from Linzhou in Henan and Feicheng in Shandong. However, only 452 subjects had results of liquid-based cytology, DNA-ICM and pathology. The sensitivity and specificity of DNA-ICM were calculated and compared with liquid-based cytology in moderate dysplasia or worse.

RESULTS: Sensitivities of DNA-ICM ranging from at least 1 to 4 aneuploid cells were 90.91%, 86.36%, 79.55% and 77.27%, respectively, which were better than that of liquid-based cytology (75%). Specificities of DNA-ICM were 70.83%, 84.07%, 92.65% and 96.81%, but the specificity of liquid-based cytology was 91.91%. The sensitivity and specificity of a combination of liquid-based cytology and DNA-ICM were 84.09% and 85.78%, respectively.

CONCLUSION: It is possible to use DNA-ICM technique as a primary screening method for esophageal squamous precancerous lesions.

Key words: DNA image cytometry; Aneuploidy; Screening; Esophageal cancer; Precancerous lesions

INTRODUCTION

Esophageal cancer, the world's eighth most common cancer, is curable if detected early. In China, the survival rates are over 85% when found at an early stage of esophageal squamous cell carcinoma (ESCC), but less than 10% when diagnosed at the advanced stage[1]. Patients in early stages are asymptomatic, and therefore, screening is important for detecting patients before they progress to advanced stage disease.

Presently, several screening methods have been explored in high-risk areas of China including conventional cytology[2-5], liquid-based cytology[6], occult blood detection[7] and endoscopic biopsy examination with Lugol's iodine staining[8]. Conventional cytology had been used in high-risk areas of China in the 1970s, but it has been replaced by liquid-based cytology. Occult blood detection has been explored in several areas in China, but because of low sensitivity and specificity, this method has not been used widely yet. Endoscopic examination with Lugol's iodine staining is mostly used in high-risk areas in China now. Although endoscopic examination with Lugol iodine staining has high sensitivity and specificity of more than 90%[8], because of the high cost, this screening method is difficult to be accepted by residents in rural high-risk areas. Meanwhile, endoscopic and pathological doctors require a lengthy qualification process. Liquid-based cytology may improve the quality of the cytological procedure and provide satisfactory diagnostic slides compared with conventional cytology, but it has limits for improving the sensitivity and specificity of screening[6,9]. Furthermore, there is a skill shortage in rural high-risk areas due to the lack of experienced cytologists.

DNA image cytometry (DNA-ICM) has been proposed as a simple, easy, sensitive and high specificity method for screening of ESCC. Changes in DNA ploidy occurring in human tumors have been shown to be a global reflection of the chromosomal and subchromosomal genetic changes which are important in tumor development and progression[10]. DNA ploidy is analyzed by DNA-ICM as a screening marker to reveal the development of ESCC. Until now, few studies have investigated the relationship between DNA ploidy and ESCC diagnosis application[11-13]. In these previous studies, researchers obtained specimens from surgical tissue, paraffin-embedded tissue and endoscopic biopsy. They have analyzed the prognostic value of DNA ploidy in the progression of ESCC, and predicted the prognosis of ESCC. Furthermore, these studies have not been performed by a population-based method, but were small sample clinical studies. DNA-ICM has been used as a screening method in cervical cancer[14], and was shown to have a higher sensitivity than that of cytology. However, no population-based screening study has focused on DNA-ICM for assessment of esophageal squamous carcinoma and precancerous lesions.

In order to evaluate sensitivity and specificity of ESCC screening by DNA-ICM, we conducted a population-based study in two high-risk areas of China.

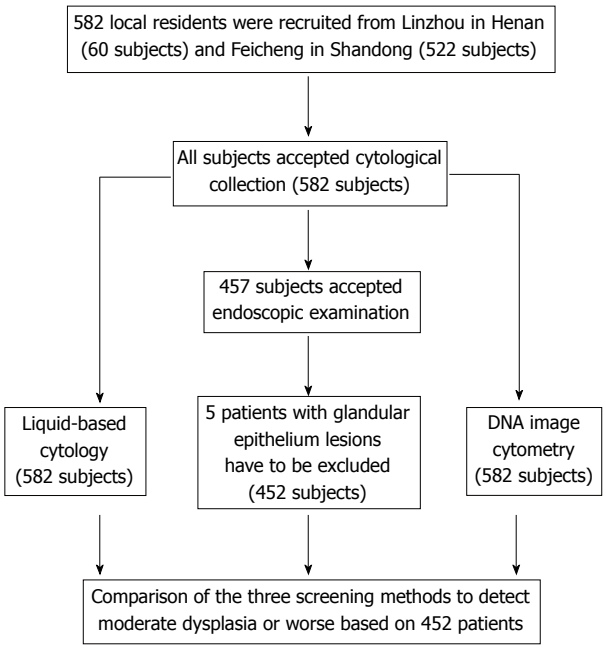

Figure 1 Study flow chart, procedure, and subjects included in the study.

MATERIALS AND METHODS

Study design and subjects recruitment

This was a population-based screening study. In two areas at high risk of ESCC, namely Linzhou in Henan province and Feicheng in Shandong province, local trained village doctors visited every family in June 2010, gathered local residents to the village hospital, and then explained this study to them. Finally, 70% of the local residents consented to participate in our study. Inclusion criteria were: (1) local resident; (2) age 40 to 69 years; (3) no contraindications for endoscopic examinations (e.g., history of reaction to iodine or lidocaine, serious cardiovascular disease, poor health status); and (4) voluntarily consenting to participate in screening and signing the informed consent document. Exclusion criteria were: participants who had a history of liver cirrhosis, esophageal varices, hematemesis, a bleeding disorder, uncontrolled congestive heart failure, unstable angina or a reaction to topical anesthetics or iodine.

The details of subject recruitment and exclusion, those with cytology and endoscopy examinations, and the study procedure are described in Figure 1.

This study was approved by the Institutional Review

Boards of the Cancer Institute/Hospital of the Chinese Academy of Medical Sciences (CICAMS) and Peking Union Medical College.

Cytological sample collection

Preparation for balloon examination: All cytological examinations were performed in the villages. After completing informed consent and a short questionnaire, patients fasted overnight prior to examination. Before balloon examination, an inflatable balloon was soaked in 75% alcohol for at least 12 h.

Collection of cytological samples[6]: Balloon examination was performed by an experienced local doctor. After cleansing the oral cavity, the balloon was inserted into the back of the throat and swallowed by the patient. Once in the stomach, the balloon and covering mesh were expanded and then gradually pulled up the esophagus. When the balloon reached the upper esophageal sphincter, it was deflated and withdrawn completely. After removal, the balloon was placed in a 50 mL centrifuge tube including Thinprep digestive fluid, the catheter was cut off, and the centrifuge tube was sealed and transferred to a CICAMS laboratory.

Reparation of cytological slides: Each sample was vortexed for 10 min to remove adherent cells from the balloon, which was then taken out of the tube. The remaining cell suspension was centrifuged at 2500 r/min for 5 min. Excess supernatant was discarded and the cell deposits remained in the tube. All cell deposits were then transferred to Eppendorf tubes, which included 20 mL of Thinprep preserving cyto-solution. Every sample in the eppendorf tube was prepared for two cytological slides. Every subject had two slides, which were divided randomly for a Pap smear or Feulgen staining. We adopted a crossover design to eliminate the impact of numbers of cells on the diagnosis.

The slides were reviewed by two cytopathologists independently, and discrepancies were adjudicated by joint review. The slides were read blindly without the pathological results. Diagnostic criteria were adapted from criteria of the original Bethesda System[15].

DNA image analysis on liquid-based specimens

The specimens were stained by the Feulgen-Thionin method as detailed in one previous study[16]. The hardware of the system included a MOTIC BA600 microscope, DELL370 workstation, automated microscope control-box, Moticam 1501 camera and assistant accessories. The software for the DNA-ICM system came from Canada[17].

This system automatically loaded each slide, scanned the areas of Thinprep deposition, stored an image of every object detected, calculated a set of 132 features for each cell nucleus, ordered the DNA content of the nucleus, and used multilevel decision-making to classify each object as either nucleus or 'junk'. Finally, two cytopathologists checked blindly the image of every nucleus repeatedly, then excluded an unsatisfactory nucleus. Figure 2 shows the interface of DNA-ICM which is used to

Table 1 Number of diploid and aneuploid cells by DNA ploidy analysis based on pathological diagnoses *n* (%)

DNA ploidy	Pathological diagnoses				
	Normal	mD	MD	SD	ESCC
Diploid	244 (72.6)	45 (62.5)	4 (13.8)	0 (0)	0 (0)

No. of aneuploid cells ≤ 20	0 (0)	0 (0)	8 (27.6)	5 (50)	2 (40)
No. of aneuploid cells > 20	0 (0)	0 (0)	8 (27.6)	2 (20)	3 (60)
Total	336	72	29	10	5

mD: Mild dysplasia; MD: Moderate dysplasia; SD: Severe dysplasia; ESCC: Esophageal squamous cell carcinoma.

assess the image of the cell nucleus with its corresponding features.

At least 400 normal epithelial cells were taken as the internal reference diploid population in each specimen. The coefficient of variation (CV) of the DNA quantity of these reference cells never exceeded 3%. This value was lower than the CV of 5% recommended by the European Society for Analytical Cellular Pathology (ESAPC)[18,19]. The DNA content of every nucleus was measured by integrated optical density (IOD).

The resulting DNA ploidy value is expressed as a "c" value for the chromosome. A DNA ploidy value of 2c indicates a normal diploid cell, 4c is a tetraploid cell, 5c is a cutoff used for aneuploidy by most authors[18].

The quality control process was implemented and depended on the reports of ESAPC[18,19].

DNA index = DNA IOD value of detected cell/Average DNA (G0/G1) IOD among reference cells nuclei

Endoscopic examination

Endoscopic screening was completed by local doctors after training by and under the supervision of experienced doctors from the CICAMS. The technical processes of endoscopic screening were as follows:

Pre-endoscopy: Firstly, subjects signed the informed consent, then were anesthetized with 5 mL 1% lidocaine *via* the mouth.

Endoscopy: Subjects were placed in the left lateral position. The entire esophagus and stomach were visually examined including careful examination of the cardiac mucosa spinal roots.

Iodine staining: During the endoscopic procedure, Lugol's iodine (1.2%) solution was used to stain the normal glycogen-containing tissue, which left the suspicious lesions unstained. Unstained foci were targeted and multiple biopsies were taken. Cleaning and disinfection of endoscopes was carried out using 2% alkaline glutaraldehyde solution.

Pathological diagnoses: Biopsy specimens were fixed in 10% buffered formalin, embedded in paraffin, cut in 5 μm sections, and stained with hematoxylin and eosin. The biopsy slides were read blindly by two experienced pathologists (WJW, LFH) without knowledge of the visual endoscopic results. Subjects with mild dysplasia needed to be followed up, but with moderate dysplasia or worse would be offered argon plasma coagulation and/or endoscopic mucosal resection, or surgery, depending on the grade of the lesion. Therefore, diagnosis of moderate dysplasia or worse has clinical implications.

Statistical analysis

The sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of DNA-ICM were calculated by SAS 9.2 software. The results of DNA-ICM ranging from 1 to 15 aneuploid cells were based on different esophageal precancerous lesions (mild dysplasia, moderate dysplasia, severe dysplasia and squamous cell carcinoma).

RESULTS

Subject demographics

The study consisted of 452 subjects, including 171 men and 281 women. The mean age of the participants was 55 years (range, 40-69 years). Overall, 60 subjects (13.3%) came from Linzhou in Henan province and 392 subjects (86.7%) from Feicheng in Shandong province. The analytic database was limited to 452 subjects who had results of liquid-based cytology, histopathology and DNA-ICM.

Results of histopathology, liquid-based cytology and DNA-ICM

There were 336 of 452 (74.3%) subjects with "negative" histology, 10 (2.2%) had severe dysplasia, 29 (6.4%) had moderate dysplasia, 72 (15.9%) had mild dysplasia and 5 (1.1%) were diagnosed with ESCC. For diagnoses with liquid-based cytology, 386 subjects were normal (85.4%) and 66 (14.6%) had cytological abnormalities, of which 39 had atypical squamous cells of undetermined significance (ASCUS), 19 had low-grade squamous intraepithelial lesions (LSIL), 3 had high grade squamous intraepithelial lesion (HSIL) and 5 cases had ESCC. For DNA-ICM, 293 of 452 (64.8%) subjects had no aneuploid cells, and 159 (35.2%) subjects had aneuploid cells.

Table 1 shows diploid cells and aneuploidy classified by pathological diagnoses. The results showed that 27.4%

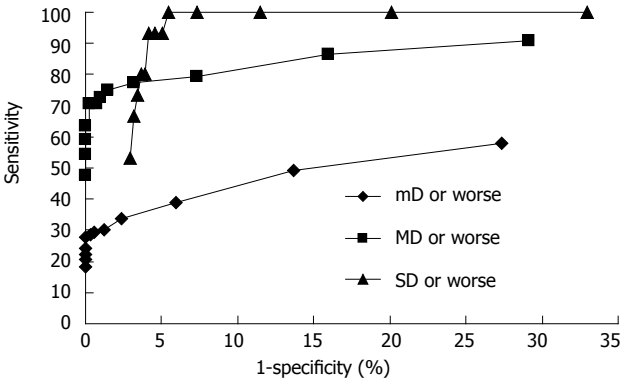

Figure 3 Receiver operating characteristics curves of DNA image cytometry based on histopathological results including mD or worse, MD and worse or SD or worse. For each curve, the 15 points from right to left are from at least one aneuploid cell to at least 15 aneuploid cells. mD: Mild dysplasia; MD: Moderate dysplasia; SD: Severe dysplasia.

Table 2 Comparison of sensitivity, specificity, positive predictive value, negative predictive value between liquid-based cytology and DNA ploidy method based on moderate dysplasia or worse as threshold

	Threshold for positivity	Total	Se (%)	Sp (%)	PPV (%)	NPV (%)
Cytology	ASCUS+	452	75.00	91.91	50.00	97.15
	LSIL+	452	52.27	99.02	85.19	95.06
	HSIL+	452	18.18	100.00	100.00	91.89
DNA ploidy	At least 1 5cER cell	452	90.91	70.83	25.16	98.63
	At least 2 5cER cell	452	86.36	84.07	36.89	98.28
	At least 3 5cER cell	452	79.55	92.65	53.85	97.67
	At least 4 5cER cell	452	77.27	96.81	72.34	97.53
	At least 5 5cER cell	452	75.00	98.53	84.62	97.34

ASCUS: Atypical squamous cells of undetermined significance; LSIL: Low-grade squamous intraepithelial lesions; HSIL: High grade squamous intraepithelial lesion; Se: Sensitivity; Sp: Specificity; PPV: Positive predictive value; NPV: Negative predictive value.

subjects with normal esophageal epithelia presented with aneuploid cells, but the proportions of aneuploid cells for subjects with mild dysplasia, moderate dysplasia, severe dysplasia, and ESCC were 37.5%, 86.2%, 100% and 100%, respectively. In particular, among subjects with severe dysplasia or ESCC, the proportion of diploid cells was zero. Furthermore, the larger the proportion of aneuploid cells, the worse the lesions.

The sensitivity and specificity of DNA-ICM compared with histopathology and were showed in ROC curve

Figure 3 shows receiver operating characteristics curves of the DNA-ICM method based on mild dysplasia or worse, moderate dysplasia or worse and severe dysplasia or worse. It also shows the sensitivity and specificity of DNA ploidy by category, which is the minimum number of cells required to define a subject as aneuploid. It is difficult to determine the exact threshold value, so optimal limits of the threshold for DNA-ICM method were determined. According to Figure 3, the optimal values for sensitivity and specificity fell around a minimum number of aneuploid cells ranging from at least 1 to 5.

Table 3 Sensitivity and specificity of a combination of cytology and DNA image cytometry based on moderate dysplasia or worse as threshold

Cytology or DNA ploidy	Se (%)	Sp (%)
⩾ ASCUS or ⩾ 1 aneuploid cells	93.18	67.65
⩾ ASCUS or ⩾ 2 aneuploid cells	88.64	79.41
⩾ ASCUS or ⩾ 3 aneuploid cells	84.09	85.78
⩾ ASCUS or ⩾ 4 aneuploid cells	81.82	88.97
⩾ ASCUS or ⩾ 5 aneuploid cells	81.82	90.69

ASCUS: Atypical squamous cells of undetermined significance; Se: Sensitivity; Sp: Specificity.

Comparison of liquid-based cytology and DNA-ICM

Table 2 shows the sensitivity, specificity, PPV and NPV of liquid-based cytology and DNA-ICM in our laboratory using these samples as determined by two blinded reviewers. ASCUS, LSIL and HSIL thresholds for cytology, and 1-5 aneuploid cells present at a DNA index of 2.5 for ploidy. For the threshold of moderate dysplasia or worse, sensitivities of the DNA-ICM method ranging from at least 1 aneuploid cell to 4 aneuploid cells were 90.91%, 86.36%, 79.55% and 77.27%, respectively. The specificities were 70.83%, 84.07%, 92.65% and 96.81%, respectively, but the sensitivity and specificity of liquid-based cytology for ASCUS or worse was 75% and 91.91%, respectively.

Combined liquid-based cytology with DNA ploidy

Table 3 shows the sensitivity and specificity of a combination of liquid-based cytology and DNA-ICM. Liquid-based cytology took ASCUS as the threshold value. The threshold value of DNA-ICM ranged from at least 1 aneuploid cell to at least 5 aneuploid cells. The combination improved sensitivity and the ability to screen for positive cases. The group "⩾ ASCUS or ⩾ 3 aneuploid cells" delivered optimal sensitivity and specificity, 84.09% and 85.78%, respectively.

DISCUSSION

This is the first population-based study to explore DNA image analysis technology as a screening method in ESCC. Our study indicated that the higher the grade of esophageal precancerous lesions the higher the proportion of aneuploid cells. This result is similar to the conclusion that early malignant changes in the esophagus are associated with alterations in DNA content in the clinical study by Blant *et al*[13] in Switzerland. Therefore, DNA image analysis may have potential clinical application as a screening method for ESCC.

Our study also showed that the sensitivities of the

DNA-ICM method ranging from at least 1 aneuploid cell to 4 aneuploid cells were 90.91%, 86.36%, 79.55% and 77.27%, respectively, in identifying moderate dysplasia or worse disease. These sensitivities were much higher than that of liquid-based cytological testing (75%) using moderate dysplasia or worse as the threshold.

One study on cervical cancer showed that the sensitivity of DNA cytometry testing for cervical cancer was 91.7%, whereas the sensitivity of cytological testing was 44.5%, and the specificity was 54.1% for DNA cytometry testing and 70.6% for cytological testing[14]. Singh *et al*[20] proposed the idea of combination screening using the DNA-ICM method, and in cervical cancer, human papillomavirus screening with cytology would be an optimal method to detect progressive lesions with the greatest possible sensitivity and specificity. In our study, the aim of combining liquid-based cytology and DNA-ICM was to explore whether the combination could improve the sensitivity in screening for ESCC and precancerous lesions. The results indicated that the group "$\geqslant$ ASCUS or $\geqslant$ 3 aneuploid cells" had the optimal sensitivity (84.09%) and specificity (85.78%). This improved the sensitivity of liquid-based cytological testing (75%) based on moderate dysplasia or worse. However, the specificities of combined cytology and DNA-ICM were lower than for the individual methodologies. If both the results of cytology and DNA-ICM are negative, the specificities of the combination were negative. This led to the low specificities. All in all, a combination of the two methods was only an indication for screening, and was not suitable for screening ESCC and precancerous lesions.

It is important to note one parameter of DNA-ICM in this study: the DNA index. In this study, we took the 5c value as the threshold value of the aneuploid cell. The ESAPC suggest that 5c is the cut-off value for aneuploidy[18]. A few studies suggested the threshold value for aneuploidy in other cancers was 5c, based on clinical samples[21-23]. DNA-ICM, used in cervical cancer screening, also set 5c as the cut-off value since results had showed that optimal values for sensitivity and specificity fell around a DNA ploidy of 5c[17]. However, this value has not been verified in esophageal cancer screening. It may be a limitation of our study, and future studies should confirm the cut-off value of DNA-ICM in esophageal cancer.

Our study is also the first study using cytological samples for DNA-ICM with Feulgen staining by inflatable balloon. Previous studies[24,25] on esophageal cancer and DNA-ICM collected biopsy specimens and then analyzed the DNA content of the nucleus. The sample collection procedure in our study was simple, and easy to perform as a screening method. Most ESCC cases occur in rural areas in China where residents have little knowledge of the capacity of medical diagnosis, and there is little heath education and inadequate treatment. These areas also lack experienced cytologists, endoscopists, and pathologists, as medical training is arduous and long. However, for DNA-ICM, a technician could work independently after 3 wk training, and 90% of slides could be diagnosed in 1 min, so this method would be easier to perform. Cytological diagnosis depends largely on the numbers of cytologists, but DNA-ICM is more objective as it is read by computer[26]. Our aim was to explore DNA-ICM as a primary screening method, which is certain to miss some positive cases compared with the "golden standard" of endoscopic examination. Nevertheless, we should not ignore the advantages of DNA-ICM: it is simple, objective, and likely to be accepted by participants. According to the data analysis, of 116 subjects with mild dysplasia or worse, 49 results of DNA-ICM were negative (false negative rate 42.2%). However, all of the 49 cases (100%) had mild or moderate dysplasia. This means that no advanced stage esophageal lesions had been missed. We also have relevant data about the efficiency of cell collection by inflatable balloon. is the so-called adequacy codes are classified into three grades: adequate for evaluation; satisfactory for evaluation but limited; and unsatisfactory. The number of subjects with adequate for evaluation cytological samples was 288, which is 63.7% of all subjects; with satisfactory for evaluation but limited samples was 163 (36.1%), and the sample of one subject was unsatisfactory (0.2%). Thus, we could say that the efficiency of cell collection by inflatable balloon was good for diagnosis by DNA-ICM.

DNA-ICM could also be used to predict the progress of lesions, as ESCC patients with diploid cells lived longer than ones with polyploidy[12]. One study in 2001 showed that the progression rate from oral dysplasia to invasive or carcinoma, based on the detection of DNA aneuploidy was only 10% after 1 year but increased significantly, to 90%, after 5 years[27]. DNA-ICM has been used as a diagnostic tool and aneuploidy tended to correlate with progression to invasive SCC[13]. Esophageal squamous cell carcinogenesis is thought to be a multistep process, influenced by multiple factors. Changes in DNA ploidy occurring in human tumors are shown to be a global reflection of the chromosomal and subchromosomal genetic changes which play a key role in tumor development and progression[10]. It had been indicated that the aneuploid cell is important in the early stage of carcinogenesis[28,29]. Therefore, we believe that aneuploid cells as a biomarker can be detected by DNA-ICM, which not only may be used for screening precancerous lesions of ESCC, but also for clinical diagnoses, prognostic evaluation and, in particular, patient follow-up and management after screening.

In summary, this is the first population-based study to focus on the relationship between the alteration in DNA content and ESCC and its precancerous lesions. We found that higher grade esophageal precancerous lesions had a higher proportion of aneuploid cells. Confirmed by pathological diagnoses from endoscopic biopsy, DNA-ICM had higher sensitivity, based on moderate dysplasia or worse as threshold, in ESCC screening than liquid-based cytology. Thus, it is possible to use DNA-ICM as the primary screening method in ESCC in high-risk areas

of China. Further larger sample studies are under consideration.

COMMENTS

Background

Several screening methods have limitation in screening esophageal squamous cell carcinoma (ESCC) and precancerous lesions. Thus, it is necessary to explore a simple, objective, sensitive method as a primary screening method.

Research frontiers

In several previous studies, researchers obtained specimens from surgical tissue and endoscopic biopsy. They analyzed the prognostic value of DNA ploidy in the progression of ESCC and predicted the prognosis of ESCC. These studies were not population-based studies, but small sample clinical studies. DNA image cytometry (DNA-ICM) has been used as a screening method in cervical cancer, which showed that the sensitivity of DNA-ICM was higher than that of cytology.

Innovations and breakthroughs

This is the first population-based study to explore DNA image analysis technology as a screening method in ESCC. Our study is also the first study using cytological sampling for DNA-ICM with Feulgen staining by inflatable balloon. According to our results, the specificities of DNA-ICM were higher than those of liquid-based cytology based for moderate dysplasia or worse.

Applications

It is possible to use DNA-ICM as a primary method in ESCC and precancerous lesions according to our results. Further larger sample studies are under consideration to verify our results.

Terminology

The diploid cell is normal according to diagnosis by DNA imaging, which means it has a normal DNA content. The aneuploid cell has abnormal DNA content.

Peer review

The authors address an important issue considering the shortage of experienced cytologists, pathologists and endoscopic doctors in rural high-risk areas.

Abstract

AIM: To investigate the association between hepatocellular carcinoma (HCC) susceptibility and a 12-bp insertion/deletion polymorphism (rs6147150) in the 3'UTR of *ErbB4*.

METHODS: Using a case-control design, the rs6147150 genotypes in 270 patients with HCC and 270 healthy controls were determined by direct polymerase chain reaction and polyacrylamide gel electrophoresis. Logistic regression was used to analyze the association between the polymorphism and cancer risk.

RESULTS: Computational modeling suggested that rs6147150 was located in the seed region of hsa-let-7c, a potential target sequence in *ErbB4* 3'UTR. Logistic regression analysis showed that, compared with individuals homozygous for wild-type, heterozygotes [adjusted odds ratio (OR) = 1.48, 95% confidence interval (CI) = 1.03-2.17, P = 0.034] and individuals homozygous for 12-bp del/del (OR = 2.50, 95% CI = 1.37-4.56, P = 0.001) were at significantly higher risk of HCC. Carriers of the "del" allele of rs6147150 had a 1.59-fold increased risk for HCC (95% CI = 1.22-2.07, P = 0.003).

CONCLUSION: rs6147150 may be associated with HCC risk, in part through let-7c-mediated regulation, and may be involved in the pathogenesis of HCC in Chinese populations.

Key words: Hepatocellular carcinoma; *ErbB4*; rs6147150; Insertion/deletion polymorphism

INTRODUCTION

Hepatocellular carcinoma (HCC) is an epithelial cancer originating from hepatocytes or their progenitor cells and is the fifth most common malignancy worldwide[1]. Carcinogenesis of HCC is a complex, multistep process, associated with various risk factors, including chronic hepatitis B virus (HBV) and hepatitis C virus (HCV) infections, cirrhosis and exposure to carcinogens[2]. Chronic HBV infection is by far the most important risk factor for HCC in China and sub-Saharan Africa, the regions of highest incidence of HCC. Epidemiological studies

have provided evidence that genetic factors are important in determining an individual's susceptibility to HCC. Advances in knowledge of the molecular pathogenesis of HCC have resulted in significant improvements in the therapeutic management of the disease[3]. For example, genetic variants within nuclear factor-κ B (NF-κ B) signaling pathways may be involved in HBV-associated hepatocarcinogenesis[4]. Significant progress in understanding the genetic predisposition to HCC has been provided by genome-wide association studies (GWAS) and intensive international collaboration[5]. However, the genetic basis of susceptibility to HCC is still poorly understood and early detection is limited by the lack of reliable clinical and molecular markers.

miRNAs are a class of endogenous, small (21-23 nucleotide), noncoding but functional RNAs. Mature miRNAs can be generated by sequential processing of primary miRNA transcripts by Drosha and Dicer enzymes, and may act as posttranscriptional regulators of gene expression by complementary base pairing to messenger RNAs[6]. Misregulation of miRNA expression has been linked to many types of cancer[7]. miRNAs recognize their targets mainly through limited base-pairing interactions between the 5' end of the miRNA (i.e., nucleotides 2-8, the seed region) and complementary sequences in the 3' untranslated regions (3'UTRs) of the target mRNAs[6]. The binding of miRNA to mRNA is critical for regulating mRNA level and protein expression. Genetic changes in the 3'UTR targeted by miRNAs have been found to alter the strength of miRNA binding, affecting the regulation of target genes and an individual's risk of cancer[8-10].

The epidermal growth factor (EGF) family of receptor tyrosine kinases consists of four members, ErbB1, ErbB2, ErbB3 and ErbB4[11]. The four ErbB receptors are selectively activated by a number of EGF-like growth factors leading to cellular responses, such as proliferation, differentiation, migration, and/or survival. Aberrant expression or activity of EGFR and ErbB2 have been strongly linked to the etiology of several human epithelial cancers including head and neck squamous cell carcinoma, non-small-cell lung cancer, colorectal cancer, and breast cancer[12]. Activating mutations in ErbB4 have been observed in metastatic melanoma, providing strong evidence for an oncogenic role of ErbB4 in cancer[13]. Furthermore, ErbB4 expression is lower in HCC than in adjacent noncancerous tissues[14]. However, no studies to date have examined the effects of *ErbB4* polymorphisms on susceptibility to HCC. Using *in-silico* analysis, we identified a 12-bp (AAAATAGGATTG) insertion/deletion polymorphism (rs6147150) in the 3'UTR of *ErbB4*, located within the seed region of the hsa-let-7c potential target sequence. Using a case-control design, we assessed whether this rs6147150 polymorphism influences susceptibility to HCC in a Chinese population.

MATERIALS AND METHODS

In-silico analysis of microRNA-binding

The mature human microRNA sequences were obtained from the microRNA database (miRBase) (http://microrna.sanger.ac.uk). A region consisting of rs6147150 plus 15 bp 5' and 3' was used to analyze hybridization of putative microRNAs. The minimum free energy required for hybridization of putative microRNA and polymorphisms was predicted by miRanda software with default parameters[15]. The difference in energies between wild type and variant was computed as ΔΔG and used to assess the impact of the polymorphism on miRNA binding.

Study populations

Peripheral blood samples were obtained from 270 HCC patients newly diagnosed, hospitalized, and treated in our department from 2004 to 2009, and from 270 cancer-free subjects matched by sex and age and selected from a community-wide nutritional survey conducted in the same regions and at the same time as the cancer patients were recruited. All subjects were unrelated ethnic Han Chinese, and none of the 270 HCC patients had received any medical treatment. HCC patients were excluded if they had: (1) primary or secondary biliary cirrhosis or Budd-Chiari syndrome; (2) autoimmune hepatitis or toxic hepatitis; (3) recurrence of HCC; (4) tumors other than HCC; or (5) liver disease due to parasitosis, diabetes, fatty liver, metabolism disorders or severe cardiovascular diseases. HCC diagnosis was confirmed by a pathological examination combined with positive results on magnetic resonance imaging and/or computerized tomography. Tumor stages were determined according to a modified American Joint Committee on Cancer (AJCC) and International Union Against Cancer (UICC) standard. Subjects who smoked more than two cigarettes per day for more than 1 year were classified as smokers; others were defined as non-smokers. Subjects who consumed at least one drink of alcohol per week were considered alcohol drinkers; others were considered non-drinkers. All participants were negative for antibodies to hepatitis C virus, hepatitis D virus and human immunodeficiency virus. The design of the study was approved by the Ethical Committee of Suzhou Municipal Hospital, and all participants provided written informed consent.

DNA extraction and genotyping

Genomic DNA was extracted from peripheral blood samples using a Chelex method[16]. DNA fragments containing the polymorphism were amplified using the primers 5'-ATTCCAGAGGCCAATTGTA-3' (forward) and 5'-TTTCCTCACCTGTTTACCAC-3' (reverse). Polymerase chain reaction (PCR) reactions were performed in a total volume of 20 μL, containing 2.0 μL 10 × PCR buffer, 1.5 mmol/L $MgCl_2$, 0.25 mmol/L of each dNTP, 0.5 mmol/L of each primer, 100 ng of genomic DNA, and 1.0 U of Taq DNA polymerase. The amplification protocol consisted of an initial denaturation at 94 ℃ for 5 min, followed by 35 cycles of denaturation for 30 s at 94 ℃, annealing for 30 s at 58 ℃, and extension for 30 s at 72 ℃, followed by a final extension at 72 ℃ for 5 min. The PCR products were analyzed by 7% non-denaturing polyacrylamide gel electrophoresis (PAGE) and visual-

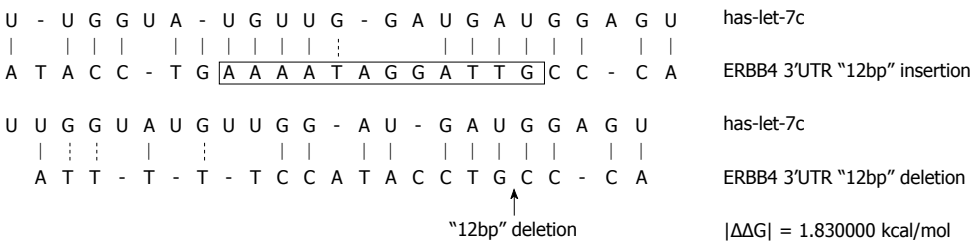

Figure 1 ***In-silico*** **analysis of microRNA-binding.** rs6147150 was located at the fifth nucleotide from the 5' end of has-let-7c. The ΔΔG value between the 12-bp insertion (up) and the 12-bp deletion (down) alleles was calculated to be 1.830000 kcal/mol.

Table 1 Demographic characteristics of the hepatocellular carcinoma case and control groups

Characteristics	Case		Control		*P* value
	n = 270	Frequency (%)	*n* = 270	Frequency (%)	
Age, (yr) (mean ± SD)	50.3 ± 9.2		50.7 ± 9.4		0.91[a]
Gender					
Male	187	69.3	190	70.4	0.78[b]
Female	83	30.7	80	29.6	
Smoking status					
Smoker	79	29.3	85	31.5	0.57[b]
Non-smoker	191	70.7	185	68.5

ized by silver staining[17]. The 12-bp deletion allele of rs6147150 yielded a band of 181 bp and the insertion allele yielded a band of 193 bp. To validate the genotyping method, we analyzed 20 randomly selected DNA samples by both direct sequencing and the PCR method; the concurrence rate of these two methods was 100%, indicating that the PCR method is reliable. Genotyping was performed without knowledge of case or control status. Moreover, 10% of the samples were randomly selected for testing by two different persons, with a reproducibility of 100%.

Statistical analysis

Hardy-Weinberg equilibrium was assessed using a goodness-of-fit χ^2 test for biallelic markers. The adjusted odds ratios (ORs) with their 95% confidence intervals (CIs) of the association between polymorphism and HCC risk were estimated by multiple logistic regression models after controlling for sex, age, smoking status, drinking status, tumor stage and HBV infection. In all cases, homozygosity for the most common allele (i.e., ins/ins) was used as the reference category. A binary logistic regression model was used for stratification by HBV infection status. All statistical analyses were performed using Statistic Analysis System software (version 8.0, SAS Institute), with statistical significance defined as $P < 0.05$ and statistical power calculated using PS software (http://biostat.mc.vanderbilt.edu/twiki/bin/view/Main/PowerSampleSize).

RESULTS

In-silico analysis of microRNA-binding

Computational modeling of the rs6147150 polymorphism suggested that it was located within the hsa-let-7c potential target sequence of the *ErbB4* 3'UTR (Figure 1). The ΔΔG value was calculated as 1.83 kcal/mol.

Association of HCC with the rs6147150 polymorphism

The demographic characteristics of the 270 HCC patients and 270 controls are summarized in Table 1. There were no statistically significant differences in sex distribution, age, or smoking or drinking status between the two groups. As expected, HBV infection was a significant risk factor for HCC. About 74.4% of the cases and 9.6% of the controls were HBsAg-positive ($P < 0.0001$). Genotype distributions showed no deviation from Hardy-Weinberg equilibrium in either cases ($P = 0.149$) or controls ($P = 0.416$). We found that rs6147150 was significantly associated with HCC susceptibility at both the allele and genotype levels (Table 2). Comparing with individuals homozygous for 12N ins/ins, those heterozygous for 12N ins/del (adjusted OR = 1.48, 95% CI = 1.03-2.17, $P = 0.034$) and homozygous for 12N del/del (OR = 2.50, 95% CI = 1.37-4.56, $P = 0.001$) were at significantly in-

creased risk of HCC after controlling for other covariates (Table 2). We also found that the frequency of the 12-bp deletion or insertion allele differed significantly between the HCC and control groups. The presence of the 12-bp deletion allele was associated with a significantly increased risk of developing HCC (OR = 1.59, 95% CI 1.22-2.07, P = 0.003). HBV stratification analysis showed no significant difference in allele frequency between HBV-positive and HBV-negative groups (Table 3). Using PS software, we estimated a power of 0.94 with an α set at 0.05 to obtain an OR of 2.0.

DISCUSSION

In addition to environmental factors, such as viral infection, an increasing number of novel genetic components identified by GWAS have been found to predispose individuals to HCC. Thus, assessments of functional variants are necessary to determine risks of developing HCC. To our knowledge, this study is the first to evaluate the association between genetic variants in *ErbB4* and HCC susceptibility. Our results indicate that rs6147150 is associated with HCC susceptibility in a Chinese population, possibly through let-7c mediated regulation.

Altered ErbB signaling has been frequently observed during malignant transformation, with ErbB overactivity often implicated in the pathogenesis of several epithelial malignancies[18,19]. In contrast, growth factor receptors with tyrosine kinase activity are known to contribute greatly to the regulation of cell behavior, such as cell growth, proliferation and mortality. ErbB4 is frequently expressed in tumors[20-22]; although, in contrast to EGFR and ErbB2, its role as a tumor-driving oncogene is unclear[23]. Although there is little evidence of an association between ErbB4 and HCC, miRNAs have been shown to modulate ErbB receptor expression and downstream signaling activity, stimulating intense interest in the development of miRNAs as therapeutic molecules and clinical biomarkers in cancer[24]. Because HCC is an epithelial cancer originating from hepatocytes or their progenitors, genetic polymorphisms in *ErbB4* may be associated with susceptibility to HCC.

Since bioinformatics analysis suggests that rs6147150 lies within a predicted binding site (seed region) for let-7c, we hypothesized that let-7c would bind tightly to ErbB4 mRNA transcripts containing the 12-bp deletion allele, negatively regulating ErbB4 expression. Conversely, binding with mRNA transcripts containing the 12-bp insertion allele would be disrupted, resulting in increased ErbB4 expression. An ErbB4-specific ligand, heparin-binding EGF-like growth factor (HB-EGF), has been shown to be involved in the development and/or progression of human HCC in an autocrine and/or a paracrine manner, especially during the early stages of HCC[25,26]. Therefore, aberrant expression of ErbB4 would influence the specific binding of HB-EGF and increase the risk for HCC. miRNAs of the let-7 family are highly conserved in bilateral animals and control stem cell division and differentiation[27]. They also function as tumor suppressors and inhibit cell proliferation and tumorigenesis. Low levels of expression of let-7 have been observed in a variety of cancers, including HCC[28].

Taken together, our results suggest that common genetic polymorphisms in *ErbB4* may influence HCC risk, at least in part by let-7c-mediated regulation which may be involved in the pathogenesis of HCC. Our results may provide a greater understanding of the mechanisms of hepatocarcinogenesis and may help in the identification of diagnostic markers for HCC. However, it is important to determine whether the association between this polymorphism and HCC risk also applies to other populations. Finally, additional functional studies are required to fully understand the involvement of *ErbB4* polymorphisms in predisposition to HCC.

COMMENTS

Background

Hepatocellular carcinoma (HCC) is the most common primary malignancy of the liver, with an increasing incidence worldwide. Epidemiological studies have indicated that genetic factors are important in determining an individual's susceptibility to HCC. However, the genetic basis of susceptibility to HCC is still poorly understood and early detection of HCC is infrequent because of the lack of reliable markers. Studies focusing on functional variants in these findings are therefore indispensable.

Research frontiers

Recent genome-wide association studies, which are routinely used to identify common polymorphisms that underlie disease susceptibility in a large population, have enhanced our understanding of the genetic predisposition to HCC. These findings have led to the identification of several genetic variants that may modulate the risk of HCC.

Innovations and breakthroughs

Relative to individuals homozygous for the rs6147150 12-bp ins/ins allele, homozygotes for 12-bp del/del and heterozygotes are at significantly higher risk of HCC. Carriers of the "del" allele are associated with a 1.59-fold increased risk of HCC relative to non-carriers. These findings suggest that common genetic polymorphisms in *ErbB4* may influence HCC risk, at least in part *via* let-

7c-mediated regulation, which may be involved in the pathogenesis of HCC in Chinese populations.

Applications

This preliminary report may help clarify the molecular pathogenesis of hepatocarcinogenesis. Polymorphisms within *ErbB4* may be used as potential markers for HCC predisposition in Chinese populations.

Peer review

This study shows that rs6147150 alleles are significantly associated with the risk of HCC, at least in part through let-7c-mediated regulation, which may be involved in the pathogenesis of HCC. The study design is reasonable and sample size is acceptable.

Abstract

AIM: To investigate the association between three tag single nucleotide polymorphisms (tagSNPs) in interferon regulatory factors (*IRF3*) and the genetic susceptibility to chronic hepatitis B virus (HBV) infection.

METHODS: We performed a case-control study of 985 Chinese cases of chronic HBV infection and 294 self-limiting HBV-infected individuals as controls. Three tagSNPs in *IRF3* (rs10415576, rs2304204, rs2304206) were genotyped with the Multiplex SNaPshot technique. The genotype and allele frequencies were calculated and analyzed.

RESULTS: The three SNPs showed no significant genotype/allele associations with chronic HBV infection. Overall allele *P* values were: rs10415576, *P* = 0.0908, odds ratio (OR) [95% confidence interval (CI)] = 1.1798 (0.9740-1.4291); rs2304204, *P* = 0.5959, OR (95% CI) = 1.0597 (0.8552-1.3133); rs2304206, *P* = 0.8372, OR (95% CI) = 1.0250 (0.8097-1.2976). Overall genotype *P* values were: rs10415576, *P* = 0.2106; rs2304204, *P* = 0.8458; rs2304206, *P* = 0.8315. There were no statistically significant differences between patients with chronic HBV infection and controls. Haplotypes generated by these three SNPs were also not significantly different between the two groups.

CONCLUSION: The three tagSNPs of *IRF3* are not associated with HBV infection in the Han Chinese population.

INTRODUCTION

Chronic hepatitis B virus (HBV) infection is considered a multifactorial and polygenic disorder with viral, environmental, genetic, and immune components. Host immunological and genetic factors may influence the course of the disease[1,2]. Genetics of the host such as single nucleotide polymorphisms (SNPs) in a variety of genes have been implicated in the diversity of the clinical course of HBV[3-8].

Interferon regulatory factors (IRFs) are transcriptional mediators of virus- and interferon (IFN)-induced signaling pathways and have been shown to be involved in antiviral defense, immune response, and cell growth regulation[9]. Among the nine identified members of the IRF family (IRF1-IRF9), three IRFs (IRF3, IRF5 and IRF7) were found to function as direct transducers of virus-mediated signaling and play a crucial role in the expression of type I *IFN* genes[10]. Interferon regulatory factor 3 (*IRF3*) is a member of the IRF family which plays a major role in gene expression of IFN regulatory factors, and is closely related to the level of interferon gene expression in condition of virus infection[11-13]. Patients with chronic HBV infection failed to activate *IRF3* following virus contraction and thereby are unable to secrete enough IFN-β to eradicate the HBV virus, which may partly contribute to persistent infection of HBV[14].

IRF3 plays an important role in the response of the innate immune system to viral infection[15]. Polymorphisms in *IRF3* can affect induction of *IFN-β1* expression[16], and *IRF3* is differentially activated during type 1 IFN responses in human macrophages[17]. The aim of this study was to clarify whether *IRF-3* polymorphisms can serve as candidates for predicting clinical outcomes of the disease caused by HBV infection.

MATERIALS AND METHODS

Participants

Samples were obtained from 1279 unrelated Chinese Han patients with HBV infection. Chronic HBV-infected patients (n = 985; 687 males and 298 females) were recruited from the Infectious Disease Department as cases, and 294 self-limiting HBV-infected individuals were recruited as controls (132 females and 162 males). The average age was 44.2 years for the HBV chronic carriers and 44.9 years for the controls. All the patients with chronic HBV infection fulfilled the diagnostic criteria of the Proposal of Prevention and Treatment of Viral Hepatitis, 2005, issued by the Chinese Society of Infectious Diseases and Parasitology and the Society of Hepatology of the Chinese Medical Association[18]. Clinical criteria for self-limiting HBV infection were positive for HBsAb and HBcAb, negative for HBsAg, and no history of HBV vaccination. Controls were age- and gender-matched to the cases.

Genomic DNA extraction

Blood samples were obtained from all participants, and DNA was extracted from peripheral blood leukocytes using a DNA extraction kit (Yuan Ping-Hao Biotechnology Co. Ltd., Tianjin, China). DNA samples (100 ng/μL) were stored at -80 ℃.

Tag SNP selection

We selected SNPs on the basis of the following principal criteria: tag SNPs (tagSNP) were identified using genotype data from the panel (Han Chinese in Beijing) of the phase II HapMap Project. The criteria for tagSNPs were $r^2 > 0.8$, minor allele frequency MAF > 0.1, functional relevance and importance, and SNPs significantly associated with diseases in previous studies. A total of three tagSNPs in *IRF3* gene (rs10415576, rs2304204 and rs2304206) were selected, which captured 100% of common SNPs (minor allele frequency > 0.1) in the HapMap Chinese database at $r^2 > 0.8$.

Genotyping

The three SNPs in *IRF3* were genotyped using the Multiplex SNaPshot technique. The primers and probes were designed by primer5.0 software and were rs10415576 (5' to 3'): forward primer: CGAGTGCAACCAGGACGTGAT, reverse primer: ATGCTCCCAAGGATGCTCAGTG, and extension primer: GCTGGTTGGCATTCAGTCC; both rs2304204 and rs2304206, forward primer: TCCCATCGGCTTTTGGGTCT, reverse primer: CTTTCCCGCTCCTCGCTCTC, and extension primer: TTTTTGTTGGTTTTATTTCAAGAAGTCGATC. The polymerase chain reaction (PCR) amplification conditions were: a 15-μL final volume containing 10 × 1.5 μL buffer, 0.3 μL dNTPs (10 mmol/L), 0.9 μL $MgCl_2$ (25 mmol/L), 0.1 μL Taq DNA polymerase (TAKARA Biotechnology Co. Ltd., Dalian, China), 0.5 μL each primer (10 pmol/L), and 1 μL DNA template (20 mg/L). Conditions for the multiplex PCR reaction using Touch-down PCR response procedures included initial denaturation at 95 ℃ for 15 min, denaturation at 94 ℃ for 40 s, annealing at 63 ℃ for 1 min, and recursive-descent 0.5 ℃, followed by extension at 72 ℃ for 1.5 min, for a total of 15 cycles. This was followed by 25 cycles of denaturation at 94 ℃ for 40 s, annealing at 56 ℃ for 40 s, and extension at 72 ℃ for 1.5 min, with a final extension at 72 ℃ for 8 min. Amplified samples were stored at 4 ℃. After amplification, 1.5 μL PCR product was examined on an agarose gel to test for successful amplification.

SNaPshot reaction: take the purified PCR product, each concentration of 0.2 μmol/L SNaPshot primer mixture, SNaPshot fluorescent mixtures (containing Taq DNA polymerase and different fluorescently labeled ddNTP, TAKARA Biotechnology Co. Ltd., Dalian,China) consisting of an PCR reaction system. SNaPshot response procedures: initial denaturation at 96 ℃ for 10 s; denaturation at 96 ℃ for 10 s, annealing at 53 ℃ for 5 s, extension at 60 ℃ for 30s, for a total of 25 cycles, and finally extension at 60 ℃ for 30s. Amplified samples were stored at 4 ℃. SNaPshot PCR products using SAP purification, in 10 μL SNaPshot PCR product with 1 U SAP or

IRF3: Interferon regulatory factors 3. HBV: Hepatitis B virus; OR: Odds ratio; CI: Confidence interval.

1 U CIP, were mixed and insulated at 37 ℃ for 1 h, and 75 ℃ for 15 min to inactivate the enzyme. The samples can be stored at 4 ℃ for 24 h or -20 ℃ permanently.

DNA sequencing: the SNaPshot product was diluted 20-fold. In a total volume of 10 μL we mixed 8.6 μL HiDiFormamide (high-purity formamide), 0.9 μL GeneScan-120 LIZ Size Standard, and 0.5 μL SNaPshot purification product. Samples were incubated at 95 ℃ for 5 min, chilled quickly for 4 min, and then loaded on an ABI 3730XL Genetic Analyzer (Applied Biosystems, CA, United States) for capillary electrophoresis, running GeneMapper4.0 software analysis of experimental results.

Statistical analysis

Allele and genotype frequencies were obtained by direct counting, and the Chi-square test was used to compare allele and genotype distributions. The quality of the genotype data was assessed by Hardy-Weinberg equilibrium in the case and control samples using Fisher's exact test ($P > 0.05$). Odds ratios (OR) and 95% confidence intervals [95% confidence interval (CI)] were calculated according to Woolf's method

RESULTS

We investigated the distribution of the three SNPs in 985 Chinese HBV-infected patients (cases) and 294 self-limiting HBV-infected patients (controls). All genotypes of the *IRF-3* polymorphisms were in Hardy-Weinberg equilibrium in both the cases and controls.

The genotype frequencies and allele distributions of *IRF3* polymorphisms in each subgroup of HBV-infected patients are summarized in Table 1. The genotype frequencies for AA, GG, and AG of *IRF3* rs10415576 were 35.23%, 13.71%, and 51.07% in case samples, and 40.48%, 11.22%, and 48.30% in control samples, respectively, without significant differences between cases and controls ($P = 0.2105$). The genotype frequencies for AA, GG, and AG of *IRF3* rs2304204 were 55.03%, 5.48%, and 39.49% in case samples, and 56.46%, 4.76%, and 38.78% in control samples, respectively, without significant differences between cases and controls ($P = 0.8372$). The genotype frequencies for CC, TT, and CT of *IRF3* rs10415576 were 64.87%, 3.05%, and 32.08% in case samples, and 64.97%, 2.38%, and 32.65% in control samples, and no significant differences were noted ($P = 0.8315$).

Table 2 Distribution of haplotypes of interferon regulatory factor tag single nucleotide polymorphisms rs10415576, rs2304204 and rs2304206 in patients with chronic hepatitis B virus infection and self-limiting hepatitis B virus infection

Haplotypes	Frequency (cases)	Frequency (controls)	χ^2	*P* value	OR (95% CI)
AAC	0.6066	0.6446	2.8246	0.0929	1.1787 (0.9729-1.4279)
GAC	0.1411	0.1139	2.8473	0.0916	0.7833 (0.5895-1.0408)
GGC	0.0609	0.0527	0.5420	0.4616	0.8586 (0.5721-1.2888)
GGT	0.1904	0.1871	0.0293	0.8642	0.9796 (0.7738-1.2402)

OR: Odds ratio; CI: Confidence interval.

In addition, no statistically significant differences were found when the allele frequencies of SNPs rs10415576, rs2304204 and rs2304206 were compared between patients with chronic HBV infection and controls. Overall allele *P* values were: rs10415576, $P = 0.0908$, OR (95% CI) = 1.1798 (0.9740-1.4291); rs2304204, $P = 0.5959$, OR (95% CI) = 1.0597(0.8552-1.3133); rs2304206, $P = 0.8372$, OR (95% CI) = 1.0250(0.8097-1.2976).

Haplotype analysis

We also estimated the *IRF3* haplotype frequencies and evaluated the association among these variants and HBV infection. We observed four haplotype combinations, but no significant association was found in the distribution of the haplotype frequencies between cases and controls ($P > 0.05$). Haplotype frequencies lower than 0.03 were ignored in the analysis (Table 2).

DISCUSSION

The human *IRF3* gene is located on chromosome 19ql3.3-ql3.4, and encodes a 50-KDa protein[19]. The ubiquitously expressed *IRF3* is activated in infected cells upon recognition of double-stranded RNA, which is considered the common signature of virus-infected cells[19,20]. Lau *et al*[21] indicated that hepatitis C virus (HCV) can transiently trigger *IRF3* activation during virus spread and that in chronic HCV, *IRF3* activation within infected hepatocytes occurs but is limited.

Several studies have described the importance of *IRF3* polymorphisms. The effect of the A to T substitution on the splicing efficiency of intron 5 of mouse *IRF3*

was confirmed using an *in vitro* splicing assay. The A to T polymorphism in intron 5 of *IRF3* affects induction of IFN-β1 expression[16]. Zhang *et al*[22] showed that SNPs in codon 427 of human *IRF3* may be related to the susceptibility to esophageal cancer. The risk of esophageal cancer in participants with the C allele is 2.38 folds higher that in those with the G allele. However, Sánchez *et al*[23] suggest that the *IRF3* polymorphisms (rs2304204, rs7251 and rs2304207) do not appear to play a major role in the susceptibility or severity of systemic lupus erythematosus in a Spanish population. We selected three SNPs in *IRF3* (rs10415576, rs2304204, and rs2304206) using genotype data from the panel (Han Chinese in Beijing) of the phase II HapMap Project. The three tagSNPs captured 100% of common SNPs (minor allele frequency > 0.1) in the HapMap Chinese database at $r^2 > 0.8$. We analyzed the associations of the three SNP alleles with HBV-infected patients compared with spontaneously cleared HBV controls. The results indicated that there were no significant differences between cases and controls in the genotype or haplotype frequencies of any of the three SNPs we analyzed, suggesting that tagSNPs of *IRF3* do not predict the outcome of HBV infection.

In conclusion, although *IRF3* is a functional gene with a relevant role in HBV pathogenesis, our study demonstrates that the tagSNPs of *IRF3* do not correlate with genetic susceptibility to chronic HBV infection in Chinese patients. Further genetic studies are needed to examine the polymorphisms in other *IRF3* SNPs and the possible association with disease progress in chronic HBV infection.

COMMENTS

Background

Persistent hepatitis B virus (HBV) infection is considered a multifactorial and polygenic disorder with viral, environmental, and genetic components, as well as contributions from HBV genomic variability, host age, gender, concurrent infection with the hepatitis C virus, hepatitis D virus, and human immune deficiency virus. Interferon regulatory factors 3 (*IRF3*) plays an important role in the response of the innate immune system to viral infection. *IRF3* polymorphisms affect induction of interferon (IFN)-β1 expression.

Research frontiers

This study is the first to investigate the association between three tag single nucleotide polymorphisms (tagSNPs) (rs10415576, rs2304204 and rs2304206) of *IRF3* and the genetic susceptibility to chronic HBV infection in Chinese patients using the Multiplex SNaPshot technique.

Innovations and breakthroughs

The three tagSNPs of *IRF3* were not related to genetic susceptibility to HBV infection.

Applications

Based on the results of this study, further genetic studies are needed to examine the roles of other *IRF3* SNPs and their association with disease progress in chronic HBV infection.

Terminology

IRF3 is located on chromosome 19ql3.3-ql3.4, and encodes a 50-KDa protein.

Peer review

The manuscript analyzed the association between polymorphisms of *IRF3* and clinical outcomes of HBV infection. Three SNPs of IRF3 were genotyped using Multiplex SNaPshot technique and compared between chronic HBV infection and self-limiting HBV infection patients. The overall data are negative and showed that SNPs of IRF3 did not affect the outcome of HBV infection. The data may have a significant clinical implication.

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1361 experts in gastroenterology and hepatology from 64 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systemically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensuses and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing
Statistical review is performed after peer review. We invite an expert in Biomedical Statistics from to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Ridit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc*. The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

Conflict-of-interest statement
In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent
Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights
When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www.clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://www.wjgnet.com/1007-9327office. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no less than 256 words) and structured abstracts (no less than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no less than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections.

AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/…"; MATERIALS AND METHODS (no less than 140 words); RESULTS (no less than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 *vs* 3.61 ± 1.67, $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: …*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of *P* values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of *P* values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that...".

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed and http://www.crossref.org/SimpleTextQuery/, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in boldfaced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in boldfaced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*

Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*

Biology: *H. pylori*, *E coli*, *etc.*

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be re-submitted online (http://www.wjgnet.com/1007-9327office/). The author should send the copyright transfer letter, responses to the reviewers, English language Grade B certificate (for non-native speakers of English) and final manuscript checklist to wjg@wjgnet.com.

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

WJG is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1300 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.

Abstract

Esophageal adenocarcinoma is a cancer with poor prognosis, and its incidence has risen sharply over recent decades. Obesity is a major risk factor for developing this cancer and there is a clear male gender bias in the incidence that cannot be fully explained by known risk factors. It is possible that a difference in the expression of estrogen, or its signaling axes, may contribute to this gender bias. We undertook a comprehensive literature search and analyzed the available data regarding estrogen and estrogen receptor expression, and the possible sex-specific links with esophageal adenocarcinoma development. Potentially relevant associations between visceral *vs* subcutaneous fat deposition and estrogen expression, and the effect of crosstalk between estrogen and leptin signaling were identified. We also found limited studies suggesting a role for estrogen receptor β expression in esophageal adenocarcinoma development. The current literature supports speculation on an etiological role for estrogen in the male gender bias in esophageal adenocarcinoma, but further studies are required.

Key words: Estrogen; Estrogen receptors; Male dominance; Esophageal adenocarcinoma

Yang H, Sukocheva OA, Hussey DJ, Watson DI. Estrogen, male dominance and esophageal adenocarcinoma: Is there a link? *World J Gastroenterol* 2012; 18(5): 393-400 Available from: URL: http://www.wjgnet.com/1007-9327/full/v18/i5/393.htm DOI: http://dx.doi.org/10.3748/wjg.v18.i5.393

INTRODUCTION

Esophageal carcinoma is the eighth most common cancer worldwide, and over the last three decades its incidence has risen significantly in all Western countries[1-4]. This change is entirely due to an increase in the adenocarcinoma subtype, and this has predominantly occurred in males[2,5-9]. Recent Western experiences report that the male:female ratio for patients undergoing esophagectomy for adenocarcinoma now exceeds 8:1. However, the identified risk factors for esophageal adenocarcinoma, including gastroesophageal reflux disease, Barrett's esophagus, obesity, alcohol, and tobacco consumption cannot adequately explain this profound gender difference. The dramatic gender difference for esophageal adenocarcinoma suggests there should be a gender-related mechanism underpinning this phenomenon. Estrogens, the primary female sex hormones, are mechanistically linked to aspects of cancer risk and cancer development. Therefore it seems reasonable to consider that estrogens might

contribute towards the gender difference for esophageal adenocarcinoma.

A link between estrogen-activated signaling and carcinogenesis in many organs, including mammary glands[10], ovaries and colon[11] has been clearly defined, although it is unclear whether a similar connection exists for the esophagus, and esophageal adenocarcinoma in particular. Additionally, estrogen is actively involved in the regulation of metabolism in adipose tissues[12], and it can be synthesized locally by activated aromatase in adipocytes in both men and women[13-15]. Involvement of estrogen signaling in regulation of adipose tissue metabolism indicates a possible connection between the effects of estrogen and male obesity - one of the main risk factors for esophageal adenocarcinoma. Given the established regulatory role for estrogen in carcinogenesis and metabolic homeostasis for other cancers, and the strong gender differences for the incidence of esophageal adenocarcinoma, it is plausible to suggest that the estrogen signaling network is involved in the progression of this cancer, and an understanding of estrogen and estrogen receptor (ER) roles in the regulation of carcinogenesis, and how this might be relevant in the esophagus, could provide a basis for developing either preventive measures or new treatments.

In this paper we review potential links between estrogen signaling and esophageal adenocarcinoma, to determine whether this might contribute to the dominance of esophageal adenocarcinoma in males. Literature pertinent to gender specific differences in estrogen synthesis, estrogen-regulated carcinogenesis, specific differences between ERs and signaling in cancer cells, and available information about estrogen signaling in esophageal adenocarcinoma is reviewed.

ESTROGEN IN WOMEN AND MEN: AGE RELATED CHANGES

In premenopausal women the ovaries are the principal source of estrogen[16]. Serum estradiol concentration is much higher in premenopausal women, compared to men, but decreases substantially after the menopause, and ultimately becomes lower than in elderly men[17]. Mass spectrometry has shown that average levels of serum estradiol in elderly men are approximately 73 pmol/L, whereas levels in postmenopausal women are markedly lower (about 15 pmol/L)[17].

When the ovaries cease to produce estrogens in postmenopausal women the main characteristics of estradiol function change, and it is produced in extragonadal sites, and acts locally at these sites as a paracrine or intracrine factor[16-20]. These sites are similar in men and postmenopausal women and include the mesenchymal cells of adipose tissue[13], osteoblasts and chondrocytes of bone[21], the vascular endothelium and aortic smooth muscle cells[22], and numerous sites in the brain[16,17,23].

Importantly, in men and postmenopausal women, circulating estrogens are not the main drivers of estrogen action, but locally produced estrogens originating in extragonadal sites are responsible for the majority of paracrine and intracrine effects of these hormones[20]. The total amount of estrogen synthesized by these extragonadal sites may be small, but the local tissue concentrations achieved are probably high and exert biological influence locally. This might impact on tumor biology. For example, it has been determined that the concentration of estradiol present in breast tumors in postmenopausal women is at least 20-fold higher than in the plasma. Aromatase inhibitor therapy is associated with a major decrease in intratumoral concentrations of estradiol and estrone and loss of intratumoral aromatase activity, which is followed by downregulation of cancer cell growth[10,24]. Local estrogen biosynthesis has also been demonstrated in men, where aromatase expression in adipose tissue is greatly increased by this process[25,26]. However, with respect to esophageal adenocarcinoma, no studies have evaluated whether the amount of estrogen synthesized in abdominal adipose tissue is sufficient to exert any paracrine effect in the esophagus.

ESTROGEN RECEPTORS: STRUCTURE AND FUNCTIONS

The effects of estrogens are mediated by their ligation to ERα and ERβ. ERα and ERβ both belong to the nuclear steroid/thyroid hormone receptor family and they are encoded by two distinct genes [encoding estrogen receptor 1 (*ESR1*) and *ESR2*] which are located on two different chromosomes 6q25.1 and 14q22-24[27,28]. ERα and ERβ have distinct cellular distributions and regulate separate sets of genes. ERα is predominantly expressed in female sex organs such as the breast, uterus and ovaries especially during the reproductive years. ERβ is widely expressed in many other tissues in both genders, but to a lesser degree in males compared to females[15,29]. Although the role of ERs in male physiology has long been neglected, there is growing evidence for estrogen involvement in multiple areas of male physiology[15-17].

The mechanism for ER signaling has been widely investigated. ERα and ERβ share common functional domains, with a conserved central DNA-binding domain which is often involved in receptor dimerization[30,31]. ERs possess two activation function domains; activation function-1 and activation function-2, with the former interacting with non-ER transcription factors, and the latter containing the ligand binding domain[31,32]. One of the most important differences between ERα and ERβ is that activation function-1 in ERβ lacks functional activity[30]. Also, it has been suggested that the main function of ERβ is to bind ERα and suppress its activation, so that ERα and ERβ as a dimer might exert inverse biological effects. Another difference between ERα and ERβ signaling is their interaction with the activator protein-1[32-35]. The activator protein-1 complex of Jun/Fos hetero- or homo-dimers is a key regulator of cell proliferation, with one of its target genes identified as cyclin

D1[33]. Depending on whether ERα or ERβ is activated, the activator protein-1 complex acts in a reciprocal fashion to stimulate or inhibit cell proliferation[35].

After binding estrogen, the receptor ligand-binding domain undergoes a conformational and surface-charge change that results in receptor dimerization. Ligand-binding is accompanied by the dissociation of intracellular ER from chaperone proteins, subsequently releasing the hormone/ER complex for attachment to estrogen response elements in the promoter region of target genes. The dimer then binds DNA to regulate gene expression at specific regions of the DNA named hormone response elements[31,35]. As a consequence, transcription of 17β-estradiol-responsive genes increases, and proliferation or differentiation of steroid-sensitive tissue is augmented. Although most steroid hormone receptors primarily localize to the nuclei, additional ERs have been identified in the cytoplasm and on the plasma membrane. Activation of cytoplasm signaling cascades has been detected after estrogen binding to its plasma membrane receptors[36].

Several isoforms of ERβ able to mediate estrogen signaling have also been found. The isoforms can exert diverse functions, and significantly complicate understanding of cellular responses to estrogens. ERβ isoforms can inhibit ERα transcriptional activity at the estrogen response elements and potentially reverse estrogen signaling[34]. A splice variant of ERβ, termed ERβcx, has been characterized[37]. ERβcx is expressed in the breast[38], the prostate and testis[37], the esophagus[39], and in gastric tissue[40]. Interestingly, ERβcx does not bind estrogen[41]. Instead it inhibits ERα from binding DNA, whilst it does not influence ERβ. The role and mechanism of ERβcx downstream signaling in esophageal tissue is largely unclear and needs to be further investigated.

ROLE OF ESTROGEN AND ESTROGEN RECEPTORS IN VARIOUS MALIGNANCIES: HARMFUL OR HELPFUL?

The biological significance of ERs in breast tumorigenesis has been studied extensively. In breast tumors, ER signaling promotes malignancy due to oncogenic mutations, sustained exposure of ERα with endogenous or exogenous estrogen, and abnormal coupling of estrogen-activated cytoplasmic machinery to growth and anti-apoptosis, all well established causative triggers of cancer in postmenopausal women[41]. Several large prospective studies have confirmed the role of estrogen in stimulation of breast tumor growth, and have demonstrated that the risk of breast cancer is increased in women taking estradiol after the menopause[42-44].

In females with breast cancer, ERα is instrumental in promoting cell proliferation and cancer progression, whereas ERβ exerts anti-proliferative effects by induction of cell cycle and growth arrest[34]. For instance, the downregulation of the cyclin D1 gene by ERβ prevents cellular progression from the G1 to S-phase of the cell cycle[45]. Loss of ERβ expression is considered to be a common feature in estrogen-dependent breast tumor progression[34,35] supporting the hypothesis that ERβ acts as a protector against the mitogenic activity of estrogen in breast pre-malignant tissues.

Estrogen is also critical for the progression of ovarian cancer[46-48]. A strong association between long-term estrogen replacement therapy and increased risk of ovarian cancer has been detected in several studies[45-47]. Similar to breast cancer, the imbalance between ERα and ERβ, along with decreasing expression of ERβ in the ovaries can also lead to uncontrolled cellular proliferation, subsequent malignancy and metastasis[49,50]. Thus, ERβ appears to be pro-apoptotic, facilitating the destruction of malignant cells, whereas ERα has anti-apoptotic activity, indicating its growth stimulatory role[34,45,49]. Confirming the role of ERβ as a tumor-suppressor, deletion of chromosome 14q, where ERβ co-localizes with some other tumor suppressors, is often detected in breast, colon, ovarian and prostate malignant tissue[51-54].

In contrast to the cancer-promoting role of estrogen in breast and ovarian cancers, it has been shown that estrogen works as a cancer suppressor for several gastrointestinal malignancies[41,42,44-56]. The Women's Health Initiative study, which included a cohort of 16 608 women randomized to hormone replacement therapy (HRT) *vs* no HRT, showed that the risk of colorectal cancer was almost halved in women using HRT[55]. A similar study in the United Kingdom of patients with esophageal and gastric cancer concluded that HRT was associated with a 50% reduction in the risk of gastric and colon adenocarcinoma, but had no significant benefit for esophageal adenocarcinoma[56]. However, due to the relatively small number of females with esophageal adenocarcinoma in this study (n = 299), the power of the study was limited and the question remains, thus, unresolved[41,42].

The male predominance of approximately 2:1 in gastric cancer incidence across the world cannot be explained on the basis of gender differences for the prevalence of known risk factors[57]. It has been hypothesized that estrogens play a protective role against gastric cancer. This statement has gained further support from a clinical study of a male cohort of patients with prostate cancer. In this study the risk of developing gastric cancer was lower amongst those who had been treated with estrogen than in those without such treatment (standardized incidence ratio, 0.87; 95% confidence interval, 0.78-0.98)[58]. Further supporting this argument are studies which have shown decreased ERβ expression in other gastrointestinal cancers, such as colon cancer, compared to benign tumors and normal tissues[59]. Tamoxifen exposure has also been shown to be a risk factor for gastric cancer[60,61], adding support to the idea that estrogen signaling has a protective role against gastrointestinal cancer.

FAT DISTRIBUTION, LEPTIN AND ESTROGEN: IS THERE A LINK?

There is a growing appreciation that estrogens are not only directly involved in the reproductive process and in regulation of carcinogenesis, but also have general metabolic roles in both sexes[15-17]. Estrogen signaling has a complex relationship with obesity that differs for premenopausal and postmenopausal women[12]. Importantly, obesity is a risk factor for esophageal adenocarcinoma in both women[62] and men[63]. In a recent study of 23 women with esophageal adenocarcinoma[63], 21 (91.3%) were in the top half of the distribution of the studied cohort with regard to waist-to-hip ratio, waist circumference, and body mass index. Multiple studies of male cohorts have demonstrated a strong association between increased abdominal diameter and esophageal adenocarcinoma, after controlling for body mass index and gastroesophageal reflux[63-68]. It is possible that associations between obesity and esophageal cancer are similar for both sexes, even though the regulation of adiposity in men and women differs significantly. For instance, distribution of body fat in men is characterized by the accumulation of visceral fat, but in women by subcutaneous fat.

Subcutaneous and visceral fat tissues express variable levels of both types of ER[69-71]. However, only ERα has a significant influence on energy homeostasis. The role of ERα in estradiol regulation of body weight and obesity is supported by the following observations: (1) both male and female mice that have been genetically altered to reduce the ability to produce estrogen by knocking out aromatase (an enzyme that catalyzes the conversion of androgen to estrogen) became obese when fed the same amounts as normal mice[72]; and (2) increased white adipose tissue and body fat were seen in both sexually mature male and female ERα-knockout mice[73,74]. Further supporting a role for estrogen signaling through ERα in the regulation of body weight are the findings that abnormal adiposity has been associated with the XbaI polymorphism of the human ERα gene[75,76].

The role of ERβ in estradiol regulation of body weight and obesity is less clear and somewhat controversial suggesting that ERβ functions more as a modulator of estrogen actions[71].

Estrogen has also been shown to contribute to the regulation of body adiposity and fat distribution through ERs in the brain[77], and by interacting with leptin signaling pathways[78]. 17β-estradiol increases leptin mRNA levels in adipose tissue[79]. Consistently, estrogen deficiency impairs central leptin sensitivity[77,78]. In women, leptin fluctuations during the menstrual cycle correlate directly with secretion of estrogen[79,80]. Estrogen has also been found to influence leptin receptor expression and hypothalamic sensitivity to leptin driving subcutaneous body fat accrual over visceral fat during the estrous cycle in rats[81]. Hence, visceral fat varies inversely with estrogen levels. Visceral fat accumulates in females when circulating estrogen levels become sufficiently low, as in postmenopausal women[76,78,82]. The accumulation of visceral fat is associated with an increased risk of various gastrointestinal malignancies, including esophageal adenocarcinoma[83]. Thus, estrogen regulation of leptin levels in women may play a protective role, directing accumulation of subcutaneous in preference to visceral fat.

The situation for men, however, is less clear, although a high level of leptin is considered to be a risk factor for males to develop esophageal adenocarcinoma[63,83]. Speculatively, the production of, and sensitivity to, leptin in men may be increased in visceral fat, and locally in tissues located in close proximity to adipose tissue where estrogen synthesis may be increased. However, mechanisms of ER and leptin signaling in males remain obscure, mostly because the majority of laboratory findings and clinical investigations of leptin and estrogen signaling have used tissues from females. To address this issue, studies are needed that specifically address the role of estrogen signaling in male adipose tissue.

IMPLICATIONS OF ESTROGEN RECEPTOR EXPRESSION IN ESOPHAGEAL ADENOCARCINOMA

In 1998, Lagergren *et al*[83] hypothesized that high estrogen and/or progesterone levels, low testosterone, or a combination of both, might contribute to the lower incidence of esophageal carcinoma in women. Epidemiological data for esophageal adenocarcinoma demonstrates a profound gender difference, with the male: female ratio exceeding 8:1, strongly supporting this hypothesis[1-4]. There are no detailed studies that compare the expression of ERs in esophageal tissues between males and females, but a limited number of studies have provided some preliminary data comparing ER expression in esophageal adenocarcinoma and its precursor lesion, Barrett's esophagus. These studies are summarized in Table 1.

In contrast to the anti-tumor role of ERβ in other cancers, some studies have identified a positive association between ERβ expression and esophageal adenocarcinoma development. Akgun *et al*[84] determined ERβ expression in the esophageal mucosa from patients with Barrett's metaplasia negative for dysplasia, Barrett's metaplasia with low grade dysplasia and Barrett's metaplasia with high grade dysplasia. The results of this study showed significant expression of ERβ (more than 50% of cells positive) in all patients with esophageal adenocarcinoma, and there was a trend towards increased expression of ERβ as the esophageal lesions progressed[85]. These results raise the possibility of ERβ as a target of therapy for esophageal adenocarcinoma. Similarly, another investigation showed a moderate increase in ER expression in tissue samples from men and women with Barrett's esophagus and esophageal adenocarcinoma. However, the subtype of ER was not determined in this study[39].

As ERβ has several isoforms, and these isoforms

Table 1 Estrogen receptor expression in patients with esophageal adenocarcinoma

	No. of patients with EAC	ERα	ERβ	Conclusion
Akgun *et al*[84]	31	Not expressed	Increased expression as esophageal lesions progressed	ERβ is suggested as a EAC therapy target
Tiffin *et al*[85]	20 (8)	Type of ER was not specified; ER were detected in EAC patients		ER may be important for further investigation
Liu *et al*[39]	33	Not expressed	Expressed in EAC, but not in Barrett's esophagus	Anti-estrogen treatment could be a promising therapeutic target for EAC
Kalayaransan *et al*[86]	45 (15)	Not expressed	Detected in all 45 patients; Expressed higher in EAC, compared to normal esophageal mucosa	ERβ suggested as marker and/or prognostic factor

EAC: Esophageal adenocarcinoma; ER: Estrogen receptor.

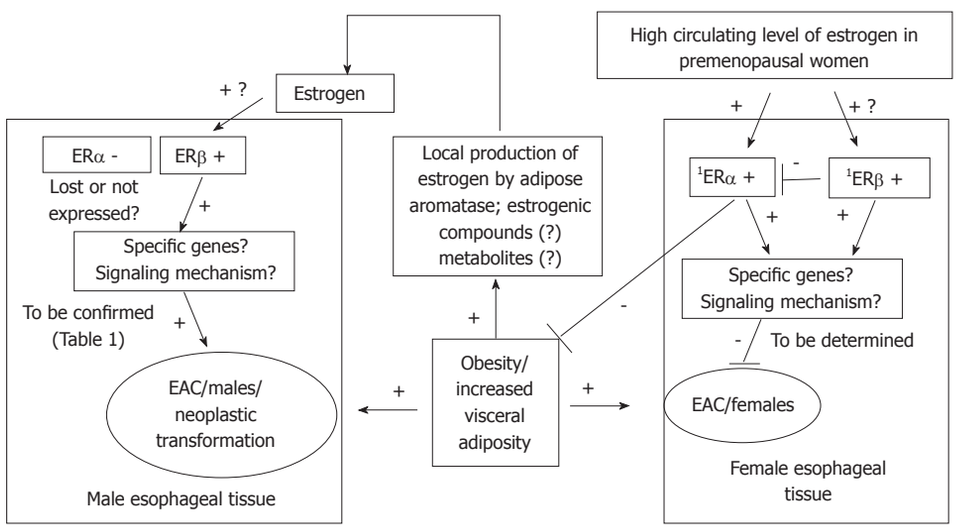

Figure 1 Role of estrogen-activated signaling in the development of esophageal adenocarcinoma: hypothetical pathway. [1]Expression level of estrogen receptor (ER) needs to be determined in esophageal tissue from females and compared to expression in males. EAC: Esophageal adenocarcinoma.

have different functions, Liu *et al*[39] identified which isoforms of ERβ were expressed in esophageal adenocarcinoma but not in Barrett's esophagus. All isoforms of ERβ showed much higher expression in esophageal adenocarcinoma, than in its precursor lesion, Barrett' s esophagus. Thus, a possible role for ERβ isoforms in the maintenance and evolution of esophageal adenocarcinoma was suggested. Although the study did not find a correlation between immunoreactivity and cancer proliferative activity, it showed that ERβ1 tended to have higher expression in invasive tumors which had penetrated the full thickness of the esophageal wall, compared to tumors limited to the esophageal wall ($P = 0.05$), and ERβ1 immunostaining tended to be most prominent in invasive esophageal adenocarcinoma. Conclusively, the study detected the presence of ERβ isoforms in esophageal adenocarcinoma and suggested the potential use of anti-estrogen treatment as a therapeutic target for esophageal adenocarcinoma. Manipulation of ERβ signaling may be considered as a potential prevention strategy to delay or block progression from dysplasia to esophageal adenocarcinoma. Figure 1 summarizes a potential mechanism for interaction between estrogen, ERs and esophageal adenocarcinoma.

Another study by Kalayaransan *et al*[86] determined the expression of ERα and ERβ in esophageal adenocarcinoma across various classifications of tumor stage, and compared expression with adjacent normal esophageal mucosa. No significant expression levels of ERα were found in esophageal adenocarcinoma, suggesting ERα is unlikely to mediate the growth of esophageal adenocarcinoma. However, immunostaining with ERβ antibodies yielded significantly higher results in esophageal adenocarcinoma, compared to normal esophageal mucosa[87]. In each group with the same degree of tumor differentiation, tumor samples had significantly higher staining scores compared to normal esophageal mucosa. Tumors with good or moderate differentiation had lower staining scores than those which were poorly differentiated, indicating that the potential effect of estrogen on esophageal adenocarcinoma could be mediated by ERβ[84,86,87]. Overall, most studies that have evaluated esophageal adenocarcinoma are consistent in suggesting a detrimental effect and prognostic value for ERβ.

Unfortunately, these clinical findings have not yet been supported by *in vitro* experiments using esopha-

geal adenocarcinoma cells. The few *in vitro* studies that have addressed the role of estrogen in the regulation of esophageal cell growth were conducted using squamous cancer cells[87,88]. It has been shown that the growth of an ER-positive esophageal squamous carcinoma cell line (ES-25C) is significantly inhibited by 17β-estradiol, whereas this effect is not observed in an ER-negative squamous carcinoma cell line (ES-8C)[87]. A similar finding was seen in another study, in which the proliferation of the ER-positive KSE-1 esophageal squamous carcinoma cell line was inhibited by 17β-estradiol[88]. In addition, *in vivo* growth of this cell line in both female and male mice was suppressed by the administration of 17β-estradiol, raising the possibility of manipulating the growth of esophageal carcinoma by manipulating the estrogen-ER system[88]. However, esophageal squamous cell carcinoma and esophageal adenocarcinoma are two biologically distinct diseases, so estrogen responsiveness in squamous cell carcinoma lines does not automatically mean that esophageal adenocarcinoma cell lines will also respond. Similar experiments need to be performed on esophageal adenocarcinoma cell lines in order to explore this possibility further.

FUTURE PERSPECTIVES

Current literature provides only limited evidence for a link between estrogen and the development of esophageal adenocarcinoma. Hence, a series of questions can be proposed, and further studies will be needed to determine whether there is any link. It is unclear whether there is a gender difference for the expression of ERβ, or correlation between tumor stage and the expression of ERβ. Most previous studies have not compared estrogen effects in both genders, and have only addressed men and women separately. Detailed comparisons have not been done for various esophageal pathologies *vs* normal esophageal mucosa within both gender groups. Another limitation of previous studies is the small number of patients studied, and for this reason reported data is yet to be verified. A systematic study which includes a sufficiently large number of men and women is needed to determine whether, within each gender group, ERβ expression is associated with the development and progression of esophageal adenocarcinoma. A confirmed link might provide support for ERβ to be used as a target for therapy, or as a prognostic marker.

Krystallis C, Masterton GS, Hayes PC, Plevris JN. Update of endoscopy in liver disease: More than just treating varices. *World J Gastroenterol* 2012; 18(5): 401-411 Available from: URL: http://www.wjgnet.com/1007-9327/full/v18/i5/401.htm DOI: http://dx.doi.org/10.3748/wjg.v18.i5.401

Abstract

The management of complications in liver disease is often complex and challenging. Endoscopy has undergone a period of rapid expansion with numerous novel and specialized endoscopic modalities that are of increasing value in the investigation and management of the patient with liver disease. In this review, relevant literature search and expert opinions have been used to provide a brief overview and update of the current endoscopic management of patients with liver disease and portal hypertension. The main areas covered are safety of endoscopy in patients with liver disease, the use of standard endoscopy for the treatment of varices and the role of new endoscopic modalities such as endoscopic ultrasound, esophageal capsule, argon plasma coagulation, spyglass and endomicroscopy in the investigation and treatment of liver-related gastrointestinal and biliary pathology. It is clear that the role of the endoscopy in liver disease is well beyond that of just treating varices. As the technology in endoscopy expands, so does the role of the endoscopist in liver disease.

INTRODUCTION

Liver disease and cirrhosis are common causes of mortality worldwide[1]. The role of endoscopy in liver disease is both diagnostic and interventional: endoscopy should be offered to patients with relevant symptoms (unsuspected liver disease may be diagnosed in this manner) and for variceal screening and treatment. Patients with liver disease can be challenging to sedate, and the complexity of endoscopy in liver disease continues to increase with rising numbers of patients with a liver transplant, and the advent of new endoscopic modalities such as capsule endoscopy and endoscopic ultrasound (EUS).

SEDATION AND ANALGESIA IN LIVER DISEASE

Pharmacodynamics are altered in advanced liver disease as a result of changes in hepatic conjugation and oxidation, shunting, decreased protein binding and an increased vol-

ume of distribution[2]. The common agents used for sedation in endoscopy are discussed, however, specific doses cannot be recommended because these are dependent on patient factors. We would recommend that an endoscopist or anesthetist who has experience with this patient group undertakes the sedation of liver patients.

Benzodiazepines

Midazolam is the benzodiazepine of choice in most endoscopy units. It is protein bound and metabolized in the liver by cytochrome P3A4. In cirrhosis, clearance of midazolam is impaired and elimination half-life is doubled. As a result, midazolam should be used with caution in patients with cirrhosis[3].

Opiates

Pethidine and fentanyl are the most commonly used analgesics for endoscopic procedures. The liver is the major site of biotransformation for most opiates. The oxidation of pethidine is reduced in patients with cirrhosis and its clearance is diminished. Therefore, there is increased bioavailability, and pethidine should be avoided in patients with liver disease[4]. The half-life of fentanyl is shorter and does not seem to be influenced by cirrhosis. Its use is preferred to pethidine[5].

Anesthetic agents

The pharmacokinetics of propofol, an anesthetic agent that is widely used in endoscopy, appears to be unaffected by cirrhosis; again, perhaps secondary to its short half-life. One study has suggested that the use of propofol rather than midazolam in patients with compensated cirrhosis facilitates a faster recovery time with less exacerbation of subclinical encephalopathy[6].

Endotracheal intubation

Gastrointestinal (GI) bleeding in patients with liver disease may be life threatening. If bleeding varices are suspected or patients are hemodynamically unstable, there is often a low threshold for endotracheal intubation to protect the airway. There is little literature on prophylactic intubation for airway protection in such patients, and two retrospective studies[7,8] have concluded that it does not prevent cardiopulmonary complications, or pneumonia. We are of the opinion that airway protection at emergency endoscopy is extremely important in patients with suspected variceal bleeding, who present with hematemesis, and particularly in hemodynamically unstable patients and those with hepatic encephalopathy or alcohol withdrawal symptoms. In such patients, endoscopy is best undertaken in a critical care environment with immediate access to anesthetic support and endotracheal intubation[9].

ENDOSCOPY IN THE CIRRHOTIC PATIENTS WITH COAGULATION ABNORMALITIES

Coagulopathy and thrombocytopenia are common in patients with chronic liver disease. The mechanisms behind coagulation abnormalities are often complex, and it is now thought that prolongation of prothrombin time may not directly relate to the risk of bleeding, and rather, it is the balance of pro- and antithrombotic factors that is important. In practical terms, there is currently no reliable way of quantifying this. Routine correction of coagulopathy at endoscopy is not recommended, although patients with chronic liver disease should receive vitamin K to correct any dietary deficiency that may result in coagulopathy.

It is recognized that diagnostic endoscopy is a low-risk procedure and safe in patients with altered coagulation. However, high-risk endoscopic therapeutic procedures have a significantly increased risk of hemorrhage and, as such, coagulopathy should be treated[10]. It is therefore common practice in cirrhotic patients to correct significant thrombocytopenia ($< 50 \times 10^6$/mL) with platelet transfusions and to correct coagulopathy with fresh frozen plasma (FFP) if prothrombin time is > 20 s to an international normalized ratio < 1.5, before high-risk procedures. Platelet and FFP transfusions are particularly helpful during an acute bleeding episode if the prothrombin time is prolonged or platelets are low, similar to the previously mentioned values[11].

Novel treatments include recombinant factor Ⅶa. This has been used as a hemostatic agent in acute variceal bleeding, but failed to show efficacy in a large randomized study[12]. Another trial has demonstrated that addition of desmopressin does not improve and may worsen the efficacy of terlipressin in controlling acute variceal bleeding in cirrhotic patients[13].

Certain endoscopic investigations have been shown to be safe in coagulopathic patients with cirrhosis, despite being relatively invasive; EUS-fine needle aspiration of the liver has been shown to be a safe alternative to percutaneous liver biopsy, particularly in patients with advanced liver disease, coagulopathy and high risk of bleeding[14]. At endoscopic retrograde cholangiopancreatography (ERCP), endoscopic papillary balloon dilation is safer than endoscopic biliary sphincterotomy for the treatment of choledocholithiasis in patients with advanced cirrhosis and coagulopathy, because it has a reduced risk of bleeding[15].

COMMON ENDOSCOPIC DIAGNOSES AND MANAGEMENT IN PATIENTS WITH LIVER DISEASE

Peptic ulcer disease

The correlation between peptic ulcer disease and cirrhosis is well described. Both duodenal and gastric ulcers are more common in cirrhosis: the reported prevalence is 24.1%[16]. It is recognized that the prevalence of gastric ulceration increases with the severity of liver disease and is related to changes in the hepatic venous pressure gradient[16,17].

A high prevalence of *Helicobacter pylori* (*H. pylori*), up

Table 1 Summary of primary prophylaxis of esophageal varices

Grade	Appearance	High-risk stigmata	Treatment
Grade 1: Small varices	Barely noticeable varices; disappear easily with insufflation	No red signs	No treatment
Grade 2: Small/medium varices	Small or medium varices; do not easily disappear with insufflation	± Red signs	NSBB or VBL
Grade 3: Medium/large varices	Medium or large varies; do not disappear with insufflation	± Red signs	NSBB or VBL

NSBB: Non-selective b blockers; VBL: Variceal band ligation.

to 89%, in patients with cirrhosis has been reported[18]. 13C urea breath testing and gastric body histology remain highly accurate in detecting *H. pylori* in cirrhosis, whereas rapid urease tests and serology are less reliable than in non-cirrhotic patients[19]. A meta-analysis of seven studies with almost 1000 patients has strongly suggested that, as with non-cirrhotic patients, *H. pylori* infection increases the risk for peptic ulcer disease in cirrhosis[20]. *H. pylori* eradication therapy is effective in chronic liver disease[21]. However, two recent studies have suggested that *H. pylori* eradication in cirrhotic patients with duodenal ulcers is not as effective at reducing ulcer recurrence as it is in the general population. These patients require maintenance acid suppression therapy[22,23].

Portal hypertension

The development of portal hypertension and formation of portosystemic shunts is a major event in the natural history of liver disease. Measurement of the portal pressure gradient is invasive and not widely available for clinical use; instead the hepatic venous pressure gradient (HVPG) is commonly used in clinical practice and it is of prognostic value: HPVG $\geqslant$ 10 mmHg strongly predicts the development of esophageal varices[24]. Similarly, the most significant risk factor associated with failure to control bleeding or early rebleeding of esophageal varices is HVPG > 20 mmHg. This is also associated with increased mortality[25].

Gastroesophageal varices are present in > 50% of patients with portal hypertension and are more likely as liver disease progresses[26]. Ectopic varices are located in sites other than the gastroesophageal region and are more common than previously thought: duodenal or colonic varices are seen at angiography or colonoscopy in up to 40% of patients with intrahepatic portal hypertension[27].

Esophageal varices

It is recommended that all patients undergo endoscopy to assess the presence and the size of varices at the time of the diagnosis of cirrhosis. Thereafter, guidelines for the interval of endoscopic screening vary. Currently, the American Association for the Study of the Liver (AASLD) recommends that, if no varices are present at index endoscopy, this should be repeated at 2-3 years in compensated cirrhosis and annually in decompensated cirrhosis[11]. The British Society of Gastroenterology recommends annual screening if grade 1 varices are present at initial screening (Table 1, grading and treatment of esophageal varices), and an interval of 3 years if there is no evidence of varices at index endoscopy[28].

Esophageal variceal bleeding occurs at a rate of 5%-15% per year in untreated patients. The main risk factors for bleeding are variceal size (grade 2 or 3), decompensated cirrhosis, and the presence of high-risk stigmata at endoscopy[29]. Variceal bleeding is a significant clinical event with a mortality rate of approximately 20% at 6 wk, and a recurrence rate of up to 60% at 2 years if secondary prophylaxis is not commenced[30].

The management of esophageal varices may be divided into pre-primary, primary and secondary prophylaxis and control of active bleeding. At present, there is no evidence to support treatment to prevent the development of varices in patients with liver disease (pre-primary prophylaxis)[31,24].

For primary prophylaxis of esophageal varices, there is no evidence that variceal band ligation (VBL) is superior to β-blockade. Due to issues with access to endoscopy and patient preference, non-selective β-blockade, typically with propranolol, is often first line when treatment is indicated[32]. Carvedilol is a potent non-selective β-blocker, with weak vasodilating properties. A reduction in the HVPG in the range of 10%-43% has been reported with a 12.5 mg/d dose. Carvedilol has therefore been adopted as the β-blocker of choice for primary prophylaxis of variceal bleeding in some centers[33-35]. Primary prophylaxis with VBL is recommended if there are contraindications to β-blockers, or concerns about patient compliance[11].

Secondary prophylaxis is indicated for patients who have had an episode of variceal hemorrhage. β-blocker monotherapy is not used as secondary prophylaxis, and patients should either be entered into a variceal banding program or receive a combination of a β-blocker and nitrate[36]. AASLD recommends a combination of β blockade and VBL[11]. However, there is no strong evidence to suggest that this strategy is associated with improved mortality[37] and our local practice is to use VBL alone. VBL should be repeated every 2 wk until obliteration of varices is achieved. Following this, a surveillance endoscopy at 1-3 mo to confirm eradication is required, and this should be repeated every 6-12 mo[11]. VBL is a safe technique: although asymptomatic banding ulcers are common after VBL, the rate of bleeding from these and requiring hospitalization does not exceed 5%[38].

The combination of terlipressin and VBL is the preferred treatment for acute variceal bleeding in many centers, and using terlipressin before endoscopy is not unreasonable if there is a delay to the endoscopy. Endo-

scopic hemostasis is usually achieved in the majority of cases[11]. Transjugular intrahepatic portal systemic shunt (TIPSS) may be considered if VBL has been unsuccessful or there is an early re-bleed (defined at Baveno V as a repeat bleed within 5 d of the index bleed). A reduction in HVPG below 12 mmHg or a 20% reduction from the baseline value, even without reaching < 12 mmHg, protects against rebleeding[39].

The use of sclerosing agents (variceal sclerotherapy) is no longer recommended as first-line treatment, because of increased mortality rates[40], nor for secondary prophylaxis because VBL treatment has been shown to be safer and more effective[41].

Recently, endoscopic placement of a specifically designed self-expanding covered metal stent has proved effective in the treatment of esophageal varices in patients in whom initial endoscopic methods have failed to achieve hemostasis[42]. This method appears to be a safe and effective means of controlling ongoing bleeding. The stent is usually removed 1 wk after the acute bleed. Currently, this technique is limited by its relative complexity of stent insertion in acute bleeding, but stenting with covered biodegradable stents when available, which do not require removal, may play an important role in the management of acute esophageal variceal bleeding[43].

Gastric and ectopic varices

Gastric varices are less prevalent than esophageal varices and less prone to bleeding: around 25% over a 2-year period[44]. There is no evidence to support the primary prophylaxis of gastric varices. The tissue adhesive cyanoacrylate ("glue") is used widely in the management of acutely bleeding gastric varices. Cyanoacrylate is a liquid with consistency similar to water, which when added to a physiological fluid like blood, polymerizes to form a solid substance[45]. Two randomized controlled studies have compared cyanoacrylate with VBL for management of bleeding gastric varices[46,47]. In one study, cyanoacrylate was more effective than VBL in achieving homeostasis, and in the second, no difference was reported, although both reported less recurrence of bleeding. Current evidence suggests that cyanoacrylate achieves control of bleeding in 87%-93% of cases, and that bleeding-related mortality is between 6.5% and 10%[46,47].

The use of bovine or more recently, human thrombin has been described as an alternative treatment for active gastric variceal bleeding. Thrombin [activated factor Ⅱ (Ⅱa)] is a serine protease that converts soluble fibrinogen into insoluble strands of fibrin clot. It has additional effects including promotion of platelet aggregation. Initial hemostasis rates have been reported at 94%-100%, and rebleeding rates of between 23% and 25%[48,49]. A single center experience of 13 patients treated with thrombin for bleeding gastric varices has reported efficient hemostasis and an overall mortality of 38% in a median follow-up of 22 mo[50].

Technical difficulties that include the risk of equipment damage and reports of severe thromboembolic complications may limit the use of cyanoacrylate, and thrombin (Figure 1) may become more widespread in the future[51,52].

The role of TIPSS as primary treatment in actively bleeding gastric varices has also been explored. Although TIPSS has a comparable mortality and rebleeding rate to cyanoacrylate, it is associated with significantly higher morbidity and is not used as first-line treatment[53,54], but remains an effective treatment when endoscopy fails to control bleeding.

Nonvariceal manifestations of portal hypertension

Portal hypertensive gastropathy (PHG), with its typical "snake skin" appearance, is present in approximately 80% of patients with cirrhosis[55†]. PHG accounts for 8% of nonvariceal bleeds in patients with liver disease, although this condition more commonly presents with anemia[56]. Patients with cirrhosis and severe PHG-related bleeding may respond to β-blockade. Endoscopic measures such as argon plasma coagulation (APC) therapy can reduce bleeding, thus controlling anemia. TIPSS should be reserved for those patients with pharmacological treatment failure[57].

The prevalence of portal hypertensive enteropathy (PHE), determined by capsule endoscopy, is as high as 63% in patients with end-stage liver disease who also have esophageal or gastric varices[58]. Portal hypertensive duodenopathy is present in around half of patients with cirrhosis, and it is more common in patients with severe PHG[59].

Gastric antral vascular ectasia

Gastric antral vascular ectasia (GAVE) is related to portal hypertension in about 30% of patients, and accounts for 4% of nonvariceal upper GI bleeds[60]. Unlike PHG, GAVE does not respond well to reduction in portal pressure[61]. The Nd:YAG laser has been widely used in the treatment of GAVE and is the most commonly reported endoscopic modality in cirrhotic and non-cirrhotic patients, with a reported overall success rate of almost 90%, although the authors did not distinguish the etiology of GAVE when reporting the outcomes[62].

APC has also proved to be effective for the treatment of GAVE-related bleeding, and it is extensively used in our unit, with a success rate of > 85%; success is defined as control of bleeding, stabilization of hemoglobin at > 100 g/dL, or hemoglobin increase > 10% from pretreatment level, and reduction of transfusion requirements by > 50% in transfusion-dependent patients. An average of four sessions of APC is usually required (Figures 2 and 3). In two published studies, with a total of 37 patients with cirrhosis, success rates in controlling bleeding were very high, and the reported rebleeding rates were between 12% and 20% after 2 years follow-up[62,63].

Although the success rates of the two aforementioned modalities are comparable, APC treatment is probably the therapy of choice due to the technical ease, safety and low cost[61]. Other endoscopic techniques have been positively reported in small series, such as VBL[64],

endoscopic mucosal ablation[65] and cryotherapy[66].

ADVANCED ENDOSCOPIC PROCEDURES AND THEIR VALUE IN LIVER DISEASE

EUS

Recently, EUS has been used to assist in the management of portal hypertension. Doppler EUS is of significant value in differentiating ectopic varices from other submucosal lesions[67] (Figure 4), and several EUS-assisted techniques have been used to identify the precise site for the intravariceal injection of sclerosant agents. Linear color EUS-guided sclerotherapy has proved to be effective in the eradication of esophageal varices, in two small studies with recurrence reported at 0% and 8.3%, respectively[68,69]. EUS catheter probes and high-frequency (20 MHz) miniprobes have both been used successfully before and after esophageal variceal sclerosant injection in two different studies to assess eradication and variceal recurrence. After a mean follow-up of 24 mo, variceal recurrence was reported at 16.6% and 26.3%, respectively[70,71].

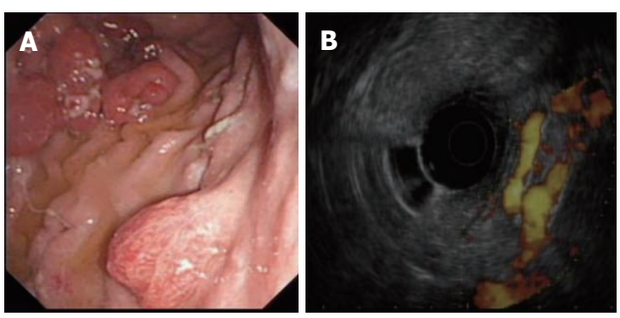

Figure 4 Endoscopic image of gastric irregular submucosal lesion. A: Gastric irregular submucosal lesion in a patient with portal hypertension; B: The same lesion examined under color Doppler endoscopic ultrasound. The submucosal lesion was hypervascular and represented a gastric varix.

Although the overall patient numbers are small, linear EUS seems to be the superior modality in assisting treatment of esophageal varices, because it permits the targeting of the feeding vessels.

EUS-assisted injection of cyanoacrylate for the treatment of gastric varices has been described in 54 patients with a mean follow-up of 24 mo. Varices recurred in 35% of patients[72]. Furthermore, a series of 15 patients with gastric or ectopic varices treated with thrombin injection in conjunction with a variety of EUS techniques (Figure 5) has recently been reported in our unit, and this proved to be effective in controlling active bleeding and achieving variceal eradication[73].

Capsule endoscopy

Esophageal capsule endoscopy (OCE) is an alternative to conventional upper GI endoscopy for the diagnosis of varices in complex patients with portal hypertension. In a recent meta-analysis of seven studies involving 446 patients, OCE had a sensitivity of 85.8% and specificity 80.5% in detecting esophageal varices[74]. However, a multicenter trial evaluating the efficacy of OCE in esophageal varices screening was less encouraging, because the standard of < 10% difference between capsule

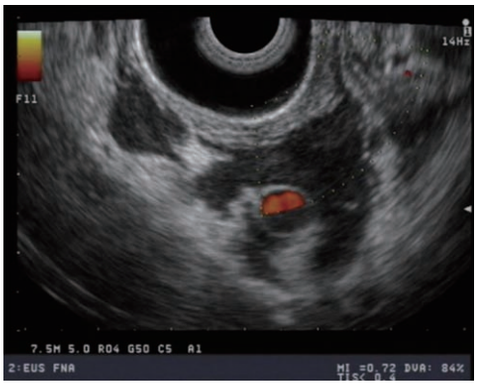

Figure 5 Color doppler endoscopic ultrasound image of duodenal varices after thrombin injection. The absence of blood flow and the speckled appearances were suggestive of thrombus formation.

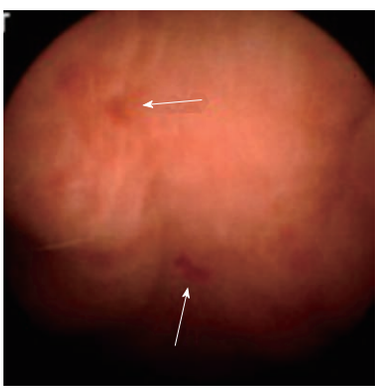

Figure 6 Small bowel capsule image of portal hypertensive enteropathy and stigmata of recent bleeding. Engorged small bowel villi and micro-hemorrhagic spots were visible.

and conventional endoscopy was not met[75]. This is not surprising, because the two techniques differ in that during conventional endoscopy, the esophagus is inevitably insufflated with air and varices can appear more flattened than during OCE examination. Further studies to take this into account are necessary. Nevertheless, OCE remains a useful tool for screening of varices in certain patient groups; patients who poorly tolerate endoscopy or who have significant comorbidity, thus increasing the risks of repeated endoscopy, and patients with high risk of variant Creutzfeldt-Jakob disease. Although this technique is limited by availability and high costs, OCE can be cost-effective for variceal screening of patients with coagulation abnormalities (e.g., hemophilia) with coexisting liver disease, because it does not require prophylactic clotting factor administration, unlike conventional endoscopy. Serial capsule examinations in the same patient may provide significant diagnostic information regarding progression of varices.

Small bowel capsule endoscopy (SBCE) has been used to characterize PHE (Figure 6), and is of value in the diagnosis of this condition in patients with advanced liver disease who continue to bleed despite treatment of esophageal/gastric varices or portal gastropathy (Figure 7).

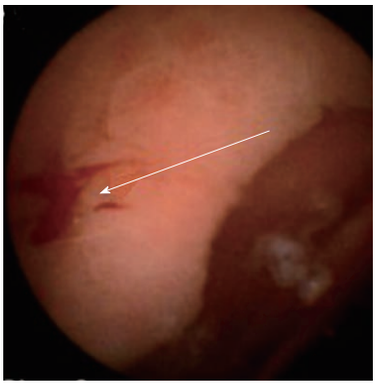

Figure 7 Small bowel capsule image of portal hypertensive enteropathy with snake-skin-like appearance of the mucosa and red spots as stigmata of recent bleeding.

The role of SBCE in portal hypertension has yet to be defined, but it is likely that it will remain a valuable tool in certain groups of patients with liver disease.

Endoscopic retrograde cholangiography

Primary sclerosing cholangitis (PSC) is characterized by fibrosis of both intrahepatic and/or extrahepatic biliary ducts. These patients are at risk of developing infectious cholangitis and up to 20% develop cholangiocarcinoma. A strategy of initial magnetic resonance cholangiopancreatography (MRCP) followed, if necessary, by ERCP is currently the most cost-effective approach to the work-up of patients with suspected sclerosing cholangitis[76†]. ERCP plus diagnostic brushing have a sensitivity of 60%-100%, and specificity of 85%-89% in differentiating between a benign dominant stricture and cholangiocarcinoma[77,78]. Recently, two advanced cytological techniques (digital image analysis and fluorescence *in situ* hybridization) have been used for the detection of malignancy in PSC-related strictures and have proved to be more sensitive and equally specific to conventional cytology[79†].

In addition, ERCP permits therapeutic interventions with balloon dilation or stent placement as appropriate.

Novel techniques and the biliary tree

Novel endoscopic modalities have been compared with conventional ERCP and brush cytology. Transpapillary cholangioscopy with tissue sampling has proved to be more sensitive (92% *vs* 66%) and specific (93% *vs* 51%) than ERCP to detect cholangiocarcinoma in PSC[80]. In a small study, narrow band imaging has demonstrated superior visualization of biliary lesions compared with conventional white light imaging[81]. In another study, transpapillary intraductal ultrasound was superior to ERCP for the detection of cholangiocarcinoma in PSC in terms of sensitivity (87.5% *vs* 62.5%) and specificity (90.6% *vs* 53.1%)[82].

Spyglass™ is a new single-operator system used for the diagnosis of a variety of pancreatobiliary disorders, such as the definition of indeterminate strictures and filling defects prior to stone extraction[83]. Although the

initial experience is promising, the modality has been only been tested in a limited number of PSC-related strictures, and unlike ERCP, this is a purely diagnostic technique.

Confocal laser endomicroscopy ("miniprobe") is a new field of endoluminal imaging that offers extremely high magnification and resolution. This technique allows visualization of pancreatic and biliary ducts. In a pilot study of 14 patients with biliary strictures, miniprobe-based microscopy after fluorescein administration proved to be more accurate than brushings and biopsy in distinguishing benign from malignant strictures (Figure 8)[84].

A novel alternative is direct cholangioscopy using ultra-slim endoscopes (4.9-5.9 mm). These endoscopes, initially developed for transnasal endoscopy, can be safely inserted into the bile duct following sphincterotomy, and not only permit high-resolution images, but also biopsy and other interventional procedures in the bile ducts, such as hydraulic lithotripsy and division of strictures in benign biliary disease. This technique is currently under development and after a full range of endoscopic accessories are available for endobiliary interventions, it could be an effective and safe approach for patients with difficult to manage biliary disease[85].

Endoscopic modalities in the lower GI tract

In comparison to the upper GI tract, colonic manifestations of portal hypertension much less often present with acute bleeding, and are more often found incidentally or during investigation of anemia. As such, data are sparse and less consistent. The reported prevalence of portal hypertensive colonopathy is 24%[86].

The most significant feature of portal hypertension in the colon is arguably the presence of rectal varices. These can be present in up to 44% of patients with cirrhosis at colonoscopy, although the reported prevalence varies widely. They are more frequent in patients with advanced liver disease[87].

Although bleeding from rectal varices is uncommon, it can be life threatening. Due to their rarity, no firm guidelines have been established for the management of bleeding colonic varices, and there is a limited evidence base. The most commonly used treatment modalities are sclerotherapy and band ligation. In a small retrospective comparative study of 15 patients, endoscopic injection sclerotherapy proved to be superior to endoscopic band ligation and achieved lower recurrence rates[88]. In our unit, thrombin has been successfully used to manage rectal variceal bleeding. Patients may require TIPSS if bleeding cannot be controlled endoscopically.

ENDOSCOPY AND THE LIVER TRANSPLANT PATIENT

Luminal diseases in liver transplant patients

Peptic ulcer disease is the most common cause of GI bleeding in post-orthotopic liver transplant (OLT) recipients, accounting for 27% of all bleeding[89]. Varices rarely recur post-transplant, and if present, require investigation to exclude portal vein thrombosis or disease recurrence[90].

Liver transplant patients are at increased risk of opportunistic infections, particularly candidiasis and cytomegalovirus[91]. These often present with GI symptoms and require endoscopic evaluation with biopsies or brushings to confirm the diagnosis.

The association of PSC with ulcerative colitis is well recognized and is an additional risk factor for the development of colorectal cancer in immunosuppressed transplant patients. It is currently recommended that these patients have an annual surveillance colonoscopy commencing 10 years after the onset of bowel symptoms[92]. Colectomy is safe in patients who have undergone OLT, and in some high-risk cases, such as when high-grade dysplasia has already been identified, a prophylactic colectomy may be performed at the time of transplantation[93].

Transplant-related biliary disease

Biliary complications (biliary strictures and leaks) following liver transplantation are a challenging and common

issue that affects 10%-30% of OLT patients. Biliary strictures are classified as anastomotic or non-anastomotic[94]. The initial approach in suspected post-transplant biliary strictures is usually MRCP, restricting the use of ERCP to patients who require intervention, or where MRCP results are equivocal[95]. Further imaging techniques include SpyGlass™, which has been successfully used for the investigation of post-transplant biliary strictures[96], and contrast-enhanced ultrasound. This is a non-invasive technique for the detection of strictures relating to hepatic artery stenosis in liver transplant patients. It provides details on the presence, location, degree, and type of stricture[97]. Treatment comprises a combination of balloon dilation and stent placement, repeated if necessary until stricture resolution.

Biliary leaks can occur in up to 22% of patients. Evidence suggests that sphincterotomy with stent placement is the best treatment option for biliary leaks following OLT[94,98]. Surgical revision and biliary reconstruction with the formation of hepaticojejunostomy is indicated when endoscopic or percutaneous treatment fails[94,98].

In patients who have a roux-en-Y anastomosis, the technique of double balloon ERCP has been devised with promising results. The technique uses a double balloon colonoscope to approach the ampulla, although there are some limitations regarding endoscopic accessories. With further development of this technique, the endoscopic treatment of biliary complications may become easier and will play a larger role in the management of such patients[99].

CONCLUSION

Endoscopy has undergone rapid expansion with numerous novel endoscopic modalities and techniques directly applicable to the diagnosis and management of complications of liver disease. Although conventional upper GI endoscopy is still the modality of choice for esophageal variceal surveillance and treatment, further options are now available with the use of capsule endoscopy and EUS. Therapeutic options for the management of upper GI bleeding in portal hypertension have also been developed. Band ligation remains the treatment of choice for esophageal variceal bleeding, whereas for gastric and ectopic varices, the use of sclerosants, particularly "glue" and thrombin are increasingly being used. APC is the preferred modality for GAVE and PHG. Biliary strictures and the risk of cholangiocarcinoma are major issues in patients with PSC. ERCP is both diagnostic and therapeutic in this setting and can differentiate benign from malignant lesions in the majority of cases. Novel endoscopic techniques such as transpapillary cholangioscopy, Spyglass Direct Visualization System, confocal laser endomicroscopy ("miniprobe") and ultra-thin cholangioscopy are increasingly being used to assist diagnosis in selected patients. Finally, in the post-liver transplant patient, upper and lower endoscopies are used to detect gastrointestinal opportunistic infections, as well as to screen for colorectal cancer in high-risk patients. Biliary complications are common after transplantation and ERCP is the modality of choice for treating such patients.

Abstract

Inflammatory bowel disease is a group of diseases that includes Crohn's disease (CD) and ulcerative colitis. CD is characterized as a chronic inflammatory disease of the gastrointestinal tract, ranging from the mouth to the anus. Although there are gross pathological and histological similarities between CD and Johne's disease of cattle, the cause of CD remains controversial. It is vital to understand fully the cause of this disease because it affects approximately 500 000 people in North America and Europe. It ranges from 27 to 48 cases per 100 000 people. There are many theories on the cause of CD ranging from possible association with environmental factors including microorganisms to imbalance in the intestinal normal flora of the patients. Regardless of the environmental trigger, there is strong evidence that a genetic disposition is a major key in acquiring CD. Many studies have proven the link between mutations in the *ATG16L*, *NOD2/CARD15*, *IBD5*, *CTLA4*, *TNFSF15* and *IL23R* genes, and CD. The purpose of this review is to examine all genetic aspects and theories of CD, including up to date multiple population studies performed worldwide.

Key words: Crohn's disease; *ATG16L*; *NOD2/CARD15*; *IBD5*; *CTLA4*; *TNFSF15*; *IL23R*

INTRODUCTION

The first description of Crohn's disease (CD) was made in 1769 by an Italian physician, Giovanni Battista Morgagni, when he diagnosed a man with chronic diarrhea. In 1898, consecutive cases were reported by John Berg, and then in 1904 by Antoni Lesniowski. Throughout the 1920s and 1930s, young adults were thought to have this same condition as they suffered from symptoms, such as abdominal cramps, diarrhea, fever and significant weight loss. In 1923, surgeons at Mt. Sinai Hospital in New York had also identified patients with comparable symptoms. In addition, in 1930, Dr. Burrill B Crohn saw a connection between this unknown debilitating condition and two of his patients. Consequently, Dr. Crohn and his

colleagues presented a paper in 1932, "Regional ileitis: a pathologic and chronic entity", describing the features of this disease to the American Medical Association. CD was named after Burrill Crohn and it became an official medical entity in 1932.

CD is a chronic inflammatory disease that can affect any portion of the digestive tract including the mouth, esophagus, and small and large intestines, but is most common in the ileum. It is also characterized as an autoimmune disease in which the body attacks itself and causes inflammation. In its mild form, it causes erosions called aphthous ulcers in the inner surface of the bowel. In severe cases, deeper and larger ulcers develop that can lead to bowel obstruction and holes in the bowel wall. If a hole in the bowel wall arises, infection to neighboring organs can occur. CD branches off to many forms depending on the location of erosion. If these symptoms take place within the large intestine, it is called Crohn's or granulomatous colitis. If it occurs in the small intestine, it is known as Crohn's enteritis, and more specifically if it occurs in the ileum, it is called Crohn's ileitis. During severe cases in which the small and large intestine are both involved, it is known as Crohn's enterocolitis or ileocolitis. CD is separated into three phenotypes: non-stricturing and non-penetrating, stricturing and penetrating CD[1,2].

CD is most prevalent in North America and Europe, and least prevalent among African Americans and Asians[3]. It affects approximately 500 000 people in North America and Europe. It ranges from 27 to 48 cases per 100 000 people. There is no difference in prevalence among males or females. Individuals with siblings affected by CD have a higher risk of acquiring the disease. There is evidence of a cause from environmental factors, thus, there are a higher number of cases in western industrialized countries. Symptoms of CD typically begin in the teens and twenties and then go into remission on and off with appropriate therapies. There is a peak incidence between 50 years and 70 years of age, which often leads to major complications due to age and the necessity of surgery.

Although the etiology is still unknown, there are many theories about what causes CD and ulcerative colitis (UC). Many believe it is caused by environmental factors, such as certain foods, bacteria, viruses, or cigarette smoke, which all can trigger an immune system response. Scientists have linked inflammatory bowel diseases (IBDs) as an autoimmune problem. In a healthy person, the immune system defends the body against harmful microbes that have entered it. Upon triggering the immune system, an inflammatory response occurs in which immune cells aggregate at the site of infection and overcome the threat. There are microbes native to our bodies that are useful rather than harmful to which the immune system does not trigger a response. In patients with CD, the immune system will attack these native luminal bacteria, disrupting the normal flora, thus characterizing this condition as an autoimmune disease.

Recent research has indicated specific genetic variations as a direct cause of CD and UC. The genetic aspects of CD have been linked by observing familial clustering of IBD cases[4]. Genetic variations in the *ATG16L*, *NOD2/CARD15* and *IL23R* genes have strongly been linked to the onset of CD[5]. Not only are individual gene mutations listed as a cause of CD, but a combination of them has also been shown in CD patients by conducting many population studies. There have also been many studies that have predicted surgical outcomes in both adults and children with specific genetic variations.

Diagnosis of CD can be tricky and requires a number of tests to be certain. Colonoscopy is the most effective way to diagnose CD but not in all cases because it only allows the physician to visualize the colon, ileum, and lower portion of the small intestine[6]. If the ulcers are located within the upper portion of the small intestine, this test will not be effective. In this case, a barium follow-through X-ray is useful because barium sulfate gives fluoroscopic images of the bowel and the physician can see areas of inflammation and narrowing[6]. Another effective method of diagnosis is the use of white blood cell scans. During this procedure, white blood cells are tagged with a radioisotope and then injected back into the patient. At specific intervals of time, the scan can locate accumulations of white blood cells in the intestine at the site of CD. This method is also useful to monitor the disease and show effectiveness in other therapies. Furthermore, a simple blood test can also diagnose CD because it can determine whether the patient is anemic or has a vitamin B12 deficiency because vitamin B12 is absorbed in the ileum and a deficiency can be due to ileitis.

CD causes a wide variety of symptoms and can be confused with UC, which is a similar disease, both under the group of IBDs. UC is only found in the colon and affects the mucosal membrane, whereas CD can occur anywhere throughout the gastrointestinal (GI) tract and affects the thickness of the GI wall. Individuals with CD can experience flare-ups followed by remissions. It can vary from one flare-up in a lifetime to multiple flare-ups that need surgical treatment. Symptoms include persistent diarrhea, abdominal pain in the affected area, fever, and weight loss[6]. There are also signs and symptoms that may occur unrelated to the GI tract, such as reddening and inflammation of the eye, joint pain, skin lesions, and sores inside the mouth.

Currently, there is no cure for CD. Treatment is focused on relieving the symptoms and putting it into remission. Since CD is characterized as an autoimmune disease, medications to suppress the immune system include 5-aminosalicylic acid and steroids, such as prednisone[6]. Antibiotics such as clarithromycin, ampicillin and metronidazole, can also be used. More than 50% of patients with CD will have to undergo surgical treatment to correct a fistula, drain an abscess, open a narrow or obstructed bowel, or remove a segment of infected intestine.

AUTOPHAGY-RELATED 16-LIKE 1 PROTEIN COMPLEX

Autophagy is a catabolic process of intracellular degradation in which cytoplasmic components are sequestered within vesicles and delivered to the lysosomes. Cells use this pathway during nutrient starvation because they can break down non-vital components and use them as nutrients. Autophagy plays a role during infection by helping rid the cell of foreign antigens by breakdown of the pathogen. This pathway can also be implemented as a repair mechanism to degrade damaged organelles and proteins. Autophagosomes, formed by the fusion of lysosomes and vesicles, are also implicated in the processing of intracellular bacteria. If the gene responsible for autophagy is mutated, it can cause a shift in normal flora as previously mentioned, and lead to many GI problems, which has been pointed out as a possible cause of CD. If the cell cannot regain nutrients or fight off foreign antigens within the GI tract, these cells will undergo programmed cell death and cause tissue damage. This damage can be seen as lesions and ulcers within the intestines, creating dead infected patches of tissue along the GI tract. The only option of treatment is surgery to remove the sections of the intestines with the diseased tissue so that the necrosis will not spread among neighboring cells.

An autophagosome, a double-membraned vesicle formed by autophagy, envelops part of the cytoplasm and delivers it to the lysosomes where it is degraded and recycled. There have been approximately 30 autophagy-related (Atg) genes identified, with two proteins having ubiquitin-like characteristics, Atg12 and Atg8[7]. These proteins covalently modify their target protein with molecules such as ubiquitin-like proteins to tag them for degradation. Both proteins also contain a conserved ubiquitin-fold region[7]. Autophagosomes use two conjugation systems, the Atg12 and LC3-Ⅱ systems[8]. These systems were first discovered during yeast genetic studies revealing a set of 17 ATG genes involved in the autophagy pathway[9]. In the Atg12 conjugation system, an Atg12-Atg5-Atg16L complex forms, and dissociates from the membrane just before or after completion of the autophagosome[8]. The ATG16L1 protein is expressed in the colon, small intestine, intestinal epithelial cells, leukocytes, and spleen[8]. Recent independent studies have shown that an ATG16L mutation, located on chromosome 2, is associated with the onset of ileal CD, and is therefore a key molecule in elucidating the genetic aspects of this disease[10].

Multiple studies have been performed with each resulting in the same conclusion that ATG16L is implicated in CD. During a genome-wide survey of 19 779 non-synonymous single nucleotide polymorphisms (SNPs), Thr300Ala within the N terminus of ATG16L was found to be highly associated with CD by using a haplotype and regression analysis[4]. This study used a total of 735 CD patients, 368 controls and 72 SNPs. A second report from the North American CD genome-wide study submitted by Rioux and colleagues also shows an association with ATG16L using a case-control analysis in 988 CD patients and 1007 controls[11]. Another group of German and British collaborators demonstrated that rs2241880, another non-synonymous variant of the *ATG16L* gene on chromosome 2q37.1, is implicated in the autophagy pathway[8].

In a study performed on an Italian cohort, the same polymorphism, rs2241880, was observed in 667 CD and 668 UC patients[12]. Both the frequency of the G allele and number of carriers of the G allele were increased in CD patients when compared to the controls[12]. These differences were only significant in the adult subgroup, which could be due to the small sample size of the pediatric subgroup. In comparison, there were no significant allele or genotype frequencies found between UC patients and controls for the groups as a whole[12]. During analysis of genotype/phenotype correlation of the rs2241880 SNP, there were no associations with disease location, behavior, and age at diagnosis based on the Montreal Classification of CD[12]. There were also no associations found in sex, smoking, and perianal fistulae[12]. For the rs2241880 variant, recent studies, specifically by Prescott[13], demonstrate an association with the ileal form of CD with or without colonic involvement, but not with isolated colonic disease[12].

In addition, a study from Oxford compared 645 CD patients with 1190 controls and showed an association of ATG16L1 with CD[14]. To understand fully the function of this gene, a study utilized oligo-based silencing RNA directed against ATG16L1 isoforms, where autophagy was induced by *Salmonella typhimurium* in ATG16L1 knockdown HEK293 cells. There was a significant difference between the knockdown cells com-pared to the control cells during the autophagy pathway[11]. It is clear to say that variants of this gene have been proven without a doubt to be directly associated with CD because autophagy plays a critical role in disease pathogenesis. Further research needs to focus on understanding how ATG16L1 variants contribute to disease susceptibility in IBD patients, and their possible therapeutic implications.

TUMOR NECROSIS FACTOR SUPER FAMILY 15

Tumor necrosis factor super family 15 (TNFSF15) is a Th-1 polarizing cytokine involved in systemic inflammation. TNF functions to regulate immune cells, induce apoptosis, induce inflammation, and inhibit tumorigenesis. TNFs are produced by macrophages, lymphoid cells, mast cells and endothelial cells. During immunological studies, it has been found that CD patients have an increased expression of TNFSF by multiple cells in the intestinal tissues when compared to controls[7]. The *TNFSF15* gene is a candidate for increased susceptibility in IBD. It binds to a specific T-cell receptor to enhance

cytokine-induced interferon expression in mucosal $CD4^+$ T cells[7].

In 2005, the first genome study involving IBD tested nearly 80 000 SNPs in Japanese CD patients. This study identified haplotypes within the *TNFSF15* gene, which included seven SNPs within a 280-kb region on chromosome 9q32[15]. By resequencing TNFSF15 from the same CD cases but with a new control group, TNFSF15 was found to be strongly associated with CD with an odds ratio (OR) of 2.17 (95% CI: 1.78-2.66), $P = 1.71 \times 10^{-14}$[15]. The Japanese wanted to see if the same patterns were seen in other population groups so they replicated their associate in two panels from Oxford, United Kingdom. Although the risk haplotype was identified in both cohorts, there was a weaker effect size ($P = 0.02$ in both family-based and case-control association panels). In addition, another study involving a Jewish cohort also showed an association of TNFSF15 with CD, and also suggested that in response to FC-gamma receptor stimulation, *TNFSF15* gene variation aggravates induction of TNFSF15[16]. However, in a separate study using a Belgian CD cohort, no significant association was observed between CD and TNFSF15[4]. This may have been due to different marker genotypes or differences in susceptibility genes between Asian and European cohorts[4]. Not enough studies have been performed regarding TNFSF15 and its possible implications in CD. Future studies have to focus on different populations to provide efficient insight.

NOD2/CARD15 GENE

Nucleotide-binding oligomerization domain containing 2 (NOD2), located on chromosome 16q12, is a protein that plays an essential role in the immune system by controlling commensal bacterial flora in the intestine[17]. NOD2 belongs to a nucleotide-binding domain, leucine-rich repeat family of cytoplasmic proteins that may detect a variety of bacteria by acting as an intracellular sensor for bacterial peptidoglycan[18]. It has the ability to respond to N-acetylmuramyl-L-alanyl-D-isoglutamine (MDP) *via* the leucine-rich repeat domain. The MDP is conserved in both Gram-negative and positive bacteria[10,19]. This leucine-rich repeat domain plays a role in protein-protein interactions and the middle portion of the protein is responsible for self-oligomerization. The N-terminal portion of NOD2 contains two caspase recruitment domains (CARDs) which play a role in apoptosis. The *CARD15* gene, which encodes for the CARD domain within NOD2, has been specifically identified as a genetic factor for CD. Three SNPs were found to be independently associated with CD: rs2066844, rs2066845, and an insertion mutation 3020insC[20]. Each variant may result in distinct phenotypic expression of CD[4]. To activate NOD2, Rip2 kinase is required because it is necessary for downstream signaling of NOD2 and signaling cascades such as nuclear factor (NF)-κB and mitogen-activated protein kinase cascades[21].

The intestinal mucosa is constantly exposed to a large number of commensal microorganisms; the majority of which inhabit the large intestine. In a healthy individual, there is a basal immune response elicited from the interaction between the intestinal immune system and commensal bacteria. This immune response is constantly present to protect the host from pathogenic and non-pathogenic bacteria. When there are changes within this balance, the intestines are susceptible to chronic intestinal inflammatory conditions, such as CD[21]. Multiple genetic studies have linked NOD2 with susceptibility to CD. However, NOD2-deficient mice do not develop colitis, suggesting that dysregulation of the NOD2 pathway is not sufficient to provoke CD[22]. This is not a surprise because the pathogenesis of CD is caused by several factors including environmental, dysfunctional immune system, and a shift in normal bacterial flora[21].

NOD2 is expressed in Paneth cells, which are found in the intestines. The exact functions of Paneth cells are still unknown, but they are likely to contribute to the host defense by secreting antibacterial compounds due to the presence of lysozyme. A NOD2 mutation can alter the function of Paneth cells, which alters their antimicrobial activity and leads to the development of ileal lesions, which correspond to the location of these cells. Of the three NOD2 mutations associated with CD, both rs2066844 and rs2066845 are the result of a two-amino-acid substitution in which rs2066844 is encoded by exon 4 and rs2066845 is encoded by exon 8[23]. The variant 1007fs is created by a frameshift mutation in exon 11[23]. Each of the three mutations occurs within or near the leucine-rich repeat and decrease the cells ability to activate NF-κB in response to peptidoglycan[18]. Interestingly, these mutations are observed in Caucasian patients but not in Japanese, Chinese and Korean patients with IBD, and they are very rare in African Americans with IBD[24,25]. An individual heterozygous for at least one NOD2 mutation is at a 2-4-fold increased risk of developing CD, whereas a homozygous individual for at least one NOD2 mutation is at a 20-40-fold increased risk when compared to healthy individuals[14].

Studies of each individual mutation in NOD2 have shown that 1007fs causes a decrease in defensin expression[26]. Defensins are cells of the immune system that assist in killing phagocytized bacteria. They function by binding to the microbial cell membrane and forming a pore in the membrane that allows outward flow of nutrients and essential ions. CD patients who are homozygous and/or heterozygous for NOD2 mutations typically have lower defensin levels in their ileostomy fluid[17]. As a result of a mutation in NOD2, the function of this protein is diminished, therefore allowing subsequent entry of bacteria into epithelial cells because they are no longer able to recognize them. This in turn alters the bacterial population in the intestines and thus, defensins are not able to function correctly because they are working in an impaired bactericidal capacity[22].

In a recent study by Van Limbergen *et al*[17], it was

proven that NOD2 is required for the regulation of commensal microbiota in the intestine. The regulation of NOD2 depends on the downstream kinase Rip2 because Rip2-deficient mice fail to establish and regulate commensal bacteria in their terminal ileum. NOD2-deficient mice do not develop spontaneous intestinal inflammation. In conclusion, the NOD2–Rip2 pathway is critical for the regulation of homeostasis between the body's normal bacterial flora and innate immunity[17]. As a controlled balance, it has been found that the expression of NOD2 and Rip2 is dependent upon and regulated by the presence of commensal bacteria[17]. This creates a negative feedback by which the commensal bacteria positively regulate NOD2, and in turn negatively regulate the normal flora. NOD2 mutations directly affect the ileum in CD patients, thus, it is possible that they are responsible for the composition of the bacterial flora in the terminal ileum[17]. This may facilitate both disease pathology and progression.

Although the exact mechanism by which NOD2 contributes to the control of commensals in the intestines is still not known, there are many possible theories proposed by this study. The first theory entertains the possibility that NOD2 regulates the commensal flora through the bactericidal activity of ileal crypt secretions[17]. The second theory is that NOD2 regulates the adaptive immune system by inducing lymphoid tissue genesis[17]. The third theory describes how NOD2 expression in myeloid lineage cells contributes indirectly to maintain the normal microbiota flora[17]. The fourth theory states that there may be other cells in the intestines, in addition to Paneth cells, that may play a role in the regulation of commensal bacteria in the intestines[17]. Further research is needed to elucidate this mechanism.

It has been reported that both adults and pediatric cohorts share a strong association between the NOD2 variants and ileal disease location[23]. Some studies have suggested that adult patients show a correlation in fibrostenotic behavior and NOD2 mutation status, whereas other studies have failed to replicate the same phenotypic effect[12]. It is necessary to study different CD cohorts from different countries to obtain an accurate effect of each mutation. Exploring the genotype-phenotype interactions in children is beneficial because they show a higher gene dosage and have less environmental influences.

A study by Lacher and colleagues has explored the association of the NOD2 mutation in German pediatric CD patients and the risk of surgery. The risk of surgery in children is important to predict because surgery is sometimes the only method of treatment. Out of 171 young CD patients, 78 (45.6%) carried at least one NOD2 mutation, with 11 being compound heterozygous, and 14 being homozygous for two NOD2 mutations[14]. The presence of rs2066844 was found in 29 (17%) children, rs2066845 was found in 18 (10.5%), and 1007fs was found in 42 (24.6%)[14]. Overall, one out of three German children with CD had at least one NOD2 mutation. In comparison, 36% of adult CD patients were heterozygous for at least one NOD2 mutation: 17.2% for rs2066844, 9.6% for rs2066845, and 11.7% for 1007fs[14]. In conclusion, the genetic alterations were observed more predominantly in German pediatric CD patients than in adults. The study also looked into each mutation and its association with localization and symptoms of the disease. A 4.73-fold increased risk of isolated ileal localization was observed in patients that were identified as 1007fs carriers when compared to children with none of the NOD2 mutations[14]. Although the 1007fs carriers were predisposed to ileal disease, there was no involvement of the ileocolonic or upper GI tract[14]. The next characterization the study explored was the association of NOD2 mutations and stricturing disease or perianal fistulae in their German pediatric CD cohort. Only 17% of patients showed a stricturing phenotype and 18.1% had a perianal fistula[14]. Among the children that showed a stricturing phenotype, 79.3% required surgery and those with the 1007fs mutation had surgical complications[14]. The outcome showed a 9.8-fold increase in surgical complications when the child carried at least one allele for the 1007fs mutation[14]. Not only is the 1007fs mutation strongly associated with isolated ileal disease, but children are at a high risk for surgical intervention. Therefore, this mutation can act as a prognostic tool in Caucasian children with CD[14].

Another study by Jurgens and colleagues has investigated the presence of fistulas and their association with NOD2 homozygosity and how they predict intestinal stenosis in CD patients. It was observed that patients with fistulas had simultaneous intestinal stenosis[15]. In another study using the same research, it was found that NOD2/CARD15 variants, especially with 1007fs homozygosity, could predict the occurrence of intestinal stenosis[27]. By using a strict screening process based on phenotypes including stenoses (stricturing CD) and fistulae (penetrating CD), and genotype, the study isolated a total of 145 patients. One hundred and twenty-five of the patients had penetrating CD with simultaneous stenosis within a 6-mo interval[28]. It was also found that all 14 CD patients homozygous for NOD2 variants suffered from stenosis[28]. To no one's surprise, 11 out of the 14 patients with stenosis and fistulas carried the NOD2 1007fs mutation[28]. These data confirm the strong risk factor of the 1007fs NOD2 mutation in the prevalence of intestinal stenosis, which may be related to the decreased intestinal barrier function found in CD patients with NOD2/CARD15 variant mutations[28]. This study has isolated the 1007fs variant as the cause in disrupting the intestinal barrier and causing the many problems often observed in CD patients.

To investigate whether stenosis occurs in a specific anatomical region, 223 patients with 248 stenoses located at different intestinal regions were examined[28]. The most common anatomical region was the terminal ileum with 68.8% of stenoses, followed by 11.7% found in the rectosigmoidal segment, and 9.3% in the jejunum or proximal ileum[28]. In conclusion, homozygosity in the NOD2/

CARD15 mutation is a strong risk factor for intestinal stenosis[28]. When the study looked into the possible association between stenosis and interleukin-23 receptor (IL-23R mutation variants, there was a weak connection with no influence on stenosis[28]. This study suggests classifying CD into four disease phenotypes instead of the current three in the Montreal Classification System. The four new classifications would be: non-stricturing[12], non-fistulizing CD[12]; stricturing, non-fistulizing CD[18]; non-stricturing, fistulizing CD[29]; and stricturing, fistulizing CD[28]. It is important to link any possible association between fistulas and stenoses because there is a strong risk factor for recurrence of CD after surgery[28].

Many studies have investigated North American, European and Asian countries and their CD patients with specific genotypes. Interestingly, the NOD2/CARD15 mutations are very rare and even absent in Asians (Japanese, Chinese and Korean), Arabs, Africans and African Americans[28]. A study by Baptista and colleagues has concentrated on a South American population for the first time. There were a total of 187 CD patients used for the study with a median age of 33 years and a median age of onset of 23 years[24]. Their patients were ethnically classified into the following groups: 58.8% were in the Brazilian subgroup, 36.9% shared a common European ancestry and were in the European-Brazilian subgroup, three were Amerindian-Brazilian, and two were Afro-Brazilian[24]. The alleles related to CD within the CARD15, rs2066844 and 3020insC variants were significant for CD susceptibility[24]. Both the rs2066845 and 1007fs variants failed to show any significant association[24]. Among their patients, 30% had at least one NOD2/CARD15 variant allele[24]. The frequency of rs2066844 (9.63%) in the Brazilian CD cohort was consistent with the reports for European populations[24]. In conclusion, this study confirmed that CARD15 variants lead to greater susceptibility to CD in the Brazilian population[24].

INTERLEUKIN-23 RECEPTOR

IL-23R is a protein consisting of an IL-12β1 and an IL-23R chain[27]. The molecular location of the *IL23R* gene is on chromosome 1 and is formed by the binding of IL-12p40 and a p19 protein[30]. It is highly expressed on the cell membrane of memory T cells and other immune cells, such as natural killer cells, monocytes, and dendritic cells, which identify foreign substances to defend the body against infection. It is highly involved in the mediation of proinflammatory activities by the production of IL-17 *via* the activation of Th17 lymphocytes[20]. IL-23R interacts with IL-23, which is a cytokine that regulates the activity of immune cells and plays an important role in the inflammatory response against infection by bacteria and viruses. It also has been suggested that the functional IL23R pathway polymorphisms play a role in modulating neonatal development of intestinal tolerance and bacterial colonization[4].

Th-17 lymphocytes are a distinct subset of T-helper cells, which mainly produce IL-17 and to a lesser extent IL-6 and TNF-α[26]. IL-17 *in vitro* and *in vivo* acts as a potent inflammatory cytokine and is involved in the destruction of cartilage and bone, as seen in rheumatoid arthritis[12]. It has been reported that IL-23 could be a key regulator in the differentiation of Th-17 lymphocytes from memory T cells. It also has been suggested that IL-23 plays a role in providing a survival advantage to already differentiated Th-17 cells[21]. The expression of the heterodimeric receptor complex, IL-23R and IL-12Rβ1, regulates activities of IL-23[12]. Therefore, the IL-23-IL17 cytokine axis is a key pathogenic mechanism that mediates the development and progress of inflammation by Th-17 cells. The role for the IL23-IL17 axis in CD patients was supported in human patients and animal models of colitis[31]. Both cytokines are increased in knockout mouse models of IBD. More specifically, IL-17 levels are increased in both intestinal mucosa and in the serum of CD patients[12]. In a study using IL-17R knockout mouse models, an association was found with colitis and disease severity[27]. Therefore, the use of anti-IL-12p40 antibody to treat CD patients is a therapeutic option because it is known to reduce production of IL-23 and IL-17 in the lamina propria cells[12]. The mechanism of IL-23R is clearly important to understand because it is directly associated with CD.

During a genome-wide association study, 2877 DNA samples from IBD patients (two-thirds CD and one-third UC), identified rs11209026 as a possible protective variant, in the *IL23* gene on chromosome 1p31[4]. There are many other variants within IL23R that are associated with IBD, but rs11209026 has the strongest association with conferring protection against CD[4]. Although the effect of IL23R variants is greatest in CD, it may have an overall effect on susceptibility to chronic intestinal inflammation.

Additional studies have confirmed the susceptibility of the *IL23R* gene to CD in North American and European populations. They include cohorts ranging from Scottish pediatric IBD, Belgian CD and an independent cohort of 883 families[4]. Due to the role of IL-23 in activation of inflammatory responses, targeting this pathway may be a good therapeutic approach. Some promising research is underway using anti-p40, which blocks IL-23 and IL-12 activities. The variant allele, rs11209026, could be exploited to define clinical outcomes, such as a pharmacological approach to mimic the rs11209026 polymorphism[4].

A study by Schmechel and colleagues has shown a link in susceptibility to CD with Th17 cell function, IL-22 serum levels, and IL23R genotype. IL-22 is a strong activator of proinflammatory gene expression and upregulates SOC3 mRNA in intestinal epithelial cells[29]. Recent evidence has shown that Th17 cells expressing IL23R play a key role in the mechanism by which IL23R modulates IBD susceptibility[32]. Previous studies have shown that Th17 plays a role in autoimmune diseases,

such as rheumatoid arthritis and CD. However, Th17 is responsible for the important function of antimicrobial immunity at epithelial barriers where it produces cytokines such as IL-22. Because it produces IL-22 in epithelial barriers such as in the intestines, theoretically by testing for increased IL-22 serum levels, a physician can determine CD and disease activity.

It has been confirmed that IL-22 serum level is increased in CD and correlates with disease activity[33]. IL-22 serum levels are also independent of CD phenotype and CARD15 genotype, but are modulated by IL23R polymorphisms[33]. The study investigated IL-17 serum because Th17 cells also produce IL-17. There was no correlation between IL-22 and IL-17 serum levels[33]. Currently, serum levels of TNF-α and IL-6 are used as inflammation markers in determining CD. There was no difference in TNF-α and IL-6 levels whether CD was active or in remission, whereas IL-22 levels were significantly higher in active CD compared to CD in remission[33]. Therefore, measuring IL-22 levels are clinically relevant in determining the disease activity in CD patients[33].

There are also strong associations between IL-22 serum levels and *IL23R* gene variants. Previous studies have shown both protective and inducing variants of IL23R in susceptibility to CD. Although rs1004819 is the CD increasing variant of IL23R, rs11209026 has shown to be a protective IL23R variant against CD. As predicted, when the IL-22 mean serum levels were tested against each variant, the serum levels were highest among SNPs that increased CD risk as opposed to the identified protective SNPs of IL23R, which had low serum levels[33]. In contrast, the three main variants within NOD2/CARD15 did not show any differences in IL-22 serum levels[33]. Although, the exact function of IL-22 in human IBD is still unknown, recent studies have observed increased β-defensin-2 expression and intestinal epithelial cell migration and proliferation upon stimulation with IL-22[29]. These data ultimately suggests a clinically useful marker to assess disease severity and Th17 cell activity in CD patients[33].

As mentioned above, a rare glutamine allele, rs11209026, in IL23R conferred protection against CD during a recent genome-wide association study. Recent studies have proven that this variant protects against CD in both Jewish and non-Jewish populations. In addition, in a study involving IBD (both UC and CD) patients of Spanish Caucasian origin, the rs11209026 variant was seen to be most significantly associated with IBD protection (OR: 0.4; 95% CI: 0.3-0.7)[34]. A study by Dubinsky and colleagues has investigated this rare allele further and how it protects pediatric CD patients. They used the transmission disequilibrium test (TDT) analysis and genotyping of whole blood samples from children with IBD and their two parents. This rare rs11209026 SNP was present in 2.67% non-Jewish CD patients and 2.94% of non-Jewish UC patients[35]. The TDT demonstrated that the allele was under-transmitted in all CD offspring and confirmed the negative association between rs11209026 and CD[35].

Another way to confirm the association of alleles with CD and UC is to use a population that is genetically isolated, such as the Finnish population. This will provide an advantage in molecular genetic studies in complex disorders[36]. A study by Lappalainen has used such a strategy to confirm the association of IL23R, TNFRSF1A, and the HLA-DRB1*0103 allele variants. The strongest association of IL23R with the marker rs2201841 (IL-23R risk variant) showed a frequency of 37.2% in CD. In most studies, the non-synonymous SNP, rs11209026 (the protective IL23R allele), has had the highest association, but is only marginally associated with Finnish CD[36]. No association has been observed between the IL23R markers and UC patients[36].

Previous studies have shown that the HLA-DRB1*0103 allele is associated with both UC and CD. In the Finnish population, this allele only has a frequency of 0.6%, which is not statistically significant, whereas it is significant for UC and IBD[36]. When looking into the genotype-phenotype association, patients carrying the rare HLA-DRB1*0103 allele have colonic involvement in CD[36]. During the TNFRSF1A analysis, the investigators genotyped a rare A36G variant and an IVS6+10A (rs1800693) variant. CD patients with both variants often show ileocolonic disease in comparison with patients without these two variants[36]. The weak association is probably due to the small sample size. Interestingly, when the protective haplotype of IL-23R (described in the above paragraph) was sequenced and compared to North American Caucasian CD patients, there was a one-nucleotide difference between Finnish (CCTGATCG) and North American (CGTGATCG) CD patients[36]. In conclusion, the HLA-DRB1*0103 allele has been confirmed in CD patients, which shows an inherited susceptibility of colonic inflammation. The *TNFRSF1A* gene variants are markers of ileocolonic involvement in CD[36]. Although this study shows a weaker association of the *IL23R* gene, it confirms the genetic involvement within a Finnish population.

In another population study among French-Canadian and English-Canadian children, the association between genetic variants of the *IL23R* gene and early-onset of CD has been investigated. To study the associations accurately, they have carried out both a case-control and a family-based study. They have targeted the 10 SNPs in IL23R achieved by the genome-wide study and the three CARD15 SNPs. In total, 259 CD patients and 139 controls were recruited with a mean age at diagnosis of 13.3 years (range: 2.6-20 years)[12]. The IL23R protective allele, rs11209026, was only present in 2% of CD case chromosomes and 6% of the control chromosomes[12]. All CARD15 variant allele frequencies were higher among CD patients when compared to the control group[12]. In the *IL23R* gene, they observed a significant association among four SNPs that did not posses any CARD15 variants[12]. Therefore, variants in the *IL23R* gene were associated with early-onset CD among Canadian children.

This study confirms previously reported findings in CD patients among North Americans.

In continuation of a study that was described in the ATG16L section of this paper, Latiano and colleagues have shown that the replication of IL23R is associated in adult and pediatric onset of IBD in Italy. Approximately 730 CD patients were genotyped for the rs7517847 and rs11209026 variants. For the rs7517847 polymorphism, significant reductions were found in minor allele (G) frequency in CD patients when compared with controls and in the number of carriers[12]. No differences were found in UC patients. When the rs11209026 polymorphism was examined, a significant increase in the frequency of the risk genotype was observed in CD patients. In either SNP, there were no correlations between phenotypes of CD and risk alleles or genotypes of the *IL23R* gene.

To specify which IL23R variant is the main disease associated variant, a study using German CD patients was conducted. Among all 10 IL23R SNPs, they chose to focus their study on the rs1004819 variant because it had the strongest association to CD when compared to controls. This variant showed high prevalence of ileal involvement when carriers had the TT genotype versus the CC wild-type genotype[28]. This identification is different from recent data published by Roberts *et al*[37], which have identified the rs7517847 variant as having the strongest association with CD, along with other overlapping North American study populations. They have only analyzed ileal cases of CD, therefore, it is assumed that IL23R variants are predisposed to an ileal disease phenotype[37]. In a recent British study, they could not identify any association between disease phenotype and IL23R variants[9]. Interestingly, they found that the rs1004819 variant was 1000-fold weaker than that reported in the German study.

Not only are the IL23R variants highly associated with CD, they are also associated with other chronic inflammatory diseases, such as the rs10489629 variant with chronic periodontitis. In psoriasis, the variant rs11209026 has been described as a predisposing haplotype[17]. In both CD and psoriasis, treatment with an anti-p40 IL-12/23 antibody has shown promising results. Antibodies to the p40 subunit block both IL-12 and IL-23, although in knockout mice studies, it has been proven that IL-23 drives chronic intestinal inflammation[28]. Therefore, IL23R can serve as a therapeutic target in many different chronic inflammatory diseases, although the variants may differ among the different diseases. It is hypothesized that this is due to alternative mRNA splicing, which results in corresponding IL23R isoforms with different tissue distribution[28].

IBD5 GENE

The *IBD5* gene is about 250 kb and is located at position 5q31. During a genome-wide linkage analysis, mapping studies have identified a risk haplotype within the IBD5 locus. Many studies have linked this gene and its two variants, SLC22A4 (OCTN1) and SLC22A5 (OCTN2), to CD. IBD is believed to originate from an uncontrolled mucosal immunity of the GI tract[17]. Although these variants are associated with CD, they act independently because there is no statistical evidence for interaction between *IBD5* and the *IL23R*, *ATG16L1* or *CARD15* genes[12].

CTLA4 VARIANTS

The *CTLA4* gene is a member of the immunoglobulin superfamily and is expressed on the surface of helper T cells. It is located within the 2q33 region, translates into a protein that plays a role in the immune system, and may have a genetic association with IBD. It is a T-cell suppressor, which is essential in the function of the $CD25^+$ $CD4^+$ regulatory cells[7]. These regulator cells control the process of intestinal inflammation. Many SNPs have been studied within this gene and it has been found that the rs3087243 variant shows the most association with IBD followed by the rs11571302, rs7565213 and rs11571297 variants[35]. Although studies have shown that the three variants in the *CTLA4* gene, g.49A > G (rs231775), g.-318C > T (rs5742909), and rs3087243, have no association with CD, other work has suggested that these variants may control the phenotype of CD[14].

A study performed by Hradsky has shown no crude association between CD and SNPs within the CTLA4 gene[12]. The study explored the possibility of interactions in CTLA4 SNPs with variants in IL23R and NOD2. The R-project package SNPassoc was used and significant interactions between the three CTLA4 variants with NOD2 p.Leu1007fsX1008 and IL23R rs11209026 were observed[12]. This may be due to complex gene-gene interactions. To characterize further the different variants and whether they determine phenotype in CD patients, the study used a case-only design. They observed a difference of minor allele frequency at the rs3087243 gene between pediatric-onset and adult-onset of CD[12]. It seems that a genetic factor has a greater impact in early-onset patients when compared to the adult-onset patients[38]. Within this study, the age of diagnosis and localization of the disease was strongly associated with the rs3087243, rs11571302 and rs11571297 variants[12].

NOD2, IL23R, OCTN1/2 AND ATG16L1 POLYMORPHISMS

Gene-gene interactions

Interactions of the major IBD alleles show a high susceptibility in CD patients. Gene-gene interaction can either enhance or weaken the effects of an individual gene, therefore making it more important than independent studies looking into the effects of single susceptibility genes. Csongei and colleagues have performed a gene-gene interaction analysis in the Hungarian CD population[5]. They concentrated on the two IL23R gene risk variants (rs2201841 and rs1004819), the ATG16L1 gene variant (Thr300Ala), and the three NOD2/CARD15

variants (rs2066844, L1007fs and rs2066845). Logistic regression analysis showed that the IL23R variants, both rs1004819 and rs2201841 and the NOD2/CARD15 variants (rs2066844 and L1007fs) conferred significant risk for CD. When the patients were homozygous for IL23R (rs1004819 and rs2201841) variants or ATG16L1, there was a highly increased risk for CD. When they analyzed possible statistical interactions between pairs of ATG16L1, IL23R and CARD15 variants, no evidence of interactions was found. Therefore, all examined loci contribute independently to CD risk. Although significant statistical interactions were not detected, these susceptibility factors may have a cumulative effect in the Hungarian population.

Further gene-gene interaction studies have been performed in another population study, as well as assessment of CD genetic risk factors. The study included five SNP variants for IL23R, the functional variants SLC22A4 and SLC22A5, and the ATG16L1 mis-sense risk polymorphism Thr300Ala. All the SNPs, except for rs1495965 of IL23R, showed significant association when carriers were either homozygous or heterozygous for the alleles[2]. Among them all, rs10889677 of IL23R, showed the strongest association with CD risk[2]. Unsurprisingly, ATG16L1 also showed a strong association with CD[2]. None of the SNPs showed an association with UC. When they evaluated correlations between genotype and phenotype for intestinal complications, carriers of the rs7517848 allele of IL23R, particularly those who were homozygous for the allele, were found to be at risk for ileal disease. No other SNPs showed differences in genotype or carrier frequencies when compared to CD patients and their history of complications.

Homozygote variants from the IBD5 and ATG16L1 genes had a greater risk than heterozygotes, suggesting a gene dosage effect[2]. When SNPs were considered two at a time, the best interactions were shown between IL23R_rs10889677 and IBD5_rs17622208, which were not statistically significant[2]. However, when using a logistic regression approach between these two markers, the IBD5_rs17622208 risk was only significant in the presence of the IL23R_rs10889677 risk allele[2]. When SNPs were considered three at a time, the model suggested statistically significant interactions between IL23R_rs10889677, IBD5_rs11739135, and ATG16L1_rs2241880[2]. When SNPs were considered four at a time, the model suggested interaction between IL23R_rs2201841, IL23R_rs7517847, and IBD5_rs11739135[2]. A study in Oxford, UK has hown that certain IL23R polymorphisms have an association with CD only when the person is positive for IBD5[2]. In conclusion, the logistic regression model did not show any significant evidence of gene-gene interaction, due to the small size of the study, even though there was a consistently small association between IBD5 and IL23R.

Childhood- vs adult-onset CD

The pathogenesis of pediatric and adult IBD differ. The age of childhood and adult onset varies between cultures to culture because different cultures base it on different aspects such as physical, mental, or puberty. North American studies choose an age cut-off of 18 years, and < 18 years is considered a child, even though an individual at this age is physically mature. This is why Canadian studies have chosen to describe a child as < 16 years old. The belief is that the lower the age cut-off, the better the results are when comparing pediatric and adult onset of disease. Recent studies have shown that a subgroup of patients with early-onset IBD may have specific phenotypes that differ from adult-onset IBD[39]. Many believe that pediatric-onset IBD is influenced by genetics compared to adult onset because there is less time for exposure to environmental modifiers to influence the onset of disease. Adult-onset is probably due to a mixture of genetics and abundant environmental exposure[25]. For example, smoking is a major variable in adult IBD patients, but has little influence on pediatric IBD cohorts. Currently, there are conflicting studies on whether NOD2/CARD15 polymorphisms are associated with the age of onset of IBD because some show an association towards a younger age, while others show no effect[40].

A study by Gazouli *et al*[25] has investigated the main polymorphisms and their association with childhood-onset of CD in a Greek cohort. While investigating the genotype and allele frequencies of the NOD2/CARD15 polymorphisms, rs2066844, rs2066845 and 3020insC, a statistically significant association between rs2066844 and adult-onset CD was observed. In both pediatric- and adult-onset CD, individuals with at least one NOD2/CARD15 polymorphism showed a genotype-phenotype correlation with ileal involvement[25]. The study also confirmed the recently described association between IL23R variants in both child- and adult-onset CD[35]. There has been conflicting evidence in studies regarding the ATG16L1 SNPs. One study has shown no association with early-onset or adult-onset CD[25]. Recent research has indicated that the ATG16L1 rs2144880 variant is associated with adult-pediatric-onset CD, whereas other studies have demonstrated an association with diagnosis at an earlier age[25]. In conclusion, the 3020insC variant in the NOD2/CARD15 gene is associated with CD and occurs considerably more often in childhood- than in adult-onset patients with CD[25].

There is growing evidence that pediatric-onset IBD shows distinct differences when compared to its adult counterpart. Familial aggregation studies have shown an age-adjusted risk of developing IBD in first-degree relatives of affected individuals compared to the general population[23]. The risk increases to > 30% for children when both parents are affected with IBD, suggesting that family history is the strongest risk factor[5]. This is especially true among CD patients. Familial cases of CD occur at a younger age with greater severity than random sporadic cases[36]. One main difference observed between pediatric- and adult-onset is that early onset shows a distinct and

more aggressive phenotype, such as the need for surgery, than similar IBD in individuals > 20 years old[41].

Although NOD2/CARD15 mutations are neither sufficient nor necessary for the development of IBD, they are associated with a younger age of onset, presence of ileal involvement, and the development of strictures[23]. There is also a gene dosage effect for CD location and complications. For example, stricture complications occur more frequently in CD children with the 1007fs mutation in the *NOD2/CARD15* gene compared to children without this variant due to early surgery[42]. Therefore, children with this mutation have a sixfold increased risk for developing a stricture complication[23].

There has been conflicting evidence among studies that have attempted to show a link between the IBD5 locus and early-onset CD. A study by Rioux has found that the IBD5 locus is associated with early-onset CD where children were defined with an age of onset of < 16 years old[23]. However, studies from pediatric-onset CD cohorts have demonstrated that the risk of IBD5 is lower compared to that in adult-onset CD, while others have demonstrated enhanced risk of developing CD when an individual has both SLC22A4-A5 and NOD2/CARD15 mutations[43]. This connection may be due to a common pathophysiological mechanism[23].

Although there is no sex difference among patients with adult-onset IBD, there is a clear and distinct difference among children with CD. Many studies from pediatric CD cohorts in the United States, Canada and the United Kingdom have shown an increase in male incidence. The higher male to female ratio continues to be unexplained. These differences are not observed among UC pediatric patients[23]. It seems that sex is an age-dependent variable that has more influence on children than adults with IBD.

There are also phenotypic differences, such as disease location, among children and adult CD. For example, increased rates of upper GI tract disease and pure colonic disease in pediatric-onset CD have been identified. This difference may be due to the amount of examination during the onset of disease. Children undergo extensive GI endoscopy, whereas adults do not[23]. These findings may be artificial or represent a true disease distinction among children and adults. Another distinction is the occurrence of colon-predominant disease during childhood-onset IBD under the age of 10 years old. With children < 5 years old, all have colon-only disease[44]. During a study of approximately 1400 North American early-onset patients, data showed a colon-predominant phenotype in children < 8 years old. In another study in Europe, the acquisition of ileal CD became increasingly common as an individual approached 16 years old[23]. These data confirm an association of colon-predominant phenotype in early diagnosed children that changes as they grow older.

Population studies with NOD2, IL23R and ATG16LI polymorphisms

NOD2, IL23R and ATG16L1 polymorphisms were studied in a Lithuanian cohort with IBD. The study included 57 unrelated patients with CD, 123 with UC and 186 healthy individuals as controls. The three NOD2 variants, the IL23R variant rs11209026, and the ATG16L1 variant Thr300Ala, were genotyped among the population sample. No individuals were carriers of all three NOD2 risk alleles, whereas two CD patients were compound heterozygotes[10]. Carriers of at least one NOD2 variant were highest among CD patients[10]. There were no significant differences observed between UC patients and the controls. The NOD2 variant, Leu1007insC, was significantly associated with increased susceptibility in the Lithuanian CD population[10]. In comparison to the other two NOD2 variants, the frequencies were very low and not significant in controls and among the IBD patients[10]. In contrast to other European studies, a positive association between rs2066844, rs2066845 and CD was not found[10]. When they further tried to analyze IL23R and ATG16L1, they were unable to replicate previous findings of increased susceptibility to IBD within the Lithuanian population[10]. They were was a trend for a possible association with the ATG16L1 risk allele[10]. It is of particular interest to study this population because Baltic countries have low IBD incidence rates, especially for CD. To confirm distinct IBD subtypes, a study using a larger North-Eastern European IBD sample needs to be investigated.

Another population study was performed among New Zealand Caucasians with IBD. Their cohort included 466 UC patients, 496 CD patients and 591 controls. All individuals were genotyped for the IL23R rs11209026 SNP, the ATG16L1 rs2241880 SNP, and the CARD15 variants. Significant interaction was detected between variants in ATG16L1, IL23R and CARD15 and CD susceptibility, whereas no significant association was observed between IL23R or ATG16L1 genotypes and IBD sub-phenotypes[37]. The strongest association occurred between the ATG16L1 rs2241880 variant and CD, with no association detected with UC[37]. ATG16L1 is suggested to have a CD-specific susceptibility locus. Unlike ATG16L1, the IL23R rs11209026 variant was strongly associated with both CD and UC. In their patient cohort, there was no evidence that IL23R or ATG16L1 genotypes influenced disease behavior, age of onset, location, or the need for surgical bowel resection[37]. On the other hand, CARD15 was consistently a susceptibility factor and predictor of CD phenotype. Similar to many other studies, all three CARD15 SNPs are significantly overrepresented in patients with IBD family history, early onset of disease, ileal disease involvement, and development of complications[33].

Interactions between NOD2 and IL23R variants with toll-like receptor-9 polymorphisms

Toll-like receptors (TLRs) are single, membrane-spanning proteins that play a key role in the innate immune system. These receptors recognize microbes that have structurally conserved molecules that breach the physical

Table 1 Key gene polymorphisms and their significance in Crohn's disease

Gene	Polymorphism	Relationship significance	Ref.
ATG16L	rs2241880	Associated with ileal form of CD with or without colonic involvement	[4,12]
	Thr300Ala	Highly associated with CD	
NOD2/CARD15	rs2066844, rs2066845, 3020insC, 1007fs	Independently associated with CD	[20]
IBD5	SLC22A4 (OCTN1), SLC22A5 (OCTN2)	Independently associated with CD	[12]
CTLA4	rs3087243, rs11571302, rs11571297, rs7565213	Associated with IBD; no crude association to CD	[35]
TNFSF15	80 000 SNPs tested, including 7 SNPs within a 280 kb region on chromosome 9q32	Strongly associated with CD for Japanese and Jewish cohorts, but not for Europeans	[4,15,16]
IL23R	rs11209026	Strongly associated with conferring protection against CD	[4,33]
	rs1004819	Highly associated with CD	

SNPs: Single-nucleotide polymorphism; CD: Crohn's disease.

barriers. Once bound, TLRs activate the immune system. The responsiveness of the GI tract to luminal bacteria is dependent on the interaction of transmembrane TLRs and the intracellular NOD2 receptor[18]. Specifically, TLR9 plays a role in the maintenance of intestinal inflammation in IBD. TLR9 is also responsible for stimulating NOD2, which in turn enhances innate immune responses. Patients with two NOD2 mutations lose the synergistic affect between NOD2 and TLR9 stimulation. Therefore, interactions of both receptors have implications for intestinal homeostasis and inflammation[18]. The TLR9 gene is located on chromosome 3p21.3, which is close to other CD susceptible loci[9]. There are four SNPs in TLR9, but two of them are sufficient to distinguish between the haplotypes, which are rs5743836 and rs352140.

There might be a synergistic effect of NOD2 and TLR9 stimulation, therefore, Torok and colleagues have tested for gene interactions between TLR9 and CD-associated variants of NOD2[18]. Significant associations between the two were observed that were specific to CD[18]. The controls and UC showed no difference in distribution of TLR9 polymorphisms and NOD2 variants[18]. Other CD variants in IL23R, ATG16L1 and IBD5 were analyzed for epistatic interactions. Aside from NOD2, the most significant association was found in the IL23R variant rs1004819, with ATG16L1 showing weaker associations with CD. There was no significant association between TLR9 polymorphisms with CD or UC phenotypes[18]. Along with previous studies, they also showed that NOD2 mutations were associated with younger age of diagnosis of CD, ileal disease, and need for surgery[18]. When there were two NOD2 mutations, there was a higher frequency of penetrating disease[18].

In conclusion, a new association between CD and a TLR9 polymorphism has been found. There is evidence that when CD patients carry CD-associated NOD2 variants, they have an increased incidence of TLR9 polymorphisms. This is not surprising because there is a synergistic effect of NOD2 and TLR9 stimulation and it is important for the maintenance of intestinal homeostasis and inflammation. TLR9 also demonstrates significant epistatic interactions with IL23R variants, but unlike NOD2, there is no association with the frequency in TLR9 polymorphisms present. This study shows the first evidence for interaction between polymorphisms in TLR9 and variants between NOD2 and IL23R[18].

CONCLUSION

CD is an autoimmune disease characteristic of chronic intestinal inflammation and lesions. It can affect people of all ages and ethnicities worldwide. Recent genome-wide studies have shown significant genetic associations of several variants and susceptibility to CD. This is true for North American, South American and European populations. Certain variants have been linked only to Asian and African cohorts. It is vital to understand the pathology of CD and the underlying genetic interactions to increase efficiency of diagnosis and develop drugs that target specific immune system pathways. There have been several genetic variants highly associated with CD, which include ATG16L1, TNFSF15, NOD2/CARD15, IL23R and IBD5 (Table 1).

The process of autophagy is an important aspect of our immune system. It is a way to destroy foreign pathogens that enter the body. The Thr300Ala variant within the N terminus of ATG16L, which is part of a complex that forms autophagosomes, has significant associations with CD. Different ethnicities show different genotype markers. This is seen in TNFSF15, which is involved in systemic inflammation and regulation of various immune cells. Seven haplotypes have been identified within a Japanese cohort, but not in other ethnic cohorts. More research needs to be conducted to characterize fully this possible genetic link to CD. The most significant association with CD is observed among NOD2/CARD15 and IL23R variants. NOD/CARD15 plays an essential role in maintaining the intestinal normal flora. There are many theories about the cause of CD, and one of them includes a shift in the intestinal bacterial flora. Therefore, it is no surprise that NOD2 variants are highly associated with CD. There are three independent variants associated with CD: rs2066844, rs2066845 and 1007fs. The other highly associated genetic link is observed within the IL23R gene. One variant that is highly associated with CD is rs1004819, whereas rs11209026 confers protection against CD. IL23R plays an essential role in

mediating proinflammatory activities. Another highly associated genetic link with CD is observed in two variants within IBD5. The two variants, SLC22A4 (OCTN1) and SLC22A5 (OCTN2), show significant association with CD, but no interactions between these variants and other CD-associated genetic variants have been observed. The last highly associated genetic link with CD is observed within the *CTLA4* gene. This gene plays a role in the immune system. The four polymorphisms associated with IBD are rs3087243, rs11571302, rs7565213 and rs11571297.

Many CD variants are associated with a specific CD phenotype, age of diagnosis, severity and location of CD, and surgical outcome. Gene-gene interactions have also been characterized among the different variants and other immune system receptors. We need to understand fully the pathogenesis of CD to target pathways for effective treatment. Further research is needed to explore all possible gene-gene interactions due to a gene dose affect associated with CD. It seems that new genetic associations are constantly being uncovered within IBD and then associated with either CD or UC. Overall, CD shows a greater genetic link than UC. Recent discoveries have led to therapies and treatments that show much promise. Researchers need to continue the search for genetic links and diseases because this may be the only way to understand the pathology of CD and develop effective treatments.

Abstract

AIM: To investigate genetic diversity of *Helicobacter pylori* (*H. pylori*) cell division-related gene A (*cdrA*) and its effect on the host response.

METHODS: Inactivation of *H. pylori cdrA*, which is involved in cell division and morphological elongation, has a role in chronic persistent infections. Genetic property of *H. pylori cdrA* was evaluated using polymerase chain reaction and sequencing in 128 (77 American and 51 Japanese) clinical isolates obtained from 48 and 51 patients, respectively. Enzyme-linked immunosorbent assay was performed to measure interleukin-8 (IL-8) secretion with gastric biopsy specimens obtained from American patients colonized with *cdrA*-positive or -negative strains and AGS cells co-cultured with wild-type HPK5 (*cdrA*-positive) or its derivative HPKT510 (*cdrA*-disruptant). Furthermore, the cytotoxin-associated gene A (*cagA*) status (translocation and phosphorylation) and kinetics of transcription factors [nuclear factor-kappa B (NF-κB) and inhibition kappa B] were investigated in AGS cells co-cultured with HPK5, HPKT510 and its derivative HPK5CA (*cagA*-disruptant) by western blotting analysis with immunoprecipitation.

RESULTS: Genetic diversity of the *H. pylori cdrA* gene demonstrated that the *cdrA* status segregated into two categories including four allele types, *cdrA*-positive (allele types; Ⅰ and Ⅱ) and *cdrA*-negative (allele types; Ⅲ and Ⅳ) categories, respectively. Almost all Japanese isolates were *cdrA*-positive (Ⅰ: 7.8% and Ⅱ: 90.2%), whereas 16.9% of American isolates were *cdrA*-positive (Ⅱ) and 83.1% were *cdrA*-negative (Ⅲ: 37.7% and Ⅳ: 45.5%), indicating extended diversity of *cdrA* in individual American isolates. Comparison of each isolate from different regions (antrum and corpus) in the stomach of 29 Americans revealed that *cdrA* status was identical in both isolates from different regions in 17 cases. However, 12 cases had a different *cdrA* allele and 6 of them exhibited a different *cdrA* category between two regions in the stomach. Furthermore, in 5 of the 6 cases possessing a different *cdrA* category, *cdrA*-negative isolate existed in the corpus, suggesting that *cdrA*-negative strain is more adaptable to colonization in the corpus. IL-8 secretions from AGS revealed that IL-8 levels induced by a *cdrA*-disrupted HPKT510 was significantly lower ($P < 0.01$) compared to wild-type HPK5: corresponding to 50%-60% of those of

wild-type HPK5. These data coincided with *in vivo* data that an average value of IL-8 in biopsy specimens from *cdrA*-positive and *cdrA*-negative groups was 215.6 and 135.9 pg/mL, respectively. Western blotting analysis documented that HPKT510 had no effect on CagA translocation and phosphorylation, however, nuclear accumulation of NF-κB was lower by HPKT510 compared to HPK5.

CONCLUSION: Colonization by a *cdrA*-negative or *cdrA*-dysfunctional strain resulted in decreased IL-8 production and repression of NF-κB, and hence, attenuate the host immunity leading to persistent infection.

Key words: *Helicobacter pylori* cell division-related gene A; Genetic diversity; Host immune response; Interleukin-8 secretion; Nuclear factor kappa B; Persistent infection

INTRODUCTION

Helicobacter pylori (*H. pylori*), a Gram-negative spiral bacterium, colonizes the human stomach and causes chronic inflammation, which may progress to peptic ulceration, atrophic gastritis and gastric cancer[1]. Although the *H. pylori* population structure appears to be clonal over short periods of time, isolates obtained from different individuals exhibit substantial genetic diversity, consistent with extensive recombination and a panmictic population structure[2-7]. Putative mechanisms for the generation of diversity within *H. pylori* include frequent horizontal genetic exchange among strains and a high level of spontaneous mutation occurring over a long evolutionary time period within a highly restricted niche[6,8].

Infection by cytotoxin-associated gene A (*cagA*)-positive *H. pylori* is a known risk factor for the development of gastroduodenal disease due to major changes in cellular morphology and the release of molecules, including cytokines, from the gastric epithelium. *H. pylori* infection up-regulates secretion of various inflammatory cytokines, including interleukin (IL)-1, IL-6, IL-8 and tumor necrosis factor α, and contributes to the pronounced inflammatory response[9]. IL-8 production induced by *H. pylori in vitro* and *in vivo* is recognized as a host response to microbes[10,11], but the role of CagA on IL-8 production is less clear[12]. IL-8 is a potent pro-inflammatory cytokine which regulates neutrophil infiltration of gastric mucosa in *H. pylori* gastritis and is released through the signaling pathway concerning nuclear factor-kappa B (NF-κB), which includes extracellular signal-regulated kinase (ERK) activity[12,13] and mitogen-activated protein kinase[14]. Among the strongest transcriptional regulators of *H. pylori*-induced cytokine expression is the NF-κB family of transcription factors[15]. Activation of NF-κB can affect the expression of several hundred genes, and activation of its signal transduction pathway occurs in response to a wide range of stimuli and results in nuclear accumulation of NF-κB transcription factors, causing changes in the expression of target genes involved in innate and adaptive immunity, and inflammation.

We described previously that the *H. pylori* cell division-related gene A (*cdrA*) not only has a repressive role on cell division but is also involved in cell elongation and cell death *via* cell wall synthesis at the division site[16,17]. The *cdrA*-disrupted mutant HPKT510 was able to survive for the long-term in liquid medium, even under serum-free and aerobic conditions, and was more resistant to bactericidal of beta-lactam antibiotics than the wild-type HPK5[16]. Inactivation of *cdrA* during infection in the stomach may have contributed to ensuring persistent infection by altering its ability to adapt to the microenvironment. In fact, the *cdrA* gene was found to be absent in 3 out of 4 colonies recovered from a mouse infected with *H. pylori* strain B128[18]. Furthermore, additional isolates of the sequenced *H. pylori* strain J99 from a patient after a 6-year interval were subjected to microarray analysis, which indicated that the *cdrA* gene was missing in additional isolates[19]. Thus, we hypothesize that a loss of *cdrA* in *H. pylori* during infection might be an evolutionary event to alter its biological characteristics, which affects the host immune response to the microbes and promotes persistent infection.

In this study, the level of IL-8 secretion induced by a *cdrA*-negative strain was approximately 50% lower than those induced by a *cdrA*-positive strain *in vitro* and *in vivo*. Genetic diversity of *cdrA* was extended in American isolates and *cdrA*-negative isolates might be more adaptable to colonize in the corpus. Western blotting analysis documented that the CagA status at the point of its translocation and phosphorylation was not different between HPK5 and HPKT510 strains. However, expression of NF-κB was lower in HPKT510 than that in HPK5, indicating that *H. pylori* with inactivation of *cdrA* might escape from rigorous immune clearance and facilitate chronic persistent infection caused by decreased levels of IL-8 and nuclear accumulation of NF-κB.

MATERIALS AND METHODS

Bacterial strains and growth conditions

Wild-type *H. pylori* HPK5 and its derivatives such as HPKT510, a *cdrA*-disrupted mutant carrying *xylE-Km* cassette[17], and HPK5CA, a *cagA*-disrupted mutant carrying *xylE-Km* cassette[20], were cultivated in Brucella broth (Becton Dickinson, United States) supplemented with 10% horse serum at 37 ℃ in an atmosphere containing 10% CO_2 as previously described[21]. Bacteria grown in 10 mL of Brucella-serum medium in 100-mL conical flasks following sub-culture were subjected to co-culture with AGS cells. Bacterial growth was measured by determining absorbance at 600 nm (A_{600}) with a spectrophotometer (GENEQUANT pro, Amersham Pharmacia Biotech), and colony forming units were determined for bacterial viability. Additional clinical isolates, 77 American and 51 Japanese isolates endoscopically obtained from 48 and 51 patients, respectively, were cultured on Brucella-serum agar at 37 ℃ in an atmosphere containing 10% CO_2. Isolates from different regions in the stomach, such as the antrum and corpus, were also included in 29 of 77 American isolates. The bacterial genomic DNA extracted by a DNA kit (Qiagen, Tokyo, Japan) according to the manufacturer's instructions were subjected to polymerase chain reaction (PCR) with specific primer pairs to examine *cdrA* gene diversity.

AGS cell culture conditions

AGS cells (human gastric adenocarcinoma epithelial cell line, CRL1739c) were grown in RPMI 1640 + 7 medium including streptomycin (20 μg/mL) and kanamycin (60 μg/mL) (Nikken bio medical Laboratory, Japan) supplemented with 10% (v/v) heat-inactivated fetal bovine serum (Biowest, France) at 37 ℃ in an atmosphere containing 5% CO_2. AGS cells were seeded at a density of 0.5 × 10^6 cells in six-well plates (SUMITOMO BAKELIFE, Japan) and grown to about 80% confluence prior to co-culture experiments.

Co-culture of AGS cells with H. pylori strains

Subconfluent AGS cells (1 × 10^6) cultured in RPMI 1640 + 7 medium supplemented with 10% serum were washed twice by phosphate-buffered saline (PBS) and subsequently cultured with or without each *H. pylori* strain (HPK5, HPKT510 and HPK5CA) at a multiplicity of infection (MOI) of 150 or 300 in 1.5 mL of RPMI 1640 medium (Gibco BRL, Eggenstein, Germany) alone for 48 h at 37 ℃ in an atmosphere containing 10% CO_2. The supernatant was collected at various times (3-48 h), centrifuged at 7000 r/min for 5 min to pellet bacteria and AGS cells, and subjected to sandwich enzyme-linked immunosorbent assay (ELISA) to measure IL-8 productions. AGS cells after co-culture were collected at the appropriate time and used in the following analyses.

Preparation of whole-cell and nuclear extracts

AGS cells were washed five times in ice-cold PBS, incubated with lysis buffer containing 50 mmol/L NaCl, 1 mmol/L EDTA, 1 mmol/L NaF, 100 μmol/L sodium orthovanadate, 10 μmol/L phenylmethylsulfonyl fluoride (PMSF) and a commercially available protease inhibitor mixture tablet (Complete, Roche Molecular biochemical, Indianapolis, IN), harvested by scraping and transferred to a microcentrifuge tube. Debris was removed by centrifugation at 10 000 *g* for 10 min (TOMY MRX-150) to collect the total proteins for whole-cell extracts. Nuclear proteins were prepared by Cellytic Nu-CLEAR Extraction Kit (SIGMA, Japan) according to a previous report[22]. Briefly, AGS cells were incubated with lysis buffer (10 mmol/L Hepes, pH 7.9, 1.5 mmol/L $MgCl_2$, 10 mmol/L KCl, 1 mmol/L DTT and 0.25 mmol/L PMSF) on ice for 15 min. The pellet precipitated containing nuclei following centrifugation for 30 s at 10 000 *g* was resuspended in 100 μL extraction buffer (20 mmol/L Hepes, pH 7.9, 1.5 mmol/L $MgCl_2$, 0.42 mol/L NaCl, 0.2 mmol/L EDTA, 25% glycerol, 1 mmol/L DTT and 0.25 mmol/L PMSF) for 30 min at 4 ℃ with agitation. After centrifuging for 5 min at 20 000 *g*, the supernatant (nuclear fraction) was collected for nuclear extracts.

Immunoprecipitation

One milligram of the lysate proteins was incubated with polyclonal rabbit anti-*H. pylori* CagA antibody (Austral Biologicals, CA, United States) for 1 h at 4 ℃, followed by an overnight incubation with a 20 μL aliquot of Protein G Plus-agarose beads (Santa Cruz, United States) at 4 ℃, as previously described[20]. Briefly, the beads were washed with lysis buffer and boiled for 10 min in 2 × electrophoresis sample buffer (50 mmol/L Tris (pH 6.8), 10% sodium dodecyl sulfate, 12% 2-mercaptoethanol, 20% (wt/vol) glycine and 1% (v/v) bromophenol blue) to elute the immunoprecipitated proteins.

Western blotting analysis

For detection of CagA and its phosphorylation, equivalent amounts of the immunoprecipitated proteins (100 μg) were resolved by 5% sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE). Proteins were electrotransferred onto nitrocellulose membranes (Millipore Corporation, United States) by a semidry blotting apparatus KS-8460 (System Instruments Co., Ltd. Tokyo). The blots were blocked overnight with 4% (wt/vol) dried skim milk in Tris-buffered saline with Tween 20 at room temperature and then incubated with monoclonal antibody PY99 (diluted 1/1000; Santa Cruz, United States) for 1 h and anti-mouse IgG peroxidase-linked species-specific whole secondary antibody (diluted 1/1000; GE Healthcare Biosciences, Co. Ltd., United Kingdom) for 1 h to detect phosphorylated tyrosine protein. Immunodetection was performed by enhanced chemiluminescence Plus Western Blotting Detection Reagents (GE Healthcare Biosciences). Next, blots were stripped, reprobed with a specific polyclonal rabbit anti-*H. pylori* CagA antibody (diluted 1/1000; Austral Biologicals. CA, United States) and incubated with a horseradish perox-

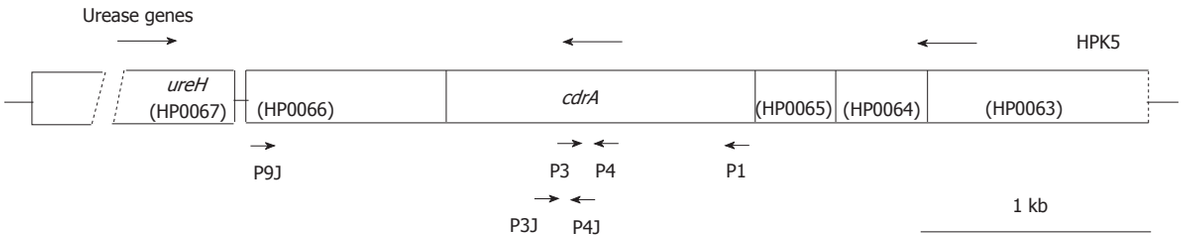

Figure 1 Location of primers used for cell division-related gene A in the region downstream of the urease gene cluster of *Helicobacter pylori* HPK5. Arrows above and below the map depict the direction of transcription and primers, respectively. The open reading frames (HP0063 to HP0067) are shown based on strain 26695.

idase-conjugated goat anti-rabbit secondary antibody (diluted 1/10 000; Jackson ImmunoResearch, PA, United States)[20]. Each 10 μg of nuclear and total proteins was subjected to 12% SDS-PAGE for detection of NF-κB and inhibition kappa B (IκB), respectively. Procedures of western blot analysis were followed as described above. Rabbit anti-human-NF-κB (p65) (diluted 1/200; Cell Signaling Technology, United States) and rabbit anti-human-IκB antibodies (diluted 1/200; Santa Cruz Biotechnology Inc, United States), and an anti-rabbit IgG antibody-HRP (diluted 1/2000; Santa Cruz Biotechnology Inc, United States) were used as primary and secondary antibodies, respectively. For a standard control, a rabbit anti-human-ERK2 antibody (diluted 1/200; Santa Cruz Biotechnology Inc, United States) was used to detect unphosphorylated ERK2 to confirm equal protein load[23]. The analyses were performed for least three independent experiments.

Measurement of IL-8 secretion from AGS cells

The amount of IL-8 secreted into culture medium after co-culture with *H. pylori* strains was determined by ELISA using the CytoSets system (BioSource International) according to the manufacturer's instructions. Fifty μL aliquots of the supernatant was briefly centrifuged at 7000 r/min for 10 min to remove bacteria and AGS cells, after which supernatants were added to an equal volume of regent on the 96-well ELISA plate. The absorbance of samples was measured at 550 nm using a 96-well microplate reader (Multiskan JX ver1.1, Thermo Labsystems, Finland), and the data was expressed as pg/mL. All samples were measured in triplicate in at least three independent experiments.

Measurement of mucosal IL-8 secretion

Frozen gastric antral biopsy specimens from 25 clinical patients infected with *H. pylori* were homogenized in 1 mL of PBS, and supernatants obtained by centrifugation were used for determination of IL-8 proteins by ELISA, as described previously[24]. Cytokine concentrations in homogenates were normalized in terms of total protein concentration of the biopsy specimen and were expressed as pg/mL.

PCR for cdrA gene diversity

To compare the *in vivo* IL-8 level in the biopsy specimens between the patients infected with *cdrA*-positive or -negative strains, PCR was utilized to examine the *cdrA* status in clinical isolates. The genomic DNA of clinical isolates, including 77 American and 51 Japanese strains, were subjected to PCR with specific primers for the *cdrA* gene of the HPK5 strain such as P1 (forward), P3 (reverse) and P4 (forward), previously described[17]. Additional new primers, P9J (reverse), P3J (reverse) and P4J (forward), based on the sequence of the *cdrA* gene of J99 strains, were also utilized in this study. The sequence of primer P1 was identical in strains, HPK5 and J99. The conditions used for PCR to amplify the 194-bp or 336-bp products in the central region of *cdrA*, which is highly conserved among strains using P3-P4 or P3J-P4J primer pairs, respectively, were as follows: pre-heat for 2 min at 96 ℃, followed by 40 cycles of 96 ℃ for 30 s, 55 ℃ for 30 s, and 72 ℃ for 30 s. To amplify the N-terminal region of *cdrA* using P1-P3 or P1-P3J primer pairs, PCR was performed with the following conditions: pre-heat for 2 min at 96 ℃, followed by 40 cycles of 96 ℃ for 30 s, 52 ℃ for 30 s, and 72 ℃ for 2.5 min. PCR was carried out at least two times with all sets of primer pairs, P1-P3, P1-P3J, P3-P4 and P3J-P4J, for determining the standing of the *cdrA* gene. In particular, for the strains representing no PCR product using various primer pairs mentioned above, P9J-P4 or P9J-P4J primer pairs were used to confirm the existence of the region from central to C-terminal on *cdrA* corresponding to flanking the downstream region of urease gene cluster. The PCR conditions were as follows: pre-heat for 2 min at 96 ℃, followed by 40 cycles of 96 ℃ for 30 s, 55 ℃ for 30 s, and 72 ℃ for 1 min. The location of these primers used for *cdrA* amplification (Figure 1) and primer sequences are shown (Table 1).

Statistical analysis

Fischer's exact test and the χ^2 test with Yates' continuity correction were applied using SPSS version 10.0 for Windows to compare differences on the level of IL-8 productions induced by *cdrA*-positive and -negative *H. pylori* strains. P value of < 0.05 were considered significant.

RESULTS

IL-8 secretion from AGS cells

To determine the effect of host response to *H. pylori*

Table 1 The sequence of primers used and the target region of cell division-related gene A amplified with combination of primers

Primers	Sequence (5′-3′)	Reference	Combination of primers	Target region of cell division-related gene A
P1 (forward)	TGAAGCACACGAAAGGA	17	P1-P3	N-terminal to central
P3 (reverse)	CATGCTCTAAAATCGTCG	17	P1-P3J	N-terminal to central
P3J (reverse)	ATCACCACGATCAGTCTG	This study	P3-P4	Central
P4 (forward)	TTTTGAGATCGGTGAAGC	17	P3J-P4J	Central
P4J (forward)	AACCACACGCTCATTTGC	This study	P4-P9J	Central to C-terminal

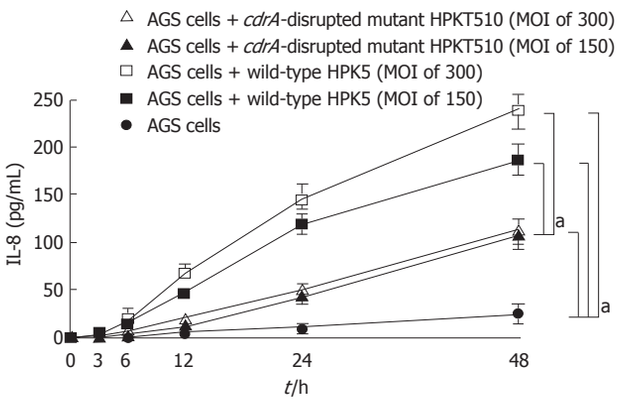

Figure 2 Interleukin-8 production from AGS cells induced by either wild-type or cell division-related gene A-disrupted mutant strains. [a]$P < 0.01$.

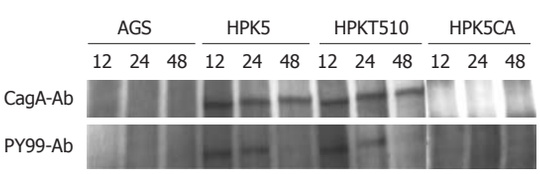

Figure 3 Cytotoxin-associated gene A status in AGS cells co-cultured with or without *Helicobacter pylori* strains. The immunoprecipitated proteins with anti-*Helicobacter pylori* (*H. pylori*) cytotoxin-associated gene A (CagA) antibody (CagA-Ab) were subjected to Western blotting with CagA-Ab (upper) and PY-99 antibody (PY99-Ab) (bottom), respectively. The assay was carried out with strains at MOI of 150. HPK5: Wild-type; HPKT510: Cell division-related gene A-disrupted mutant; HPK5CA: *cagA*-disrupted mutant.

during persistent infection in the human stomach, *in vitro* levels of IL-8 production from AGS cells co-cultured with HPK5 or HPKT510 strains were examined relative to time (Figure 2). Both strains induced the secretion of IL-8 from AGS cells and the levels increased time-dependently, but HPKT510, the *cdrA*-disrupted mutant, showed significantly lower levels, corresponding to 50%-60% of levels induced by wild-type HPK5 at MOI of 150 ($P < 0.01$). Furthermore, the levels of IL-8 were increased dose (MOI)-dependently by HPK5, but not HPKT510, which showed identical levels between MOI of 150 and 300.

Western blotting for CagA

Ultrastructural analyses revealed that the HPKT510 strain had a slightly wider periplasmic space between the inner and the outer membrane than that of HPK5[16]. To determine whether such morphological difference affects translocation of CagA into AGS *via* type Ⅳ secretory component system (T4SS) and its phosphorylation, which are considered to be risk factor for development of gastroduodenal disease, western blotting following immunoprecipitation with anti-*H. pylori* CagA antibody was carried out. CagA was detected in AGS cells co-cultured with HPK5 or HPKT510 strains, but no CagA was observed in AGS alone or when co-cultured with a *cagA*-disrupted mutant, HPK5CA as a negative control (Figure 3). The intensities of each CagA band are similar between both strains. Phosphorylation of CagA was detected up to 24 h after co-culture with HPK5 or HPKT510 strains and had similar intensity, indicating that there were no differences in the status of CagA between both strains.

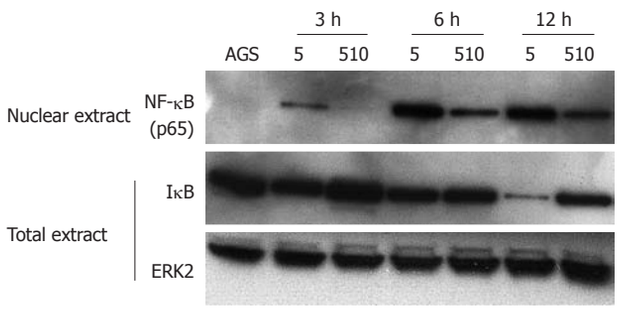

Figure 4 Detection of nuclear factor kappa B (p65) (upper), inhibition kappa B (middle) and extracellular signal-regulated kinase 2 (bottom) in nuclear and total extracts, respectively at 3, 6 and 12 h after being co-cultured with *Helicobacter pylori*. Unphosphorylated extracellular signal–regulated kinase 2 (ERK2) was detected as the control in this study[23]. Molecular weights of nuclear factor kappa B (NF-κB), inhibition kappa B (IκB) and ERK2 are 65, 35-37 and 42 kDa, respectively. The assay was carried out with strains at a MOI of 150. AGS: AGS cells co-cultured without *H. pylori*; HPK5: AGS cells co-cultured with wild-type HPK5; HPKT510: AGS cells co-cultured with *cdrA*-disrupted mutant HPKT510.

Western blotting for NF-κB (p65) and IκB

To determine how the expression level of NF-κB transcription factor affects the expression of many genes involved in inflammation and immunities, western blotting was carried out utilizing AGS cells co-cultured with HPK5 or HPKT510 strains for 3, 6 and 12 h. Overall, NF-κB levels in the nuclear extracts from AGS cells with HPKT510 were definitely lower compared to those with HPK5, whereas IκB levels in total extracts were found to be higher in HPKT510 (Figure 4), indicating that activation of NF-κB was relatively repressed in AGS cells stimulated by *H. pylori* with disruption of *cdrA*.

Table 2 ***Helicobacter pylori*** **cell division-related gene A status (positive or negative) and genotype (allele type) in clinical isolates *n* (%)**

H. pylori cdrA			
Status	**Genotype**	**United States (48 patients)[1]**	**Japan (51 patients)**
Positive	Type I	0 (0)	4 (7.8)
	Type Ⅱ	13 (16.9)	46 (90.2)
Negative	Type Ⅲ	29 (37.7)	1 (2.0)
	Type Ⅳ	35 (45.4)	0 (0)
Total		77[2]	51

H. pylori cdrA: *Helicobacter pylori* cell division-related gene A. [1]In 29 out of 48 patients, each isolate was obtained from both antrum and corpus in same stomach; [2]The total 77 isolates include 44 and 33 isolates obtained from antrum and corpus, respectively.

Table 3 Comparison of cell division-related gene A status and genotype (allete type) between antrum and corpus isolates in 29 American patients

	***cdrA* status[1]**		***cdrA* genetype (allele type)**		
cdrA positive (6 cases)	Same[2]: 1	Antrum (+)[3] Corpus (+)	Identical[4]: 1	Antrum Type Ⅱ	Corpus Type Ⅱ

				11 Type Ⅳ	Type Ⅳ
	Difference: 1	Antrum (-) Corpus (+)	Difference: 7	4 Type Ⅲ	Type Ⅳ
				2 Type Ⅳ	Type Ⅲ
				1 Type Ⅳ	**Type** Ⅱ
Total (%)	Same: 23 (79)		Same: 17 (59)		
	Difference: 6 (21)		Difference: 12 (41)		

[1]The status of cell division-related gene A (*cdrA*) determined with isolate from antrum was divided to two category groups (*cdrA* positive and negative); [2]Same or difference: *cdrA* status is same or difference between isolate (antrum and corpus); [3]+: *cdrA* positive isolate; -: *cdrA* negative isolate; [4]Identical or difference: the genotypes of *cdrA* is identical or difference between isolate (antrum and corpus). Bold denotes the 6 cases representing differences at *cdrA* status and genotype between isolates (antrum and corpus).

Genetic diversity of H. pylori cdrA

To examine the *cdrA* status [category such as *cdrA*-positive and -negative, including 4 allele types (Ⅰ to Ⅳ)] in 128 clinical isolates, PCR was performed with appropriate specific primer pairs. In a previous report, PCR with P1-P3 yielded the 731 bp (short fragment) and approximately 2 kb (long fragment) in HPK5 and other three strains examined respectively, demonstrating that the shorter product of HPK5 was due to partial deletion in the N-terminal region of *cdrA*. However, *cdrA* was functionally involved in cell division, morphology, long-term survival and susceptibilities to beta-lactam and its transcript could be detected[16,17]. On the other hand, the 194-bp amplified in the central region of *cdrA* was detected in all strains, indicating that size diversity exists within the N-terminal region of *cdrA* among individual strains[17]. In this study, 128 clinical isolates (77 American and 51 Japanese) were subjected to PCR with N-terminal primer pairs (P1-P3 and P1-P3J) which demonstrated that the short fragment (allele type Ⅰ) was obtained in only 4 Japanese isolates (7.8%) including HPK5 and the long fragment (allele type Ⅱ) was detected in 13 American (16.9%) and 46 Japanese (90.2%) isolates. In addition, no product was observed in the 64 American (83.1%) and 1 Japanese (2.0%) isolates by PCR with central region primer pairs (P3-P4 and P3J-P4J). Of the 64 American isolates showing no amplification on the central region, 35 isolates have no product amplified on the C-terminal region with P9J-P4J and P9J-P4 pairs. The results revealed that the downstream region of the urease gene cluster, including *cdrA,* was absent in the 35 isolates (allele type Ⅳ). However, PCR product on the C-terminal region with P9J-P4J or P9J-P4 pairs was detected in remaining 29 isolates, demonstrating that they have partial *cdrA* sequence loss between the N-terminal and central regions (allele type Ⅲ). Taken together, the status of the *cdrA* gene among individual isolates examined was divided into two categories; *cdrA*-positive including allele types Ⅰ (HPK5) and Ⅱ (J99 and 26695), and *cdrA*-negative including allele types Ⅲ and Ⅳ (Table 2).

Comparison of cdrA status between antrum and corpus

The *cdrA* allele type of each isolate from the antrum and corpus in the stomach of 29 American patients demonstrated that *cdrA* allele between the regions was identical in 17 patients (59%); however, 9 of the remaining 12 patients possessing a different allele had a isolate with more loss of the *cdrA* sequence in the corpus compared to the antrum (Table 3). Regarding the status of *cdrA*, 6 out of 29 patients had different *cdrA* status between the regions, and of which, 5 patients harbored *cdrA*-positive and -negative isolates in the antrum and corpus, respectively (Table 3).

Measurement of mucosal IL-8 secretion

The *cdrA*-disrupted mutant HPKT510 showed significantly lower levels of IL-8 secretion *in vitro* compared to wild-type HPK5. To investigate whether *cdrA* is associated with IL-8 production *in vivo*, mucosal IL-8 secretion of biopsy specimens was measured using samples obtained from 20 American patients infected with *cdrA*-negative and 5 American patients with *cdrA*-positive *H. pylori*. Measurement of IL-8 in these specimens demonstrated that the *cdrA*-negative group exhibited lower IL-8 levels than those of *cdrA*-positive group. The average value of IL-8 in the *cdrA*-negative group was 111 pg/mL, corresponding to the average of 60% in the *cdrA*-positive group (156 pg/mL). This tendency was consisted with *in vitro* data, revealing that *cdrA*-negative *H. pylori* does not induce IL-8 secretion as strongly in the human stomach as *cdrA*-positive strains.

DISCUSSION

H. pylori colonizes more than half of the world's population. While it is clear that this organism induces a strong innate and adaptive immune response leading to active inflammation in the gastric mucosa, the ability of *H. pylori* to establish persistent infection so efficiently has not been fully elucidated. *H. pylori* possesses a number

of virulence factors, and some, such as urease, flagella and lipopolysaccharide (LPS), contribute to its persistence[25-27], whereas others, such as CagA and vacuolating cytotoxin, appear to confer increased virulence[28,29]. Furthermore, the strain-specific genes found outside of the *cag* pathogenicity island, especially genes in the plasticity regions[30] and genes with variable structures/genotypes, have considerable interest in their contribution to pathogenesis and the host immune response. Nearly half of the strain-specific genes of *H. pylori* are located in the plasticity regions in strains 26695[31] and J99[30,32]. There is evidence that genetic recombination among *H. pylori* may occur during the course of infection in the stomach. The diversity or phase variation in *H. pylori* genes such as *babA*[33] and *fucT1*[26] likely contributes to the evasion of the host immune response and thereby has a role in the establishment of persistent infection in the stomach. Based on the genomic information of the sequenced *H. pylori* strains 26695[31] and J99[32], more than a third of *H. pylori* genes have unknown function, suggesting that there may be strain-specific genes such as *ctkA*[34] involved in the mechanisms of persistence as well as the host immune response.

One of unique genes found in the HPK5 strain, *cdrA* located in the downstream region of urease gene cluster, has not only a inhibitory role for cell division, but is also involved in elongation and death of cells *via* cell wall synthesis at the site of division[16,17]. Furthermore, the *cdrA*-disrupted mutant HPKT510 had a longer survival time compared to the wild-type HPK5 in both liquid and solid media, as well as in serum-free medium and aerobic conditions[16]. Loss of the *cdrA* gene during infection is frequently found in a mouse infected with *H. pylori* strain B128[18] and in the human stomach infected with J99[19]. The present study found that *cdrA*-negative strains resulted in lower levels of IL-8 production *in vitro* and *in vivo* compared to *cdrA*-positive strains. *In vitro* data showed that increased IL-8 production was dose-dependently observed by *cdrA*-positive HPK5, but not *cdrA*-disrupted HPKT510. In addition, nuclear accumulation of NF-κB in AGS co-cultured with HPKT510 was lower compared to HPK5, suggesting that activation of the NF-κB signaling pathway was relatively repressed by stimulation of the *cdrA*-negative strain, which coincided with decreased IL-8 production. These indicated that *cdrA*-defective *H. pylori* may evade immune clearance due to limiting bactericidal effects of pro-inflammatory molecules leading to promotion for persistent infection, likely *via* repression of the NF-κB signaling pathway. Persistent infection was not observed in IL-10-deficient mice with strong inflammation, implying that attenuate host immunity is necessary for *H. pylori* colonization[35]. Accordingly, it is acceptable that *H. pylori* infection occurred in the stomach with immature immunity during infantile generation. The proper NF-κB transcriptional response is primarily regulated by post-translational modification of NF-κB signaling components. On the other hand, alternative splicing of NF-κB signaling components is another way to control the NF-κB signaling pathway[36,37]. Alternative splicing of some NF-κB signaling components can be induced by prolonged exposure to a NF-κB-activating signal, such as LPS, suggesting a mechanism for negative feedback to dampen excessive NF-κB signaling. In particular, alternative splicing events in Toll/interleukin-1 NF-κB signaling pathways *via* Toll like receptors can inhibit the NF-κB response[38]. This raises the possibility that changes in bacterial constituents concerned with disruption of *cdrA*, such as cell envelope components including LPS, may exert on the complicated NF-κB signaling pathway.

As HPKT510 had a slightly wider periplasmic space[16], the effector protein, CagA, was investigated to determine whether this morphological change altered the function of T4SS. The CagA production, its translocation and phosphorylation were indistinguishable between HPK5 and HPKT510 strains, indicating that such morphological differences related with inactivation of *cdrA* had no effect on CagA-associated pathogenicity, including CagA-related signaling pathway and T4SS. Cytoplasmic nucleotide-binding oligomerization domain (Nod) molecules, Nod1 and Nod2, have been shown to be specific ligands of diaminopimelic acid-containing muropeptides and muramyl dipeptide, respectively[39,40], and were important components of the innate immune response. A peptidoglycan-derived muropeptide possessing a Nod1 motif was translocated through T4SS and affected cell signaling *via* activation of NF-κB in the host cell, leading to the stimulation of an intracellular pro-inflammatory response[41]. In terms of conserved domains, part of HPK5 *cdrA* belongs to the SM1-NRK4 family, beta glucan and cell wall synthesis enzyme family, and another belongs to the SpoIIE-FtsK-ATPase family. The properties of penicillin-binding proteins such as PBP1, PBP2, PBP3 and PBP4 varied between HPK5 and HPKT510 strains[16], suggesting that an alteration of such peptidoglycans influences the level of IL-8 production *via* the Nod1-NF-κB signaling pathway. In fact, the measurement of *nod1* transcript level in AGS by real-time RT-PCR documented that HPKT510 induced lower level of *nod1* transcript compared to HPK5 (data not shown), which supports the Nod1-NF-κB pathway involved in the difference of IL-8 production.

The *cdrA* status in almost all Japanese isolates were *cdrA*-positive (98%), but not in isolates obtained from Americans, demonstrating that American isolates had a greater diversity and higher prevalence of *cdrA*-negative strains (83.1%). Evaluation of *cdrA* status in isolates obtained from different regions of the stomach revealed that in 5 of the 6 cases possessing different status between the antrum and corpus of the stomach, the *cdrA*-negative isolate was from the corpus, suggesting that a *cdrA*-negative strain might be more adaptable to colonize in the corpus over a longer time period than the *cdrA*-positive strain. A *cdrA*-disrupted mutant could survive

longer under the stresses, such as presence of beta-lactam antibiotics, serum-free and aerobic conditions, than the wild-type strain[16]. It is possible that changes in biological behavior accompanied by inactivation of *cdrA* are necessary to stay balanced for the establishment of long-term infection in the human stomach. When the HPK5 *cdrA* sequence was compared to reference strain 26695[31], the *cdrA* sequence was a fusion of the ~130 codon hp0064 gene to the middle ~one third of the hp0066 gene, with deletion of the interstitial hp0065 and first part of hp0066. A similar fusion is evident with respect to the reference strain J99 (jhp0059 and jhp0061) or HPAG1 (hpag1_0064 and hpag1_0067)[42]. These two reference strains might represent the majority class in the Japanese population, which gave 2 kb instead of 730 bp PCR products. In contrast, two other sequenced strains, Shi470[43] and G27[44], seem to contain only the ~130 codon ORF, not the longer one, and thus might possibly represent one of the major classes in the United States population. The HPK5 type *cdrA* stems from gene fusion and synthesizes a partially defective protein that impacts cell wall synthesis or structure and a greater release of peptidoglycan fragments, which can be proinflammatory through the Nod1-NF-κB pathway. More studies are required in the future to dissect the mechanistic role of *cdrA* and the alteration of comprehensive genomix/proteomix affected by inactivation of *cdrA*. Analysis for putative deletion alleles might actually provide us with insights to elucidate whether the phenomenon resulted from such sources as large insertions or genome rearrangements.

In histological observation, as far the confined tissue sections of small biopsy specimens were examined, no significant finding was observed in the gastric mucosa colonized with either *cdrA*-positive or *cdrA*-negative *H. pylori* strains. We may need more examinations in detail with extended sections and specimens to confirm the differences in histological findings, including inflammation with neutrophil infiltration.

We concluded that the presence of *H. pylori cdrA* was associated with effective production of pro-inflammatory cytokine, IL-8, both *in vitro* and *in vivo*. Therefore, *cdrA*-inactivated *H. pylori* strains may result in attenuated host immunity and evade immune clearance due to repression of the NF-κB signaling pathway in the host cell, leading to persistent infection. Finally, our studies suggest that *cdrA*-negative *H. pylori* strains are more likely to colonize in the corpus over long time periods compared with *cdrA*-positive strains.

COMMENTS

Background

Helicobacter pylori (H. pylori) infection up-regulates secretion of various inflammatory cytokines including interleukin-8 (IL-8), whose production *in vitro* and *in vivo* is recognized as a host response to microbes. The levels of IL-8 production differ among individual strains, suggesting the existence of unique genes involved in host response and genetic diversity during infection in the stomach. Furthermore, the effect of fundamental constituents belonging to cell division of *H. pylori* on host response is unclear.

Research frontiers

H. pylori infection and its persistence in the stomach is the most important event to actually lead a variety of diseases. However, the functions and practices of the cell division of strains colonized in an individual stomach remain unclear. Furthermore, how the bacterial behaviors concerned with the host response is still unknown. In this study, the authors demonstrate that *H. pylori* cell division-related gene A (*cdrA*) required for cell division and morphological shape could be a potential role for mediating IL-8 secretion.

Innovations and breakthroughs

Reports have highlighted the importance of *H. pylori*-host interaction to understand host immunity and pathogenesis. Certain molecules, such as cytotoxin-associated gene A (*CagA*) and outer membrane proteins, were shown to be involved in these phenomena; however, the relationship between cell division- and morphological shape-related molecules and host response associated with persistent infection in the stomach is unknown. This is the first study to report that *cdrA* influenced IL-8 secretion (*vivo* and *vitro*) and loss of *cdrA* may attenuate the host immunity due to repression of NF-κB, leading to persistence.

Applications

In this study, how *H. pylori cdrA* functions and influences bacterium-host interaction was investigated, which provides insights into understanding bacterial fundamental components and their effect on the stomach, including host response, and a future strategy for therapeutic intervention in the treatment of patients with *H. pylori* infection.

Terminology

H. pylori cdrA, one of the unique genes discovered in strain HPK5, has not only a repressive role on cell division but is also involved in cell elongation and cell death *via* cell wall synthesis (mainly penicillin binding proteins) at the division site. The *cdrA*-disrupted mutant is able to survive for long time periods and is more resistant to the bactericidal of beta-lactam antibiotics than the wild-type. The *cdrA* gene tends to be lost during infection to facilitate adaption in the stomach, resulting in a persistent infection.

Peer review

This interesting manuscript showed that the presence of *H. pylori cdrA* was associated with the effective production of IL-8 compared to the inactivation of *cdrA in vitro* and *in vivo*. Additionally, they observed that *cdrA*-inactivated *H. pylori* strains may result in attenuated host immunity and evade immune clearance due to repression of the NF-κB pathway, leading to persistent infection.

Abstract

AIM: To establish an appropriate primate model of fulminant hepatic failure (FHF).

METHODS: We have, for the first time, established a large animal model of FHF in *Macaca mulatta* by intraperitoneal infusion of amatoxin and endotoxin. Clinical features, biochemical indexes, histopathology and iconography were examined to dynamically investigate the progress and outcome of the animal model.

RESULTS: Our results showed that the enzymes and serum bilirubin were markedly increased and the enzyme-bilirubin segregation emerged 36 h after toxin administration. Coagulation activity was significantly decreased. Gradually deteriorated parenchymal abnormality was detected by magnetic resonance imaging (MRI) and ultrasonography at 48 h. The liver biopsy showed marked hepatocyte steatosis and massive parenchymal necrosis at 36 h and 49 h, respectively. The autopsy showed typical yellow atrophy of the liver. Hepatic encephalopathy of the models was also confirmed by hepatic coma, MRI and pathological changes of cerebral edema. The lethal effects of the extrahepatic organ dysfunction were ruled out by their biochemical indices, imaging and histopathology.

CONCLUSION: We have established an appropriate large primate model of FHF, which is closely similar to clinic cases, and can be used for investigation of the mechanism of FHF and for evaluation of potential medical therapies.

INTRODUCTION

Fulminant hepatic failure (FHF) is an uncommon and challenging clinical disease characterized by sudden and severe hepatic injury and dysfunction, with many different symptoms and complications, and high mortality. The term was first used in 1970 to describe a potentially reversible disorder that was the result of severe liver injury in the absence of pre-existing liver disease, with an onset of encephalopathy within 8 wk of symptom appearance[1]. The incidence and etiology of FHF vary according to different geographic regions[1,2], and viral hepatitis and drug or toxin ingestion are the most common causes. As the pathophysiological changes are complicated and still need to be investigated, a clinically relevant large-animal model would be an indispensable tool. Orthotopic liver transplantation has been proved to be an effective treatment[3-6], but the shortage of donor organs has restricted its wide application[7-9]. The development of new therapies, including hepatocyte transplantation, stem cell transplantation, tissue engineered liver and bioartificial liver support systems, is still under investigation[3-6]. Before these treatments can be used clinically, their effects should be determined in large animal models. For a satisfactory animal model of FHF, seven criteria were suggested by Terblanche *et al*[10] and Fourneau *et al*[11]: (1) reversibility; (2) reproducibility; (3) death from liver failure; (4) presence of a therapeutic window; (5) a large animal model; (6) minimal hazard to personnel; and (7) a conscious animal model. Previous reports have described different animal models of FHF induced by various methods[7,12,13], but all the established models did not entirely satisfy all these criteria. Moreover, selection of a species with similar metabolic and physiological properties to humans is of importance. In this article, we describe, for the first time, the establishment of a *Macaca mulatta* model of FHF and the dynamic biochemical, pathological and imaging changes are also described.

MATERIALS AND METHODS

Chemicals

Lipopolysaccharide (LPS) from *Escherichia coli* was purchased from Sigma-Aldrich. Inc., St. Louis, MO. α-amanitin was from Alexis Biochemicals Co., Lausen, Switzerland. Gd-BOPTA (multihance) and SonoVue, contrast media for magnetic resonance imaging (MRI) and ultrasonography, respectively, were from Bracco Sine Pharmaceutical Co., Shanghai, China.

Animals

Two healthy female *Macaca mulattas*, 3 and 4 years old and with body weights of 5.5 kg and 4.6 kg, respectively, were purchased from the Safe and Secure Experimental Animal Breeding Base in Chengdu, China. They were housed in a large animal care facility with a constant temperature of 20 ℃ ± 1 ℃ and a 6 am to 6 pm light cycle. Two weeks were allowed for the animals to acclimatize to the animal facility before the study. They were fed with standard dry monkey food, washed apples and water *ad libitum*. Animal procedures and care were conducted in accordance with the institutional guidelines and in compliance with national and international laws and policies.

Study design

After premedication with ketamine (15 mg/kg im), skin preparation was performed on the posterior legs for blood collection from the saphenous vein and on the abdomen for intraperitoneal infusion and hepatic needle biopsy. LPS (1 μg/kg) and α-amanitin (0.1 mg/kg) were mixed in 50 mL physiological saline and slowly infused into the peritoneal cavity. Before their administration, blood biochemical parameters of the liver, kidney, heart and pancreas were measured, and total body MRI and ultrasonography were performed to acquire the physiological data as baseline values (expressed as "0" in the figures). After administration, blood biochemical parameters were measured every 12 h. An imaging examination was performed every 24 h.

Core needle biopsy of the liver guided by ultrasonography scan was performed 12 h after administration and repeated every 24 h. Part of the needle biopsy specimens was subjected to frozen section and oil red O staining.

The state of consciousness and behavior of the animals was observed and the hepatic encephalopathy was defined according to the West-Haven criteria in humans[14].

The two *Macaca mulattas* underwent necropsies after death, which included a full macroscopy and a histological evaluation of the liver, kidneys, lungs, heart, brain, spleen, pancreas and lymph nodes. Tissues were fixed in 10% neutral buffered formalin, sectioned at 5 μm and stained with hematoxylin and eosin (H and E).

RESULTS

Clinical features and animal survival

The animals showed a gradual increase in listlessness and loss of appetite after toxin administration. Anorexia and vomiting occurred 24 h after administration, followed by grasping disability, mental indifference, drowsiness and coma. Hepatic coma appeared at 42 h and 56 h, and decease occurred at 49 h and 70 h, respectively.

Biochemical results

We measured the liver enzymes, bilirubin and coagulation indices to determine the extent of liver injury. The data below were the average values from the two *Macaca mulatta* models when both were alive, or from one monkey when one died. After administration, the values of alanine aminotransferase and aspartate aminotransferase began to increase significantly and reached a peak at 36 h with over 300-fold and 200-fold increases from the baseline, respectively (Figure 1A), then the values sharply decreased. The total bilirubin, direct bilirubin and indirect bilirubin all increased gradually, and the final measured values exceeded a 30-fold rise from the corresponding

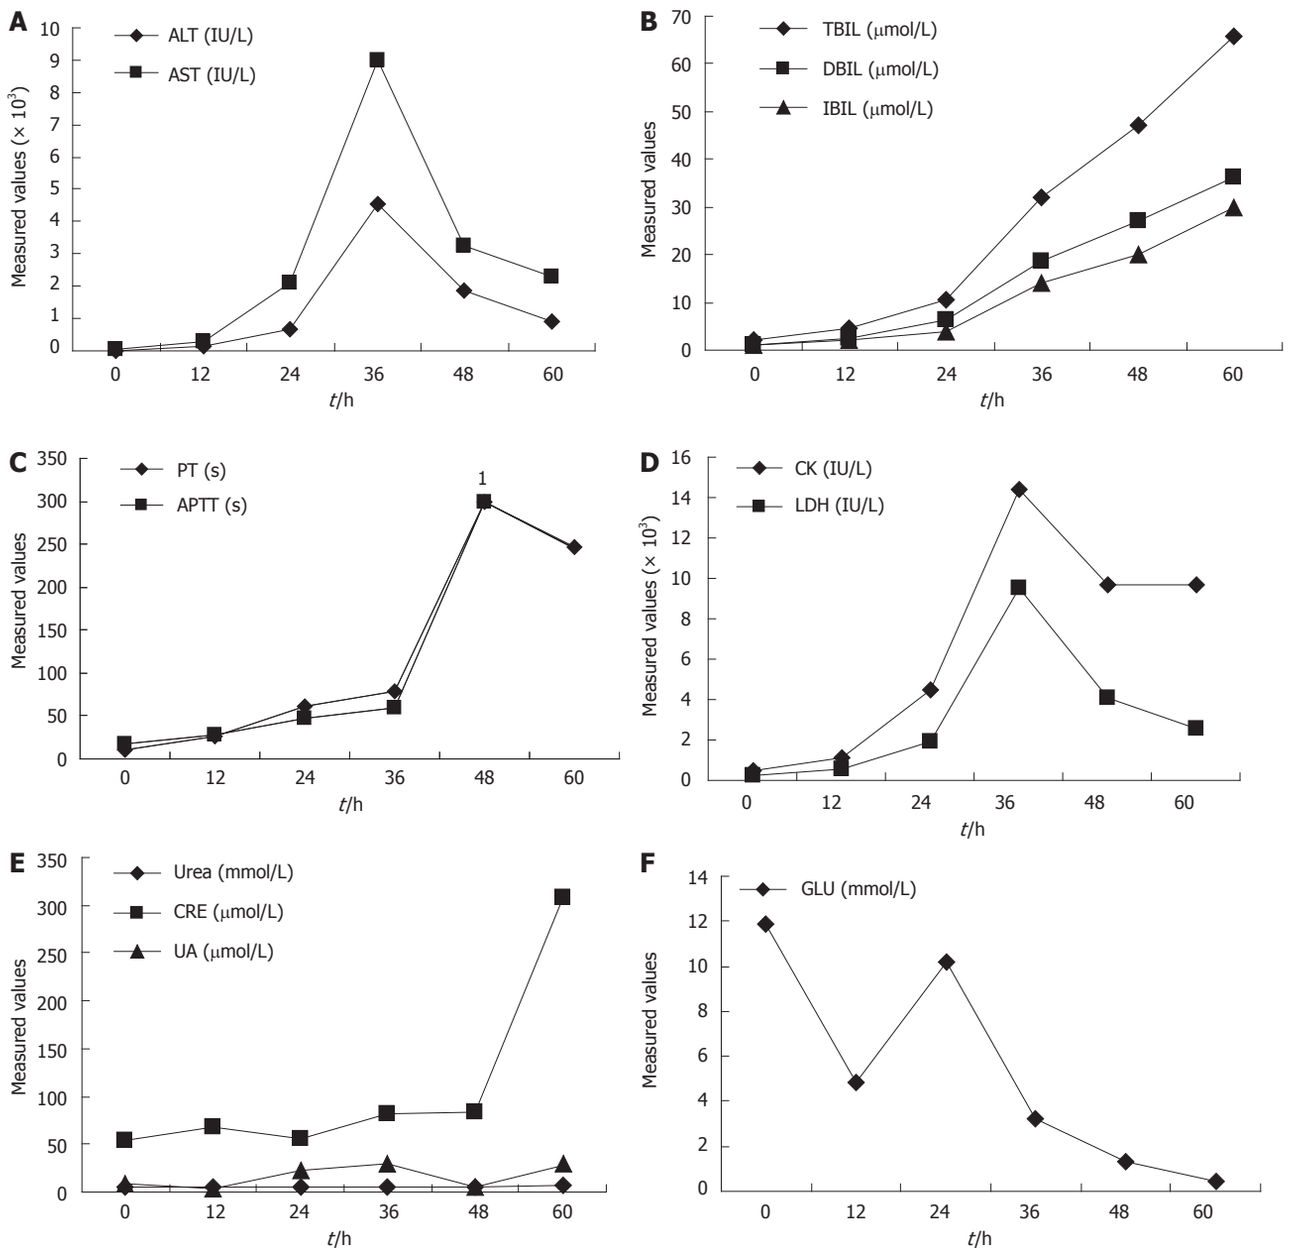

Figure 1 Blood biochemical parameters of the *Macaca mulatta* model of fulminant hepatic failure. The abscissa and ordinate represent measured time and value, respectively. ALT: Alanine aminotransferase; AST: Aspartate aminotransferase; TBIL: Total bilirubin; DBIL: Direct bilirubin; IBIL: Indirect bilirubin; PT: Prothrombin time; APTT: Activated partial thromboplastin time; CK: Creatine kinase; LDH: Lactate dehydrogenase; CRE: Creatinine; UA: Uric acid; GLU: Glucose; FHF: Fulminant hepatic failure. [1]Represents values > 300 s, which exceeded the range of the equipment, so we did not obtain an exact measurement.

baseline values (Figure 1B). The consistent increase in bilirubin and the notable decrease in enzymes after 36 h suggest the emergence of enzyme-bilirubin segregation. The prothrombin time (PT) and activated partial thromboplastin time (APTT) were also prolonged after administration. At 48 h, both the levels exceeded 300 s so that we could not measure the exact number using the machine. Even the last two measured levels of PT and APTT showed little diminution, and at 250 s were still 14- to 22-fold of the baseline (Figure 1C). The ratios of prothrombin activity were 1.18% and 5.53%.

To determine whether the toxins damaged other organs, the biochemical parameters of the heart, kidneys and pancreas were measured. Creatine kinase (CK) and lactate dehydrogenase (LDH), markers of myocardial injury, also displayed peaks at 36 h with values 27-fold and 38-fold that of baseline, respectively (Figure 1D). Of the three kidney-associated parameters, i.e., urea, creatinine (CRE) and uric acid, only the level of CRE obviously increased after 48 h (Figure 1E). The blood glucose concentration decreased (Figure 1F), and the serum amylase of the pancreas did not show any significant changes.

Imaging

MRI and ultrasonography were performed every 24 h, and the final scans were performed when the animal

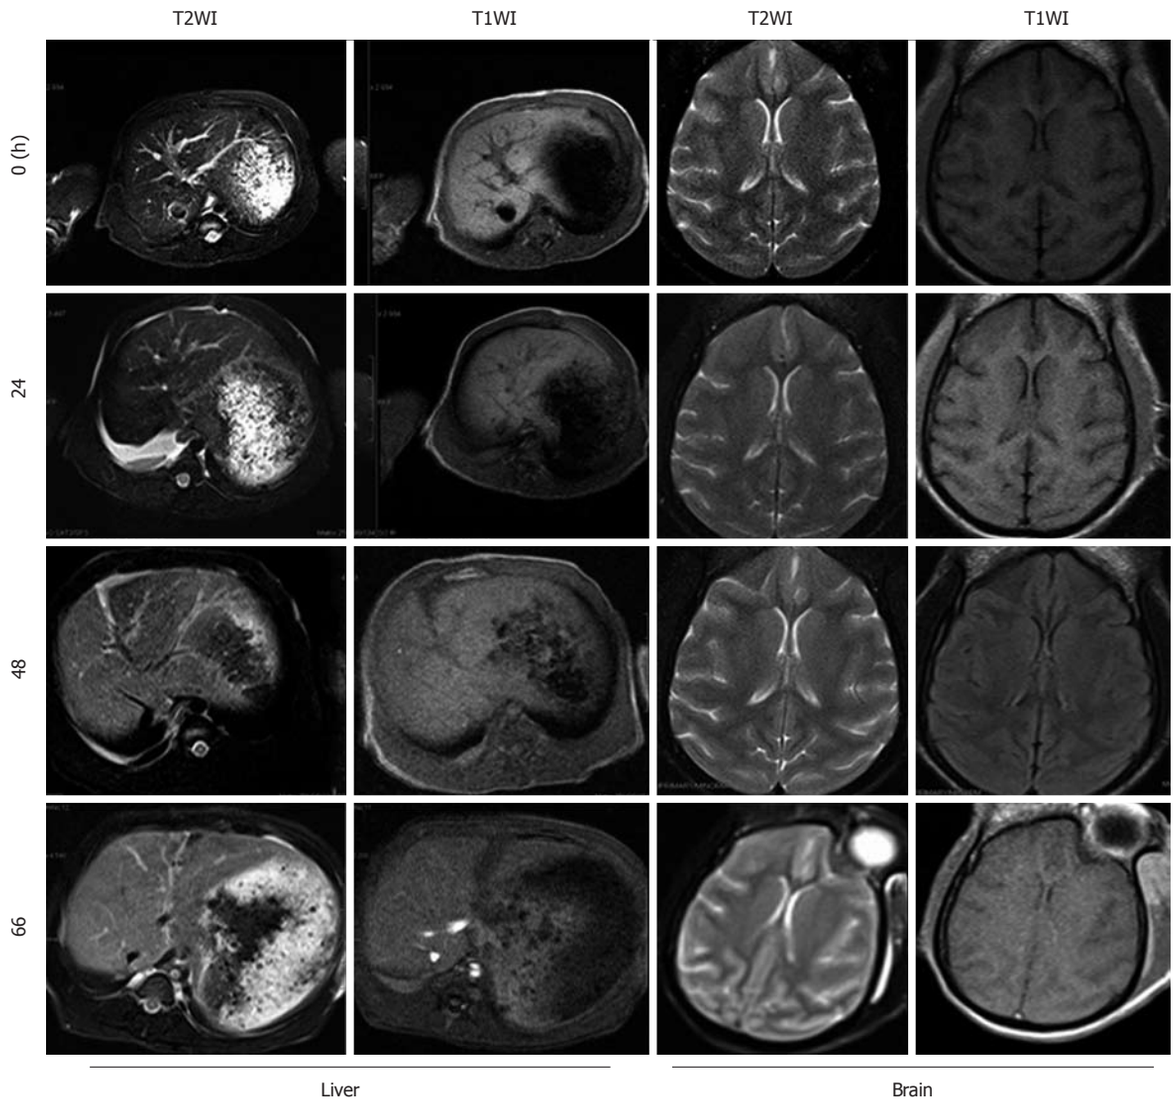

Figure 2 Magnetic resonance imaging of the liver and brain of *Macaca mulatta* model at different times. T2WI: T2-weighted imaging; T1WI: T1-weighted imaging.

died. At 24 h, MRI showed slight signals emerging in the left lobe of the liver, and Gd-enhanced T1-weighted imaging demonstrated homogeneous intensity. The signal began to increase heterogeneously in the parenchyma at 48 h, and became more heterogeneous and diffuse at 66 h, and the intensity decreased on a widespread basis in the hepatobiliary period (Figure 2). In ultrasonography, the echo of the liver parenchyma was slightly enhanced at 48 h, especially in the left lobe, and the contrast sonogram with SonoVue showed low perfusion. The hepatic artery resistance index increased. At 60 h, the echo was still enhanced slightly, but the portal vein velocity decreased and the hepatic artery resistance index increased further (Figure 3). Before 48 h, no predominant changes were found in brain MRI, but at 66 h, abnormal rhythmic signals emerged in the frontal lobe and both temporal lobes, which demonstrated hyperacute ischemia (Figure 2). We also scanned the thoracic and abdominal organs and no marked abnormality was found (data not shown).

Pathological changes

Core needle biopsies were performed at 12 h and 36 h after administration and the animals underwent necropsies after death. The main organs were evaluated, including the liver, kidneys, lungs, heart, brain, spleen, pancreas and lymph nodes, for macroscopic and histological changes.

H and E and oil red O staining showed that the liver developed severe steatosis at 36 h after toxin infusion, and in the necropsy liver, extensive parenchymal necrosis was found. The hepatic cord was dissociated, with disordered hepatocytes, and the hepatic sinusoid was extended with hyperemia. Vacuoles appeared in the cytoplasm, and patchy necrosis was found in the portal areas. In the non-necrotic areas, most hepatocytes were stained reddish-orange by oil red O. In the necropsy section, massive necrosis caused loss of almost all of the hepatocytes, and only the reticular structure remained, which is similar to the case in humans suffering from acute severe viral hepatitis (Figure 4).

With the naked eye, the livers appeared softer and smaller, with sharper and thinner edges, than the normal liver. The surface color was red and yellow, and it was a uniform yellow at the cut surface (Figure 4). Vascular dilatation and hyperemia were found on the surface of

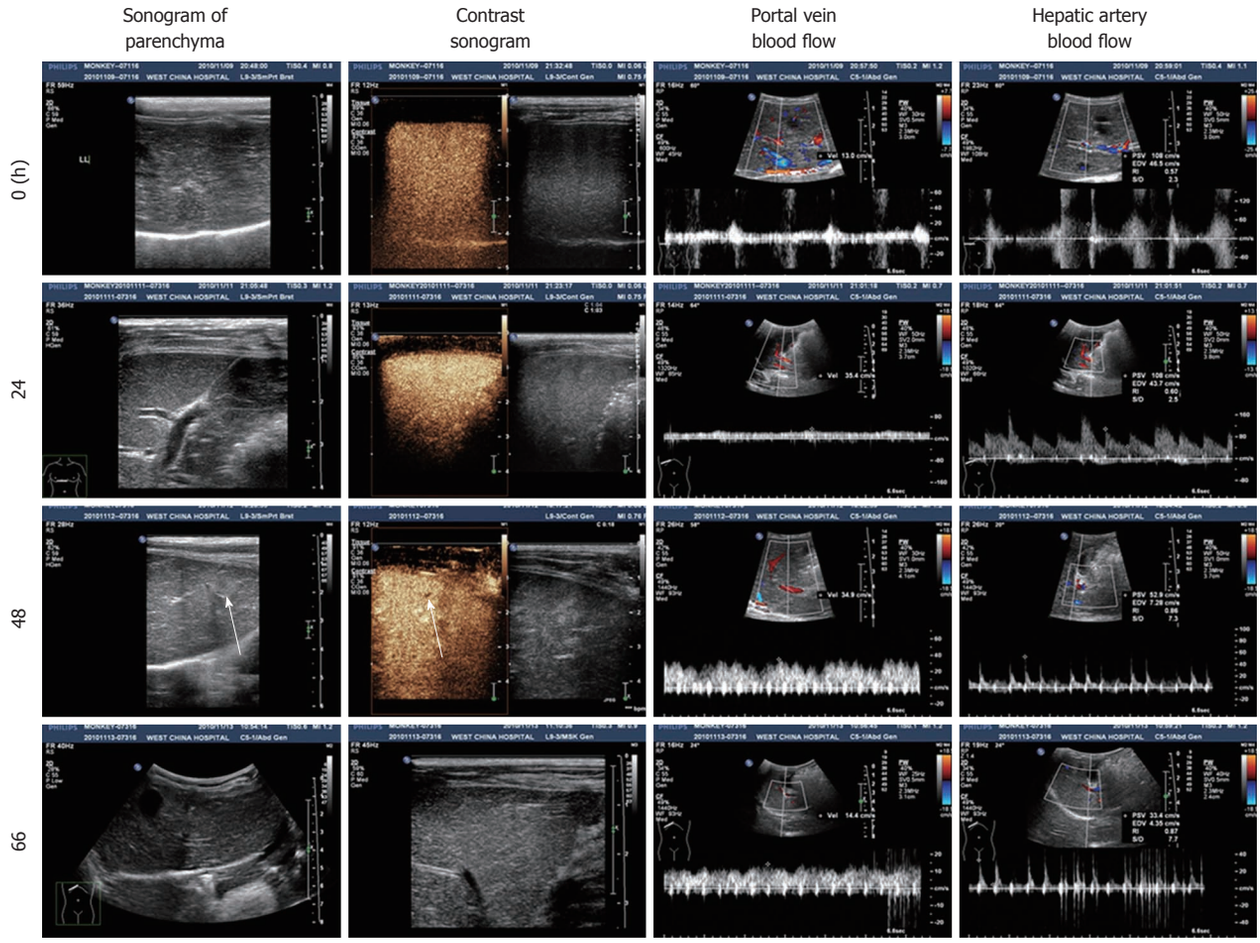

Figure 3 Liver sonogram of the *Macaca mulatta* model at different times. Arrows show a slightly enhanced echo and lower perfusion of SonoVue at 48 h.

the brain and cerebral edema was proved by widened gyri and shallowed sulci (Figure 5). Under microscopy, the superficial layer of the brain was loose, edematous and weakly stained (Figure 6).

Both kidneys showed hyperemia. The heart, spleen and pancreas did not display obvious gross changes (Figure 5). No peritoneal hyperemia, adhesions or edema in the peritoneal cavity was found. The lymph nodes located in the mesentery were enlarged and darkened. Under microscopy, they showed diffuse bleeding and lymphocytes were extensively reduced with much histiocyte proliferation. Arterioles in the lymphoid follicles were found to have hyaline degeneration. Both kidneys were also injured and demonstrated ectasia and hyperemia of the capillaries in the renal glomerulus and the stroma of the kidney tubules, and there was cellular swelling in the tubule epithelial cells. Only a wave-like change of the myocardium was found in the heart (Figure 6).

DISCUSSION

In this study, we have established, for the first time, a *Macaca mulatta* model of FHF, which satisfies all of the criteria for a large animal model of FHF proposed by Terblanche *et al*[10] and Fourneau *et al*[11], especially a conscious animal model for observation of the development of hepatic encephalopathy. All the clinical features and biochemical parameters, including liver enzymes, bilirubin as well as coagulation activity, confirmed that this model matched all the diagnostic criteria of human FHF. In addition, we dynamically examined and recorded the pathological and imaging changes in the liver and extrahepatic organs during disease progression.

Animal models of FHF are urgently needed to fully investigate the pathogenesis, progression, diagnosis and treatment of this serious disease clinically. Novel therapeutic strategies including hepatocyte transplantation, stem cell transplantation, tissue engineered liver and bioartificial liver support systems are under investigation. However, all the therapies need to be tested in an animal model before clinic use. Over the past 30 years, various animal models of FHF have been created with different methods[7,12,13], including models using rodents[15-18], dogs[19-23] and pigs[24,25]. However, differences in the metabolic and physiological properties in these distantly relative species restricted the application of the results to humans. As the closest relative to the human, the primate possesses much more similar metabolic and physiological properties, and a primate with FHF is considered to be the best large animal model for use in basic and pre-clin-

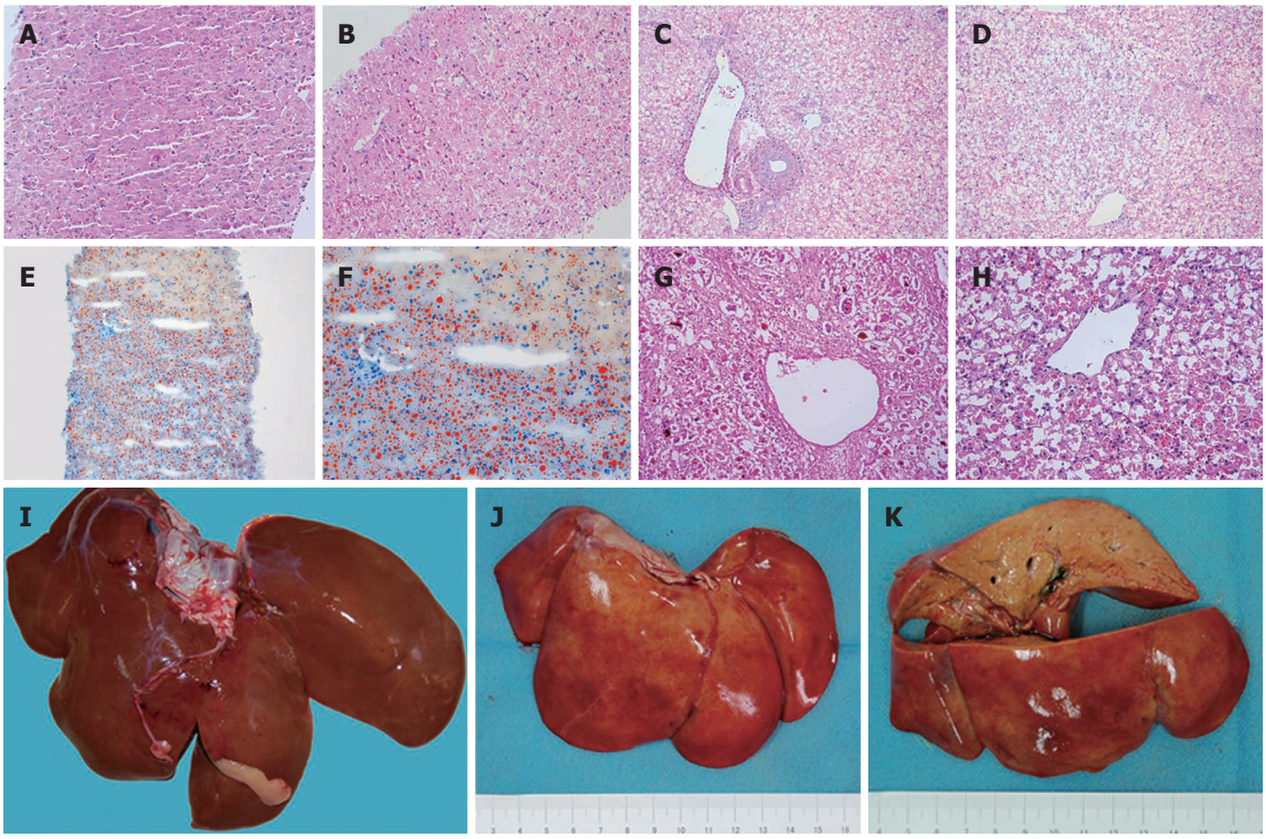

Figure 4 Histopathological changes of the liver. A: Tissue from needle biopsy at 12 h. Changes in organizational structure and cell morphology were not obvious [hematoxylin and eosin (H and E) stain, × 200]; B: Tissue from needle biopsy at 36 h. Vacuoles appeared in the hepatocellular cytoplasm (H and E stain, × 200); C, D: Tissue from necropsy after death at 70 h. Hepatocellular necrosis was distributed in the portal area (C) and central area (D) (H and E stain, × 200). Massive necrosis caused almost all of the hepatocytes to be lost, and only the support structure remained; E: Frozen tissue from needle biopsy at 36 h. The extensive reddish-orange color suggested serious fatty degeneration (oil red O stain, × 100); F: Frozen tissue from needle biopsy at 36 h. In the borderline between necrosis and steatosis, the reddish-orange color was obvious (oil red O stain, × 200); G, H: Comparison of pathological changes of fulminant hepatic failure in humans induced by viral hepatitis (G) and a *Macaca mulatta* model induced by α-amanitin and lipopolysaccharide (H) (H and E stain, × 200); I: Normal liver of *Macaca mulatta* for comparison; J: The surface view of the experimental liver on necropsy appeared red and yellow; K: The cut surface view of the experimental liver was uniformly yellow.

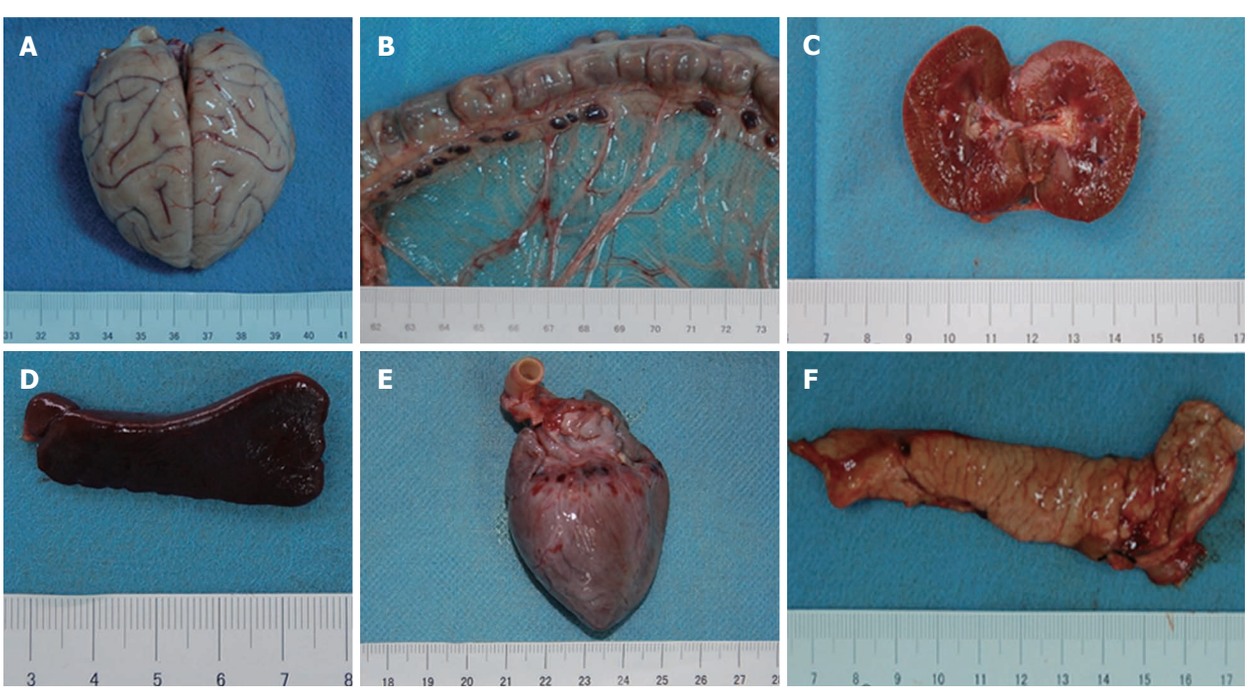

Figure 5 Other main organs on necropsy. A: The brain with cerebral edema; B: Mesenteric lymph nodes enlarged and beaded; Hyperemia of the kidney (C), spleen (D), heart (E), and pancreas (F) without obvious gross lesions.

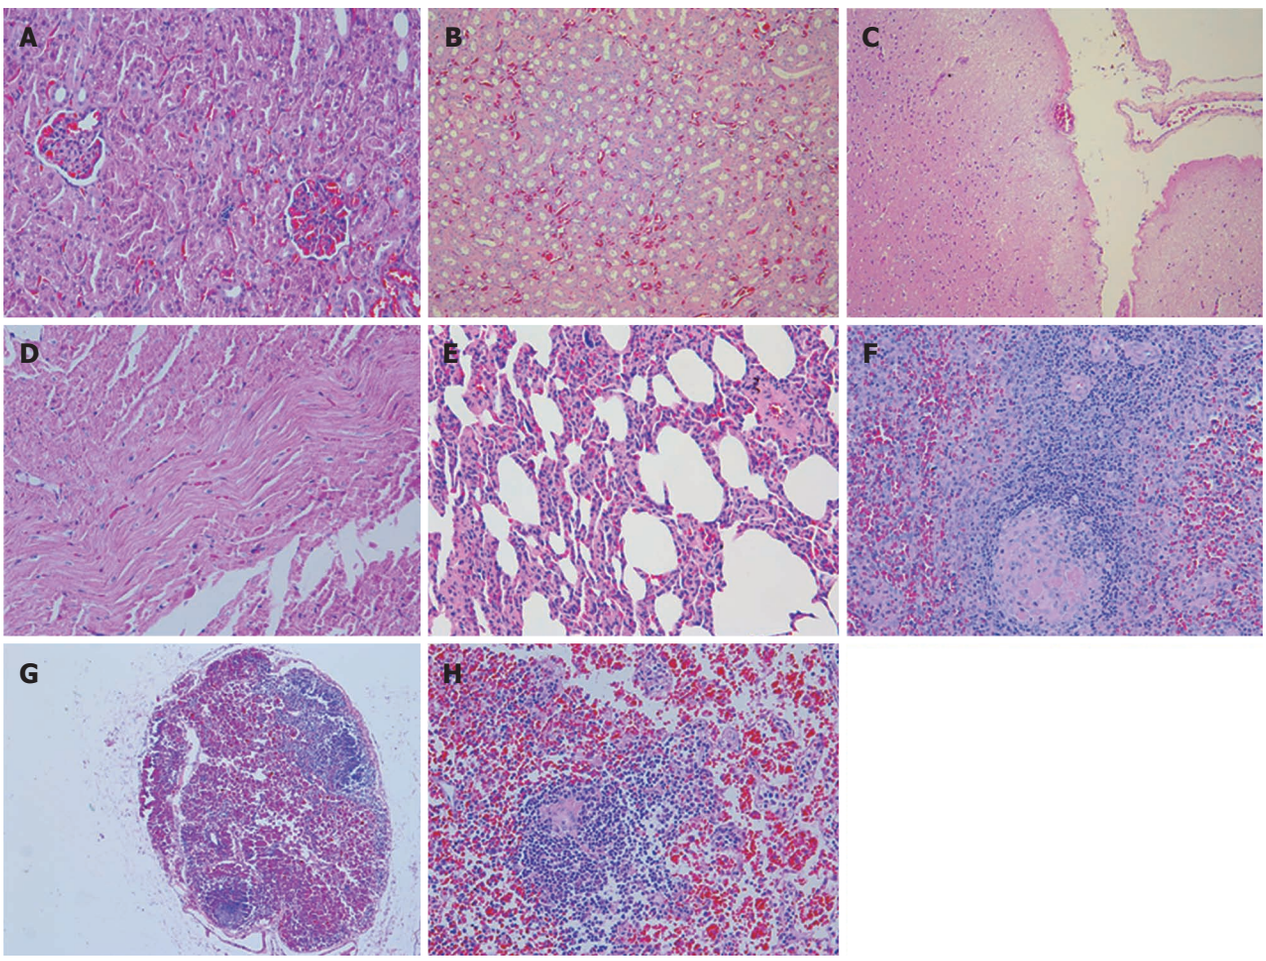

Figure 6 Histopathological changes of other organs. A: Ectasia and hyperemia of capillaries in the renal glomerulus [hematoxylin and eosin (H and E) stain, × 200]; B: Widespread hyperemia of capillaries in the renal stroma and cellular swelling in the tubular epithelial cells (H and E stain, × 100); C: Weak staining in the superficial layer of the brain suggest cerebral edema (H and E stain, × 100); D: Wave-like changes in the myocardium (H and E stain, × 200); E: Hyperemia of capillaries in the stroma and hyaline changes in the arterioles of the lung (H and E stain, × 200); F: Hyaline changes in the central artery of the spleen (H and E stain, × 200); G: Widespread reduction in lymphocytes and hemorrhage in the mesenteric lymph nodes (H and E stain, × 50); H: Hemorrhage and histiocyte proliferation in the mesenteric lymph nodes. Hyaline change appeared in the vessel wall of lymphoid follicles (H and E stain, × 200).

ical research. To the best of our knowledge, our *Macaca mulatta* model of FHF is the first large primate model in this field.

Methods used to induce the FHF models included surgical intervention and hepatotoxin administration. Total or partial hepatectomy and hepatic ischemic injury were widely used, but these relied on extensive surgical expertise and were influenced by individual variations in the animals. Hepatotoxins, which induce massive hepatic necrosis, are widely used in the establishment of a FHF model. Acetaminophen and galactosamine were the two most widely used hepatotoxins[17,19,22,26-31], and in some studies, carbon tetrachloride[32], thioacetamide[33,34], azoxymethane[35,36], concanavalin A[37] and amanita phalloides[38,39] were also employed. However, a lack of standardization, especially a lack of reproducibility, is the major disadvantage of models induced by acetaminophen[7,10]. The high costs restrict the application of galactosamine in large-scale models[40]. Amatoxin, a polypeptide extracted from a hypertoxic mushroom, has been used as a hepatotoxin in pigs with an endotoxin (LPS), and this model was reported to satisfy the criteria of near-universal mortality from highly reproducible hepatic failure, of mortality occurring in a defined time range, of damage specific to the liver, and of potential for recovery of the damaged liver[38,39]. In our preliminary experiment, LPS (2.25 μg/kg) and α-amanitin (0.225 mg/kg) were injected in a *Macaca mulatta* through a branch of the mesenteric vein by laparotomy at the dose converted from that used in pigs, which received LPS and α-amanitin at a dose of 1 μg/kg and 0.1 mg/kg, respectively[38,39]. However, the animal died within 8 h. We supposed that the direct and undiluted toxic effects to the liver might be the main cause of death and the surgery might promote the death of the *Macaca mulatta*. Thus, we reduced the dose of the two hepatotoxins to the level used in pigs, which was nearly half of our preliminary dose. We then improved the administration pathway by slow intraperitoneal infusion of the toxins diluted in 50 mL physiological saline instead of direct portal injection. Our results showed that the animals survived for at least 49 h and all the features of FHF were clearly presented. Most importantly, the

prolonged disease course ensures a wide therapeutic window. It is possible that intraperitoneal infusion of toxins could lead to severe peritonitis. Fortunately, we did not find any symptoms and signs of peritonitis, either in imaging examination or in necropsy.

Induced by α-amanitin and LPS, the hepatocytes presented severe steatosis first and massive necrosis at the end stage of FHF, which is similar to the case in humans suffering from acute severe viral hepatitis. Serum parameters, including hepatic enzymes, bilirubin, and coagulation activities, as well as serum ammonia, are often considered as the markers representing the level of damage of hepatocytes, since a biopsy is seldom carried out because of the restriction of invasive operation and bleeding. In fact, the hepatic injury during the course of FHF still needs direct confirmation. Our model offers an appropriate model to obtain real-time pathological changes in the hepatocytes, which makes it valuable for study of clinical features based on the pathological changes.

We also monitored the continuous alteration of the liver by imaging, and this is the first report on dynamic MRI of the liver during the course of FHF, either in patients or in an animal model. Combining the biopsy and the MRI, it is feasible to establish the diagnostic criteria of the damage level based on the MRI values, thus offering a non-invasive strategy to reveal the level of hepatic injury.

Hepatic encephalopathy is one of the most important clinical features and causes of death of FHF. Being consanguineous with humans, the *Macaca mulatta* presents similar behavior and consciousness to humans suffering from FHF. In addition, the brain volume and the similar gyrus outline make it suitable for MRI examination of the cerebral edema, ischemia or infarction. In our model, the progressing symptoms of listlessness, anorexia, grasping disability, mental indifference, drowsiness and coma are fully developed and thoroughly recorded. The behavior and conscious alterations, combined with the MRI and pathological changes, make it a valuable model for further investigation of the pathogenesis and pathophysiology of hepatic encephalopathy, which could not be reproduced in humans or in any other animals. As a noninvasive means of detection, MRI may be an appropriate strategy to monitor the progression of the hepatic encephalopathy. The first objective assessment of MR brain changes specific to hepatic encephalopathy was made in the early 1990s. It was noted that in patients with cirrhosis, the basal ganglia appeared hyperintense on T1-weighted MRI[41]. However, continuous data are still absent to reveal the correlation between the degree of encephalopathy and the MRI parameters during the course of FHF. With our model, it is feasible to obtain the dynamic imaging alterations during the whole course of hepatic encephalopathy.

It is necessary to rule out that animal death was induced by extrahepatic organ failure. In our experiment, the main extrahepatic organs were also evaluated. The increasing of CRE happened late, suggesting that the damage to the kidneys was a result of hepatorenal syndrome rather than direct toxin damage. The values of CK and LDH increased immediately after toxin administration, but no marked abnormality was found by echocardiogram and no myocardial necrosis was observed in histopathological examination. The cause of the increased CK and LDH still needs clarification. The lesion of the mesenteric lymph nodes might be associated with the toxins, which needs further study. We did not find any pathological evidences indicating cell injury of the lung and pancreas. Above all, we can conclude that the toxicity of intraperitoneal infusion of amatoxin and endotoxin is liver-specific and animal death is directly correlated with FHF and not extrahepatic organ failure.

We describe, for the first time, a *Macaca mulatta* model of fulminant hepatic failure, which satisfies all of the criteria for a large animal model of FHF[10,11]. With similar metabolic and physiological properties to humans, our primate animal model of FHF offers a valuable model to be used for investigation of the pathophysiology of FHF and for evaluation of potential medical therapies. Compared with other animals, primate models are more expensive, and the ethics of using such animals should be taken into consideration.

COMMENTS

Background

Fulminant hepatic failure (FHF) is an uncommon and challenging clinical disease characterized by sudden and severe hepatic injury and dysfunction, and it results in many different symptoms and complications with a high mortality. Previous reports have described different animal models of FHF induced by various methods, but all the established models did not entirely satisfy all the criteria.

Research frontiers

Animal models of FHF are urgently needed to fully investigate the pathogenesis, progression, diagnosis and treatment of this serious disease in the clinic. Recently, more studies have focused on large animal models and therapy for FHF. Novel therapeutic strategies including hepatocyte transplantation, stem cell transplantation, tissue engineered liver and BAL support systems are under investigation. Also, various animal models of FHF have been created with different methods, including models using rodents, dogs and pigs. However, differences in metabolic and physiological properties in these distantly relative species restricted the application of the results to humans. No primate animal model with FHF has been created before.

Innovations and breakthroughs

In this article, the authors describe, for the first time, a *Macaca mulatta* model of FHF, which satisfies all of the criteria for the large animal model of FHF. It is important that with the model, it is feasible to obtain dynamic imaging and pathologic alterations, and this is the first report about dynamic MRI of the liver during the course of FHF, either in patients or in animal models. Though lipopolysaccharide and α-amanitin were reported to induce a pig model of FHF, the main extrahepatic organs were not evaluated. In this article, the authors improved the administration pathway and evaluated the main extrahepatic organs.

Applications

The primate animal model of FHF offers a valuable model to be used for investigation of the mechanism of FHF and for evaluation of potential medical therapies.

Terminology

Macaca Mulatta: A species of the genus *MACACA* inhabiting India, China, and other parts of Asia. The species is used extensively in biomedical research and adapts very well to living with humans.

Peer review

The authors show an appropriate large primate model of fulminant hepatic failure. They described the rigid data of hepatic failure by biochemical results, imaging, and pathological changes. The primate animal model of fulminant hepatic failure has clinical benefit because of similar metabolic and physiological properties to human. This paper is an interesting and instructive manuscript. It is well written.

Abstract

AIM: To investigate the impact of chronic fatigue on disease-related worries in inflammatory bowel disease (IBD) and the potential multicolinearity between subjective questionnaires.

METHODS: Patients in remission or with mild-to-moderate disease activity completed the fatigue questionnaire (FQ), the rating form of IBD patient concerns (RFIPC), the Short-Form 36 (SF-36), and IBD questionnaire (N-IBDQ). In addition, clinical and epidemiological data were obtained.

RESULTS: In total, 140 patients were included; of which 92 were diagnosed with ulcerative colitis and 48 with Crohn's disease. The mean age of patients with chronic fatigue was 44.2 years (SD = 15.8) and for non-fatigued patients was 44.7 years (SD = 16.0). Chronic fatigued patients had clinically significantly increased levels of disease-related worries, as measured by Cohen's *d* effect size. Worries about having an ostomy bag, loss of bowel control, and energy levels were most prominent in both chronic fatigued and non-chronic fatigued IBD patients. Variance inflation factor (VIF) and tolerance indicated that there were no problematic multicolinearity among the FQ, RFIPC, SF-36 and N-IBDQ responses (VIF < 5 and tolerance > 2).

CONCLUSION: Chronic fatigue is associated with increased levels of disease-related worries and concerns in IBD. Increased levels of worries were also associated with impaired health-related quality of life.

Key words: Fatigue; Worries; Health-related quality of life; Patient reported outcome; Inflammatory bowel disease

INTRODUCTION

Inflammatory bowel disease (IBD) includes ulcerative colitis (UC) and Crohn's disease (CD). Both UC and CD are chronic, recurrent diseases of the gastrointestinal tract, with symptoms that include abdominal pain, frequent bowel movements, and rectal bleeding[1,2]. Traditionally, these diseases have been defined as abnormalities in the structure and function of both organs and tissues[3]. However, given that IBD is associated with impaired health-related quality of life (HRQoL), increased fatigue, and increased worrying regarding the potential consequences of the disease[4-7], this definition seems too restrictive. The concept of illness might therefore be broader, embodying the subjective experiences of reduced health and bodily function[3].

Living with chronic illness can be challenging, and individual responses to these challenges vary widely[8]. Several HRQoL studies have found that many patients with IBD tend to do well[9]. However, there are subgroups of patients - such as patients with more severe disease or anxiety - who seem to be particularly affected[4,5,9]. It was recently reported that IBD patients with chronic fatigue (CF) (defined as an elevated fatigue level of a duration longer than six months) had clinically significant reductions in HRQoL, compared to patients without CF[10]. Thus, an important aspect of measuring subjective health is to identify patients who are most severely affected.

Both generic (i.e., irrespective of illness/condition) and disease-specific HRQoL questionnaires have been developed[11-13]. In addition, questionnaires such as the rating form of IBD patient concerns (RFIPC) and the fatigue questionnaire (FQ) are used to quantify other aspects of living with chronic illness[7,14]. We hypothesised that measuring aspects such as worries/concerns (RFIPC) and fatigue (FQ) might help us to identify subgroups of patients that tend to have a poorer outcome. Potentially, however, there might be areas of overlap between the various questionnaires, which is often referred to as multicolinearity. Multicolinearity refers to a situation wherein predictor variables in a regression model are strongly correlated and, consequently, that variables included in the model are closely related.

The primary aim of this study was to examine the impact of chronic fatigue on disease-related worries in IBD. In addition, we wanted to investigate whether the potential association between worries, fatigue and HRQoL in IBD exhibit multicollinearity.

MATERIALS AND METHODS

Subjects

Patients, who were over the age of 18 years, had IBD that was previously verified clinically, endoscopically, or histologically, and who were either in remission or with mild-to-moderate disease activity [defined as Simple Clinical Colitis Activity Index (SCCAI)[15] or Simple Crohn's Disease Activity Index (SCDAI)[16] score of less than 10], were eligible for inclusion in this study. Patients were excluded if they had cognitive impairment, were deemed unlikely to comply with the study procedures, or if they participated in another study. Participants were consecutively recruited from three outpatient clinics in South-Eastern Norway (the counties of Østfold and Hedmark) during routine follow-up visits. At each of the centre, a senior gastroenterologist was in charge of the study protocol. The inclusion period was from August 23, 2005 to January 29, 2007.

Clinical and sociodemographic data

Sociodemographic variables were gathered by interview, and data regarding clinical status and symptoms were obtained from laboratory tests, medical records and disease activity indices (SCCAI/SCDAI)[15,16]. In addition, we asked the patients to complete a symptom-based questionnaire that graded their self-perceived IBD symptoms during the previous 14 d, using the following categories; no symptoms, mild symptoms (did not interfere with everyday activities), moderate symptoms (interfered with everyday activities and may have resulted in sick leave), and severe symptoms (unable to perform everyday activities, on sick leave, or hospitalized)[5].

Each patient's phenotype was classified according to the Vienna Classification for CD patients, as the Montreal Classification did not exist when the study protocol was designed. The UC patients were classified into three subgroups: proctitis, left-sided colitis (with inflammation up to the splenic flexure), and extensive colitis (with inflammation beyond the splenic flexure).

The information regarding fatigue was collected with the FQ[14], the generic HRQoL with the Short-Form 36 (SF-36)[11], the disease specific HRQoL with the Norwegian version of the IBD questionnaire (N-IBDQ)[17], and disease-related worries and concerns with the RFIPC[7] (Table 1). The questionnaires were self-administered by the patients at the various centres, following a standardized procedure, which allowed the patients to fill out the questionnaires in the peace and quiet of the hospital's outpatient clinic.

Questionnaires

The RFIPC: The RFIPC is a disease-specific questionnaire that was developed by Drossman *et al*[7]. This questionnaire rates various important worries and concerns that are raised by IBD patients. The questionnaire consists of the 25 most frequently reported concerns reported by IBD patients, with every item framed in the same style: "Because of your condition, how concerned are you with…?" The responses were scored on a 100-mm horizontal visual analog scale. A score of 0-mm represents no worries/concerns, and a score of 100-mm represents the highest possible worries and concerns. The mean scores of all 25 items yields the "sum score". The RFIPC has been translated into Norwegian and validated (Jelsness-Jørgensen LP, Moum B, Bernklev T. Worries and concerns among inflammatory bowel disease patients followed prospectively over one year. Submitted:

Table 1 Main characteristics of the questionnaires used in this study

Questionnaire	Number of items and dimensions	Main characteristics
SF-36 Ware *et al*[11]	36 items, divided into 8 dimensions	Measure generic HRQoL Scale scores from 0-100, with higher scores indicating better HRQoL
N-IBDQ Bernlev *et al*[17]	32 items, divided into 5 dimensions	Measure disease-specific HRQoL Scale scores from 32-224, with higher scores indicating better HRQoL
FQ Chalder *et al*[14] Jelsness-Jørgensen *et al*[10]	11 items, divided into 2 dimensions The FQ contains 2 items asking about duration and extent of fatigue symptoms	Measure both physical and mental fatigue Scale scores from 0-33 with higher scores indicating higher levels of fatigue In addition scored as a dichotomized scale where original scores 0 + 1 = 0 and 2 + 3 = 1 Chronic fatigue defined as a score of ≥ 4 on the dichotomized scale and duration of fatigue symptoms ≥ 6 mo
RFIPC Drossman *et al*[7]	25 items, divided into 6 dimensions	Measure the 25 most frequently reported disease-related worries/concerns by IBD patients

IBD: Inflammatory bowel disease; SF-36: Short-Form 36; N-IBDQ: IBD questionnaire (Norwegian version); FQ: Fatigue questionnaire; RFIPC: Rating form of IBD patient concerns; HRQoL: Health-related quality of life.

Gastroenterol Res Pract).

Factor analysis of the Norwegian version of the RFIPC yielded six factors. F1: Impact of disease (e.g., financial difficulties/energy/loss of bowel control); F2: Expectancy (e.g., developing cancer/dying early); F3: Treatment (e.g., effects of medication); F4: Intimacy (e.g., ability to perform sexually); F5: Stigma (e.g., feeling dirty/smelly); and F6: Complications (e.g., undergoing surgery/ostomy bag placement).

FQ: The FQ was developed by Chalder *et al*[14] and consists of 11 items that are divided into two main dimensions: physical fatigue (PF), which contains seven items, and mental fatigue (MF), which contains four items. The available responses included four options: 0 = better than usual, 1 = no more than usual, 2 = worse than usual, and 3 = much worse than usual. A higher score reflects a higher level of fatigue. Combining the scores of PF and MF yields the total fatigue score, with a maximum possible scale score of 33. The scale scores of the FQ were also scored on a dichotomized scale (0 = better than usual and no more than usual; 1 = worse than usual and much worse than usual). In addition to measuring episodic fatigue (irrespective of the duration of symptoms), the FQ contains two questions regarding the duration and extent of fatigue symptoms. Based on the results of the original validation study, the Norwegian validation study, and general consensus[14,18,19], CF was defined as dichotomized scores ≥ 4 and duration > 6 mo. The FQ was recently validated for use in IBD[6].

SF-36: The SF-36 is a generic, self-administered questionnaire containing 36 questions[11] that are divided into eight multi-item scales consisting of: physical functioning, role limitations due to physical problems, bodily pain, general health, vitality, social functioning, role limitations due to emotional problems, and mental health (MH). For each question, the raw score was coded and transformed into a scale from 0 to 100, with 0 and 100 representing the lowest level and highest level of function, respectively. The SF-36 has been validated by others[20]. Missing data were treated following published recommendations: if data for half of the items within a scale or fewer were missing, they were replaced by the mean value of the respondent's completed items in the same scale in accordance with the SF-36 scoring algorithms[21].

N-IBDQ: The IBDQ is a disease-specific questionnaire that was developed by Irvine[12,13]. The original version consists of 32 items divided into four dimensions: bowel symptoms (e.g., loose stools or abdominal pain), systemic symptoms (e.g., fatigue or altered sleep patterns), social function (e.g., work attendance) and emotional function (e.g., anger or depression). The Norwegian validation study (N-IBDQ) revealed a five-dimensional structure: emotional function-1 (fatigue, energy), bowel function-1 (stool consistency and pattern), bowel funtion-2 (bowel pain and discomfort), social function (work attendance, cancelling social events) and emotional function-2 (worries)[17]. All of the responses were scored on a 7-point Likert Scale, with a score of 7 representing no problems and a score of 1 representing severe problems. This gives a possible score range of 32-224, with a higher score reflecting improved HRQoL[12,13,17].

Statistical analysis

To assess the characteristics of the patients, we used descriptive analyses and frequencies. A student's *t* test was used to evaluate the differences in the distribution of epidemiological and clinical variables between the diagnostic groups.

To test potential associations between the RFIPC, FQ, N-IBDQ and SF-36 questionnaires, both bivariate correlation analysis with spearman's ρ and linear regression analysis were used. In addition, the latter analysis was used to explore potential multicollinearity. A variance inflation factor (VIF) greater than 5 and a reciprocal tolerance value of less than 0.20 were defined as indicative of colinearity in accordance with published recommendations[22,23]. We chose to analyse the RFIPC sum score, the FQ and N-IBDQ total score as dependents only, to reduce the number of dimensions tested.

Table 2 Main clinical/sociodemographic characteristics *n* (%)

	UC (*n* = 92)	CD (*n* = 48)
Age, (yr), mean ± SD	46.9 ± 5.8	40.0 ± 15.0
Age range, (yr)	20-82	19-69

L1 terminal ileum		11 (22.9)
L2 colon		17 (35.4)
L3 ileocolon		18 (37.6)
L4 upper GI		2 (4.1)
Perceived IBD symptom score		
No symptoms	23 (25.0)	9 (18.8)
Mild symptoms	41 (44.6)	22 (45.8)
Moderate symptoms	25 (27.2)	13 (27.1)
Severe symptoms	3 (3.2)	4 (8.3)

UC: Ulcerative colitis; CD: Crohn's disease; IBD: Inflammatory bowel disease; GI: Gastrointestinal.

To control for and eliminate the effect of potential confounding factors that are known to influence RFIPC scores, age, gender, and educational level were entered as covariates through univariate analysis of variance. Perceived IBD symptoms were hypothesized to affect the RFIPC scores and we therefore additionally chose to correct for this factor as well. The effect size was calculated with Cohen's *d*[24]. Operational definitions of 0.2, 0.5 and 0.8 were categorized as small, medium and large effect sizes, respectively[24].

All tests were 2-sided with a 5% significance level. All statistics were performed using the Predictive Analytics Software, PASW, version 18.0 (IBM Corporation, Route 100 Somers, NY 10589).

Ethical considerations

This study was performed in accordance with the principles of the Helsinki declaration and approval was obtained from the Regional Ethics committee and the Norwegian Data Inspectorate.

RESULTS

One hundred and forty-four patients who were diagnosed with either UC or CD gave their written informed consent for participation in the study. One patient was excluded due to severe disease activity at inclusion (SCDAI > 10), one patient withdrew from the study after a few weeks, and two patients were excluded from analysis due to incomplete responses to the questionnaires. A total of 140 patients provided complete data sets and were suitable for statistical analysis.

Epidemiological and clinical characteristics

The CD patients were significantly younger than the UC patients ($P = 0.014$). There were no significant differences in the perceived IBD symptoms or the duration of disease between the two diagnostic groups. Twenty of the 92 (22%) UC patients and 14 of the 48 (29%) CD patients were judged to have CF. There were no significant differences in age, gender, disease duration or educational level between CF and non-CF patients. However, the perceived IBD symptoms were more severe in CF than in non-CF patients ($P < 0.01$). The primary characteristics of the participants are presented in Table 2.

CF and RFIPC scores

CF was associated with significantly higher RFIPC scores in one of the six dimensions in CD and in five of the six dimensions in UC. In addition, the RFIPC sum score was significantly higher in UC patients with CF compared to those without CF (Table 2). Among the individual RFIPC items, the differences between UC patients with and without CF were most pronounced in worries regarding loss of bowel control, developing cancer, dying early, energy level, being a burden to others, having surgery, or an ostomy bag ($P < 0.01$ for all items). In addition, the scores for the following RFIPC items were significantly higher in CD patients with CF compared to those without CF: ability to achieve full potential, financial difficulties, and energy level ($P < 0.05$ for all items). When comparing RFIPC dimensional scores for UC patients with CF to CD patients with CF, the analysis revealed no statistical difference. Only one of the twenty-five individual RFIPC items (worries about pain and suffering) was significantly different between UC and CD patients with CF, with CD patients reporting more worries in this item ($P < 0.01$).

Effect size (Cohen's *d*) is a measure of the estimated magnitude of a relationship between two variables and is calculated by subtracting the mean dimensional RFIPC scores of CF patients from non-CF patients, then dividing by the common σ of both groups. The analysis revealed that the RFIPC factors that were statistically significant in CF *vs* non-CF patients - regardless of their IBD diagnosis - also produced a large Cohen's *d* ($d > 0.80$) (Table 3). The analysis further revealed that although they did not reach statistical significance, the numerical differences produced small-to- medium effect sizes. Among the CD group, the differences between CF and non-CF patients resulted in a medium effect size ($d > 0.50$) in the RFIPC sum score, whereas the effect size in the remaining five out of six dimensions were small ($d > 0.20$). Among the UC group, one out of the six RFIPC factors did not differ significantly between CF and non-CF patients, producing a small Cohen's *d* ($d > 0.20$).

RFIPC: Rating form of inflammatory bowel disease patient concerns; CD: Crohn's disease; UC: Ulcerative colitis; CF: Chronic fatigue; IBD: Inflammatory bowel disease. Significance levels are between patients reporting CF or not: [a]$P \leqslant 0.05$, [b]$P \leqslant 0.01$, [c]$P \leqslant 0.001$.

were adjusted for the covariates age, gender and education, statistically significant differences were reproduced in the same RFIPC factors as in the raw, unadjusted analysis for both the UC and CD patients. Furthermore, when controlling for the perceived IBD symptom score, the significance level increased in two of the six factors (expectancy/stigma) for the UC group. One RFIPC factor (intimacy) in the UC group changed from non-significant to significant. Among the CD patients, controlling for perceived IBD symptoms had only a minor effect.

The correlation between RFIPC sum score, total fatigue, N-IBDQ total score and subdimensions of the SF-36 questionnaire

In both the UC and CD patient groups, increased RFIPC sum scores were associated with higher fatigue levels (measured as total fatigue) and reduced HRQoL (Table 5).

Table 5 Correlation (Spearman's ρ) between rating form of inflammatory bowel disease patient concerns sum, fatigue questionnaire sum, Norwegian inflammatory bowel disease questionnaire total and Short Form 36 dimensions

	CD (*n* = 48) RFIPC sum score	UC (*n* = 92) RFIPC sum score

RFIPC: Rating form of inflammatory bowel disease patient concerns; CD: Crohn's disease; UC: Ulcerative colitis; FQ: Fatigue questionnaire; TF: Total fatigue; N-IBDQ: Norwegian inflammatory bowel disease questionnaire; SF-36: Short Form 36; PF: Physical functioning; RP: Role physical; BP: Bodily pain; GH: General health; VT: Vitality; SF: Social functioning; RE: Role emotional; MH: Mental health.

The latter showed a negative Spearman's ρ both for N-IBDQ and the SF-36 subdimensions. In general, these associations were stronger for the UC group than for the CD group.

Multicolinearity

Testing for multicollinearity revealed satisfactory values of both the VIF and tolerance (Table 6). The VIF was below the limit of 5 and the tolerance above the crucial threshold of 0.2 for both the UC and CD group. In the CD group, the ranges for the VIF and tolerance were 1.6-4.9 and 0.21-0.61, respectively. In the UC group, the ranges of the VIF and tolerance were 1.9-4.1 and 0.24-0.54, respectively.

DISCUSSION

The ramifications of IBD on patients subjective health has been thoroughly studied, identifying both a sub-

RFIPC: Rating form of inflammatory bowel disease patient concerns; CD: Crohn's disease; UC: Ulcerative colitis; TF: Total fatigue; CF: Chronic fatigue; N-IBDQ: Norwegian inflammatory bowel disease questionnaire; SF-36: Short Form 36; PF: Physical functioning; BP: Bodily pain; VT: Vitality; SF: Social functioning; VIF: Variance inflation factor.

group of patients with a worsening in HRQoL scores and other subgroups of patients with HRQoL scores that are comparable to the general population[4,5,9,15]. This division of patient responses to IBD can partly be explained by demographic differences and differences in clinical variables[4,5,9,15]. Recently, CF was reported to be at least twice as prevalent in IBD as in the general population, and CF has been reported to lead to clinically significant reductions in HRQoL[6,10].

In the present study, we hypothesized that chronic fatigue might influence the level of disease-related concerns in IBD patients, and we found significant differences in the RFIPC scores between UC patients with CF and UC patients without CF. Although only one factor was significantly higher for CD patients with CF compared to CD patients without CF, there was a tendency of elevated scores in all RFIPC factors. In addition, we calculated effect sizes according to Cohen[24], because statistical significant differences need not be of clinical importance and insignificant differences might be. As expected, the effect sizes were more pronounced in UC patients than in CD patients. The five RFIPC factors that were not significant in CD were, however, within Cohen's limits of small-to-medium effect sizes[24]. This finding indicates that there are clinically important differences between IBD patients with CF and IBD patients without CF among all of the RFIPC scales.

IBD is often characterized by periods of remission and exacerbation; therefore, potentially negative consequences of the disease may become the primary focus in daily living[1,2,5]. This has also been reported by Drossman[7]. Worries and concerns are aspects of subjective health that can lead to decreased well-being[7]. These worries may potentially be linked to situations in which the patient's expectations regarding physical and mental functioning in "normal life" do not match their experienced reality[8].

Within the published literature, there appears to be a pattern regarding which of the individual RFIPC items are rated by IBD patients as being most important[7,25-27]. Our results concur with previous studies in this regard. However, the presence of chronic fatigue seems to further increase worries in IBD patients. To our knowledge, this association has not been previously reported for IBD. Among CD patients, we found that CF was associated with increased worries regarding pain and suffering. Research has highlighted the negative association between body pain and CD[5] and recently it was reported that chronic fatigue further decreased body pain scores[10]. In addition, patients with CD and CF seem to negatively relate their perceived energy capacity with their ability to achieve full potential and experience financial difficulties. The latter may be related to their ability to work and provide a household income. Indeed, studies have found that patients who are on sick-leave because of their IBD have a significant deterioration in HRQoL[28].

The nature of worry is not clear; however, it is most often prospective and predominated by negative thinking[29]. In IBD patients, these processes are linked to potentially negative events that may or may not occur in the future, including requiring surgery or an ostomy bag[3,7,25-27]. IBD patients are reported to believe that stress influences the course of the disease[30]. However, this potential link between psychological stress and inflammatory exacerbations is the subject of debate[31-33]. Addressing the worries and concerns of patients might therefore have a potentially positive influence on both fatigue and HRQoL; on the other hand, Borgaonkar *et al*[34] found that providing disease-related information to IBD patients worsens their short-term HRQoL.

In the present study, we found that increased levels of worrying were associated with both increased fatigue levels and reduced HRQoL. When investigating the potential association between worries, fatigue, and HRQoL in IBD patients, it is natural to wonder which is the cause and which is the effect. Is increased worrying a result of chronic fatigue or vice versa? Does impaired HRQoL increase worries and fatigue, or is HRQoL exaggerated by worries? The cross-sectional design of our study makes it difficult to reach any final conclusions. Our hypothesis, which we regard as plausible, is that both reduced HRQoL and increased fatigue are secondary effects of increased disease-related worries and concerns. This theory has also been proposed by others[30]. Potentially, elevated levels of disease-related concerns may increase energy loss and thus manifest as increased fatigue and reduced HRQoL[35].

The RFIPC was developed just a few years after the IBDQ, which may explain why the questionnaire has received much less attention in the literature[7,12,36,37]. As shown by our study, employing a set of various questionnaires that measure subjective health increases the

likelihood of detecting subgroups of IBD patients who are at risk of coping less successfully[8]. Naturally, there is the potential risk that subdimensions of different questionnaires are in fact operationalizations of the same phenomena[22,23]. However, both the VIF and tolerance were within acceptable limits for both UC and CD patients, indicating that the questionnaires seem to measure different aspects of health perception. Given these results, we would argue that patient-reported outcome, rather than HRQoL, seems to be a more adequate definition in cases were one is interested in a wide variety of outcomes (e.g., worries, concerns, fatigue, HRQoL).

A limitation of the present study is that we did not include a specific questionnaire for measuring depression. This precludes the possibility of adjusting for depression as a potentially confounding variable for fatigue. Several reports have indicated a connection and overlap between fatigue and depression[7,19,38]. However, the MH dimension of the SF-36 questionnaire indicated that the patients in our study did not differ from the general population in this respect. Consequently, depression does not appear to be a particular problem in this patient population. Moreover, in the CD patient group there may be type 2 statistical errors, as we were not able to obtain the strong associations between levels of worries and fatigue, as was shown for UC patients.

In conclusion, we report that chronic fatigue is associated with clinically significantly increased levels of disease-related worries in both UC and CD patients. This study provides additional information to the complex nature of understanding how IBD patients perceive their own subjective health.

ACKNOWLEDGMENTS

The authors wish to thank Professor Trudie Chalder, Kings College London, for the permission to use the fatigue questionnaire (FQ) in this study; Professor Jon Håvard Loge, University of Oslo and Professor Stein Kaasa, University Hospital of Trondheim, for the permission to use the validated Norwegian version of FQ; and Professor Leiv Sandvik, University of Oslo, for the statistics. Hege Hølmo Johannessen is acknowledged for correcting the manuscript for grammatical errors. Furthermore, we wish to thank Marita Nilsen (Innlandet Hospital), Hilde Næs, Brita Olafsen and Margrethe Solheim (Østfold Hospital Trust) for their contribution in gathering the data for this study.

COMMENTS

Background

Fatigue is reported to be a prevalent symptom in chronic diseases. In inflammatory bowel disease (IBD), however, there has been a lack of studies with fatigue as the primary endpoint. Recent publications have revealed that the amount of patients reporting long-lasting, chronic fatigue is two to three times elevated in patients with IBD compared to the background population.

Research frontiers

Chronic fatigue has been reported to significantly reduce IBD patients' health-related quality of life. In this study, the authors demonstrate that chronic fatigue is a potential important contributor to increased disease-related worries and concerns.

Innovations and breakthroughs

Recent studies have highlighted the importance of fatigue as a subjective symptom in IBD. This is the first study to report that chronic, long-lasting fatigue symptoms is associated with increased levels of disease-related worries.

Applications

By adding further complexity to the understanding of subjective health experiences in IBD, this study might help clinicians to detect patients at risk of less successful coping, potentially enhancing the patient's quality of life, and also their course of disease.

Terminology

Chronic fatigue refers to fatigue symptoms of some intensity, which have a long-lasting duration of six months or more.

Peer review

This is a very interesting and novel original contribution analyzing the problem of chronic fatigue and its relationship with worries associated with IBD. The study is interesting, seems well done and well reported. It adds a valuable bit of information to the IBD literature.

Abstract

AIM: To share our experience of the management and outcomes of patients with pneumatosis cystoides intestinalis (PCI).

METHODS: The charts of seven patients who underwent surgery for PCI between 2001 and 2009 were reviewed retrospectively. Clinical features, diagnoses and surgical interventions of patients with PCI are discussed.

RESULTS: Seven patients with PCI (3 males, 4 females; mean age, 50 ± 16.1 years; range, 29-74 years) were analyzed. In three of the patients, abdominal pain was the only complaint, whereas additional vomiting and/or constipation occurred in four. Leukocytosis was detected in four patients, whereas it was within normal limits in three. Subdiaphragmatic free air was observed radiologically in four patients but not in three. Six of the patients underwent an applied laparotomy, whereas one underwent an applied explorative laparoscopy. PCI localized to the small intestine only was detected in four patients, whereas it was localized to the small intestine and the colon in three. Three patients underwent a partial small intestine resection and four did not after PCI was diagnosed. Five patients were diagnosed with secondary PCI and two with primary PCI when the surgical findings and medical history were assessed together. Gastric atony developed in one case only, as a complication during a postoperative follow-up of 5-14 d.

CONCLUSION: Although rare, PCI should be considered in the differential diagnosis of acute abdomen. Diagnostic laparoscopy and preoperative radiological tests, including computed tomography, play an important role in confirming the diagnosis.

Key words: Pneumatosis cystoides intestinalis; Peritoneal free air; Radiological tools; Diagnosis

INTRODUCTION

Pneumatosis cystoides intestinalis (PCI) is a relatively uncommon condition, characterized by the presence of multiple gas-filled cysts within the wall of the gastrointestinal tract[1-12]. The term "pneumatosis intestinalis" was first used by Duo Vernoi while observing autopsy specimens in 1730. The entity defined by Duo Vernoi is what we now know as primary PCI. The term "second-

ary PCI" was termed by Koss in 1952, who analyzed 213 pathological specimens and attributed 85% of the cases to a secondary disease[1,2].

One of the pathognomonic features of PCI is pneumoperitoneum without peritoneal irritation as a result of a cyst rupture. In contrast, air retention leading to acute abdominal findings may be seen in some cases[3].

PCI is a radiological or exploratory entity, not a disease, and the underlying causes are numerous. PCI may develop either after a benign procedure, such as endoscopy, or from an unknown cause (primary or idiopathic). In some cases, a more serious disease, such as secondary necrotizing enterocolitis, may be the cause. No clear consensus has yet been established, although many mechanical, bacterial, and pulmonary hypotheses have been proposed regarding the etiopathogenesis of PCI[4]. PCI usually does not lead to clinical findings and may disappear spontaneously in cases in which the primary disease is treated. Steroids, an elemental diet, hyperbaric oxygen, antibiotics, and surgery have been used as treatments. In this study, we describe seven PCI cases, which were diagnosed and treated at our clinic.

MATERIALS AND METHODS

Seven patients were admitted to Firat University Faculty of Medicine, Department of Surgery, Emergency Unit, between January 2001 and August 2009. Their medical records were evaluated retrospectively to obtain follow-up and clinical data, including age, sex, initial complaints, medical histories, white blood cell, abdominal and thoracic radiography, intraoperative findings, surgical intervention, duration of hospital stay, complications and follow-up time (Table 1). Preoperative tests were performed, including routine biochemistry and thoracic and abdominal radiography. Five of the patients had findings consistent with an acute abdomen and were operated on. Contrast-enhanced abdominal computed tomography (CT) was performed in one case due to vague abdominal findings. The CT findings were consistent with a rectal perforation. Abdominal ultrasonography (USG) was also used in one patient who had marked tenderness in the right upper quadrant. All patients operated on underwent emergent surgery, and all patients were diagnosed with PCI intraoperatively. Surgical team consensus was used to determine which patients would be resected after a laparotomy and/or laparoscopic exploration. The affected segment was resected in cases with suspicion of bowel perforation and ischemia, whereas no additional surgical intervention was performed in cases in which only PCI was detected. The primary or secondary nature of the PCI was determined by considering the medical history and preoperative findings. Cases with no underlying predisposing disease were considered primary or idiopathic PCI, whereas those accompanying some disease, such as appendicitis, Crohn's disease, pyloric stenosis, necrotizing enterocolitis, peptic ulcers, cystic fibrosis, or chronic obstructive lung disease, were regarded as secondary PCI. Follow-up time was determined from the time of surgery to the last visit to our outpatient clinic.

RESULTS

Data for seven patients with PCI (3 males, 4 females; age, 50 ± 16.1 years (mean ± SD); range, 29-74 years) were analyzed retrospectively. Of the patients who presented at the Emergency Unit, three had severe abdominal pain, two had abdominal pain and vomiting, and two had abdominal pain, vomiting, and constipation. Liver and renal function tests as well as electrolyte values were normal in all patients, while marked leukocytosis was detected in four. Exam findings in six of the patients were consistent with acute peritonitis, whereas no findings other than minimal tenderness were noted in one patient (female, aged 29 years). Subdiaphragmatic free air was detected on plain thoracic and abdominal radiographs in four patients. Abdominal USG used in one patient (female, aged 74 years), who had marked tenderness in the right upper quadrant, revealed cholecystitis together with an image consistent with a stone in the lower tip of the choledoch. An abdominal CT of a 29-year-old female patient with vague findings revealed free air extending into the retroperitoneum, indicating a rectal perforation. This patient was diagnosed with acute abdomen and was scheduled for urgent surgery. A PCI diagnosis was established in seven patients after a laparotomy in six and a laparoscopic exploration in one. An appearance consistent with PCI was observed in the small intestine of four patients and in the small intestine and colon of three (Figure 1A). A small intestinal perforation was observed in only one (female, aged 34 years) of these cases (Figure 1B). PCI was detected incidentally in a 74-year-old female patient who was scheduled for bile duct surgery (cholecystectomy and choledoch exploration only). Three patients underwent a partial small intestinal resection and anastomosis, while four had no additional surgical procedures after PCI was diagnosed. All patients were given 3 L/min oxygen during the first 3 postoperative days. During the 5-14 d clinical follow-up, a 48-year-old male developed gastric atony, whereas the remaining six patients were discharged with no complications. No additional complications were observed in any of the patients during the 15 ± 5.4 mo (range, 8-23 mo) follow-up. After considering the surgical findings and medical and surgical histories, five of these patients had secondary PCI and two had primary PCI.

DISCUSSION

PCI is a rare condition characterized by multilocular gas-filled cysts localized in the submucosa and subserosa of the gastrointestinal tract[5,13-17]. The term "pneumatosis intestinalis" was first used by Duo Vernoi during postmortem observations. A PCI diagnosis in surviving patients was first established by Hahn in 1899. A PCI diagnosis *via* preoperative radiological findings was first

described by Baumann-Schender in 1939. The condition originally described by Duo Vernoi is what we now consider primary PCI. The term "secondary PCI" was coined by Koss in 1952, who analyzed 213 pathological specimens and attributed 85% of the cases to a secondary disease[1-3].

Several hypotheses have been proposed regarding the development of PCI, although its pathogenesis is still controversial. Two main hypotheses regarding the fundamental pathogenesis of PCI are mechanical and bacterial[17]. The mechanical hypothesis postulates that PCI develops when defects in the mucosa, in combination with increased intraluminal pressure, allow gas to infiltrate the gastrointestinal (GI) tract wall. A subgroup of patients with severe pulmonary conditions may present with PCI arising from pulmonary causes, such as cough and rapid changes in intra-abdominal pressure. The bacterial hypothesis proposes that PCI develops when gas-producing bacteria gain entry into the GI tract wall and produce gas pockets. Much of the supporting evidence for these two hypotheses is derived from observational studies, and mechanical and bacterial mechanisms may occur simultaneously[4,6,7].

Although PCI may occur anywhere in the gastrointestinal tract, from the esophagus to the rectum, it is usually seen in the intestine. A previous study reported that 20%-51.6% of all PCI cases involve the small intestine, 36%-78% involve the colon, and 2%-22% include both the small intestine and colon. The small intestine was involved in 57.1% of the cases we presented here and 42.9% involved the small intestine and the colon[1,2,6,8].

PCI is not a disease but a clinical entity. The etiology can be classified by considering factors thought to play a role in its development. Based on this notion, PCI can be divided into primary and idiopathic (15%) or secondary (85%) type[9]. No identifiable underlying or predisposing factor is present in the primary or idiopathic type. However, numerous gastrointestinal diseases, including appendicitis, necrotizing enterocolitis, Crohn's disease, pyloric stenosis, ulcerative colitis, diverticular disease, necrotizing enterocolitis, gastroduodenal ulcer, and sigmoid volvulus, may accompany PCI as a secondary cause. PCI has also been reported as accompanying some non-gastrointestinal diseases, such as chronic obstructive pulmonary disease, collagen tissue diseases, acquired immune deficiency syndrome, and glucocorticoid use. PCI

cases secondary to surgical or endoscopic trauma have also been reported[10,11].

Lesions are usually localized to the left hemicolon or its mesentery or to the submucosal layer and are frequently characterized by segmentary involvement in the primary form of the disease. However, involvement is usually subserosal in the secondary form, and occurs in the stomach, small intestine, and right colon, usually in a generalized or segmented pattern[7].

The incidence of PCI is unknown, because it is usually asymptomatic. Symptoms, if any, are usually secondary to an underlying disease. Together with non-specific symptoms, such as abdominal discomfort, diarrhea, constipation, rectal bleeding, tenesmus, or loss of weight, severe complications, including volvulus, intestinal obstruction, tension pneumoperitoneum, bleeding, intussusception, and intestinal perforation may be seen in 3% of patients[18-23].

Radiological tools are important for diagnosing PCI. These include plain radiographs, USG, barium series, CT, CT-colonoscopy, magnetic resonance imaging and MRI-colonography, endoscopy, and colonoscopy[19,20]. X-ray is of great importance, because it is readily available in every emergency room. Cysts usually appear as radiolucent shadows, similar to a bunch of grapes, close to the intestinal lumen on radiographs. Free air underneath the diaphragm may be seen if these cysts perforate. An appearance of bulging into the lumen as a filling defect is seen on barium-colon radiographs[15,23]. Linear or spot-like hyperechoic images may be seen in the intestinal wall on USG. CT is the most useful method for diagnosing PCI and is important because it provides data on other abdominal pathologies. However, CT may not provide data on intestinal ischemia and necrosis[1,4,7,12]. The colonoscopic findings may be similar to multiple polyposis or collections of submucosal tumors, but subserous pneumatosis may go undetected[20]. A laparoscopic exploration is quite useful to confirm a PCI diagnosis, if the physical examination findings are suspicious, and particularly in cases that are not preoperatively diagnosed clearly using the above-mentioned radiological methods. Diagnostic laparoscopy provides the convenience of converting to open surgery as well as confirming the diagnosis.

When presence of such an entity is confirmed radiologically, gastroenterologic surgeons begin to feel annoyance. The answer to the question, "What should we do to these patients?" is correlated with the experience of each surgeon on that entity. The approach to a patient with PCI should be determined by evaluating the underlying causes and exam findings together. A specific treatment is not recommended in asymptomatic patients who are detected as having PCI radiologically and whose examination findings are negative. Conservative approaches, including nasogastric decompression, intestinal rest, antibiotic therapy and oxygen, are recommended for patients with positive examination findings and normal biochemical parameters who are confirmed radiologically to have no intestinal ischemia or perforation[24]. Applying 250 mmHg PO_2 pressure or 70% oxygen inhalation for 5 d or 2.5 atmospheres of hyperbaric oxygen pressure for 150 min/d for 3 consecutive days can lead to resolution of gas collection within a cyst[10,13,24,25]. An urgent laparotomy is necessary in cases of intestinal ischemia, obstruction, intestinal bleeding, or peritonitis[14,16]. Definitive surgery should be performed during a laparotomy if necrosis, perforation, or marked ischemia is observed in the intestine. Furthermore, no additional surgical procedures should be conducted unless other pathology is detected in addition to serosal or subserosal air cysts.

Consequently, clinical suspicion, physician experience, radiological tools, and team spirit are important in terms of the approach to PCI. When and how to treat these patients is the main issue to lower mortality and morbidity.

COMMENTS

Background

Pneumatosis cystoides intestinalis (PCI) is a pathologic condition defined as infiltration of gas into the wall of the gastrointestinal tract.

Research frontiers

The authors retrospectively reviewed the diagnosis and management of seven patients with pneumatosis cystoides intestinalis.

Innovations and breakthroughs

Clinical suspicion, physician experience, radiological tools and team spirit are important in terms of the approach to PCI. When and how to treat these patients is the main issue to lower mortality and morbidity.

Applications

According to authors' opinion, specific treatment is not recommended in asymptomatic patients who are detected to have PCI radiologically and whose examination findings are negative. However, laparotomy is necessary in cases of intestinal ischemia, obstruction, intestinal bleeding or peritonitis

Terminology

The primary and idiopathic or secondary nature of the PCI is determined by considering the medical history and by preoperative examination. Cases with no underlying predisposing disease are considered primary PCI, whereas those accompanying some disease, such as appendicitis, Crohn's disease, pyloric stenosis, necrotizing enterocolitis, peptic ulcers, cystic fibrosis or chronic obstructive lung disease, are regarded as secondary PCI.

Peer review

This is a well written report on a small series of a rare entity. It has some educational value in the presentation and the figures.

Abstract

AIM: To investigate the clinical features and survival of patients treated for cholangiocarcinoma in our institution and to analyze the factors affecting their survival.

METHODS: This retrospective cohort study assessed patients diagnosed with cholangiocarcinoma between January 1997 and December 2007 at the University Malaya Medical Centre in Malaysia. The clinical data and associated outcomes were collected using a structured proforma.

RESULTS: Of the 69 patients diagnosed with cholangiocarcinoma, 38 (55%) were male; mean patient age was 61 years. Twelve patients (17%) had intrahepatic, 38 (55%) had perihilar and 19 (28%) had distal tumors. Only 12 patients underwent curative surgery, including seven R0 resections. Only one patient died within 30 d after surgery. The overall median survival was 4 mo, whereas the median survival of R0 resected patients was 16 mo. The overall 1-, 2- and 3-year cumulative survival rates were 67%, 17% and 17%, respectively. Survival rates were significantly associated with curative resection (P = 0.002), intrahepatic tumor (P = 0.003), negative margin status (P = 0.013), early tumor stage (P = 0.016), higher tumor differentiation (P = 0.032) and absence of jaundice (P = 0.038). Multivariate analysis showed that tumor location was a significant independent predictor of patient survival.

CONCLUSION: Curative, margin-negative resection of early stage, well-differentiated intrahepatic tumors is associated with improved patient survival.

INTRODUCTION

Cholangiocarcinoma is a rare malignant neoplasm of biliary tract epithelium, accounting for less than 2% of all human malignancies[1]. Cholangiocarcinoma is the second most common primary hepatic malignancy after hepatocellular carcinoma (HCC)[2] and is associated with

poor patient outcomes. Over the past three decades, however, the worldwide incidence of and mortality from cholangiocarcinoma have steadily increased[3].

Cholangiocarcinoma is difficult to diagnose and is usually fatal, due to its late clinical presentation and the absence of effective non-surgical therapeutic modalities[4]. The incidence of cholangiocarcinoma peaks in patients aged 50-70 years, and there is a slight male predominance[5]. Most patients have unresectable disease at the time of diagnosis and usually die within 6-12 mo from the cancer cachexia, liver failure and biliary sepsis[6]. The 5-year survival rate is low (about 5%), and has remained virtually unchanged over the past 20 years[5,7]. Surgical resection remains the only hope for cure, and radical resection has improved outcomes, although it is also associated with high perioperative morbidity and mortality rates[8]. Since most patients with cholangiocarcinoma present with advanced disease, palliative stenting and chemoradiation are reserved for non-resectable patients, those with recurrence, and those who refuse surgical treatment[3].

Little is known about the survival of cholangiocarcinoma patients in Malaysia. We therefore analyzed the factors affecting survival of patients with cholangiocarcinoma treated at the University Malaya Medical Centre, Malaysia.

MATERIALS AND METHODS

This retrospective cohort study assessed patients diagnosed with cholangiocarcinoma and treated between January 1997 and December 2007 at our center, a tertiary referral center in Malaysia with a specialized hepatobiliary surgery unit and a gastroenterology unit. Patients with a diagnosis of cholangiocarcinoma confirmed histologically by tissue biopsy, and patients without a histologically confirmed diagnosis but with a strong provisional diagnosis by clinical examination, biochemical results and positive endoscopic or imaging [i.e., endoscopic retrograde cholangiopancreatography (ERCP)/magnetic resonance cholangiopancreatography (MRCP) or computed tomography (CT) of the abdomen] results[7] were included. Patients with HCC, tumor at the head of the pancreas and gallbladder carcinoma were excluded.

Combinations of ultrasonography, CT, MRCP, ERCP and percutaneous cholangiography (PTC) were used for tumor diagnosis and staging, and for assessment of resectability. Metastatic disease was evaluated by CT of the thorax, abdomen and pelvis and/or chest radiography (CXR).

Patients were classified into three groups based on the anatomic location of the primary lesion, specifically intrahepatic, perihilar and distal types as proposed by the guidelines for the diagnosis and treatment of cholangiocarcinoma[5]. Intrahepatic tumors were defined as those confined to the liver and not involving the extrahepatic biliary tree. Perihilar tumors were defined as those involving or requiring resection of the hepatic duct bifurcation and were typically located in the extrahepatic biliary tree proximal to the origin of the cystic duct. Distal tumors were defined as extrahepatic lesions located in the peripancreatic region[9].

Patients were staged according to the tumor-node-metastasis (TNM) system[6,10] and assessed for resectability. Variables assessed included therapeutic options (surgical or palliative treatment), operative data, and 30-d postoperative morbidity and mortality. Survival was measured from the date of first presentation to the date of death or last follow-up visit.

Statistical calculations were performed using SPSS version 13.0. Categorical variables were compared using χ^2 tests for association. One-way analysis of variance was used to compare continuous variables among the three groups of patients classified by tumor location. Results were presented as means ± SD, unless otherwise specified. Survival curves were calculated using the Kaplan-Meier method and compared using log-rank tests (Mantel-Cox). Cox proportional hazard models were used to calculate adjusted hazard ratios. A P value < 0.05 was considered significant.

RESULTS

Demography

Of the 69 patients included in this study, 12 (17%) had intrahepatic, 38 (55%) had perihilar and 19 (28%) had distal tumors. Thirty-eight patients were male (55%) and 31 (45%) were female (a male to female ratio, 1.2:1). Mean ± SD patient age was 61 ± 14.2 years (range, 18-91 years), although patients with intrahepatic tumors were younger than those with perihilar and distal tumors (P < 0.05). When subdivided ethnically, 42 patients (61%) were Chinese, 20 (29%) were Malay and 7 (10%) were Indian.

Risk factors

Of the 69 patients, 22 (29%) had a history of chronic cigarette smoking, 13 (19%) each had diabetes mellitus and regular alcohol intake, and 5 (7%) had chronic hepatitis B, with only 1 each (1.4%) having hepatolithiasis and choledochal cyst. None of our patients had other strong risk factors, such as inflammatory bowel disease, primary sclerosing cholangitis or liver fluke infestation.

Clinical evaluation

The most common symptoms among our patients were jaundice (78%), anorexia (57%), weight loss (52%), abdominal pain (44%), abdominal mass (44%), itchiness (25%), vomiting (9%) and fever (7%). Ninety-eight percent of the patients with extrahepatic cholangiocarcinoma were jaundiced (63% of perihilar tumor and 35% of distal tumor patients), whereas only 2% of intrahepatic patients was jaundiced (P < 0.001). No specific symptom was significantly related to any of the three types of cholangiocarcinoma. The median duration of complaints prior to medical consultation was 30 d (range 1-365 d). However, patients with intrahepatic lesions present somewhat later (P

Table 1 Laboratory data on admission and location of tumours

	Total (n = 69)	Intrahepatic (n = 12)	Perihilar (n = 38)	Distal (n = 19)	P value[1]
Total bilirubin (mmol/L)	178 (158)	45 (109)	216 (163)	188 (131)	0.003
Conjugated bilirubin (mmol/L)	140 (122)	31 (87)	170 (123)	151 (102)	0.002
INR	1.2 (0.7)	1.1 (0.1)	1.0 (0.1)	1.6 (1.1)	0.005

[1]Analysis of variance. Values in mean (SD); P value < 0.05 is significant. INR: International normalized ratio.

< 0.05) than those with perihilar or distal lesions.

Investigations

When we assessed laboratory variables in these patients, we found that total bilirubin concentration was significantly higher in patients with perihilar than in those with distal or intrahepatic lesions (P = 0.003) (Table 1). The international normalized ratio (INR) value was also predictive of lesion site, as it was higher in patients with distal than with perihilar or intrahepatic lesions (P = 0.005).

The tumor markers carcinoembryonic antigen, alpha-fetoprotein and carbohydrate antigen 19-9 were measured in about 50% of these patients, but none of them significantly correlated with tumor location.

Imaging

Ultrasound was the first line non-invasive imaging method used in 45 (65%) patients, detecting 50%-76% of obstructed biliary systems. Almost 91% of these patients underwent CT scans to further assess the extent of pathology, including liver masses, lymph nodes and the involvement of major vessels. We found that about 20% of the abdominal lesions were not detected by ultrasound alone, but were detected on CT scan. Only four patients underwent MRCP.

In 58 (84%) patients, ERCP was the first invasive method used to assess the obstructed biliary system. ERCP showed that 51 (74%) patients had strictures at various levels of their biliary trees. Plastic stents were inserted successfully into 44 (76%) of these patients to relieve their biliary obstructions, whereas the other seven (14%) failed in stent insertion; five later underwent PTC drainage. Cytology brushing of suspicious strictures was performed in 22 (38%) patients, with 10 (45%) being positive for cancer.

Preoperative staging for resectability was predicted based on ultrasound, CT scan, MRCP and CXR. None of these patients underwent staging laparoscopy because it was not a routine practice in our center.Based on the American Joint Committee on Cancer TNM staging system, 23 (33%) patients had stage 1 tumors, 7 (10%) had stage 2, 17 (25%) had stage 3 and 22 (32%) had stage 4. Stages 3 and 4 were considered unresectable.

Surgical treatment

Although preoperative staging indicated that 30 (43%) patients were candidates for surgical resection, only 22 (32%) patients underwent laparotomy with curative intent. Three patients (and their relatives) refused surgery, citing age as their primary concern (mean age 78 years), whereas five were excluded from surgery due to age (mean 71 years) and/or associated comorbidity. At laparotomy, 10 patients had extensive local disease and/or hepatic metastasis that precluded resection. The remaining 12 patients underwent potentially curative resection (resectability rate, 55%). All except one with evidence of biliary obstruction underwent preoperative biliary drainage either by endoscopic stenting or percutaneous transhepatic biliary drainage (PTBD). The type of surgery depended on the location of the tumor (Table 2). In general, intrahepatic tumors were treated by hepatic resection; perihilar lesions by excision of the extrahepatic biliary tree and lymph node dissection, with or without hepatic resection; and distal tumors by Whipple pancreaticoduodenectomy. Biliary reconstructions were mostly by Roux-ex-Y hepaticojejunostomy. All operations were performed by trained hepatobiliary surgeons.

Table 2 Types of surgical resection

Types of surgery	Patients (n = 12)
Left hemihepatectomy	2
Right hemihepatectomy	1
Segmental hepatic resections	2
Extrahepatic bile duct resection	5
Whipple's procedure	2

Surgical morbidity and mortality

Complications occurred in patients with all three tumor types, but the differences were not statistically significant. Three patients developed post-operative ileus, which resolved after conservative treatment. Two patients had intra-abdominal hemorrhage. One had undergone a Whipple procedure and was re-explored within 24 h because of portovenous bleeding; unfortunately, this patient died the next day. The second patient did not require intervention and was treated with blood transfusion and correction of coagulopathy. Three patients developed intra-abdominal collection, later complicated by abscesses, including one caused by bile leakage from the anastomosis. None of these patients, however, required surgical or percutaneous intervention. Two patients had surgical site infections, including one with anastomotic stenosis and the other with deep venous thrombosis (DVT) despite DVT prophylaxis. Only one patient died of complications within 30 postoperative days; hence the perioperative mortality rate was 8%.

Of the 10 patients who underwent surgery but were found to have advanced inoperable disease at laparotomy, 3 underwent a palliative bypass procedure, consisting of hepaticojejunostomy and gastrojejunostomy, whereas four underwent gastrojejunostomy alone. Two patients underwent cholecystectomy and biliary stent insertion, whereas one underwent only laparotomy and biopsy.

Tumor characteristics

Of the 12 patients who underwent curative resection, 11 (92%) had adenocarcinoma and one had a papillary adenocarcinoma. The mean ± SD tumor diameter was 9.6 ± 15.2 cm (range, 0.5 cm-55 cm). Intrahepatic tumors were larger than perihilar and distal tumors ($P < 0.05$). Five (42%) patients had well-differentiated adenocarcinoma and the others had moderately or poorly differentiated adenocarcinoma. Seven (58%) patients had perineural involvement, 5 (42%) had lymphovascular invasion and 4 (33%) had regional lymph node metastases. Seven (58%) patients were resected with negative margins (R0 resection), whereas the other 5 (42%) had microscopically positive margins. Table 3 summarizes the characteristics of these tumors.

Palliation

Forty-seven (68%) patients did not undergo surgery but received palliative treatment, including 31 (66%) who underwent palliative biliary drainage by endoscopic stenting, 23 (49%) who underwent PTBD with or without concurrent stenting and 13 who underwent both. Sixteen patients had their stents changed on subsequent follow-up, of whom, nine had self-expanding metal stents. Three (6%) patients received palliative chemotherapy alone, using a variety of chemotherapeutic agents (5-fluorouracil, cisplatin, gemcitabine). Three (6%) patients were too ill and hence received best supportive care.

DISCUSSION

We have described our experience managing patients with cholangiocarcinoma, a rare type of tumor. The incidence of this tumor is likely increasing in Malaysia. The latest National Cancer Registry 2003-2005 Peninsular Malaysia has classified cholangiocarcinoma into the category of liver and gallbladder cancers rather than as a separate tumor. The incidence of liver cancer in Malaysia has been reported to be 3.6% for males and 1.2% for females, while the rates of gallbladder cancer were 0.8% and 0.7%, respectively. Morphologically, about 2.2% of these liver cancers and 33.9% of these gallbladder cancers were cholangiocarcinomas. The incidence of both liver and gallbladder cancers was higher for Chinese than for Malays and Indians.

Cholangiocarcinoma is best classified according to its anatomical location into intrahepatic, perihilar and distal tumors[9,11,12]. Most (40%-60%) tumors are perihilar or Klatskin tumors, with 20%-30% being distal and 10% being intrahepatic tumors[9,13]. Our findings were similar to these rates, in that 17% of tumors were intrahepatic, 54% were perihilar and 29% were distal.

The demographic characteristics of our patients were comparable to those of patients in other larger series. Mean patient age was 61 years (range, 18-91 years), while a review of 294 patients with cholangiocarcinoma by Nakeeb *et al*[9] showed a mean age of 62.2 years and a review by DeOliveira *et al*[13] of 564 patients showed a median age of 65 years. We found, however, that patients with intrahepatic tumors were significantly younger than those with perihilar or distal tumors. We observed a slight male predominance, with a male to female ratio of 1.2:1, similar to the ratios of 1.2:1[9] and 1.38:1 reported previously[13].

Of these patients, 32% presented in 1997-2002, whereas 68% presented in 2003-2007. We observed similar increases in the number of patients with primary tumors, suggesting that these higher rates may be due to improvement in tumor detection, ERCP proficiency, or increased awareness of the availability of local surgical expertise.

Only a few patients in our series had strong risk factors such as chronic hepatitis B, hepatolithiasis and choledochal cyst[14-16]. None had a history of primary sclerosing cholangitis[14] or liver fluke infestation[17], the latter of which is not endemic in Malaysia. Chronic cigarette smoking, regular alcohol intake and diabetes mellitus were among the risk factors[18,19] observed in our population, but none of these risk factors was associated with any particular tumor site.

The most common symptom observed in these patients was jaundice. Jaundice was significantly more common in patients with extrahepatic (i.e., perihilar and distal) than with intrahepatic cholangiocarcinoma ($P < 0.001$). This was confirmed by laboratory results showing that the concentration of bilirubin was significantly higher in patients with perihilar (extrahepatic) than in those with intrahepatic tumors ($P = 0.002$). Similar results have been reported previously[13,20]. We also found that INR was higher in patients with distal tumors ($P =$

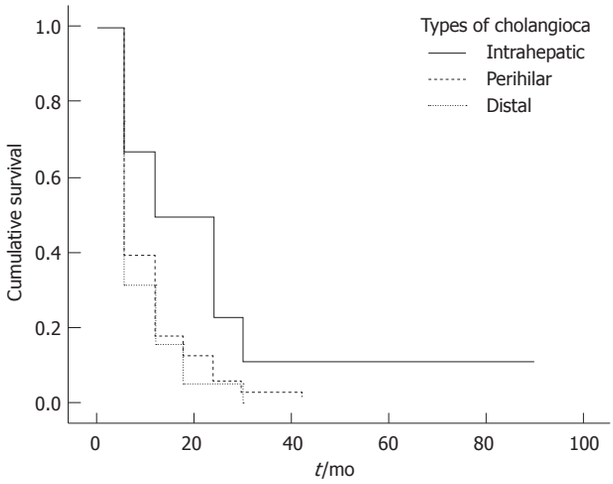

Figure 1 Overall survival by types of cholangiocarcinoma regardless of surgery or not, *P* = 0.027.

0.005). Obstructive jaundice may decrease the concentrations of vitamin K-dependent coagulation factors, resulting in aberrant coagulation profiles[5]. However, none of the other symptoms or blood parameters we assayed was significantly related to tumor location.

Many of our patients initially underwent ERCP, not MRCP. ERCP enables cytological brushing and can decompress the obstructed biliary system[6]. Although we found that the success rate of internal stent placement for drainage was high, PTBD may also play a role, especially when the endoscopic approach has failed. PTBD can also be used to visualize proximal biliary tumors and anatomy[5]. Failure of biliary decompression may result in an infected biliary system and further risks of liver failure and sepsis[21]. These risks may be prevented by decompression of an obstructed biliary system in patients with potentially resectable cholangiocarcinoma, although a series by Figueras *et al*[22] demonstrated no significant differences in morbidity and mortality between patients with and without preoperative biliary drainage. None of our patients who underwent hepatic resection developed postoperative liver failure.

Despite improved diagnostic methods and a relatively early presentation (median duration of symptoms, 30 d), only about one-third of our patients (32%) underwent surgery, and only 12 underwent curative resection. More than half of our patients (58%) were considered to have advanced unresectable disease, whereas the remaining patients were considered unsuitable for surgery because of comorbidity and/or advanced age, findings similar to those observed previously[7]. Our overall resectability, 55% (12/22), was similar to previously reported rates 18%-70%[23]. Postoperative complications were not associated with tumor location. In high volume centers with considerable experience, the operative mortality and morbidity rates varied from 6%-14% and 32%-65%, respectively[24-26]. Our 30-d postoperative mortality and morbidity rates were similar, 8% and 67%, respectively.

Patients who underwent surgical resection had a definite survival advantage over those who did not, confirming that surgical resection is the best treatment available for patients with cholangiocarcinoma and providing further evidence that potentially resectable patients should be referred early to a specialized surgical team[7,10]. The median survival time for the 12 patients who underwent curative resection was 16 mo, compared with 3 mo for the 57 patients who did not undergo curative resection (P = 0.002). The 1-, 2- and 3-year cumulative survival rates in patients who underwent resection were 67%, 17% and 17%, respectively, significantly higher than the 14%, 8% and 0%, respectively, in those who did not. Furthermore, complete surgical resection with histologically negative margins offers the best chance for cure and long-term survival[27-30].

Univariate log-rank analyses of tumor related variables in Table 4 showed that absence of jaundice (P = 0.038), tumor location (P = 0.027) (Figure 1)[17], curative resection (P = 0.002) (Figure 2)[31], early tumor stage (P = 0.016)[32], negative margin status (P = 0.013) (Figure 3)[17,32,33] and higher degree of tumor differentiation (P = 0.032) (Figure 4)[17] were significant predictors of longer survival. In contrast to previous reports, regional lymph node metastasis[28] and perineural invasion[34] were not associated with survival in resected patients. Moreover, we found that age, gender, race and risk factors were not predictors of survival.

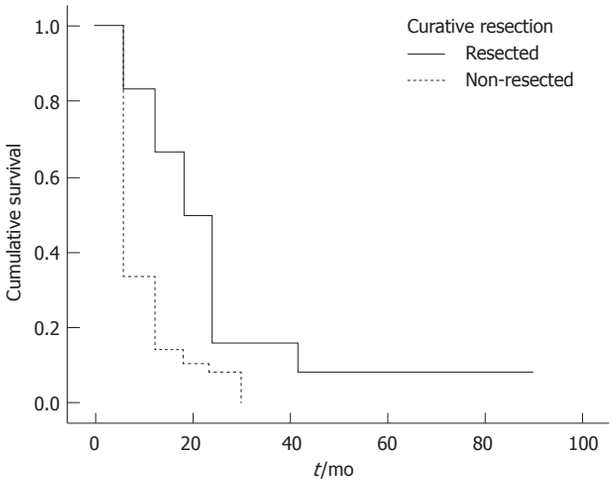

Figure 2 Cumulative survival curves after curative resection, *P* = 0.002.

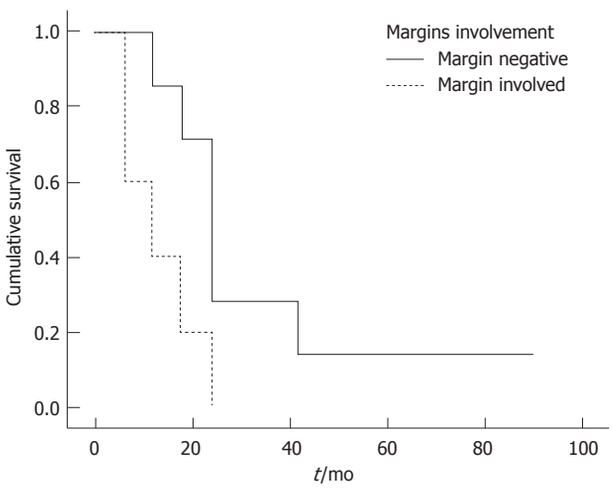

Figure 3 Cumulative survival curves after resection according to histologic margin clearance, *P* = 0.013.

Multivariate analysis showed that tumor location was the only independent predictor of long-term survival. Survival was significantly lower in patients with perihilar than in those with intrahepatic and distal tumors (HR = 0.016, 95% CI: 0.01-0.607; $P = 0.026$), in agreement with the findings of other series showing that patients with intrahepatic tumors had the best survival[17,2]. This could be explained by the fact that, compared with extrahepatic tumors, intrahepatic tumors are characterized by different epidemiology and tumor biology, younger age ($P < 0.05$), and lower rate of tumor negative margins[10,17].

For the majority of patients with cholangiocarcinoma who cannot undergo curative resection, palliative treatment to relieve jaundice, pruritus and cholangitis and to avoid liver failure becomes the priority. This can be achieved surgically *via* biliary-enteric bypass or stent placement *via* PTBD or ERCP[33]. We found however, that neither palliative surgical bypass nor biliary drainage had significant survival benefits, in agreement with previous findings by Prat *et al*[34] Both groups had a median survival of 3 mo.

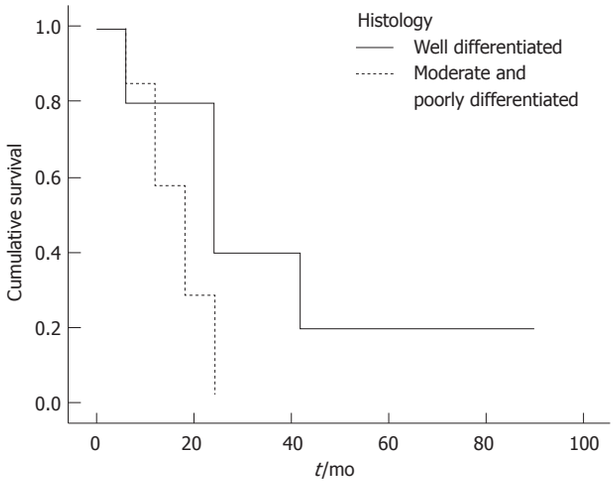

Figure 4 Overall survival according to degree of tumour differentiation, *P* = 0.032.

A novel palliative therapy for unresectable cholangiocarcinoma, photodynamic therapy (PDT), has shown promising benefits in terms of patient survival, cholestasis and quality of life[35]. PDT utilizes the intravenous photosensitizer sodium porfimer, which accumulates in tumor tissues. Upon illumination of the tumor bed by a specific endoscopic light, the porfimer becomes activated and forms oxygen free radicals, resulting in tumor necrosis[36].

The major limitation of our study was its involvement of patients at a single center. Therefore, our findings may not be representative of patients with cholangiocarcinoma throughout Malaysia.

The incidence of cholangiocarcinoma is increasing throughout Malaysia, as shown by the increase in the number of patients diagnosed per year throughout our study period. This may be due to an increased detection rate and to increases in referrals to our center. Curative surgical resection with clear histological margins of early stage well-differentiated intrahepatic tumors is associated with improved long-term survival. Further prospective randomized studies involving multiple centers are warranted.

ACKNOWLEDGMENTS

The authors would like to thank Dr. Aqel Mohd Dhaher of Universiti Teknologi MARA and Dr. Azlan Darus of the University of Malaya for their assistance with the data analysis.

COMMENTS

Background

Cholangiocarcinoma is a rare malignant cancer of the bile duct with poor prognosis. This cancer is difficult to diagnose and often the patient presented late when curative surgical resection that can provide the chance for cure, is not feasible. Any person in his or her fifth decade with jaundice and significant

weight loss should raise a suspicion of this cancer. Despite its rarity, the incidence of this cancer has been steadily increasing worldwide.

Research frontiers

Many studies have concurred that early detection together with radical surgery will increase the survival period of these patients. A research article to be published in the *World Journal of Gastroenterology* has further emphasized the importance of early diagnosis and early referral to a specialized surgical centre with vast experience in the management of this cancer.

Innovations and breakthroughs

The authors have analysed various factors that affect the survival of their cholangiocarcinoma patients treated over a 10-year period. It was found that the survival period will improve if complete tumour excision is performed whereby the margins are tumour-free on histology. The outcome is also favourable if surgery is performed early when the abnormal cells are still at their early grade and have not spread elsewhere. Despite a range of palliative procedures available for inoperable cancer, none could surpass the result of a successful surgical treatment. These have further consolidated similar findings and recommendations of early aggressive surgery from other larger centres in the West and Far East.

Applications

The study also shows that cholangiocarcinoma is an important health problem in Malaysia. Although the increase in number of patient being treated may not truly reflect a true increase in incidence, this would mean more need to be done to address such problem. This study provides a framework for future studies in Malaysia and hopefully stimulates other groundbreaking research in this region especially concerning the epidemiology and pathophysiology of this fatal cancer.

Peer review

This 10-year retrospective review defines treatment modalities and survival statistics for cholangiocarcinoma in a Malaysian Referral Hospital. Not surprisingly, patients who underwent R-O resections had higher cumulative survival rates than patients palliated surgically, endoscopically or by percutaneous transhepatic biliary drainage. This manuscript is worthy of publication.

Abstract

AIM: To evaluate the efficacy of thalidomide in combination with other therapies to treat patients with advanced hepatocellular carcinoma (HCC).

METHODS: We performed a retrospective analysis of all patients with HCC who were treated with thalidomide for at least two months. The medical records of patients with HCC who were treated at our institution between April 2003 and March 2008 were reviewed. Image studies performed before and after treatment, tumor response, overall survival, and the decrease in α-fetoprotein (AFP) levels were evaluated.

RESULTS: A total of 53 patients with HCC received either 100 or 200 mg/d of thalidomide. The patient population consisted of 9 women and 44 men with a median age of 61 years. Thirty patients (56.6%) were classified as Child-Pugh A, and 12 patients (22.6%) were classified as Child-Pugh B. Twenty-six patients had portal vein thrombosis (49.1%), and 25 patients had extrahepatic metastasis (47.1%). The median duration of thalidomide treatment was 6.0 mo. Six of the 53 patients achieved a confirmed response (11.3%), one achieved a complete response (1.9%) and 5 achieved a partial response (9.4%). The disease control rate (CR + PR + SD) was 28.3% (95% CI: 17.8-42.4), and the median overall survival rate was 10.5 mo. The 1- and 2-year survival rates were 45% and 20%, respectively. Only one complete response patient showed an improved overall survival rate of 66.8 mo. Sixteen patients (30.2%) showed more than a 50% decrease in their serum AFP levels from baseline, indicating a better response rate (31.3%), disease control rate (43.8%), and overall survival time (20.7 mo). The therapy was well tolerated, and no significant toxicities were observed.

CONCLUSION: Thalidomide was found to be safe for advanced HCC patients, demonstrating anti-tumor activity including response, survival, and AFP decreases of greater than 50% from baseline.

Key words: Thalidomide; Hepatocellular carcinoma

INTRODUCTION

Hepatocellular carcinoma (HCC) is the most frequent primary liver cancer, the fifth most common malignancy worldwide (with over 700 000 new cases per year), and the third most common cause of cancer deaths[1]. In

Taiwan, HCC, which ranks second among the major types of cancer in the list of cancer-related mortalities, is responsible for approximately 7000 to 8000 deaths per year[2]. Unfortunately, most patients seek treatment when the disease is beyond curative treatment (surgery or percutaneous ablation), and palliative care is the only alternative. According to the Barcelona Clinic Liver Cancer (BCLC) staging classification[1] and treatment schedule, chemoembolization is the best option for intermediate-stage patients. However, for advanced-stage patients, no standard treatment was established until 2007. Systemic chemotherapy is generally ineffective and is associated with significant toxicity because hepatic function is often impaired by underlying cirrhosis that is often accompanied by hypersplenism and peripheral cytopenia[3]. Fortunately, after the positive results of the Study of Heart and Renal Protection (SHARP) trials[4], a new treatment, sorafenib, was approved for advanced-stage patients, which offers major improvements in overall survival and time to progression compared to placebo. There are many new modalities of treatment with more favorable therapeutic indices that are suitable for patients with advanced HCC. HCC is a hypervascular tumor that is one of the most antiangiogenic and angiogenesis-dependent tumors[5,6]. Consequently, it is reasonable to hypothesize that antiangiogenesis therapy may inhibit the growth of HCC. A number of antiangiogenic agents have been developed, including thalidomide, which is a glutamic acid derivative that was first described in 1953 when it was labeled as a sedative and anti-emetic agent. However, it was withdrawn from the European market 30 years ago because of its teratogenic effects[7]. Recently, oral thalidomide has been shown to inhibit basic fibroblast growth factor- and vascular endothelial growth factor-induced angiogenesis of cancer cells[8,9]. Studies published on the efficacy of thalidomide in advanced hepatocellular carcinoma have reported modest responses to therapy with acceptable toxicity[10-12]. Treatment of patients with HCC continues to present a major challenge. We retrospectively analyzed our records of HCC patients who received thalidomide in combination with other therapies to determine whether thalidomide was effective.

MATERIALS AND METHODS

Patients

Between April 2003 and March 2008, 53 patients with HCC were treated for at least two months with either 100 or 200 mg/d of thalidomide (50 mg/capsule, TTY Biopharm Co. Ltd., Taipei, Taiwan) at Changhua Christian Medical Center in Taiwan. HCC was diagnosed by histological examination and imaging findings. The diagnosis of HCC was confirmed by histological examination or the presence of all of the following criteria: (1) pathological diagnosis of HCC; (2) cirrhotic liver with a tumor size greater than 2 cm plus one dynamic image [computed tomography (CT) or magnetic resnane iamge (MRI)] or alpha fetoprotein (AFP) > 200 ng/mL; (3) cirrhotic liver with a tumor size of 1-2 cm plus two dynamic images (CT + MRI); and (4) non-cirrhotic liver greater than 2 cm plus one dynamic image (CT or MRI) and AFP > 200 ng/mL. The inclusion criteria were as follows: (1) advanced HCC (surgically unresectable); (2) failed previous local therapy, such as radiotherapy, hepatic arterial chemoembolization, radiofrequency ablation, or percutaneous interventional therapy; and (3) distant metastasis (lung, lymph node, or bone) that is not eligible for curative surgery and radiotherapy or locoregional therapy failure [e.g., transarterial chemoembolization (TACE), recurrence-free interval or percutaneous ethanol injection (PEI)]. All patients had bidimensionally measurable disease that was staged by the pathological tumor-node-metastasis (TNM) system, the Okuda system, and the BCLC parameters for HCC. The demographic data, details of the primary tumors, serum AFP levels, dates of recurrence, length of survival, and last follow-up dates were analyzed retrospectively. The responses to thalidomide were determined by CT performed according to the Response Evaluation Criteria in Solid Tumor Guidelines[13], and the AFP levels were also analyzed before and after thalidomide treatment. Overall survival was calculated from the date of the start of chemotherapy and analyzed by the Kaplan-Meier method. Follow-up data were obtained for all patients until the time of their death or the last follow-up.

RESULTS

Patient and demographic characteristics

A total of 53 patients with HCC were available for analysis, and their demographic characteristics are shown in Table 1. The patient population included 9 females (17.0%) and 44 males (83.0%) with a median age of 61 years (range, 29-88 years). Of the 53 patients, 10 had not received prior treatment or therapy. Pretreatment curative surgery had been performed on 12 patients (22.6%), transarterial embolization on 13 patients (24.5%), TACE on 16 patients (30.2%), radio frequency ablation on 10 patients (18.9%), and radiotherapy (RT) on 10 patients (18.9%). Twenty-six patients had portal vein thrombosis (49.1%), and 25 patients had extrahepatic metastasis (47.2%). The prevalence of hepatitis B was 56.5% (30/53), that of hepatitis C was 37.7% (20/53), and that of concomitant hepatitis was 1.9% (1/53). Of the 53 patients, most patients had TNM stage Ⅳ (45.3%), Okuda stage I (51.9%), and BCLC stage C (71.2%). There were 22 patients (41.5%) whose serum AFP levels were greater than 400 ng/mL above the baseline. The liver functions of the majority of patients were classified as Child-Pugh A (56.6%), and the median duration of treatment was 6.0 mo (range, 1.5-53.9 mo) (Table 1).

Efficacy

Of the 53 patients, one had a complete response (CR, 2.9%) to thalidomide, five had a partial response (PR, 9.4%) and nine were classified as stable disease (SD,

17.0%). The remaining 38 patients had disease that continued to progress after the thalidomide treatments. The objective response rate was 11.3% (95% CI: 4.3-23.0), and the disease control rate (CR + PR + SD) was 28.3% (95% CI: 17.8-42.4). The median overall survival rate was 10.5 mo (95% CI: 6.9-23.3). The 1- and 2-year survival rates were 45% and 20%, respectively. Sixteen patients (30.2%) showed more than a 50% decrease in their serum AFP levels below the baseline and showed a better response rate (31.3%), disease control rate (43.8%), and overall survival time (20.7 mo) (Table 2, Figure 1). The prognostic factors for the response rate, disease control rate, and overall survival in HCC patients receiving thalidomide are listed in Table 3. Multivariate analysis showed that almost all of these patients qualified as having independent prognostic factors for the efficacy analysis. The only significant difference in the efficacy activity was an AFP decrease of > 50% after treatment. The median overall survival time of the patients who registered > 50% AFP decrease was 20.7 mo, with a response rate of 31.3% and a disease control rate of 43.8%. The median overall survival time of those patients with a < 50% AFP decrease was 7.1 mo, with a response rate of 2.7% and a disease control rate of 21.6% (Table 3, Figure 1). Table 4 is a comparison of the patients who responded and the patients whose disease progressed. Patients in the CR + PR + SD group had a significantly longer survival time (33.3 mo) than those in the progressive disease (PD) group (6.9 mo, $P < 0.003$) (Figure 1).

DISCUSSION

Thalidomide has been used in the treatment of advanced HCC patients. Hsu *et al*[10] reported an overall response rate of 6.3% with an overall survival time of 18.7 wk when an escalating dose (100-600 mg/d) of thalidomide was used for the treatment of advanced HCC. Patt *et al*[14] also showed a 5% overall response rate with a 6.8-mo overall survival time when a high dose (400-1000 mg/d) of thalidomide was used. In a phase Ⅱ study[12], high-dose (200-800 mg/d) single-agent thalidomide demonstrated a response rate of 3.9% with an overall survival time of 123 d. The first retrospective study to analyze the efficacy and tolerability of fixed low-dose thalidomide in the treatment of advanced HCC patients[15]

CR: Complete response; PR: Partial response; SD: Stable disease; PD: Progressive disease; AFP: Alpha fetoprotein.

showed that low-dose thalidomide has a comparable single-agent activity (response rate of 5%, with an overall survival time of 4.3 mo) but fewer treatment-related toxicities than high-dose thalidomide when treating advanced HCC patients. Patients treated with low-dose thalidomide have similar overall survival times compared to patients treated with chemotherapeutic agents, with a far better toxicity profile and less hematological toxicity (no grade 3/4 neutropenia or thrombocytopenia)[15,16]. The largest randomized phase Ⅲ trial for HCC (the SHARP trial) showed better progression free survival and overall survival times with sorafenib than with placebo[4]. The primary drug-related adverse events were dermatological (constitutional and hand-foot skin reactions) and gastrointestinal[4,17]. The toxicity of sorafenib is a serious problem because approximately 50% of the patients had to interrupt or stop their treatment because of sorafenib-induced toxicity. The tolerance of low-dose thalidomide in HCC patients may be worth further investigation.

The treatment of hepatoma with thalidomide appears to be feasible. A complete response was rare with thalidomide treatment of HCC; the PR rate was 5%-10%, and the SD rate was approximately 37%[10,12,14], depending on the duration of observation, cancer stage, and the definition of stability. In our study, one patient had complete remission; the PR rate was 9.4%, and the SD rate was 17%. One CR patient received thalidomide alone after a TACE therapy failure; the duration of the treatment

AFP: Alpha fetoprotein; CR: Complete response; PR: Partial response; SD: Stable disease; PD: Progressive disease; NA: Not assessable. [a]$P < 0.05$ between the two groups (CR + PR + SD *vs* PD); [b]$P = 0.0003$ (less than 0.005) between progress disease and CR + PR + SD.

was 53.9 mo, the patient had no recurrence, and he is still alive (66.8 mo post-treatment). The most interesting finding was the AFP decrease from 11 005.3 ng/mL at diagnosis to < 20 ng/mL (Table 4). Of the 5 patients with partial responses, 2 had prior TACE treatments, 2 had RT, 1 had PEI and 1 had systemic therapy. The median survival time among these patients was 502 d (range, 248-1263 d), and 3 of them are still alive. The median survival time of patients with stable disease was 412 d (range, 60-1013 d).

Patients in the CR + PR + SD group had a significantly longer survival time (33.3 mo) than those in the PD group (6.9 mo, $P < 0.003$). Thalidomide may offer HCC stabilization and prolong survival, especially in patients with stabilization. Survival time should be the focus of future clinical trials of thalidomide therapy. In this study, we evaluated the clinical implication of the AFP tumor marker response in assessing the therapeutic effects of thalidomide in HCC. The results showed that the AFP response was an independent prognostic factor for the response rate, disease control rate, and overall survival time. We also identified patients with more than or less than a 50% decrease in serum AFP levels from the baseline, which made a significant difference in their response rates (31.3% *vs* 2.7%, $P = 0.007$). There was a better trend in the disease control rate (43.8%) and overall survival time (20.7 mo) when there was greater than a 50% AFP decrease (Table 3). The AFP response may correlate with the biological response and, consequently, predict the survival benefits of thalidomide in HCC.

In conclusion, thalidomide has shown modest clinical activity, including response and survival, and was safely administered to patients with advanced HCC. Because the present study is retrospective in nature with a relatively small number of patients, a larger, randomized phase Ⅱ/Ⅲ study is needed to clearly define the role of single-agent thalidomide in the treatment of HCC as an alternative to the expensive molecular-targeted therapies.

COMMENTS

Background

Hepatocellular carcinoma (HCC) is the most frequent primary liver cancer, the fifth most common malignancy worldwide (with over 700 000 new cases per year), and the third most common cause of cancer deaths. However, for advanced-stage patients, no standard treatment was established until the positive result of the Study of Heart and Renal Protection study. However, there are many new modalities of treatment with more favorable therapeutic indices that are suitable for patients with advanced HCC.

Research frontiers

HCC is a hypervascular tumor that is one of the most antiangiogenic and angiogenesis-dependent tumors. Recently, thalidomide was shown to inhibit the angiogenesis of cancer cells and studies have reported modest responses to this therapy in advanced HCC. The authors retrospectively analyzed the records of HCC patients who received thalidomide in combination with other therapies to determine whether thalidomide was effective.

Innovations and breakthroughs

Studies published on the efficacy of thalidomide in advanced hepatocellular carcinoma have reported modest responses to the therapy with acceptable toxicity. Some of them highlighted the alpha fetoprotein (AFP) tumor marker response in assessing the therapeutic effects of thalidomide in HCC. In this study, the authors concluded thalidomide showed modest clinical activity, including response and survival, and was safely administered to patients with advanced HCC. Furthermore, they also identified patients with more than or less than a 50% decrease in serum AFP levels from the baseline, which made a significant difference in their response rates.

Applications

The results showed that the AFP response was an independent prognostic factor for the response rate, disease control rate, and overall survival time. The AFP response may correlate with the biological response and, consequently, predict the survival benefits of thalidomide in HCC.

Peer review

This is an interesting and well written manuscript summarising the effects of thalidomide on HCC patients in a retrospective study.

Abstract

AIM: To develop a pharmacodynamic model of portal hypertension from chronic hepatitis.

METHODS: Pathological changes and collagen depositions were analyzed using morphometry to confirm CCl_4-induced chronic hepatitis. At d_0, d_{28}, d_{56} and d_{84} of the process, the portal perfused velocities (μL/min) in isolated rat livers were exactly controlled with a quantified pump. The pressure (mmHg) was monitored with a Physiological System. The geometric concentrations of phenylephrine or acetylcholine were added to a fixed volume (300 mL) of the circulating perfusate. The equation, the median effective concentration and its 95% confidence intervals of phenylephrine or acetylcholine were regressed with Prism-4 software in non-linear fit and various slopes. In the isolated perfused rat livers with chronic hepatitis, both median effective concentrations were defined as the pharmacodynamic model of portal hypertension.

RESULTS: At d_0, d_{28}, d_{56} and d_{84}, the equations of portal pressure potency from the concentrations of phenylephrine used to constrict the portal vein in isolated perfused rat livers were $Y = 0.1732 + 0.3970/[1 + 10^{(-4.3061-0.4407 X)}]$, $Y = -0.004934 + 0.12113/[1 + 10^{(-3.1247-0.3262 X)}]$, $Y = 0.0104 + 0.2643/[1 + 10^{(-8.8462-0.9579 X)}]$, and $Y = 0.01603 + 0.12107/[1 + 10^{(-5.1134-0.563 X)}]$; the median effective concentrations were 1.69×10^{-10} mol/L, 2.64×10^{-10} mol/L, 5.82×10^{-10} mol/L, and 8.24×10^{-10} mol/L, respectively. The equations from the concentrations of acetylcholine used to relax the portal vein were $Y = -0.4548 + 0.3274/[1 + 10^{(6.1538 + 0.5554 X)}]$, $Y = -0.05391 + 0.06424/[1 + 10^{(3.8541 + 0.3469 X)}]$, $Y = -0.2733 + 0.22978/[1 + 10^{(3.0472 + 0.3008 X)}]$, and $Y = -0.0559 + 0.053178/[1 + 10^{(5.6336 + 0.5883 X)}]$; the median effective concentrations were 8.40×10^{-10} mol/L, 7.73×10^{-12} mol/L, 5.98×10^{-11} mol/L, and 2.66×10^{-10} mol/L, respectively.

CONCLUSION: A pharmacodynamic model of portal hypertension in isolated perfused rat livers with chronic hepatitis was defined as the median effective concentrations of phenylephrine and acetylcholine.

Key words: Chronic hepatitis; Isolated portal perfused rat liver; Pharmacodynamic model; Portal hypertension

A pharmacodynamic model of portal hypertension in isolated perfused rat liver. *World J Gastroenterol* 2012; 18(5): 472-478 Available from: URL: http://www.wjgnet.com/1007-9327/full/v18/i5/472.htm DOI: http://dx.doi.org/10.3748/wjg.v18.i5.472

INTRODUCTION

Patients with portal hypertension have significant mortality[1]. A lack of drugs[2] to treat this disease is derived from the failure to use the reversible mechanisms in its pathogenesis[3]. Being similar to amiloride, a candidate drug for portal hypertension[4], molecules from medical plants have been demonstrated to affect portal hypertension in rats[5-7] and in patients[8] with chronic hepatitis. The effect of these molecules on relaxation of the extrahepatic portal rings did not account for the efficacy of these therapies *in vivo*[9]. A novel mode of portal perfusion has been characterized with both controlled velocity and monitored pressure in the isolated portal perfused rat liver (IPPRL)[10-12]. With the primary velocity and preload at the various advanced stages of CCl_4-induced chronic hepatitis in rats, constriction with phenylephrine (PE) and relaxation with acetylcholine (Ach) were more sensitive than those reported previously[13,14]. With standardization of the IPPRL[15], both median effective concentrations of Ach and PE were defined as the pharmacodynamic model of portal hypertension. Both the controlled velocity and monitored pressure made the model sensitive enough for the basis of systems biology in portal regulation[16].

MATERIALS AND METHODS

Materials

Thirty two healthy male Wistar rats weighing 200-220 g were supplied by the Animal Center of the Chinese Academy of Medical Sciences. Standard rodent pellets for rats were prepared by Beijing Scientific Animal Feedstuff Company. The study was approved by the Animal Study Committee of the Chinese Academy of Medical Sciences. All experimental procedures were performed in accordance with the Guidelines of Animal Experiments from the Committee of Medical Ethics, National Health Department of China. All rats were maintained in a temperature-controlled room (25.0 ℃ ± 0.2 ℃) in the SPF laboratory, with a 12-h/12-h light/dark photoperiod and 45% ± 2% humidity. The rats were fed standard rodent pellets and allowed free access to tap water throughout the experiment.

Carbon tetrachloride (CCl_4, MW 153.84, CAS 56-23-5), Olive oil (CAS 8001-25-0) and Heparin sodium (MW 12 000, CAS 9041-08-1) were purchased from Sinopharm Chemical Reagent Company to induce chronic hepatic hepatitis or for anticoagulation.

As the perfusate in portal perfusion, Krebs-Henseleit solution consisted of KCl 4.7, KH_2PO_4 1.2, $CaCl_2$ 2.5, $MgSO_4$ 1.2, NaCl 118, and Glucose 11.0 mmol/L in the final concentration at pH 7.35-7.45 equilibrated with 95% O_2-5% CO_2 and warmed to 37.8 ℃ before being added to the livers.

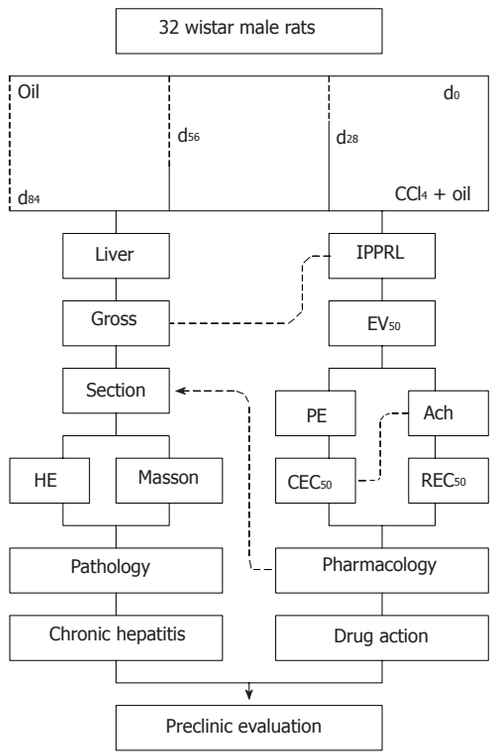

Figure 1 Group design of pharmacological model of portal hypertension. Oil indicated was administered subcutaneously with 3 mL/kg olive oil twice weekly for 84 d, as was CCl_4 + Oil 40% (v/v) CCl_4 in olive oil; IPPRL: Isolated portal perfused rat livers; EV_{50}: Median effective velocity; PE: Phenylephrine; Ach: Acetylcholine; CEC_{50}: Median effective concentration of PE constriction; REC_{50}: Median effective concentration of Ach relaxation; HE: Hematoxylin and eosin.

Phenylephrine hydrochloride (PE, MW 203.67, CAS 61-76-7) and Acetylcholine chloride (Ach, MW 181.67, CAS 60-31-1) were purchased from Sigma (United States) as the α_1-adrenoceptor and M_3-cholinoceptor agonist, respectively, used to elevate or reduce portal pressure.

Experimental design

Male Wistar rats were randomly divided into four groups. In four rats, PE was used to constrict the portal vein and in the other rats Ach was used to relax the portal vein in each group. Group 1 was the vehicle control without CCl_4 In this group, rats were subcutaneously administered 3 mL/kg olive oil twice weekly for 84 d. Groups 2, 3 and 4 were model groups with CCl_4-induced chronic hepatitis, the rats in these groups were subcutaneously administered the same volume of a mixture of 40% (v/v) CCl_4 in olive oil twice weekly for 28 d, 56 d and 84 d, beginning at d_{58}, d_{28}, and d_0, respectively (Figure 1). Forty-eight hours after the last CCl_4 injection, rats were anesthetized with 50 mg/kg pentobarbital sodium subcutaneously; a midline incision was made to expose the liver and its vessels. The hepatic artery, portal vein and hepatic vein were canalized. The remaining blood in the IPPRLs

Table 1 Hepatic pathological changes in model rats (mean ± SE, n_1 = 8)

Advanced	Lobule ratio	Collagen ratio
d_0	0.38 ± 0.05	0.0000700 ± 0.0001180
d_{28}	0.33 ± 0.04[b]	0.0019658 ± 0.0024864[b]
d_{56}	0.11 ± 0.04[b,d]	0.0043315 ± 0.0048768[b,d]
d_{84}	0.06 ± 0.01[b,d,f]	0.0143996 ± 0.0143860[b,d,f]

Lobule ratio is the average percentage obtained from ten random fields using Image-Pro Plus v 5.1 software, and each field had a ratio of lobule area per total analyzed field area in hematoxylin-eosin stained sections under a Digital Pathology System at × 20 magnification from isolated portal perfused rat livers. Collagen ratio is the average percentage obtained from ten random fields using Image-Pro Plus v 5.1 software, and each field had a ratio of collagen area per total analyzed field area in Masson-stained sections under a Digital Pathology System at × 40 magnification from isolated portal perfused rat livers. a and b denote significant ($^bP < 0.01$) differences between those at d_0 and at d_{28}, d_{56}, or d_{84}. c and d denote significant ($^cP < 0.05$ and $^dP < 0.01$) differences at d_{28} and at d_{56}, or d_{84}. e and f denote significant ($^eP < 0.05$ and $^fP < 0.01$) differences at d_{56} and at d_{84}.

was eliminated using Krebs-Henseleit perfusate through the hepatic artery. When portal perfusion was complete, a small portion of the liver was removed for pathological examination following fixation with 40 g/L formaldehyde solution and subsequent embedding in paraffin.

Protocol for portal perfusion

When CCl_4-induced chronic hepatitis was complete, eight rats from each group were randomized into two subgroups, one for PE constriction and the other for Ach relaxation of the portal vein. Each IPPRL was instrumented for portal pressure measurement.

Each IPPRL was perfused in a recirculation at a fixed temperature of 37.8 ℃ and equilibrated with 95% O_2-5% CO_2 mixed gas (Beijing Specialized Mixed Gas Institute), portal velocity was precisely controlled by a quantified BTO_1 pump (Beijing Yidaxk Technical Company), and 3935.50, 4720.63, 4753.35, and 5164.16 (μL/min) at d_0, d_{28}, d_{56}, and d_{84}, were chosen, respectively, the equation of portal perfusion median velocity (Y) from the day (x) of chronic hepatitis was Y = 13.28x + 4085 (r = 0.935, P < 0.01)[12].

The portal pressure of perfusion (mmHg) was continuously monitored and recorded with a strain-gauge transducer connected to the portal inflow cannula 6 cm proximal to the perfusion cannula with BL-420S Physiological Systems (Taimeng Instruments, Chengdu) according to a previously published method[10-14]. The global viability of livers was assessed by gross appearance and perfusate stable pH.

Pharmacodynamic actions

Perfusions were performed in the recirculating system containing 300 mL Krebs-Henseleit solution. Each preparation was allowed to stabilize for 15 min. The flow rate during each individual perfusion was maintained at a constant rate equalized to the portal perfusion median velocity at d_0, d_{28}, d_{56}, and d_{84}, respectively, the average portal pressure during this condition had been designated as the baseline. With a fixed volume of the recirculating perfusate in the portal perfusion system, cumulative geometric concentrations of PE (10^{-12}-10^{-6} mol/L) were added to elevate portal pressure.

After the median effective concentration of PE to constrict the portal vein was added, cumulative geometric concentrations of Ach (10^{-13}-10^{-7} mol/L) were added to reduce portal pressure.

Concentration-response curves were obtained following the addition of PE and Ach, and the changes in intrahepatic resistance expressed as the percentage increase or decrease in perfusion pressure from baseline in the various portal perfused velocities were obtained.

Pathological changes due to chronic hepatitis

To observe pathological changes after portal perfusion, a portion of the left liver lobe (40 mg) from each liver was fixed in 40 g/L formaldehyde solution for 48 h, embedded in paraffin, sectioned (6 μm), and stained with hematoxylin-eosin and Masson according to standard procedures.

Images were acquired with a Nano Zoomer Digital Pathology system (Hamamatsu, Japan), at a low magnification (× 20); all the compartments of the liver were analyzed. At high magnification (× 40), the collagen density in the liver section was quantified using a computerized image analysis system (Image-Pro Plus v 5.1). The density of collagen in blinded specimens was expressed as a percentage (the ratio of collagen area per total analyzed field area). The average of the score taken from ten random fields was used to generate a single score for each IPPRL.

Statistical analysis

All primary data are presented as means ± SE for each dosage in each group. Statistical significance was calculated using Student's t test between groups, P < 0.05 was significant. (1) Dose-effect relationship: The equation, the median effective concentration and its 95% confidence intervals of PE or Ach were calculated by regression analysis using Graph-Pad Prism 4 in non-linear fit and various slopes, to express the dose-effect relationship; and (2) Time-effect relationship: The median effective concentrations of PE or Ach were calculated by linear regression analysis with the duration (0 d, 28 d, 56 d, and 84 d) of chronic hepatitis, to express the time-effect relationship of pathological conditions affecting the portal response to both molecules.

RESULTS

Pathological changes due to chronic hepatitis

Lobule or pseudo-lobule ratio: Hepatic tissues were clear in hematoxylin and eosin-stained sections. When compared with those in control rats at d_0, the lobule ratios (Table 1) in the model rats at d_{28}, d_{56} and d_{84} were significantly decreased by 4.04%, 70.22%, and 83.82%, respectively (P < 0.01). When compared with those at d_{28}, the pseudo-lobule ratios in the model rats at d_{56} and d_{84} were significantly decreased by 65.35% and 81.00%, respectively (P < 0.01). In addition,

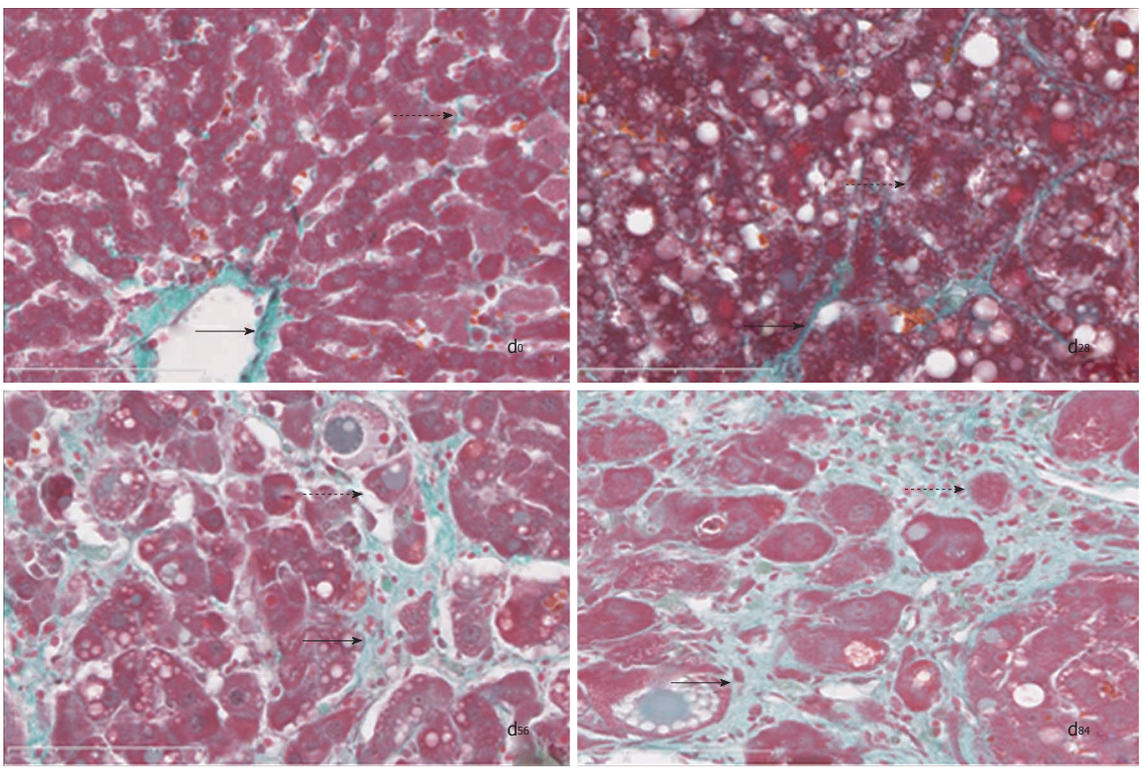

Figure 2 Collagen distributions in rat model livers (Masson × 40). Normal hepatic structure (d_0) was demonstrated in control rats administered 3 mL/kg olive oil subcutaneously twice weekly for 84 d. Hepatic degeneration (d_{28}), fibrosis (d_{56}) and cirrhosis (d_{84}) were seen in the chronic hepatitis model rats administered 3 mL/kg 40% (v/v) CCl_4 in olive oil subcutaneously twice weekly for 28 d, 56 d, and 84 d, respectively. There was less collagen mainly around the central veins (solid arrow) and the portal areas, with some staining noise signals in lobules (dashed arrow) in normal hepatic structure (d_0). The collagen fiber bundles (solid arrow) had partly spread into the lobules from the portal areas, the hepatic cells had obvious watery and fatty degeneration (dashed arrow) and had not been isolated by collagen during hepatic degeneration (d_{28}). The collagen fiber bundles (solid arrow) had completely separated some of the lobules to form many pseudo-lobules, several hepatic cells with obvious fatty degeneration (dashed arrow) had been completely isolated by collagen in hepatic fibrosis (d_{56}). The collagen fiber bundles (solid arrow) had limited smaller pseudo-lobules, some single hepatic cells (dashed arrow) were completely isolated by collagen in hepatic cirrhosis (d_{84}).

these ratios were significantly decreased by 45.67% at d_{84} compared with those at d_{56} ($P < 0.01$).

Hepatic collagen distribution: Hepatic histological changes in Masson-stained sections showed collagen depositions along with CCl_4-induced chronic hepatitis (Figure 2). (1) Normal structure at d_0: The histological structure in control rats showed normal hepatic architecture with some fatty degeneration and less collagen located at the lobules; (2) Degeneration at d_{28}: The pathological changes in the model rats at d_{28} showed mainly hepatic fatty degeneration and cellular swelling, collagen was deposited around the center veins, thus the enlarged hepatic cords severely narrowed the hepatic sinusoid; (3) Hepatic fibrosis at d_{56}: The pathological changes in the model rats at d_{56} showed more collagen deposited in the lobules, thus the enlarged hepatic cords led to significant widening of the hepatic sinusoid; and the collagen in interlobular area extended into the lobules, some separating the lobules completely, therefore the direction of the circulating blood did not change in the hepatic sinusoid of the lobules; and (4) Hepatic cirrhosis at d_{84}: The pathological changes in the model rats at d_{84} showed extensive collagen deposited in the lobules, which were all pseudo-lobules instead of normal lobules, thus the direction of the circulating blood had completely changed in the hepatic sinusoid.

Deposited collagen ratio: Compared with the control rats (Table 1), the collagen ratio in the model rats at 28 d, 56 d and 84 d was significantly increased by 2707.65%, 60 860.51%, and 20 466.49%, respectively ($P < 0.01$). Compared with the model rats at 28 d, the collagen ratio in the model rats at 56 d and 84 d was significantly increased by 120.34% and 632.52%, respectively ($P < 0.01$). The collagen ratio in the model rats at 84 d increased by 232.44% compared to that at 56 d ($P < 0.01$).

Pharmacodynamic actions on the portal vein

Phenylephrine elevated portal pressure: Geometric concentrations of PE to activate the α_1 receptor were added to the recirculating perfusate to elevate perfused portal pressure (Table 2 and Figure 3). The equation, the median effective concentration of PE and its 95% confidence intervals were regressed: (1) dose-effect at d_0: The data showed that the equation of PE was $Y = 0.1732 + 0.3970/[1 + 10^{(-4.3061-0.4407\ x)}]$ ($r = 0.9701$, $P < 0.01$); the median effective concentration with its 95% confidence intervals was 1.69×10^{-10} (4.9769×10^{-12} - 5.7599×10^{-9}) mol/L; (2) dose-effect at d_{28}: The data showed that the equation of PE was $Y = -0.004934 + 0.121134/[1 +$

Rats with chronic hepatitis at three stages, hepatic degeneration (d_{28}), fibrosis (d_{56}) and cirrhosis (d_{84}), were administered 3 mL/kg 40% (v/v) CCl_4 in olive oil subcutaneously twice per week for 28 d, 56 d and 84 d, respectively. Ach: Acetylcholine.

10^{-11}) mol/L; (3) dose-effect at d_{56}: The data showed that the equation of Ach was Y = -0.2733 + 0.22978/[1 + $10^{(3.0472 + 0.3008\ x)}$] ($r$ = 0.9964, P < 0.01); the median effective concentration with its 95% confidence intervals was 5.98 × 10^{-11} (4.2797 × 10^{-12} - 8.3556 × 10^{-11}) mol/L; (4) dose-effect at d_{84}: The data showed that the equation of Ach was Y = -0.0559 + 0.053178/[1 + $10^{(5.6336 + 0.5883\ x)}$] ($r$ = 0.9956, P < 0.01); the median effective concentration with its 95% confidence intervals was 2.66 × 10^{-10} (6.5887 × 10^{-11} - 1.0701 × 10^{-9}) mol/L; and (5) time-effect: The linear regression equation was Y = 0.046 X -1.470 (r = 0.945, P < 0.05) between the median effective concentrations of Ach (0.0773, 0.598 and 2.66) × 10^{-10} mol/L and the durations (28 d, 56 d and 84 d) of chronic hepatitis.

DISCUSSION

Patients with portal hypertension have significant morbidity and mortality[1] without special drugs[2] based on the reversible pathogenesis of this disease[3]. Some candidate drugs from chemicals and medical plants have demonstrated effects on portal hypertension in animal experiments and in clinical trials[4-8]. Data from the extrahepatic portal rings failed to account for these effects[9]. Consequently, sensitive portal perfusion for intra-hepatic portal resistance has been developed with both controlled velocity and monitored pressure in IPPRLs[10-14]. The pharmacodynamic model of portal hypertension has further been defined as the median effective concentrations of Ach and PE in the IPPRLs at various stages of CCl_4-induced chronic hepatitis.

At d_0, d_{28}, d_{56}, and d_{84} in CCl_4-induced chronic hepatitis, there were similar portal pressure potency equations with various coefficients due to the concentrations of PE and Ach in the IPPRLs. The median effective concentrations of PE increased geometrically during the process, suggesting that the function of portal smooth muscle cells gradually decreased. A similar effect was noted with the median effective concentrations of Ach in advanced stages, which suggested that portal endothelia were gradually damaged. During portal perfusion with both controlled pressure and monitored velocity, as reported previously, the effective range of PE and Ach concentrations was from 10^{-3} mol/L to 10^{-8} mol/L[15,16]. In this novel model of portal perfusion with both controlled velocity and monitored pressure, the effective range was from 10^{-6} mol/L to 10^{-12} mol/L, which indicated that this novel mode was more sensitive than the previous mode by 10^3-10^6 times in IPPRLs.

Hepatocyte injuries originate from the free radicals of CCl_4 metabolites[3]. Amiloride reduced intra-hepatic portal resistance through inhibition of the Rho kinase pathway in hepatic stellate cells[4]. Glycyrrhizinate and Salvianolic acid B are representative molecules from medical plants used for portal hypertension in rats[5-7] and patients[8] with chronic hepatitis, however, their biomolecular mechanisms are not yet clear. PE, as a α_1-adrenoceptor agonist, constricts vascular smooth muscle[13] and Ach, as a M_3-cholinoceptor agonist in endothelia, relaxes vascular smooth muscle[14]. Due to these mechanisms in IPPRLs, the median perfused velocity in portal pressure has been defined as the primary flow rate of portal perfusion in this novel mode, the median effective concentration of PE for elevating portal pressure as the preload, the median effective concentration of Ach for reducing the portal pressure as the positive action at the classic stages of the pathological process in chronic hepatitis.

The pharmacodynamic model of portal hypertension has been defined as both the median effective concentrations of PE and Ach in the IPPRLs with advanced chronic hepatitis in this study. This model may be used to evaluate the preclinical effects of candidate drugs for the treatment of portal hypertension. Both controlled velocity and monitored pressure[10-12] made this model more sensitive than previous models[13-14]. Based on the standardization[15] of the IPPRL, this sensitive model is considered the basis of systems biology for portal regulation in an isolated setting[16].

COMMENTS

Background

Portal hypertension results in significant mortality without the administration of special drugs. Candidate drugs for this condition require serious pre-clinical evaluation using suitable methods.

Research frontiers

The recently identified reversible pathogenesis of portal hypertension may allow the development of new drugs for this disease. Candidate drugs derived from medical plants used in Chinese medical practices have confirmed its reversible pathogenesis. A sensitive pressure transducer was used here for exploiting the reversible pathogenesis as the pharmacological models. The optimal conditions for each step of the procedure can be defined as an available model.

Innovations and breakthroughs

Reversible portal hypertension was replicated in the advanced stages of chronic hepatitis in rats using CCl_4. A pharmacological model was developed using the median primary velocity of perfused flow as the anatomical preload, median effective concentrations of phenylephrine to constrict portal veins as the physiological preload, and the median effective concentrations of acetylcholine to relax portal veins in IPPRLs with chronic hepatitis.

Applications

This novel pharmacological model can be used to evaluate candidate drugs for the treatment of portal hypertension.

Terminology

This novel mode of portal perfusion is characterized by both controlled velocity and monitored pressure in the isolated portal perfused rat livers. The controlled velocity creates the optimal conditions for research purposes, and the monitored pressure gives exact data from vascular smooth muscle or endothelia.

Peer review

The authors investigated to develop a pharmacodynamic model for portal hypertension from chronic hepatitis. They have developed a pharmacodynamic model for portal hypertension in rats with chronic hepatitis and demonstrated that the model had been defined as the median effective concentrations of phenylephrine and acetylcholine. The results are clear and informative for the study on portal hypertension.

Abstract

AIM: To assess the safety of *Bifidobacterium longum* (*B. longum*) JDM301 based on complete genome sequences.

METHODS: The complete genome sequences of JDM301 were determined using the GS 20 system. Putative virulence factors, putative antibiotic resistance genes and genes encoding enzymes responsible for harmful metabolites were identified by blast with virulence factors database, antibiotic resistance genes database and genes associated with harmful metabolites in previous reports. Minimum inhibitory concentration of 16 common antimicrobial agents was evaluated by *E*-test.

RESULTS: JDM301 was shown to contain 36 genes associated with antibiotic resistance, 5 enzymes related to harmful metabolites and 162 nonspecific virulence factors mainly associated with transcriptional regulation, adhesion, sugar and amino acid transport. *B. longum* JDM301 was intrinsically resistant to ciprofloxacin, amikacin, gentamicin and streptomycin and susceptible to vancomycin, amoxicillin, cephalothin, chloramphenicol, erythromycin, ampicillin, cefotaxime, rifampicin, imipenem and trimethoprim-sulphamethoxazol. JDM301 was moderately resistant to bacitracin, while an earlier study showed that bifidobacteria were susceptible to this antibiotic. A tetracycline resistance gene with the risk of transfer was found in JDM301, which needs to be experimentally validated.

CONCLUSION: The safety assessment of JDM301 using information derived from complete bacterial genome will contribute to a wider and deeper insight into the safety of probiotic bacteria.

Key words: *Bifidobacterium longum*; Safety assessment; Genome; Antibiotic resistance; Harmful metabolite; Virulence factor

INTRODUCTION

Bifidobacteria spp are high-GC content, Gram-positive bacteria which belong to the *Actinobacteria* branch and these species naturally colonize the gastrointestinal tract (GIT) of mammals, birds and insects[1]. Scientists have determined the major probiotic properties of *Bifidobacteria* spp isolated from the human intestine and these properties include the strengthening of the intestinal barrier, modulation of the immune response and antagonism of pathogens[2].

Bifidobacterium spp has been reported to possess various glycosyl hydrolases (GH) and these hydrolases metabolize plant- or milk-derived oligosaccharides including nondigestible ones such as galacto-oligosaccharides (GOS) and fructo-oligosaccharides (FOS)[3,4]. The capability to utilize nondigestible oligosaccharides confers a competitive advantage to *Bifidobacterium* spp in the human gut.

Bifidobacterium longum (*B. longum*) and various other bifidobacteria strains are often added to probiotic products in combination with other lactic acid bacteria (LAB). Through their long and safe history of application, LAB have acquired the status of "Generally Regarded As Safe" (GRAS), but the safety of *Bifidobacteria* and other LAB strains selected for probiotics still need to be carefully evaluated. The key safety aspects for use of bifidobacteria and other LAB strains in probiotics include antibiotic resistance, production of harmful metabolites and the potential for virulence. Antibiotic resistance in potential probiotic strains is not considered a risk factor unless resistance is transferred to pathogens or it renders the *probiotic untreatable* in very rare cases of infection[5]. Biogenic amines, D-lactic acid, azoreductases and nitroreductases produced by bifidobacteria and other LAB strains are potential health hazards[6,7] and the safety of some of these compounds have been evaluated[8]. Virulence genes may be present in commensal bacteria and absence of virulence in these bacteria needs to be proved on a case by case basis.

Probiotic agents are widely used in the food and drug industry and as more commercial probiotic products are being introduced in the market, it is timely to reassess the safety of these probiotic products using the latest technology. Information from the complete genome sequences of *Bifidobacteria* will provide additional insight into the genetic basis for their safety. We sequenced the complete genome sequences of *B. longum* JDM301 (GenBank accession number CP002010), a commercial strain used widely in China with several probiotic functions, for this purpose[9].

The aim of the present work was to assess the safety of *B. longum* JDM301 based on complete genome sequences. The criteria used were the potential to transfer antibiotic resistance to pathogens, the potential for production of harmful metabolites and the potential for virulence.

MATERIALS AND METHODS

Bacterial strains and growth conditions

JDM301 was isolated from commercial probiotic product and identified using a sequence analysis of its 16S rRNA gene. De Man-Rogosa-Sharpe (MRS) broth (Difco) supplemented with 0.05% L-cysteine·HCl (Sigma) was used for cultivating JDM301. Cultures were incubated at 37 ℃ under anaerobic conditions.

Genome sequencing and assembly

We determined the complete genome sequence of JDM301 at the Chinese National Human Genome Center in Shanghai using the GS 20 system (454 Life Science Corporation, Branford, Connecticut). A total of 192 888 reads with an average length of 210 bps were assembled into 112 contigs by the 454 assembly tool. The order of most large contigs, which were larger than 500 bp, was determined through the basic local alignment search tool (BLAST) analysis with the reference strain *B. longum* ATCC15697 (GenBank accession number CP001095) and the others were arranged by multiplex polymerase chain reaction (PCR). Gap closure was carried out by sequencing gap-spanning PCR products or clones using ABI 3730 xl DNA sequencers. Primer design and sequence assembly were performed by the Phred/Phrap/Consed software package[9]. The locations of low-quality sequences in genome were verified by directly resequencing the PCR products spanning the low-quality sequences using the ABI 3730 xl DNA sequencers.

Statistical analysis

The genome sequences of *Bifidobacteria* except JDM301 were retrieved from GenBank at the National Center for Biotechnology Information (http://www.ncbi.nlm.nih.gov/)[10]. Potential open reading frames (ORF) were identified using Glimmer[11] and ZCURVE[12] 1.0 using default settings. Clusters of orthologous group (COG) functional categories were used for functional classification of all genes in the genome sequences of JDM301 and the COGs. A BLAST analysis of the translations with GenBank's nonredundant database was performed, which was followed by manual curation. The best matches were chosen for preliminary product assignments. Insertion sequences (IS) elements, prophage sequences and clustered regularly interspaced short palindromic repeats (CRISPR) were identified by IS finder (http://www-is.biotoul.fr/is.html), Prophage Finder[13] and CRISPRFinder (http://crispr.u-psud.fr/crispr/)[14] respectively. Putative orthologues were determined by Omics Explorer (http://omics.biosino.org:14000/kweb/about.jsp) using default values. Ribosomal RNA genes were detected on the basis of BLASTN searches and transfer RNA genes were identified using tRNAscan-SE[15]. The atlas of genome was drawn using GenomeViz1.1[16]. Putative virulence factors and putative antibiotic resistance genes were identified by blast with virulence factors database (VFDB) (http://www.mgc.ac.cn/VFs/main.htm)[17] and antibiotic resistance genes database (ARDB) (http://ardb.cbcb.umd.edu/)[18] respectively.

Antibiotic susceptibility

Minimum inhibitory concentration (MIC) of 16 common

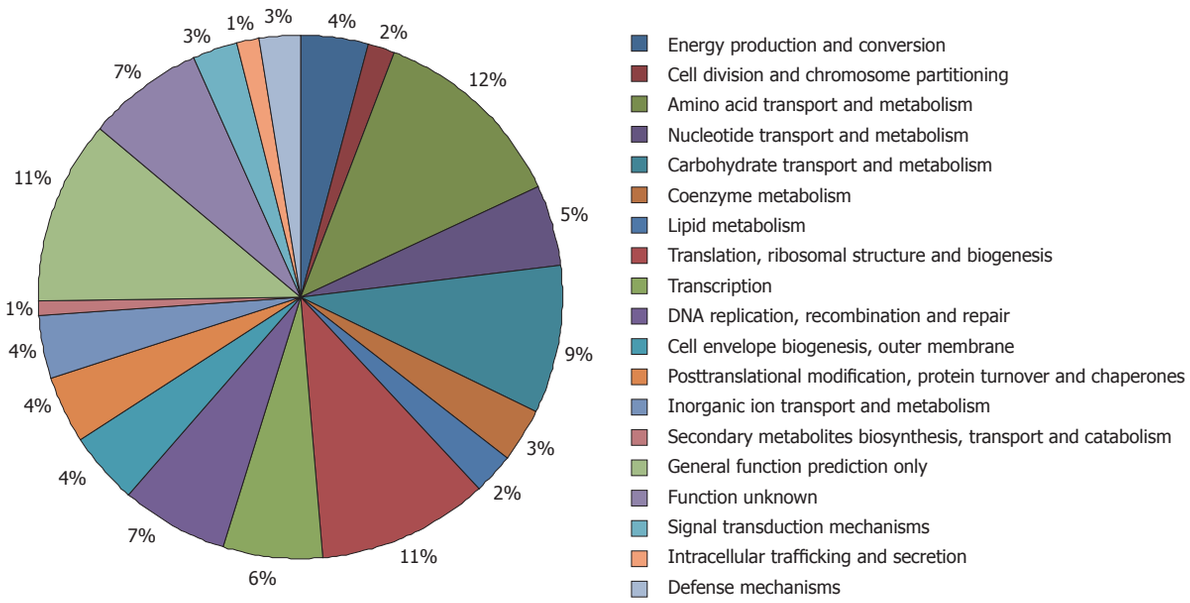

Figure 1 Functional distribution of *Bifidobacterium longum* core proteins. A total of 1265 proteins were conserved in all four *Bifidobacterium longum* (*B. longum*) strains (*B. longum* JDM301, *B. longum* NCC2705, *B. longum* DJO10A and *B. longum* ATCC15697), representing the "core" genome of *B. longum*.

antimicrobial agents was evaluated by *E*-test (AB Biodisk, Solna, Sweden) including amoxicillin (0.016-256 mg/L), amikacin (0.016-256 mg/L), ampicillin (0.016-256 mg/L), bacitracin (0.016-256 mg/L), cephalothin (0.016-256 mg/L), ciprofloxacin (0.002-32 mg/L), cefotaxime (0.016-256 mg/L), chloramphenicol (0.016-256 mg/L), erythromycin (0.016-256 mg/L), gentamicin (0.016-256 mg/L), imipenem (0.002-32 mg/L), rifampicin (0.016-256 mg/L), streptomycin (0.016-256 mg/L), tetracycline (0.016-256 mg/L), trimethoprim-sulphamethoxazol (0.002-32 mg/L), and vancomycin (0.016-256 mg/L). Tests were done with MRS agar supplemented with 0.05% L-cysteine·HCl (Sigma) and were conducted in triplicate for each antibiotics. Cultures sub-inoculated into the MRS agar supplemented with 0.05% L-cysteine·HCl were incubated anaerobically at 37 ℃ for 24 h.

RESULTS

Comparative genomic analysis of Bifidobacteria

The predicted proteins of *B. longum* JDM301 were functionally categorized. The functional distribution of genes assigned to clusters of orthologous groups of proteins was relatively similar to the other *Bifidobacteria*, e.g., *B. longum* and *B. adolescentis* in the GIT and *B. dentium* in the oral cavity[3,4,19]. The top four functional categories in *B. longum* JDM301, namely, carbohydrate transport and metabolism, amino acid transport and metabolism, were identical with other *Bifidobacteria*[20].

Putative orthologues among *B. longum* strains were determined in a comparative study (Figure 1). Overall, 1265 proteins were conserved in all four *B. longum* strains (*B. longum* JDM301, *B. longum* NCC2705, *B. longum* DJO10A and *B. longum* ATCC15697). These proteins represent the "core" genome of *B. longum*, whereas 219 proteins are unique to *B. longum* JDM301. The most common functional distributions of the core proteins were these involved in housekeeping functions including amino acid transport and metabolism, translation, ribosomal structure and biogenesis, carbohydrate transport and metabolism and DNA replication, recombination and repair. Twenty-one percent of the core proteins were dedicated to carbohydrate and amino acid transport and metabolism, indicating the important roles of these proteins in *Bifidobacteria*.

Stability of the genome of B. longum JDM301

Horizontal gene transfer (HGT) events are responsible for introduction of alien genes, which may reinforce the adaptation of bacteria in their specific niches. Genes on plasmids, bacteriophages, genomic islands and IS are sensitive to HGT[21]. Twelve phage-related fragments were identified in the genome of *B. longum* JDM301[9], but no complete prophages were found. The JDM301 chromosome also possesses 15 complete or disrupted IS elements[9]. The number of IS element in JDM301 is relatively smaller than the other sequenced *B. longum* spp[3,4]. Another set of genes disseminated by HGT in *Bifidobacteria* is the CRISPR-related system. No CRISPR was discovered in the genome.

One complete type Ⅱ restriction-modification (R-M) system and one type Ⅲ R-M system were present in the genome of JDM301. A complete and incomplete type Ⅰ R-M system was also identified in this genome. Two complete type Ⅱ R-M systems and one type Ⅰ R-M system were present in the genome of *B. longum* NCC2705, while one complete type Ⅱ R-M system and type Ⅰ R-M system were found in *B. longum* DJO10A.

Antibiotic resistance determinants

The antibiotic resistance genes in JDM301 were identified

ABC: ATP-binding cassette; RND: Resistance-nodulation-cell division.

using ARDB (E < 1e-2, coverage > 70%)[18]. Homologs of the antibiotic resistance determinants for vancomycin, methicillin, tetracycline, chloramphenicol and trimethoprim were found in the genome of JDM301 (Table 1) and 6 putative resistance genes for vancomycin. *B. longum* JDM301 also possessed 5 putative bacitracin efflux pumps, 5 homologs of macrolide efflux proteins. Additionally, 7 putative multidrug resistance efflux pumps belonging to an ATP-binding cassette (ABC)-type transport system, a major facilitator superfamily transporter and resistance-nodulation-cell division (RND) family were found in the genome. The genome of *B. longum* JDM301 also contains 4 tetracycline resistance genes encoding for TetV, TetW, TetPB and TetQ. The gene for TetW shows a strong difference in G + C content (53.0%) compared to the average value of *B. longum* JDM301 (59.8%) genome and it is flanked by genes encoding for integrases, indicating that this region may have been acquired by HGT.

Table 2 Minimum inhibitory concentration values of 16 antibiotics for *Bifidobacterium longum* JDM301

Antibiotics	Minimum inhibitory concentration (mg/L)
Ciprofloxacin	> 32
Amikacin	> 256
Gentamicin	> 256
Bacitracin	26.67
Streptomycin	170.67
Vancomycin	0.9
Amoxicillin	0.064
Cephalothin	1.33
Chloramphenicol	0.25
Erythromycin	0.04
Ampicillin	0.058
Cefotaxime	0.19
Rifampicin	0.074
Tetracycline	8
Imipenem	0.19
Trimethoprim-sulphamethoxazol	1.83

The antibiotic susceptibility of *B. longum* JDM301 to 16 antibiotics was determined by an *E*-test to probe the *in silico* analyses of the complete genome sequence. The results of the *E*-test are summarized in Table 2. The breakpoints for determining susceptibility were determined using accepted protocols[22-25]. *B. longum* JDM301 showed a high resistance to ciprofloxacin, amikacin and gentamicin, moderate resistance to streptomycin and bacitracin and were sensitive to tetracycline, vancomycin, amoxicillin, cephalothin, chloramphenicol, erythromycin, ampicillin, cefotaxime, rifampicin, imipenem and an antimicrobial compound, trimethoprim-sulphamethoxazol.

Putative enzymes for harmful metabolites

Genes encoding enzymes responsible for harmful metabolites, including beta-glucosidase (GS), arylsulphatase (AS), beta-glucuronidase (GN), nitroreductase (NR), azoreductase (AR), D-lactate dehydrogenase (DLD), amino acid decarboxylase (AD) and conjugated bile salt hydrolase (CBSH) were searched for in the genome of *B. longum* JDM301. Two GS genes (BLJ_1280, BLJ_1540) and one CBSH gene (BLJ_0948) were found in the chromosome of *B. longum* JDM301. Homologs of DLD (BLJ_1306, BLJ_1436) and NR (BLJ_1980) were also discovered in the genome. Enzymes involved in putatively harmful metabolites, AR, GN, AD and AS were not found in JDM301 genome.

Putative virulence factors

Published reports of rare infections involving *Lactobacilli* or *Bifidobacteria* are available and the potential virulence of *Lactobacilli* or *Bifidobacteria* used as probiotics should be assessed[5]. Putative virulence genes of *B. longum* JDM301 were determined by BLAST analysis of the VFDB[17]. A total of 141 homologs of virulence factors were identified in the genome of JDM301, including 28 sugar-binding transcriptional regulators, 20 genes associated

with iron, amino acid and sugar transport, 5 transposases, and 2 glutamine synthetase related to plasminogen (Plg)-binding (Table 3).

Although the ability to adhere to the intestinal wall has been one of the selection criteria for probiotics and also a characteristic of commensal bacteria in the intestine, adhesion is also considered to be a significant step in the initial pathogen infections[26]. Thus, predicted proteins for adhesion of JDM301 were also included in the analysis of virulence. A total of 21 predicted proteins for adhesion were identified in JDM301 (Table 4). A large number of predicted surface and extracellular proteins were identified in JDM301, which may be involved in the bacterium-host interaction as in other LAB[27]. A total of 217 proteins with probable Sec-type signal peptides were identified by the tool, Signal P[28]. The genome of JDM301 also harbors 18 copies of extracellular solute-binding protein (SBP, pfam01547) which is predicted to bind oligosaccharides (SBP family 1) as a component of the ABC transporter complex.

DISCUSSION

As more probiotic strains are used in the food and drug industry, more attentions should be paid to the safety of strains used as probiotics. Thus, the safety of LAB used as probiotics need to be reassessed using the latest technology. *B. longum* JDM301, is a commercial probiotic strain used in many probiotic products sold in China. Analysis of the genome of JDM301 reveals several potential risk factors needing further experimental validation, including a tetracycline resistance gene (*tetW*) with the risk of transfer, and the genes associated with harmful metabolites.

Bifidobacteria were considered free of phage infection until prophage-like elements were identified in the genomes of *B. longum* NCC2705, *B. longum* DJO10A and *B. breve* UCC2003[29]. Absence of complete prophages is important for the stability of genomes and for industrial applications of probiotic bacteria[21,30]. Absence of complete prophages and scarcity of IS element may play important roles in promoting genome stability of JDM301[31]. Another set of genes disseminated by HGT in *Bifidobacteria* is the CRISPR-related system (CASS), which is involved in defense against phages and plasmids[32]. No CRISPR was discovered in the genome. R-M systems are diverse and widespread in nature and they are considered as barriers to HGT, e.g., in transformation and phage infection[33]. The diversity of R-M systems in *B. longum* JDM301 may be significant to the stability of genome and its use in industry compared with the other two *B. longum* strains.

B. longum JDM301 was not resistant to tetracycline as the minimum inhibitory concentration (8.0 mg/L) was not higher than the breakpoint value (8.0 mg/L)[34]. However, the MIC for *B. longum* strains ranges from 0.5 to 2 mg/L in a report[35]. Thus, further experiments may be needed to determine the microbiological breakpoint. The *tetW* (BLJ_1245) gene encodes for a ribosomal protection protein and *tetW* genes were responsible for acquired tetracycline resistance in human *B. longum* strains[36]. The rest of the tetracycline resistance genes found in *B. longum* JDM301 were *tetV* (BLJ_0814), *tetQ* (BLJ_1401) and *tetPB* (BLJ_0594). The gene *tetV* encodes for a tetracycline efflux pump and the genes *tetQ* and *tetPB* encode for ribosomal protection proteins. Further experiments are needed to confirm whether the *tetW* gene in the chromosome of *B. longum* JDM301 is a transferable antibiotic resistance determinant and responsible for resistance to tetracycline in human *B. longum* strains.

The MIC of *B. longum* JDM301 to bacitracin was 26.7 mg/L, which indicated a moderate resistance. A previous report[25] indicated that *B. longum* strains were susceptible to bacitracin. A total of 7 putative bacitracin resistance genes were identified, including 6 genes encoding for ABC transporters and 1 for an uncharacterized bacitracin resistance protein. These genes may be responsible for the resistance to bacitracin.

The resistances to ciprofloxacin, amikacin, gentamicin and streptomycin and susceptibility of JDM301 to vancomycin, amoxicillin, cephalothin, chloramphenicol, erythromycin, ampicillin, cefotaxime, rifampicin, imipenem and an antimicrobial compound, trimethoprim-sulphamethoxazol were consistent with reported findings[22-25,36]. However, there are discrepancies between the phenotype and the genotype. *B. longum* JDM301 was sensitive to vancomycin and chloramphenicol but the genome contained vancomycin and chloramphenicol resistance genes. Further analysis will be needed to determine this discrepancy.

Several cases of D-lactic acidosis associated with consumption of LAB in patients with short bowel syndrome were reported[37,38], implying that bacteria used as probiotics should be screened for the ability to generate D-lactate. In this study, two homologs of DLD genes were identified in the genome of JDM301. Since there were no reported cases of D-lactic acidosis caused by bifidobacteria[37-39], the activities of these homologous DLDs in bifidobacteria may be low so that the amount of lactate produced is insufficient to cause D-lactic acidosis.

Although biogenic amines (BA) play an important physiological role in mammals, a high amount of BA in the diet may have a variety of toxic effects[40]. The main BA contained in food and beverage includes histamine, tyramine, putrescine, and cadaverine, some of which are associated with toxicological characteristics of food poisoning[41]. The decarboxylase activities of histidine, tyrosine and ornithine were reported in lactobacilli and the capabilities might be strain-dependent rather than species-dependent[42]. Therefore, BA production, especially thylamine and tyramine, must be carefully evaluated for individual strains.

Bacterial enzymes, such as GN, GS, NR, AR and AS, play important roles in the metabolism of carcinogens and other toxicants in the intestine. Homologs of GS are common in sequenced *Bifidobacteria* genomes where GS and GN facilitate the absorption of a variety of toxicants and may contribute to the development of colon cancer. The link between *Bifidobacteria* and the genotoxic enzyme activities of intestinal microflora has been reported[43,44], with *Bifidobacteria* inhibiting the activity of some genotoxic enzymes[45]. NR activity is common in oral bacteria and it plays an important role in bacterial nitrate reduction. Although NR activities have been reported in *Bifidobacteria*, the activity of this enzyme is lower than the NR activity of other gut bacteria[6].

CBSH mediates microbial bile tolerance and enhances microbial survival in the intestine[46]. Metagenomic analyses demonstrated that CBSH activity is enriched in the human gut microbiome, and has the potential to greatly influence host physiology[46]. In *Bifidobacterium* spp. and *Lactobacillus* spp., CBSH activity is also common and nearly all *Bifidobacteria* species and strains have bile salt hydrolase activities[47]. However, bile salt hydrolase activity releases free bile acids which are harmful to the human body and may act as mutagens[48,49]. Recommendations have been made for absence of bile salt transformation capacity in bacteria added to food[50]. However, it is noteworthy that the evidence for harmful effects is inconclusive so far and bile salt deconjugation activity may play a role in reducing human serum cholesterol[51]. Given the huge CBSH pool in intestinal microflora, the CBSH activities of the small number of additional bacteria consumed as probiotics can be ignored[48].

Putative genes for Plg-binding proteins, DnaK (BLJ_0123) and glutamine synthetase (BLJ_0624 and BLJ_1324) were found in the JDM301 genome, where these proteins play a role in the interaction with human epithelial cells. The protein DnaK has been shown to be present on the surface of pathogens, such as *Neisseria meningitides*[52]. The glutamine synthetases BLJ_0624 and BLJ_1324 had a 62.11% and 32.49% similarity to the glutamine synthetases in *Mycobacterium tuberculosis* H37 Rv. In

the presence of Plg activators, Plg binding to the bacterial surface is converted to plasmin, which is a broad-spectrum serine protease involved in degradation of fibrin and noncollagenous proteins of extracellular matrices and activates latent procollagenases[53]. It is believed that the capability to intervene with the Plg/plasmin system of a host is a strategy for host colonization and bacterial metastasis shared by several pathogens and commensals of the human intestinal tract[53,54]. The plasminogen-dependent proteolytic activity of *B. lactis* BI07 and *B. longum* was shown to be dose-dependent[55,56].

A homolog (BLJ_0880, 24.18% identity) of a gene encoding a component in ferric dicitrate uptake system (Fec) of *Shigella flexneri* serotype 2a, FecE, was identified in the genome of JDM301. As an iron uptake system, Fec is critical for bacterial survival and plays an important role in bacterial virulence[57]. In addition, BLJ_1105 and BLJ_0409 proteins associated with iron acquisition in JDM301 were 24.49% and 25.56% similar to pyochelin biosynthesis protein in *Pseudomonas aeruginosa,* and BLJ_0712, BLJ_1796 and BLJ_0662 proteins were 25.4%, 27.31 and 29.06% similar to iron transporters of *Salmonella enterica*.

The human pathogen, *Helicobacter pylori*, produces a neutrophil activating protein (NAP) which activate human leukocytes and induces an inflammation, which facilitates the growth of the pathogen[58]. A homolog (BLJ_0021; 26.83% identity) of the gene encoding a NAP was identified in the genome of JDM301.

In JDM301, BLJ_0012 encodes a protein harboring fibronectin-binding motif (Pfam number 07174) that allows mycobacteria to bind to fibronectin in the extracellular matrix and may mediate the adhesion of JDM301 to its host[59]. A potential protein for *Bifidobacteria* adhesion to intestinal cells is the putative LPXTG-motif protein with collagen binding motifs (Cna_B, pfam05738) encoded by BLJ_1801, which shows a 34% identity to a predicted fimbrial subunit in the genome of *B. dentium* Bd1. This protein may be involved in the recognition of and adhesion to mucosal epithelial cell surfaces[19]. Its homologous proteins were also identified in the genome sequences of both *B. longum* NCC2705 and *B. longum* DJO10A genomes[3,60]. *B. longum* subsp. *infantis* 15697, *B. longum* NCC2705 and *B. adolescentis* contains 21, 10 and 11 copies of extracellular solute-binding protein, respectively[3,4]. Comparably, the SBP family 1 proteins are more abundant in JDM301 than the three other *Bifidobacteria* strains due to the genome size.

Finally, JDM301 encodes a number of proteases and peptidase that may contribute to virulence owing their ability to degrade host proteins for bacterial nutrition sources[61]. However, not all the genes associated with virulence have been known until now. Thus, despite the evaluation based on the whole genome sequences, it is recommended that the rat endocarditis and the immunocompromised mouse model should be used for *in vivo* assessment of safety for the low pathogenicity of LAB[48].

Recently, there has been more interest in using probiotic products to promote health and treat diseases. Probiotics have been investigated in clinical trials, such as treatment for diarrhea, D-lactic acidosis, necrotizing enterocolitis, inflammatory bowel disease and so on[39,62-64]. The mechanisms by which probiotics exert their effects are still obscure, which may include modification of gut pH, antagonism of pathogens, modulation of immunity as well as supplements of some nutrients[65]. However, safety issues of probiotics have been discussed in many reports[5,48]. There are reported cases of infections associated with probiotic strains[5]. Although the strain is safe based on phenotype, the information derived from complete bacterial genome sequences reveals some putative unfavorable genes, such as genes encoding for Plg-binding proteins, proteases and genes associated with production of D-lactate. In addition, patients are generally more susceptive to infection and harmful metabolites, such as D-lactate than healthy persons. Thus, the biosafety of probiotics, especially strains used in therapy, must be assessed more carefully and comprehensively.

In conclusion, this study compared the genome of JDM301 with other *Bifidobacteria* and assessed the genomic stability, the potential for antibiotic resistance, the potential for virulence and the potential production of harmful metabolites of this strain. The core genome of *B. longum* is composed of 1265 genes, and 219 genes are unique in JDM301. Our data showed putative virulence genes in the genomes of JDM301 as well as putative genes associated with production of harmful metabolites. In addition, a potentially transferable antibiotic resistance gene was detected in the chromosome of JDM301, which needs to be experimentally validated. This assessment provides information on potential risk factors, which should be further evaluated experimentally, e.g., *in vivo* assessment using animal models.

The authors thank Dr. Hua-Jun Zheng from Shanghai-MOST Key Laboratory of Health and Disease Genomics, Chinese National Human Genome Center at Shanghai for kindly providing us assistance in data analysis.

COMMENTS

Background

Bifidobacterium longum JDM301 is a commercial strain used widely in China with several probiotic functions. Recently, there has been more interest in using probiotic products to promote health and treat diseases. As model probiotic bacteria, *Bifidobacteria* are often added to probiotic products in combination with other lactic acid bacteria. The biosafety of probiotic bacteria is attracting more attentions with its enlarged applications. As more commercial probiotic products are being introduced in the market, it is necessary to reassess the safety of these probiotic products using the latest technology.

Research frontiers

With a long and safe history of application, lactic acid bacteria have acquired the status of "Generally Regarded As Safe". However, published reports of rare infections involving *Lactobacilli* or *Bifidobacteria* are available. The strains selected as probiotics are needed to be assessed carefully and comprehensively. This study may contribute to a better biosafety assessment of probiotic bacteria.

Innovations and breakthroughs

This is the first study to assess the biosafety of probiotic bacteria based on

complete genome sequences. Through bioinformatics analysis of the genome sequences, the authors found that although the strain was safe based on phenotype, the information derived from complete bacterial genome sequences revealed some putative unfavourable genes that should be paid attention to.

Applications

The study provides a comprehensive assessment on potential risk factors of a probiotic strain based on complete genome sequences. The information related to biosafety derived from the genome of JDM301 will contribute to a wider and deeper insight into the safety of probiotic bacteria.

Peer review

This is a very nice and comprehensive study assessing the genomic stability, potential of antibiotic resistance, virulence and production of harmful metabolites. This adds valuable information to current knowledge about probiotics.

Abstract

Helicobacter pylori (*H. pylori*) virulence factors promote the release of various chemoattractants/inflammatory mediators, including mainly the neutrophil-attractant chemokine interleukin-8 and neutrophil-activating protein (NAP), involved in *H. pylori*-induced gastric pathologies. Co-administration of Chios mastic gum (CMG), which inhibits *H. pylori* NAP, with an *H. pylori* eradication regimen might add clinical benefits against *H. pylori*-related gastric pathologies, but possibly not CMG as main therapy. Although *H. pylori* NAP and other *H. pylori*-related cytotoxins [i.e., vaculating cytotoxin (VacA)] appear to play a major role in generating and maintaining the *H. pylori*-associated gastric inflammatory response and *H. pylori* NAP is a promising vaccine candidate against *H. pylori* infection (*H. pylori*-I), concerns regarding its potential drawbacks, particularly neurogenic ones, due to possible cross-mimicry, should be considered. Possible cross-mimicry between *H. pylori* NAP and/or bacterial aquaporin (AQP) and neural tissues may be associated with the anti-AQP-4 antibody-related neural damage in multiple sclerosis (MS)/neuromyelitis optica patients. Moreover, the sequence homology found between *H. pylori* VacA and human Na+/K+-ATPase A subunit suggests that antibodies to VacA involve ion channels in abaxonal Schwann cell plasmalemma resulting in demyelination in some patients. A series of factors have been implicated in inducing blood-brain barrier (BBB) disruption, including inflammatory mediators (e.g., cytokines and chemokines induced by *H. pylori*-I) and oxidative stress. BBB disruption permits access of AQP4-specific antibodies and T lymphocytes to the central nervous system, thereby playing a major role in multiple sclerosis pathogenesis. Relative studies show a strong association between *H. pylori*-I and MS. *H. pylori*-I induces humoral and cellular immune responses that, owing to the sharing of homologous epitopes (molecular mimicry), cross-react with components of nerves, thereby contributing and perpetuating neural tissue damage. Finally, *H. pylori* NAP also plays a possible pathogenetic role in both gastric and colon oncogenesis.

Key words: *Helicobacter pylori*; Neutrophil-activating protein; Chios mastic gum; Cross-mimicry; Multiple sclerosis; Demyelination; Gastric carcinogenesis

TO THE EDITOR

In their recent paper published in this journal, Choli-Papadopoulou *et al*[1] consider the development of new drugs targeting *Helicobacter pylori* (*H. pylori*) neutrophil-activating protein (NAP) and this raises some concerns.

With reference to a study[2] focusing on *H. pylori* NAP-mediated neutrophil activation before and 2 mo after *per os* administration of Chios mastic gum (CMG), the authors claimed that "these results indicate a substantial down-regulation of the innate cellular immune effectors, which, according to unpublished clinical data in the context of this study, are accompanied by a significant clinical improvement of the patients' complaints (dyspepsia, epigastric discomfort, distention)"[1]. However, such clinical benefits cannot be deduced from this study[2] and, as mentioned, relative clinical data on CMG as treatment for *H. pylori* and peptic ulcer are controversial[2]. Although *H. pylori* virulence factors promote the release of various chemoattractants/inflammatory mediators including mainly the neutrophil-attractant chemokine interleukin-8 and *H. pylori* NAP involved in *H. pylori*-induced gastric pathologies[3], our clinical experience suggests that only co-administration of CMG with an *H. pylori* eradication regimen might add clinical benefits against *H. pylori*-related gastric pathologies, but possibly not CMG as main therapy, as the authors claimed[1,2]. In particular, co-administration of CMG might be a potential therapy to reduce damage of gastric mucosa induced by *H. pylori* NAP. However, large-scale relative prospective studies are needed to elucidate this field.

The authors, further considering data on the safety and immunogenicity of a vaccine comprising *H. pylori*-induced vaculating cytotoxin (VacA), cytotoxin associated gene and *H. pylori* NAP, suggested that the obtained neutrophil activation by the C-terminal region of *H. pylori* NAP opens new pathways for drug design directed at *H. pylori* inflammation[1]. In particular, both VacA and *H. pylori* NAP play a major role in generating and maintaining the *H. pylori*-associated gastric inflammatory response, and *H. pylori* NAP is a promising vaccine candidate against *H. pylori* infection (*H. pylori*-I). However, concerns regarding potential drawbacks of *H. pylori* NAP, particularly neurogenic ones, should be considered. For instance, possible cross-mimicry between *H. pylori* NAP and/or bacterial aquaporin (AQP) and neural tissues may be associated with the anti-AQP-4 antibody-related neural damage in multiple sclerosis (MS)/neuromyelitis optica (NMO) patients. In this regard, by using histology, the practical gold standard for the diagnosis of *H. pylori*-I, we have shown a strong association between *H. pylori*-I and MS[4]. *H. pylori*-I induces humoral and cellular immune responses that, owing to the sharing of homologous epitopes (molecular mimicry), cross-react with components of nerves, thereby contributing and perpetuating neural tissue damage[4]. In this respect, *H. pylori* NAP, as a virulence factor, recruits leukocytes from the vascular lumen, and activates neutrophils, monocytes and mast cells, as mentioned by the authors. Besides, the sequence homology found between *H. pylori* VacA and human Na+/K+-ATPase A subunit suggests that antibodies to VacA involve ion channels in abaxonal Schwann cell plasmalemma resulting in demyelination in some patients[5]. Moreover, VacA exhibits chemotactic activities to the bone marrow-derived mast cells (BMDMCs) and induces BMDMCs to produce pro-inflammatory cytokines[5]. A series of factors have been implicated in inducing blood-brain barrier (BBB) disruption, including the aforementioned inflammatory mediators (e.g., cytokines and chemokines induced by *H. pylori*-I) and oxidative stress. BBB disruption permits access of AQP4-specific antibodies and T lymphocytes to the central nervous system, thereby playing a major role in MS/NMO pathogenesis[6]. Therefore, *H. pylori* NAP and *HP*-I itself, by inducing several mediators, may influence MS/NMO (including relapsing type) pathophysiology, thereby raising possible concerns regarding even the C-terminal region of *H. pylori* NAP use as a candidate vaccine. Accordingly, relative studies are also needed to clarify the aforementioned concerns.

Finally, the possible *H. pylori* NAP pathogenetic role in gastric carcinogenesis, mentioned by the authors, may also apply to colon oncogenesis[2,7].

INSTRUCTIONS TO AUTHORS

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1361 experts in gastroenterology and hepatology from 64 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article *via* online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systemically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensuses and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing
Statistical review is performed after peer review. We invite an expert in Biomedical Statistics from to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Ridit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc*. The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

Conflict-of-interest statement
In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent
Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights
When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www.clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://www.wjgnet.com/1007-9327office. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no less than 256 words) and structured abstracts (no less than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no less than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections.

AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/…"; MATERIALS AND METHODS (no less than 140 words); RESULTS (no less than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 *vs* 3.61 ± 1.67, $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: …*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of *P* values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of *P* values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that...".

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed and http://www.crossref.org/SimpleTextQuery/, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in boldfaced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in boldfaced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*

Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*

Biology: *H. pylori*, *E coli*, *etc.*

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be re-submitted online (http://www.wjgnet.com/1007-9327office/). The author should send the copyright transfer letter, responses to the reviewers, English language Grade B certificate (for non-native speakers of English) and final manuscript checklist to wjg@wjgnet.com.

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

WJG is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1300 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.

Abstract

Endoscopic ultrasound (EUS)-guided biliary drainage has emerged as a minimally invasive alternative to percutaneous and surgical interventions for patients with biliary obstruction who had failed endoscopic retrograde cholangiopancreatography (ERCP). EUS-guided biliary drainage has become feasible due to the development of large channel curvilinear therapeutic echo-endoscopes and the use of real-time ultrasound and fluoroscopy imaging in addition to standard ERCP devices and techniques. EUS-guided biliary drainage is an attractive option because of its minimally invasive, single step procedure which provides internal biliary decompression. Multiple investigators have reported high success and low complication rates. Unfortunately, high quality prospective data are still lacking. We provide detailed review of the use of EUS for biliary drainage from the perspective of practicing endoscopists with specific focus on the technical aspects of the procedure.

Key words: Bile duct; Biliary obstruction; Biliary drainage; Endoscopic ultrasound; Endoscopic ultrasound-guided biliary drainage

INTRODUCTION

Endoscopic retrograde cholangiopancreatography (ERCP) has become the procedure of choice for the management of biliary obstruction[1]. If ERCP fails to achieve biliary drainage, more invasive options are usually considered. These include percutaneous transhepatic biliary drainage (PTC) and surgical intervention but they have been associated with a higher risk of complications and prolonged hospital stay[2]. Recently, endoscopic ultrasound (EUS)-guided biliary drainage has been introduced as an alternative for patients who had failed ERCP. EUS was developed in the early 1980s to overcome the limitations of abdominal ultrasonography and computed tomography for pancreatic imaging[3]. Since its introduction, EUS has become a very valuable imaging tool to visualize the gastrointestinal luminal wall and its adjacent structures. The proximity of the EUS probe to the area of interest not only provides high resolution images but also allows for real time EUS-guided fine needle aspiration (FNA) tissue sampling. The high quality imaging combined with FNA capability has made EUS an indispensable diagnostic modality. EUS has also been utilized as a therapeutic tool but until recently its role has been confined mostly to injection of various substances[4,5]. The availability of larger channel echo-endoscopes has allowed the broadening of the therapeutic applications of EUS by combining the advantages of real-time ultrasound and fluoroscopy imaging with the use of ERCP based devices and tech-

niques. As a result of these developments and combination of technologies, EUS-guided biliary drainage has become possible.

EUS-guided diagnostic cholangiography was first reported by Wiersema *et al*[6] in 1996 and the first EUS-guided biliary drainage was reported in 2001 by Giovannini *et al*[7] by creating a choledochoduodenal fistula using a needle knife followed by transduodenal stenting in a patient with pancreatic cancer. These initial reports were followed by the description of technique modifications and expanding indications including EUS-guided hepaticogastrostomy with stent placement[8], transduodenal EUS-rendezvous biliary access[9,10] and EUS-guided biliary therapy of choledocholithiasis with the creation of a neopapilla[11]. Since then a number of series have reported variations on these techniques[12-31] including the recent description of a placement of a fully covered metal stent as a route for interventional endoscopic procedures in the bile duct[32]. A published large case series (≥ 10 cases) on EUS-guided biliary drainage is shown in Table 1.

The purpose of this manuscript is to provide a detailed review of the use of EUS for biliary drainage from the perspective of practicing endoscopists with specific focus on the technical aspects of the procedure. We performed a Medline search using the key words EUS, biliary drainage, biliary obstruction, therapeutic EUS and interventional EUS. In addition we manually reviewed the references of the identified review papers.

INDICATIONS FOR EUS-GUIDED BILIARY DRAINAGE

ERCP guided stent placement has become the procedure of choice for biliary decompression but it can be occasionally associated with difficulty gaining access to the obstructed biliary tract. In a recent prospective study, first attempt ERCP failed in 25% of patients with obstructive jaundice due to pancreatic cancer[33]. The two main reasons for failed ERCP are failure to cannulate the bile duct or inability to reach the papilla due to duodenal stenosis or post surgical changes. For patients with accessible papillae, most endoscopists will consider a second attempt at ERCP to gain access to the bile duct. Traditionally, patients who had ultimately failed ERCP have been offered PTC or surgical biliary decompression but these approaches are associated with a higher rate of complications and prolonged hospital stay[2]. Lately, EUS-guided biliary drainage emerged as a less invasive alternative for biliary drainage. EUS-guided decompression is not only minimally invasive but it is a single step procedure that provides more physiological internal bile drainage with improved patient comfort and decreased risk for fluid and electrolyte disturbances. Furthermore, EUS-guided biliary drainage using transgastric puncture of the intrahepatic duct or the common bile duct is feasible in patients with inaccessible papillae due to duodenal obstruction, surgically altered anatomy or hilar block due to cholangiocarcinoma or gallbladder cancer[11]. Finally, EUS-guided biliary drainage may be safer than PTC since the bile duct is accessed under real-time EUS guidance using Doppler to avoid blood vessels in the needle path[34-36]. The patient preparation for EUS-guided biliary drainage is not different from the standard preparation for ERCP as the patient's position is prone on the fluoroscopy table. All patients should receive periprocedural antibiotics. General anesthesia can be considered but the majority of cases can be done with monitored sedation. Contraindications include coagulopathy and severe hemodynamic instability.

INSTRUMENTATION

Both EUS and fluoroscopy equipment should be available in the procedure room. The use of a therapeutic channel (3.7 mm on the Olympus and 3.8 mm on the Pentax linear echo-endoscopes) is recommended. It is possible to use the diagnostic channel (2.8 mm) linear echo-endoscope to perform the puncture and wire insertion into the bile duct and then exchange the scope over the wire with the therapeutic channel ERCP scope but this maneuver is more complex and the bile duct access can be easily lost during the scope exchange.

Both 22 and 19 gauge EUS needles can be used for the initial puncture of the bile duct. In general, the use of a 19 gauge needle will allow the passage of 0.035 inch wire but the stiffness of the 19 gauge needle may provide a challenge to advance the needle tip to the desired target (i.e., bile duct). The 22 gauge needle provides better flexibility but allows passage of only 0.018 inch guidewire. The new blunt-tip Access Needle (Cook Endoscopy, Winston-Salem, NC, United States) is now available for initial puncture. This needle allows smooth guidewire manipulation and prevents guidewire damage as seen with the standard sharp tip needles. The EUS needle can be preloaded with the guidewire and pre-flushed with contrast using a three way Ⅳ adaptor so that contrast can be injected without removing the guidewire during its manipulation. Besides the standard ERCP devices, an over-the-wire needle-knife sphincterotome or Cystotome (Cook Endoscopy, Winston-Salem, NC, United States) should be available along with choices of plastic (straight or pigtail) and self-expandable metallic stents (uncovered, partially covered or fully covered) of varying calibers and lengths[35,37,38]. A list of the typical devices that are needed to perform EUS-guided biliary drainage is presented in Table 2.

TECHNIQUES

The reported success rate of EUS-guided biliary drainage ranges from 73% to 97%[14,19,22,30,31,39,40]. EUS-guided biliary drainage should be as effective as transpapillary biliary drainage once the stent is successfully placed. Simultaneous tissue diagnosis and staging can be provided in the same setting. Several approaches to access the biliary tree

and provide biliary drainage have been described either *via* the duodenum or the stomach into the common bile duct or hepatic duct, respectively. EUS-guided biliary drainage can be divided into three principal methods[41]. (1) EUS-ERCP rendezvous technique. With this technique the EUS is used solely to puncture the obstructed duct and pass a guidewire antegrade through the papilla for subsequent rendezvous by ERCP[30]; (2) Stent placement *via* the EUS endoscope across the site of biliary obstruction in antegrade fashion in which EUS is used to create a temporary fistula *via* a transgastric or transduodenal access to allow stent placement; and (3) Transluminal drainage in which EUS is used to create a permanent fistula and subsequent stent placement is performed across that fistula between bile duct and bowel wall. In this approach the site of biliary obstruction is not traversed by a stent but rather an alternative tract for bile drainage is created by creation of a bilioenteric fistula.

EUS access to the biliary tree is first gained under real time guidance using the EUS needle. Contrast is then injected *via* the needle under fluoroscopic visualization to obtain a cholangiogram followed by insertion of a guidewire into the biliary tree. The use of 0.035 inch guidewire (requires 19-gauge needle for initial access) is preferred because it may facilitate traversing of strictures and stent placement. The created fistula can then be enlarged with an ERCP cannula, tapered biliary dilators, needle-knife, cystotome, or biliary balloon dilator and in some cases may require the use of several devices[34]. Once the fistula tract is enlarged, the type of stent placement is decided based on the obstruction site (whether the stricture is accessed in antegrade or retrograde fashion and whether the stricture has been traversed with the guidewire). When the site of obstruction cannot be traversed, then transluminal stenting may be performed with the end of the stent lying within the biliary tree proximal to the obstruction and the other end of the stent lying in the stomach or duodenum. Stent placement can also be done through an existing duodenal metal stent in combined biliary and duodenal obstruction situations[42]. Combined duodenal stent placement and EUS-guided biliary drainage can be used for malignant duodenal obstruction with biliary stricture[43].

Bile duct access

Bile duct access depends on the level of obstruction and whether the ampulla is endoscopically accessible.

Transhepatic approach (hepaticogastrostomy): The echo-endoscope is positioned within the proximal stomach (cardia or proximal body) and oriented along the lesser curvature of the stomach or more posterior position to visualize the dilated left intrahepatic bile ducts. Color Doppler is used to rule out overlying vasculature before inserting the needle into the identified dilated intrahepatic bile duct branch. Bile is aspirated and contrast is instilled to confirm placement. Several options exist based on the level of obstruction, success of traversing the obstruction with guidewire and availability of endoscopic assess to the papilla. (1) A guidewire is advanced in an antegrade fashion through the EUS needle and manipulated across the biliary obstruction and into the duodenum under fluoroscopic and endosonographic guidance. Several loops of wire should be created to reduce the risk of wire dislodgement. If access to the second portion of the duodenum is feasible the procedure can be completed with the rendezvous technique with standard ERCP scope; (2) If the stricture is traversed with the guidewire and the duodenum is not accessible, a stent can be inserted across the biliary stenosis in antegrade fashion. To allow passage of the stent, the fistula tract should be enlarged as previously described; and (3) If the guidewire cannot be

advanced across the obstruction, a transluminal drainage approach can be utilized by deploying a stent that bridges the fistulous tract (the distal end of the stent is in the dilated intrahepatic duct within the left lobe and the proximal end of the stent is in the cardia of the stomach).

Extrahepatic approach (transcholedochal or choledochoduodenostomy): The echo-endoscope is placed in the distal antrum or duodenum, permitting imaging of the common bile duct. Color Doppler is used to rule out overlying vasculature. Bile duct puncture is carried out with an EUS needle under endosonographic control. The bile duct typically is entered in its midportion (superior to the intrapancreatic portion and inferior to the hilum) then several options are available depending on the site of obstruction: (1) for distal (intrapancreatic portion) main bile duct obstruction, a stent can be deployed bridging the created fistulous tract and therefore creating choledochoduodenostomy proximal to the obstruction; (2) alternatively, an attempt to manipulate the wire and traverse the stricture in antegrade fashion can be made and then the procedure can be completed with the duodenoscope by rendezvous technique; and (3) if the obstruction is proximal to the entry point in the bile duct (e.g., hilum), the stricture should be traversed in retrograde fashion and then stented.

Stent placement

Enlargement of the fistulous tract is usually necessary before stent placement. Stent insertion may be performed in an antegrade fashion *via* the echo-endoscope or as a rendezvous procedure with ERCP depending on the transpapillary accessibility and the ease of stent deployment. Rendezvous drainage requires endoscopic access to the region of the papilla, while direct transluminal stent placement entirely by EUS does not.

Antegrade: The stent is placed using the echo-endoscope in an antegrade fashion. Stent placement can be transluminal (transgastric or transduodenal). An attempt should be made to traverse the stricture followed by stent placement with the stent bridging the stricture. Stent placement creating bilioenteric anastomosis is an option if trans-stricture stenting is unsuccessful. If feasible, placement of the stent across the site of obstruction is the preferred approach.

Rendezvous (retrograde): This technique is for ERCP access *via* the native papilla or surgical anastomosis by EUS-guided placement of a guidewire and subsequent access by ERCP. EUS-guided rendezvous was first reported for pancreatic duct access in 2001 and for both biliary and pancreatic ductal drainage in 2004[9]. The bile duct is accessed proximal (superior) to the obstruction (transgastric or transduodenal). The wire is used to transverse the stricture in antegrade fashion and then curled in the duodenum. The echo-endoscope is removed carefully while leaving the wire in place. A duodenoscope is advanced to the duodenum and the wire exiting the papilla is grasped with a snare and withdrawn through the accessory channel. The procedure is then completed with standard ERCP techniques.

It is believed that placement of a longer stent may diminish the risk of bile leak. In our institution, we favor the use of a fully covered metal stent but there are no studies evaluating the performance among different stents.

Exchanging the occluded stent

An occluded stent can be removed by using snare or a Dormia basket through the duodenoscope. The fistulous tract can then be recannulated, followed by new stent placement[44]. If the stent has not been *in situ* for 2-3 wk and there are concerns for the maturity of the fistula, the guidewire should be inserted into the bile duct through or alongside the occluded stent by ERCP catheter before removing the stent[44]. If a metal stent was used at the initial procedure, a plastic stent can be inserted *via* the occluded metal stent. EUS-guided stent placement can be an option for biliary diversion for an occluded biliary metal stent after a failed reinterventional ERCP[45].

Technical tips: The extrahepatic bile duct is very close to the portal vein in the first and second portion of the duodenum and the intrahepatic bile duct is close to the intrahepatic portal vein. Therefore, the puncture should be done very carefully especially in patients with mild dilatation of the hepatic bile duct. Angling the needle combined with gradual retraction and re-advancement can help the guidewire advance and traverse the obstruction[46]. The use of the EchoTip Ultra Access Needle (Cook Endoscopy, Winston-Salem, NC, United States) may significantly facilitate wire manipulation once bile duct access is achieved. The Access Needle has a sharp beveled stylet that protrudes beyond the blunt needle tip to facilitate easy puncture. Once the tip of the needle reaches the bile duct, the stylet is then removed. The blunt needle tip allows for smooth wire manipulation including advancement and withdrawal and prevents "pilling" of the hydrophilic wire coating as it frequently happens with standard sharp tip EUS needle. In addition, fluoroscopic techniques allowing imaging at different angles may facilitate wire passage. Care should be taken to limit the volume of the contrast injection to help maintain the visualization of the targeted area.

RESULTS OF EUS-GUIDED BILIARY DRAINAGE

The reported success rate of EUS-guided biliary drainage ranges from 73% to 97%[14,19,22,30,31,39,40]. EUS-guided biliary drainage should be as effective as transpapillary biliary drainage once the stent is successfully placed. Simultaneous tissue diagnosis and staging can be provided in the same setting. EUS-guided biliary drainage appears

to carry significant advantages over PTC and surgical biliary decompression and can be considered as a first step in patients who had failed ERCP[34-36]. It should be emphasized that the perceived advantages of EUS-guided biliary drainage over PTC or surgery have not been evaluated in prospective randomized studies and therefore the final choice of therapeutic modality should be based on local expertise and patient preferences.

COMPLICATIONS

The reported complication rates vary from 4% to 21%[14,38,40,47]. Internal drainage eliminates skin infection and maintenance issues of external drainage. Pancreatitis is a complication associated with prior failed ERCP and not attributed to EUS biliary drainage because of the lack of influence on the pancreatic duct[19].

The most common complications are biliary leakage and pneumoperitoneum (perforation into the peritoneal cavity or retroperitoneum, depending on the path of the access)[7,13,14,21,26,27]. The pneumoperitoneum is an early complication and usually self-limited[38]. Biliary leakage may occur predominantly with extrahepatic duct puncture, transluminal drainage, and larger hole[14,20,26,27]. Confirmation of the absence of bile leakage can be done using contrast medium on fluoroscopy. Focal bile peritonitis tends not to occur if the stent is promptly placed after dilation of the fistula[13,25]. Other common complications include abdominal pain and cholangitis[31]. Other reported complications include bacteremia, bleeding, biloma, ileus, aspiration pneumonia, cholecystitis, duodenal perforation and cardiopulmonary failure[11,14,19,31]. The use of color Doppler ultrasound to detect vascular structures can decrease the risk of bleeding[13,25]. No mortality has been reported to date. When comparing drainage using a stent across a fistula *vs* the rendezvous technique, the rendezvous drainage is less likely to lead to perforation, leakage, bleeding, or peritonitis which is attributed to the more physiological approach[41].

Late complications are stent migration and occlusion[31,35]. To date, there have been no long term follow-up reports on stent patency in a large number of patients. A case series of five cases reported by Yamao *et al*[48] using 7-8.5-Fr plastic stents *via* EUS-guided choledochoduodenostomy had an average stent patency of 211.8 d. The relatively long patency time of stent is believed to be due to the stent placement being far from the obstructing tumor[44].

LIMITATIONS

Advanced or complex strictures may not be traversed by EUS-guided approach and hence the percutaneous or surgical approach should remain an option.

The plastic stents' size is limited by the working channel of the linear echo-endoscope. Furthermore, the therapeutic EUS scopes channel is smaller than the therapeutic ERCP scope channel (4.2 mm *vs* 3.8 mm). Although a 10-Fr plastic stent can be deployed *via* the therapeutic EUS scope, it can be technically challenging due to significant friction in the relatively narrow channel. Finally, simultaneous passage of two wires into the bile duct as a safety measure to preserve access follow by 10-Fr stent placement over one of the guidewires is impossible with the current EUS therapeutic channel size.

These EUS drainage techniques have exciting potential but are performed mostly in tertiary referral centers by expert therapeutic endoscopists. Only endoscopists who are skilled at both ERCP and EUS should perform this procedure to avoid potential serious complications. Additionally, trained hepato-biliary surgeons and interventional radiologists should be available in the event of failure or complication.

At present, there are no dedicated devices for EUS-guided biliary drainage. The standard EUS and ERCP devices are being used for this purpose.

Although many case series have been reported, firm conclusions are limited due to great variations among studies in the endoscopic approaches applied, procedural goals, technical and clinical endpoints, definitions of success and duration and extent of follow-up. Furthermore, we lack data from well designed prospective randomized controlled studies comparing different therapeutic approaches.

We do not have a firm understanding on the exact rate of EUS guided biliary drainage complications as it is well recognized that underreporting can occur in retrospective case series.

CONCLUSION

EUS-guided biliary drainage has provided a new and promising route for biliary decompression. It has been reported to be feasible, highly successful and safe. It provides significant advantages over PTC and surgical biliary drainage and has become the procedure of choice in patients with obstructive jaundice who had failed ERCP in many institutions. The procedure is technically complex and confined to major referral centers. Despite the perceived advantages of EUS-guided drainage over PTC or surgery, well-designed, prospective, comparative studies are lacking. Therefore the choice of therapeutic modality in patients with biliary obstruction who had failed ERCP should be based on local expertise and patient preference.

Abstract

Hepatocellular carcinoma (HCC) is a lethal disease in most patients, due to its aggressive course and a lack of effective systemic therapies for advanced disease. Surgical resection and liver transplantation remain the only curative options for a small subset of patients. Few patients with HCC are diagnosed early enough to be eligible for curative treatment. Angiogenesis inhibition is a natural therapeutic target for all solid tumors, but particularly for the highly vascularized HCC tumors. With the approval of the targeted agent sorafenib, there are now additional options for patients with HCC. Although sorafenib does produce some improvement in survival in HCC patients, the responses are not durable. In addition, there are significant dermatologic, gastrointestinal, and metabolic toxicities, and, as importantly, there is still limited knowledge of its usefulness in special subpopulations with HCC. Other angiogenesis inhibitors are in development to treat HCC both in the first-line setting and for use following sorafenib failure; the furthest in development is brivanib, a dual fibroblast growth factor pathway and vascular endothelial growth factor receptor inhibitor. Additional agents with antiangiogenic properties also in phase Ⅱ and Ⅲ development for the treatment of patients with HCC include bevacizumab, ramucirumab, ABT-869, everolimus and ARQ 197.

Key words: Hepatocellular carcinoma; Angiogenesis; Vascular endothelial growth factor; Fibroblast growth factor; Sorafenib; Tumor response; Brivanib

INTRODUCTION

Primary liver cancer, including hepatoma and hepatocellular carcinoma (HCC) is diagnosed in more than 560 000 people worldwide each year[1], including more than 24 000 Americans[2]. HCC accounts for up to 90% of all primary liver cancers[3]. HCC can be treated curatively with surgical resection or liver transplantation if diagnosed at an early stage; however, since most HCC patients present with advanced disease, only 15% are eligible for curative treatments[4]. Even for patients undergoing surgical resection, recurrence rates may be as high as 50% after 2 years and 76% by 10 years[5,6]. Patients meeting the Milan criteria who undergo liver transplantation can achieve a 5-year cancer-free survival rate greater than 60%[7].

As most patients with HCC are diagnosed with advanced disease, they generally have a poor prognosis, with median survival times of less than 1 year[3]. This is due, at least in part, to the absence of effective systemic therapies. Systemic therapies examined in the past, including both cytotoxic and hormonal agents, have provided limited or no benefit for these patients[6]. In late 2007, the angiogenesis inhibitor sorafenib was approved for use

in advanced HCC based on an improvement in survival compared with placebo[8,9]. While initial responses are observed, over time a loss of efficacy is apparent that may be due to "resistance" *via* escape/compensatory mechanisms. Like other angiogenesis inhibitors, sorafenib also has known class side effects, including skin-related toxicities, hypertension, proteinuria, diarrhea, and an increased risk for thromboembolism and bleeding events[10-12]. While most are manageable, certain rare events can be life-threatening (i.e., gastrointestinal perforation, fatal hemoptysis, thromboembolic events). Thus, the balance between risk and benefit in every clinical setting is an integral part of the differentiation and evaluation of targeted agents.

RATIONALE FOR ANGIOGENESIS INHIBITION IN HCC

Angiogenesis is a ubiquitous process that is required for tumor growth[13,14]. Angiogenic processes are also indirectly involved in tumor invasion and metastasis through the secretion of matrix-degrading proteinases by vascular endothelial cells[15] and the ability of tumor cells to travel to distant sites *via* the vascular network[16].

Proangiogenic factors are attractive therapeutic targets because they stimulate cancer formation, growth, and proliferation *via* angiogenesis using a number of distinct mechanisms. Established proangiogenic factors and their receptor signaling pathways include vascular endothelial growth factor (VEGF), fibroblast growth factor (FGF)-2, platelet-derived growth factor (PDGF), angiogenin, and angiopoietin-2 (Ang-2)[17]. Other mediators, such as c-MET and mTOR, although not directly related to new vessel formation, affect angiogenesis *via* influences on downstream signaling.

HCC tumors are generally hypervascularized[18], suggesting that they may be especially vulnerable to angiogenesis inhibition. Several endogenous proangiogenic factors are expressed in HCC[19-22], and evidence indicates they play a role in HCC pathogenesis. For instance, serum VEGF levels increase with advancing HCC stages, being highest in patients with metastatic disease[23]. Elevated VEGF levels after locoregional therapy also are associated with poor prognosis and diminished response to therapy[24,25]. Expression of the proangiogenic factor FGF-2, the target of newer agents, is also elevated in patients with HCC[22] and its expression in HCC correlates with tumor microvessel density[26] and postoperative recurrence rate[27]. Tumor angiogenin expression correlates with microvascular density in patients with HCC, and high serum angiogenin levels are associated with decreased survival at 5 years[28]. Finally, mRNA angiopoietin expression level (*via* Ang-2/Ang-1 ratio) is positively correlated with tumor portal vein invasion, diameter, microvascular density, and poor prognosis[29]. Taken together, this evidence provides a strong rationale for targeting angiogenesis and related proangiogenic factors to provide more effective therapies for the treatment of HCC.

CHALLENGES AND LIMITATIONS OF SORAFENIB IN TREATING HCC

Sorafenib was the first systemic targeted therapy to be approved by the US Food and Drug Administration for patients with unresectable HCC[30], based on a 2.8-mo survival advantage over best supportive care (BSC) [hazard ratio (HR) 0.69, $P = 0.00058$] in the Sorafenib Hepatocellular carcinoma Assessment Randomized Protocol (SHARP) trial[31]. Sorafenib, which is also approved for advanced renal cell carcinoma (RCC)[30] inhibits the following receptor tyrosine kinases: VEGFR-2, VEGFR-3, PDGFR-β, c-KIT, and Flt-3[32]. It also binds to the serine-threonine kinases Raf, MEK, and ERK[32,33]. The VEGFR and PDGFR pathways and Raf-1 have all been implicated in the pathogenesis of HCC[34,35], providing a rationale for sorafenib activity in HCC.

Although sorafenib represents a much needed treatment option for patients with HCC, it also produces toxicities that may significantly affect patients' quality of life. High rates of dermatologic side effects are commonly reported with sorafenib, the most clinically significant being hand-foot skin reaction (HFSR)[36]. HFSR typically develops in the first few weeks of therapy, with painful hyperkeratotic lesions on the palms and soles that are surrounded by a ring of erythema localized on areas of pressure or flexure[37]. A meta-analysis examining the incidence of HFSR in phase Ⅱ and Ⅲ trials across solid tumors reported an incidence of 33.8% with sorafenib use, 8.9% of which were grade 3[38]. In the SHARP trial, sorafenib-associated HFSR had an overall incidence of 21% and a grade 3 incidence of 8%[9]. Of particular concern, HSFR appears to be more prevalent in Asian patients, the population most affected worldwide by HCC. A phase Ⅲ trial conducted solely in Asian patients with HCC reported a doubling of the overall incidence of HFSR compared with the SHARP trial[8,9]. Similarly, a phase Ⅲ trial of sorafenib monotherapy following transarterial chemoembolization in Asian patients reported an HFSR incidence of 82%[39].

Bleeding events, albeit rare, are also a toxicity of sorafenib and other angiogenesis inhibitors. In a meta-analysis of 2109 patients enrolled in sorafenib clinical trials or expanded-access programs, the relative risk of bleeding events was 1.86 ($P < 0.001$) and the incidence of grade 3 or higher bleeding events was 2.2%[40]. It is notable that patients with HCC have not demonstrated an increased incidence of bleeding events with sorafenib; for example, in the SHARP trial, grade 3/4 bleeding events were 1% in the sorafenib arm.

By design, SHARP was conducted in the Americas, Europe, and Australasia, and thus generated limited data in Asian patients. Patients included in SHARP had preserved liver function and were of mostly Child-Pugh (C-P) A status[9]. In order to gain additional data, a randomized phase Ⅲ trial in Asian patients with advanced HCC was completed, but again C-P B and C patients were excluded[8,39]. The overall trend of response to sorafenib from

this Asian population was similar to those of SHARP, with time to progression (TTP) and overall survival (OS) improved compared with placebo, and similar treatment effects (HRs of 0.68-0.69). However, median OS appeared to be shorter (6.2 mo) *vs* SHARP (10.7 mo), most likely due to more advanced disease based on performance status, number of tumor sites, and presence of lung metastases compared with SHARP[8,9]. A subsequent single-arm, phase Ⅱ trial was conducted in Asian patients with worse prognosis, including C-P B and C status (29%) and portal vein thrombosis (43%)[41]. In this trial, 26% of patients derived clinical benefit from sorafenib. Again, the incidence of toxicities was higher than in SHARP, with grade 3/4 diarrhea occurring in 20% and grade 3/4 HFSR in 16% of patients. As the majority of HCC cases are found in Asia[42], the development of safe and more effective therapies for this population represents a significant unmet need.

Hence, while the sorafenib trials have provided valuable information in patients with preserved liver function[8,9,41], determining efficacy and safety in the substantial portion of patients with advanced HCC remains a challenge. Other recent phase Ⅱ trials are beginning to provide preliminary evidence of sorafenib safety and efficacy in patients with more advanced disease. A trial of sorafenib monotherapy in 59 patients with unresectable HCC, including 39% with C-P B status and 17% of C-P C status, showed promising activity regardless of disease stage and liver function[43]. Responses for patients of C-P B status were similar to those from SHARP. Median OS, however, declined with more advanced C-P status, most likely due to underlying cirrhosis, and because drug toxicities are more prevalent with compromised liver function, causing liver-related or systemic complications that lead to early treatment discontinuations. In a second phase Ⅱ trial, pharmacokinetic profiles of sorafenib were similar in both C-P A and B subgroups, while median TTP and OS appeared shorter and adverse events related to poorer liver function were more frequent in C-P B patients[44]. Finally, another single-arm, phase Ⅱ trial in 51 Asian patients, including 15 (29%) with C-P B/C status, found no significant differences between C-P B/C status patients and C-P A patients in disease control rate, median OS, grade 3/4 hematologic toxicities, or grade 3/4 nonhematologic toxicities[41].

Despite initial responses to sorafenib, and similar to other targeted agents, most HCC patients experience a loss of efficacy. Furthermore, across clinical trials, 20%-38% of patients discontinued sorafenib due to adverse events[8,9,41]. Similar to what has been reported with bevacizumab, some data indicate that patients who discontinue sorafenib therapy may experience "rebound," whereby symptom and tumor progression develops rapidly upon discontinuation[45]. While this accelerated growth effect appears to be temporarily curtailed with re-initiation of therapy, insensitivity to treatment returns quickly. No effective second-line treatment options currently exist outside of clinical trials for patients who are resistant or refractory to and/or intolerant of sorafenib.

THE FAILED PROMISE OF SUNITINIB

Next to sorafenib, sunitinib is the most studied multitargeted tyrosine kinase inhibitor. Like sorafenib, sunitinib is an inhibitor of VEGFR and PDGFR and is currently indicated for the treatment of RCC, as well as for gastrointestinal stromal tumors[46]. While early indications were that sunitinib would have efficacy in HCC, the phase Ⅲ SUN 1170 trial comparing sunitinib with sorafenib in patients with advanced HCC was discontinued due to increased serious sunitinib-related adverse events and the improbability of achieving noninferior efficacy[47]. As a result, sunitinib is no longer in development for the treatment of HCC.

CHALLENGES IN ASSESSING TUMOR RESPONSE

The 2 traditional imaging criteria widely used for measuring tumor responses to treatment are Response Evaluation Criteria In Solid Tumors (RECIST)[48], which are used primarily in the United States, and the World Health Organization (WHO) criteria[49], which are used internationally. With the advent of targeted therapies that are cytostatic, and in particular regarding HCC tumors, these traditional criteria are limited in their usefulness to assess treatment response because (1) cirrhotic livers may not remodel around a necrotic tumor; (2) HCC tumors are occasionally diffuse and infiltrative in cirrhotic livers; (3) arterial phase enhancement of premalignant dysplastic nodules can be mistaken for progression; and (4) cytostatic targeted agents alter tumor vascularity without affecting tumor size[50]. Both criteria have been updated in the past decade to account for HCC tumor viability in order to appropriately evaluate the extent of tumor necrosis and/or viability to quantify treatment response. The European Association for the Study of the Liver updated the WHO criteria in 2000[51], and in 2008 the American Association for the Study of Liver Diseases updated RECIST[52] and then further clarified the modified criteria in 2010[53]. Specific differences between these current criteria-modified WHO (mWHO) and modified RECIST (mRECIST)-for treatment response in HCC are listed in Table 1.

As an example of the variability in response assessment that can arise according to which of the 2 criteria is used, Finn *et al*[54] retrospectively compared response assessment by the necrosis-adjusted mRECIST (mRECIST has not yet been validated) for HCC with the prospective use of mWHO criteria in 101 patients with HCC who received brivanib, an antiangiogenic targeted agent. They found that mWHO criteria underreported treatment benefit compared with mRECIST for HCC, with 31 patients classified as having progressive disease under the mWHO criteria but stable disease or partial response under mRECIST. This suggests that these patients may have been prematurely discontinued from treatment while still deriving benefit. These discrepancies can be explained by differences in the methodologies of mRECIST and

Table 1 Response assessment by modified World Health Organization criteria and modified Response Evaluation Criteria in Solid Tumors

Parameter	Modified WHO	Modified RECIST
Type of assessment	Spiral CT	Spiral CT or dynamic MRI
Frequency of assessment	⩾ 4 wk	6-8 wk
Measurement of tumor volume	Bidimensional measurement	Unidimensional measurement
Tumor necrosis measurement	Reduction in viable tumor area using contrast-enhanced radiological imaging	Reduction in viable tumor area using contrast-enhanced radiological imaging
Viable tumor definition	Enhanced areas inside treatment lesions	Uptake of contrast agent in the arterial phase
Complete response	Complete disappearance of tumor enhancement determined by 2 observations ⩾ 4 wk apart	Disappearance of any intratumoral arterial enhancement in all target lesions
Partial response	> 50% reduction in total area of tumor enhancement determined by 2 observations ⩾ 4 wk apart	⩾ 30% decrease in the sum of diameters of viable target lesions, taking as reference the baseline sum of the diameters of target lesions
Stable disease	Insufficient shrinkage to qualify for partial response and insufficient increase to qualify for progressive disease	Any cases that do not qualify for either partial response or progressive disease
Progressive disease	> 25% increase in total area of tumor enhancement or the appearance of new lesions	⩾ 20% increase in the sum of the diameters of viable target lesions, taking as reference the smallest sum of the diameters of viable target lesions recorded since the treatment started or the appearance of 1 or more new lesions

CT: Computed tomography; MRI: Magnetic resonance imaging; RECIST: Response Evaluation Criteria in Solid Tumors; WHO: World Health Organization.

Table 2 Agents with antiangiogenic properties in development for the treatment of hepatocellular carcinoma

Agent	Therapeutic target	Phase of study
Brivanib	VEGFR, FGFR	Ⅲ
Bevacizumab	VEGF	Ⅱ
Ramucirumab	VEGFR-2	Ⅲ
ABT-869	VEGFR-1, VEGFR-2, PDGFR-β, c-KIT, Flt-3	Ⅲ
Everolimus	mTOR	Ⅲ
ARQ 197	c-MET	Ⅱ

PDGFR: Platelet-derived growth factor receptor; VEGFR: Vascular endothelial growth factor receptor.

mWHO, which employ different measurements and calculations of tumor size, thereby producing distinct interpretations of treatment response. In addition, there are differences in how progression is defined, with cytologic confirmation of ascites required with mRECIST and small new lesions (< 1 cm) unlikely representing progression with the mRECIST. While not conclusive, these results suggest that treatment response based on assessment criteria vary widely and indicate the need for further clinical validation.

LOSS OF EFFICACY TO ANTIANGIOGENIC THERAPY: ESCAPE AND RESISTANCE

Clinical trials of antiangiogenic agents have shown that most patients with advanced tumors eventually experience progression, including those who initially respond to treatment[8,9,55-57]. Recent evidence suggests that relapse during treatment with antiangiogenic agents occurs due to VEGF inhibition-driven hypoxia, which induces upregulation of alternate proangiogenic signals such as FGF, which overrides the VEGFR inhibition[58]. This was demonstrated preclinically in murine tumors that initially responded to treatment with an anti-VEGFR-2 antibody, but relapsed after 2 wk, showing higher levels of other proangiogenic signals, including FGF-1 and FGF-2, than untreated tumors[59]. Moreover, blockage of FGF signaling in this model slowed tumor growth and attenuated its revascularization during the relapse phase. Clinically, this has been observed in patients with HCC[26,27,60] and, more recently, in glioblastoma patients treated with the pan-VEGFR inhibitor AZD2171, in whom increased plasma levels of FGF were detected upon relapse[61]. Another study showed that approximately half of patients with metastatic colorectal cancer who received bevacizumab plus chemotherapy had more than a 5-fold increase in either placental growth factor or FGF prior to progression[62]. Patients with late-stage breast cancer have been reported to express a large number of proangiogenic factors, including FGF-2, in contrast to earlier stage lesions, which primarily express VEGF[58,63]. Taken together, these data support the hypothesis that tumor progression during inhibition of angiogenesis may be facilitated *via* activation of compensatory proangiogenic and tumorigenic mechanisms.

COMPOUNDS IN DEVELOPMENT FOR TREATMENT OF HCC

Several compounds in development stand to address the challenges and limitations of targeted therapy in the treatment of HCC. These are discussed in the following sections and summarized in Table 2.

Brivanib

Brivanib is currently in phase Ⅲ trials in HCC. It is distinct from both sorafenib and sunitinib in that it is an oral, selective, dual inhibitor of the FGF and VEGF signalling pathways[64,65]. Since FGF signaling may contribute to acquired "resistance," or compensatory signaling,

during anti-VEGFR therapy[58], the simultaneous inhibition of these[64,65] 2 pathways by brivanib may both delay initial progression in response to antiangiogenic therapy (as first-line treatment) and successfully treat tumors that have already progressed during anti-VEGFR therapy (as second-line treatment). With respect to its potential as first-line therapy, brivanib has delayed initial progression compared with sorafenib in preclinical studies[66]. It has also shown specific inhibitory activity in patient-derived HCC xenografts implanted in mice[67]. Clinically, brivanib has demonstrated a disease control rate of 51%, a median TTP of 2.8 mo, and an OS of 10 mo as first-line monotherapy in a phase Ⅱ trial of predominantly Asian patients with HCC[68]. A retrospective analysis using mRECIST for HCC criteria also demonstrated an objective response rate of 25%, with 9% complete responses[68]. Brivanib was also associated with a low incidence of grade 3/4 adverse events, including hypertension (10.9%), diarrhea (3.6%), and HFSR (1.8%)[68]. Due to its unique mechanism of action and favorable safety profile, brivanib is currently under phase Ⅲ investigation as first-line therapy *vs* sorafenib in patients with advanced HCC (BRISK-FL). As a potential second-line agent following antiangiogenic therapy, brivanib has demonstrated activity against xenograft tumors that were nonresponsive to bevacizumab[69]. Allen *et al*[66] also used a mouse model of pancreatic neuroendocrine cancer to show that brivanib administered after sorafenib failure could delay tumor growth modestly, despite showing evidence of revascularization. In a phase Ⅱ trial of brivanib in patients with HCC who had been treated with sorafenib, brivanib produced a median TTP of 2.7 mo and an OS of 9.8 mo[70]; in a retrospective analysis of paired TTP, at least 40% of patients had longer TTP with brivanib than with prior sorafenib[71]. Brivanib is currently under investigation in 2 second-line phase Ⅲ trials-1 in Asian patients following sorafenib failure (progression or intolerance; BRISK-APS), and another similar trial that is enrolling an ethnically unselected patient population (BRISK-PS).

Bevacizumab

The anti-VEGF monoclonal antibody bevacizumab was the first angiogenesis inhibitor to be approved as an antineoplastic agent[72]. Bevacizumab has shown activity in phase Ⅱ HCC testing in combination with chemotherapy[72-75], with the epidermal growth factor receptor inhibitor erlotinib[76], and as monotherapy[77]. Despite initial safety concerns, particularly gastrointestinal bleeding and thrombosis, phase Ⅱ trials in HCC have shown toxicities to be manageable[78]. New bevacizumab combinations are under investigation in ongoing phase Ⅱ HCC trials, including combination with sorafenib, everolimus, temsirolimus, chemoembolization, and hepatic arterial infusion of floxuridine and dexamethasone.

Ramucirumab

The monoclonal antibody ramucirumab is a specific inhibitor of VEGFR-2[79]. A phase Ⅱ study of 42 patients with advanced HCC and primarily well-preserved liver function (75% C-P A status) showed that first-line ramucirumab monotherapy produced a disease control rate of 50% and a median progression-free survival (PFS) of 4.3 mo[80]. This positive study prompted the initiation of the phase Ⅲ REACH trial in HCC, which is comparing ramucirumab/supportive care with placebo/supportive care for second-line treatment after sorafenib.

ABT-869

ABT-869 is a multitargeted tyrosine kinase inhibitor that inhibits multiple members of the VEGFR and PDGFR families[81]. In a xenograft model of HCC, ABT-869 significantly reduced tumor burden, either alone or in combination with rapamycin[82]. Interim phase Ⅱ results in patients with advanced HCC showed a median TTP of 3.7 mo with ABT-869 treatment and a safety profile consistent with angiogenesis inhibition[83]. ABT-869 is in phase Ⅲ testing as a first-line treatment for advanced HCC versus sorafenib.

INHIBITION OF OTHER ANGIOGENIC AND TUMORIGENIC PATHWAYS

mTOR inhibitors: Everolimus and sirolimus

mTOR inhibitors are not traditionally considered direct angiogenesis inhibitors; rather, they have well-known immunosuppressive properties. In fact, 2 of these agents, sirolimus and everolimus, are used to prevent rejection in organ transplant recipients[84]. mTOR inhibitors also have antineoplastic properties, *via* mTOR regulation of tumor proliferation and metabolism[85]. MTOR indirectly modulates angiogenesis through regulation of VEGF expression and translation of proteins involved in angiogenesis[86]. Clinically, there is growing evidence to suggest that mTOR inhibitors may reduce *de novo* malignant growth[87] and recurrence in the liver post-transplant[88]. In patients with advanced HCC, everolimus produced a median PFS of 3.8 mo and a disease control rate of 44% in phase Ⅰ/Ⅱ testing[81]. Consequently, the ongoing phase Ⅲ EVOLVE-1 trial has been initiated to compare everolimus with BSC in patients with HCC who progressed on or after sorafenib or who were intolerant to sorafenib.

ARQ 197

Similar to everolimus, ARQ 197 has antiangiogenic properties, but is not considered an angiogenesis inhibitor. ARQ 197 is an inhibitor of the oncogene c-MET, which stimulates tumor growth, invasion, metastasis, and angiogenesis *via* binding of its ligand, hepatocyte growth factor[89]. In phase I testing in cirrhotic patients with HCC, ARQ 197 demonstrated some activity and was well tolerated, with serious adverse events that were primarily hematologic[90]. ARQ 197 is currently in phase Ⅱ testing in second-line advanced HCC.

CONCLUSION

Unmet needs for HCC remain, despite the availability of

sorafenib. Indeed, sorafenib has some significant limitations, including modest, transient benefits, and toxicity challenges; and its use in patients with more advanced liver disease and in Asian patients has not yet been fully defined. The development of newer targeted therapies that inhibit angiogenesis simultaneously with inhibition of other key proangiogenic factors in HCC, such as FGFR or c-MET signaling, is providing further insights into the underlying pathogenesis of HCC tumors. Compounds that directly block angiogenesis and tumorigenesis *via* dual inhibition of FGFR and VEGFR, such as brivanib, and other compounds that indirectly modulate angiogenesis, such as mTOR inhibitors, are providing novel mechanisms that exploit critical pathways in HCC tumor progression and may have the potential to improve clinical outcomes both as monotherapy and in the case of escape from sorafenib. In the coming years, a number of phase Ⅲ clinical trials examining these angiogenesis inhibitors will be mature, providing a better picture of the clinical utility and treatment options for patients with HCC.

Abstract

AIM: To investigate a dual labeling technique, which would enable real-time monitoring of transplanted embryonic stem cell (ESC) kinetics, as well as long-term tracking.

METHODS: Liver damage was induced in C57/BL6 male mice (n = 40) by acetaminophen (APAP) 300 mg/kg administered intraperitoneally. Green fluorescence protein (GFP) positive C57/BL6 mouse ESCs were stained with the near-infrared fluorescent lipophilic tracer 1,1-dioctadecyl-3,3,3,3-tetramethylindotricarbocyanine iodide (DiR) immediately before transplantation into the spleen. Each of the animals in the cell therapy group (n = 20) received 5 × 10^6 ESCs 4 h following treatment with APAP. The control group (n = 20) received the vehicle only. The distribution and dynamics of the cells were monitored in real-time with the IVIS Lumina-2 at 30 min post transplantation, then at 3, 12, 24, 48 and 72 h, and after one and 2 wk. Immunohistochemical examination of liver tissue was used to identify expression of GFP and albumin. Plasma alanine aminotransferase (ALT) was measured as an indication of liver damage.

RESULTS: DiR-stained ESCs were easily tracked with the IVIS using the indocyanine green filter due to its high background passband with minimal background autofluorescence. The transplanted cells were confined inside the spleen at 30 min post-transplantation, gradually moved into the splenic vein, and were detectable in parts of the liver at the 3 h time-point. Within 24 h of transplantation, homing of almost 90% of cells was confirmed in the liver. On day three, however, the DiR signal started to fade out, and *ex vivo* IVIS imaging of different organs allowed signal detection at time-points when the signal could not be detected by in vivo imaging, and confirmed that the highest photon emission was in the liver (P < 0.0001). At 2 wk, the DiRsignal was no longer detectable *in vivo*; however, immunohistochemistry analysis of constitutively-expressed GFP was used to provide an insight into the distribution of the cells. GFP +ve cells were detected in tissue sections resembling hepatocytes and were dispersed throughout the hepatic parenchyma, with the presence of a larger number of GFP +ve cells incorporated within the sinusoidal endothelial lining. Very faint albumin expression was detected in the transplanted GFP +ve cells at 72 h; however at 2 wk, few cells that were positive for GFP were also strongly positive for albumin. There was a significant improvement in serum levels of ALT, albumin and bilirubin in both groups at 2 wk when compared with the 72 h time-point. In the cell therapy group, serum ALT was significantly (P = 0.016) lower and albumin (P = 0.009) was significantly higher when compared with the control group at the 2 wk time-point;

however there was no difference in mortality between the two groups.

CONCLUSION: Dual labeling is an easy to use and cheap method for longitudinal monitoring of distribution, survival and engraftment of transplanted cells, and could be used for cell therapy models.

INTRODUCTION

Acute liver failure (ALF) is a life-threatening condition which often progresses rapidly to hepatic encephalopathy and multi-organ failure, leading to death within days. Viral hepatitis is the most common cause of ALF worldwide, with hepatitis B virus responsible for about 70% of cases[1]. ALF following hepatic resections is rare, occurring in only 2.6% of patients. However, it produces significant morbidity and mortality[2]. Another causative factor, which is more commonly encountered in the Western world, is acetaminophen (APAP) overdose, which leads to excessive production of its active metabolite N-acetyl-p-benzoquinone imine in the liver, causing depletion of the glutathione stores. This is ultimately followed by centrilobular hepatic necrosis and loss of functioning hepatocytes[3]. APAP-induced liver toxicity is of significant importance because of its continued increase in incidence; it is currently the most common cause of ALF in the Western world[4].

Several specific therapies have been designed to treat APAP-induced ALF. These have been in the form of drugs, such as N-acetyl cysteine being used to replenish glutathione stores in APAP-induced ALF[5], or bioartificial devices to remove toxic metabolites and provide temporary support until native hepatocytes regenerate or as a bridge to liver transplantation (LTx)[6]. LTx is the definitive therapy in patients not responding to conservative therapies which can only maintain the patients until a liver graft becomes available with moderate hypothermia as a bridge to LTx[7,8]. Although the patient's survival after LTx for ALF is lower than that for chronic liver diseases, it is still highest among all other treatment options, with a long-term survival rate of about 70%[9]. However, LTx may not always be feasible due to the severe shortage of donors. One alternative to LTx would be the use of pluripotent or multipotent cells to support the regeneration of the native liver.

So far, only a limited number of experimental studies used terminally differentiated hepatocytes to treat ALF with variable outcomes[10,11]. Hepatocytes seem to be the optimum cell type to replenish the damaged liver; however, they need to be isolated from the donor livers. Also, they cannot be cultured for indefinite periods *in vitro*, and multiple hepatocyte transplantations may be required to achieve a satisfactory regenerative drive[12].

These problems can be bypassed by the use of pluripotent or multipotent cells of different sources such as bone marrow, umbilical veins, fatty tissue or embryonic stem cells (ESCs). These cells have been used in the experimental set up to deliver genes to the liver in models with metabolic diseases[13], and also used to treat chronic liver diseases such as cirrhosis[14]. In the present study, we used undifferentiated ESCs in a mouse model of ALF to evaluate the cell kinetics. The ideal way of tracking transplanted cells used to repopulate damaged livers and improve their function remains to be elucidated. Optimizing cell therapies in patients would require an accurate, highly sensitive and non-invasive means to properly assess cell survival, biodistribution and fate in the same patient over time. Cell labeling offers the advantage of imaging distinct cell populations *in vivo* and investigating the efficacy of these therapies using non-invasive imaging techniques.

In this study, we wanted to evaluate a dual labeling technique, which enabled real-time monitoring of the kinetics of the transplanted ESCs as well as long-term tracking of the cells. A unique dual labeling of the cells was performed using a fluorescence dye and, for long-term tracking, a lentivirus mediated and constitutively expressed green fluorescence protein (GFP).

MATERIALS AND METHODS

Animals and experimental design

Forty male C57/BL6 mice (Charles River laboratories) at 5-6 wk of age with an average weight between 20-25 g were used for this study. All the surgical and experimental procedures were carried out according to the guidelines set by the University College London institutional procedures. All animals were acclimatized for 7 d prior to the experiments. The animals were allocated into 2 groups. Group 1 (n = 20) with cell therapy and group 2 (n = 20) with vehicle only. The group size was not powered for a mortality study. All animals received a single dose of APAP 300 mg/kg administered intraperitoneally[15]. To ensure adequate dissolution, APAP was sonicated over-

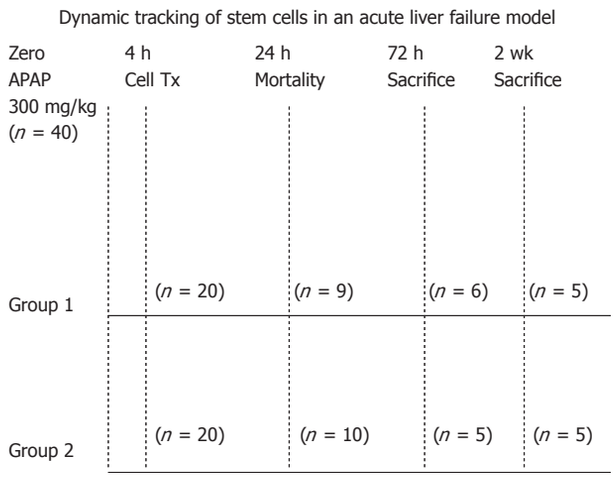

Figure 1 Experimental animal design. Forty mice were treated with acetaminophen (APAP). The animals were then divided into 2 groups. The cell therapy group = Group 1 with cell transplantation and the control group = Group 2. During the first 24 h, 19/40 animals died due to the effect of APAP. Animals from both groups were then killed at 72 h when the signal started to decay and at two weeks when the signal could no longer be detected *in vivo*.

night in a water bath at 42 ℃ and the temperature was maintained until injection time. APAP administration was preceded by a subcutaneous injection of 10% dextrose in order to prevent mortality from severe hypoglycemia[16]. The SC injection of 10% dextrose was repeated every 6 h during the first day of the experiment. At selected time points, the animals were killed by exsanguination (Figure 1). Time points were selected to have an optimal evaluation of ESC cell homing in organs using *ex vivo* imaging and for immunohistochemical (IHC) studies.

Embryonic stem cell line and culture conditions

Undifferentiated C57/BL6 ESCs constitutively expressing GFP (Millipore, Co Durham, United Kingdom) were maintained in the undifferentiated state using MilliTrace mouse ESC expansion medium (Millipore, Co Durham, United Kingdom), supplemented with 15% fetal bovine serum and leukemia inhibiting factor. Puromycin was added to the medium (0.5 μg/mL) for selective growth of GFP-positive cells. Cells were cultured on 0.1% gelatin coated T-75 cell culture flasks until 80% confluence was reached. The undifferentiated state of the ESCs was confirmed by alkaline phosphatase expression in more than 90% of the ESC colonies. Cell fixation was performed with 4% paraformaldehyde for 2 min followed by incubation with a mixture of fast red violet, naphthol AS-BI phosphate solution and water in a 2:1:1 ratio in a dark room for 15 min.

Dual labeling protocol

In order to achieve dual labeling of the GFP expressing ESCs for the purpose of *in vivo* tracking, the cells were labeled with the fluorescent lipophilic tracer 1,1-dioctadecyl-3,3,3,3-tetramethylindotricarbocyanine iodide (DiR) (Invitrogen Ltd, United Kingdom). The excitation/emission spectrum of DiR is in the near infrared range (excitation 750 nm and emission 782 nm). After preparation of the stock solution, 5 mL of cell-labeling solution was directly applied to 1 mL cell suspension, mixed and incubated at 37 ℃ for 20 min. The labeled suspension was centrifuged at 1500 rpm for 5 min and the cell pellet was resuspended in warm fresh medium. This procedure was repeated twice to ensure complete removal of any unbound dye.

Cell preparation and transplantation

Following labeling with DiR, 5×10^6 cells were used per transplantation, which would be equivalent to approximately 7.5%-8% of the host liver hepatocytes[17]. The cells were suspended in 100 μL of sterile phosphate buffer solution (PBS) in a syringe that was kept on ice until the time of transplantation. Cell transplantation was performed 4 h following treatment with APAP. Under adequate anesthesia and strict aseptic technique, a 1 cm incision was made in the left flank of the abdomen and the spleen was delivered outside the incision. The cells were injected into the spleen over a period of 5 min to prevent any loss of the cells due to overflow. Following injection, the needle was removed and fibrin glue applied to the injection site to prevent bleeding and cell loss. After confirming hemostasis, the spleen was replaced back into the abdominal cavity and the abdominal wall closed in a single layer. The same procedure was performed for the control group with PBS only.

Tracking of the transplanted cells

The mice were anesthetized with inhaled isoflurane and placed into the *In vivo* Imaging System (IVIS Lumina 2) chamber (Caliper Life Sciences, Cheshire, United Kingdom) and images were acquired using the CCD camera at 30 min post-transplantation, then at 3, 12, 24, 48 and 72 h, and after one and 2 wk. Following the sacrificing of the animals in groups at predetermined time periods, the spleen, liver, lung and kidney were placed inside the IVIS and images were acquired of the regions of interest to quantify the cell uptake in different organs. Three fluorescence filters [GFP, tricarbocyanine 5.5 and indocyanine green (ICG)] were used to identify the filter with the least background autofluorescence Data analysis was performed using the Living Image™ Software 3.0 (Caliper Life Sciences, Cheshire, United Kingdom).

Green fluorescence protein fluorescence

A Nikon fluorescence microscope (E501) was used for direct detection of GFP+ cells using the fluorescein isothiocyanate filter on frozen tissue sections.

Blood and tissue sampling

Following the culling the animals at 72 h and 2 wk, blood was collected by puncturing the suprahepatic vena cava, preserved on ice, then centrifuged to collect serum for further analysis of liver functions. Tissue samples of the liver and spleen were also collected and preserved for hematoxylin and eosin (HE) staining and IHC.

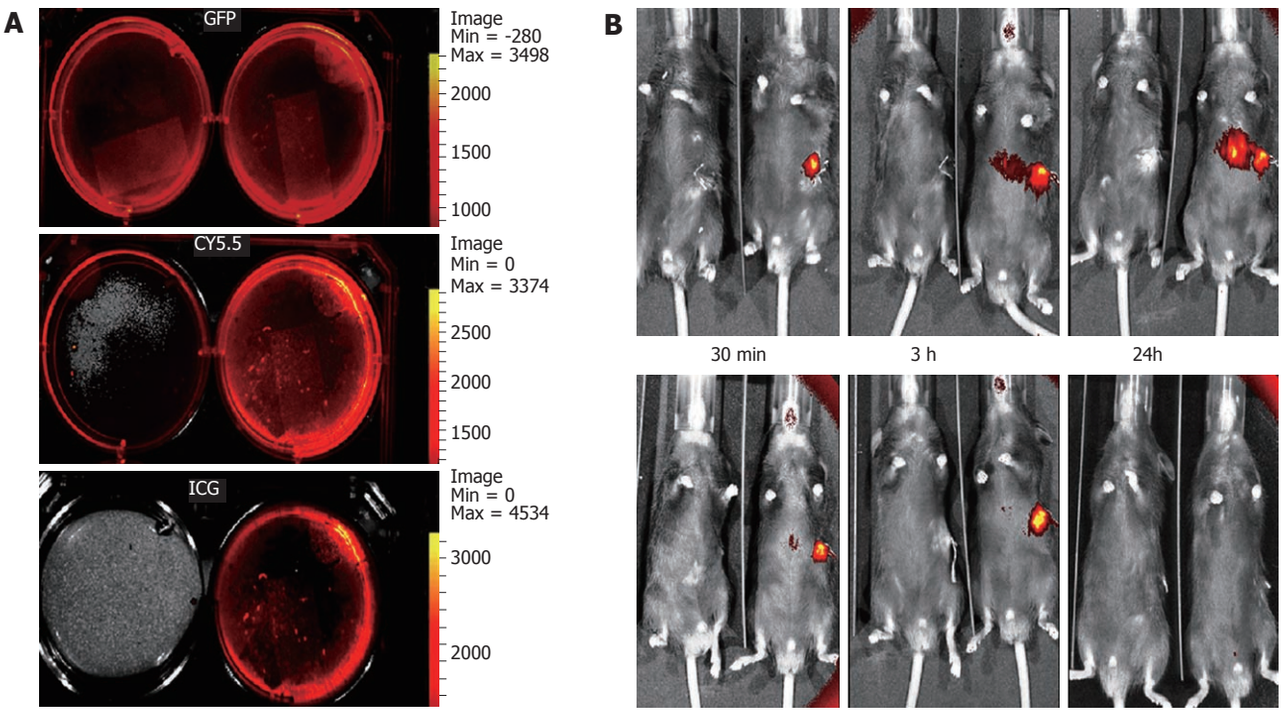

Figure 2 Labeling and tracking of the fluorescent embryonic stem cell following acetaminophen administration. IVIS images of green fluorescence protein (GFP) +ve cultured embryonic stem cells (ESCs) without 1,1-dioctadecyl-3,3,3,3-tetramethylindotricarbocyanine iodide (DiR) staining (LT) and with DiR staining (RT) showing background fluorescence using the GFP and tricarbocyanine 5.5 filters, but not with the indocyanine green (ICG) filter (A). Images of a pair of mice (B), one from the cell therapy group-RT and the other from the control group-LT, were compared using IVIS. At 30 min following transplantation, a strong signal could only be detected from the spleen where the cells were injected. Between 3 and 24 h following the cell transplantation, the signal started to intensify between the spleen and the liver, which is most probably the splenic vein owing to its tortuous course. A strong signal was detected in the liver over 24 h post-transplantation, which faded out by the 72 h time-period. After one week, the signal could not be detected in the liver, but was still strong and was detectable over the spleen, which had completely disappeared by 2 wk.

Measurement of liver function tests

Measurement of hepatic enzyme and serum albumin levels were performed using the COBAS Integra 400 biochemistry analyzer (Roche) for measurement of plasma alanine aminotransferase (ALT), albumin, bilirubin and urea.

Immunohistochemistry

Sections of both the liver and spleen were preserved in 10% buffered formalin for HE staining and IHC studies. The IHC study was performed using the streptavidin ABC duet kit (Dako, Cambridgeshire, United Kingdom) on 5 μm thick paraffin embedded tissue sections. Briefly, sections were dewaxed in xylene, rehydrated in graded alcohol and rinsed with PBS. Antigen retrieval was performed by heating in citrate buffer solution at 95 ℃ for 10 min. Endogenous peroxidase activity was blocked by incubating the slides with 3% hydrogen peroxide for 20 min. The sections were incubated at 4 ℃ overnight with primary antibodies; polyclonal rabbit anti-GFP (1:10, Millipore), and anti-albumin antibody (1:1000, Abcam). Streptavidin-peroxidase labeled secondary antibody was applied for 30 min at room temperature. Between steps, slides were rinsed with PBS solution. Color was developed with the chromogen 3,3'-diaminobenzidine (Dako, Cambridgeshire, United Kingdom), and counterstained with Mayer's hematoxylin solution.

Statistical analysis

Continuous variables were expressed as mean ± SD. Differences were compared by *t*-test or Mann-Whitney *U* test as appropriate. For comparison of multiple groups, one-way ANOVA with Scheffe's *post-hoc* test was used. Differences in survival were analyzed by Kaplan Meier and a log rank test was used for significance. Statistical significance was taken as $P < 0.05$. All statistical analyses were done using the SPSS software for Windows 14.0 (SPSS, Inc., Chicago, IL).

RESULTS

In vivo detection of the transplanted cells

IVIS proved to be effective in precisely identifying the cells labeled with DiR in the liver and spleen at different time-points. This was possible only by using the ICG filter due to its high background passband of 665-695 nm with minimal background fluorescence (Figure 2A). At 30 min post-transplantation, the cells were confined inside the spleen and then gradually moved into the splenic vein and part of the liver at 3 h time point. By 24 h, the cells spread out over almost all areas of the liver and a residual signal was received over the spleen as well. The signal of DiR emitted from the liver faded out at 72 h. No signal could be detected in any other organs (Figure 2B).

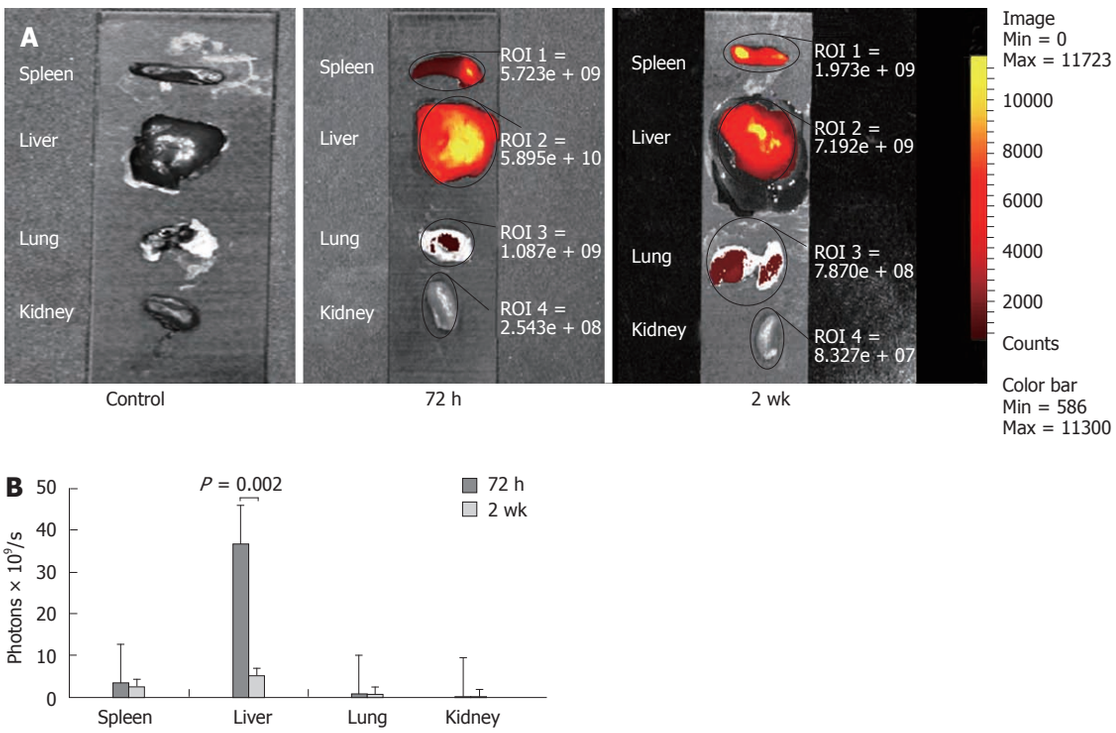

Figure 3 ***Ex vivo*** **images showing the distribution of fluorescent cells in different organs as detected by the indocyanine green filter of the IVIS.** A signal was detected at the site of injection in the spleen; however, the highest signal was noticed in the center of the liver at 72 h. which faded out by the 2 wk time-point. A weak fluorescent signal was also detected in the lungs at 72 h and 2 wk, but not seen in kidneys at any time-points (A). A graph showing the highest uptake of cells in the liver at all time-points with a significant drop at 2 wk (B).

Ex vivo imaging

A very clear fluorescent signal was detectable from both the liver and spleen when the organs were taken out and imaged directly with the IVIS. Eliminating the barrier effect of the anterior abdominal wall allowed signal detection at time-points when the signal could not be detected by *in vivo* imaging. Similar to *in vivo* imaging, the ICG filter was the most accurate filter to localize the cells with no autofluorescence from the organs. A weak signal was also detectable in the lungs and kidneys, in contrast to the *in vivo* imaging (Figure 3A). DiR uptake in the liver was significantly higher than the sum of uptake in all other organs at 72 h ($P < 0.0001$). At 2 wk, the amount of photons emitted from the liver decreased significantly from $3.67 \times 10^{10} \pm 1.7 \times 10^{10}$ photons/s at 72 h to $5.18 \times 10^{9} \pm 1.58 \times 10^{9}$ ($P = 0.002$). However, in the liver, the emission was still significantly higher than the spleen ($P = 0.002$), lungs ($P < 0.0001$) and kidneys ($P < 0.0001$) (Figure 3B).

Engraftment of the transplanted cells in the liver

Frozen liver sections, using fluorescent microscopy, were studied to validate that the signal detected using the IVIS was definitely emitted from the engrafted cells and not from the released fluorescent dye DiR following cell death. GFP fluorescence from the transplanted cells was easily detectable by direct fluorescence microscopy at 72 h, however, it became much weaker at 2 wk and, therefore, we relied on IHC detection of GFP positive cells. At 72 h, discrete GFP +ve colonies were located under the liver capsule and around the central veins (Figure 4A). GFP +ve cells were detected using IHC staining with anti-GFP +ve antibody. GFP +ve cells resembling hepatocytes were dispersed throughout the hepatic parenchyma with the presence of a larger number of GFP +ve cells incorporated within the sinusoidal endothelial lining (Figure 4E). GFP +ve cells could still be detected after 2 wk in the spleen, mainly around the central arteriole and the trabeculae (Figure 4F).

Effect of embryonic stem cell therapy on acetaminophen-induced liver injury

All mortality occurred during the first 24 h following APAP administration with 10/40 (25%) mice dying in the control group and 9/40 (22.5%) in the cell therapy group. According to the Kaplan Meier analysis, there was no significant difference in survival between the control and cell therapy groups ($P = 0.755$, log rank test). All animals surviving the initial 24 h lived until the time of sacrifice.

Liver damage was detected at 72 h, most prominent in the centrilobular regions with hepatocyte necrosis and secondary infiltration of inflammatory cells in both the cell therapy and control groups (Figure 4C and D). Improvement in liver histology was noticed both in both groups at 2 wk, with less inflammatory cell infiltration in the treatment group (Figure 4G and H).

In order to identify the nature of the transplanted cells, we stained with albumin antibody, which revealed very faint albumin expression in the GFP +ve cells at 72

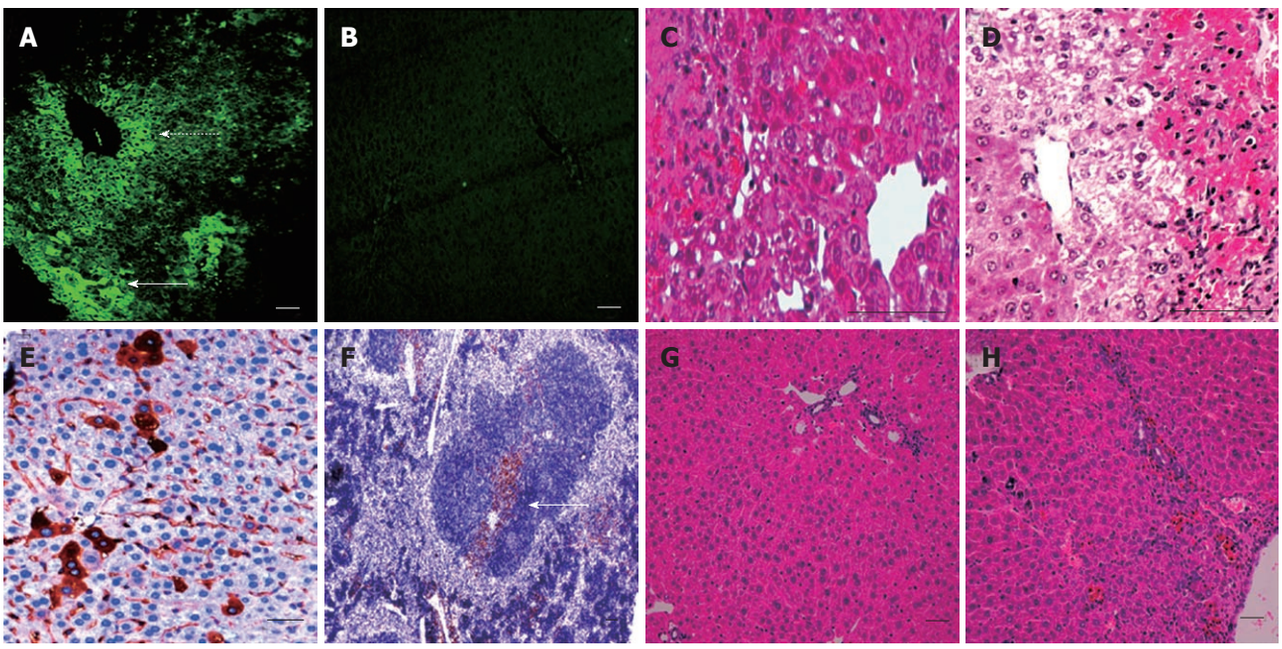

Figure 4 Embryonic stem cell liver engraftment following acetaminophen induced damage. A and B: Green fluorescence protein (GFP) +ve cells were present under the liver capsule (a-solid arrow) and around the central veins of the liver at 72 h, as seen under direct fluorescence (a-dashed arrow) with no fluorescence detected in the control group (B); C and D: The characteristic pattern of acetaminophen-induced liver damage after 72 h mainly affected the centrilobular portions of the liver, with marked damage of the pericentral hepatocytes in both the cell therapy and control groups, although pericentral vacuolation was more evident in the control group; E: At 2 wk, the GFP +ve cells could be detected using IHC in the hepatic parenchyma and within the sinusoidal lining; F: Localized colonies of GFP +ve cells were also detected in the spleen at 2 wk; G and H: After 2 wk the liver recovered in both groups, with the liver sections from the cell therapy group (G) showing less inflammatory cells and congestion than in the control group (H) (scale bar = 200 μ).

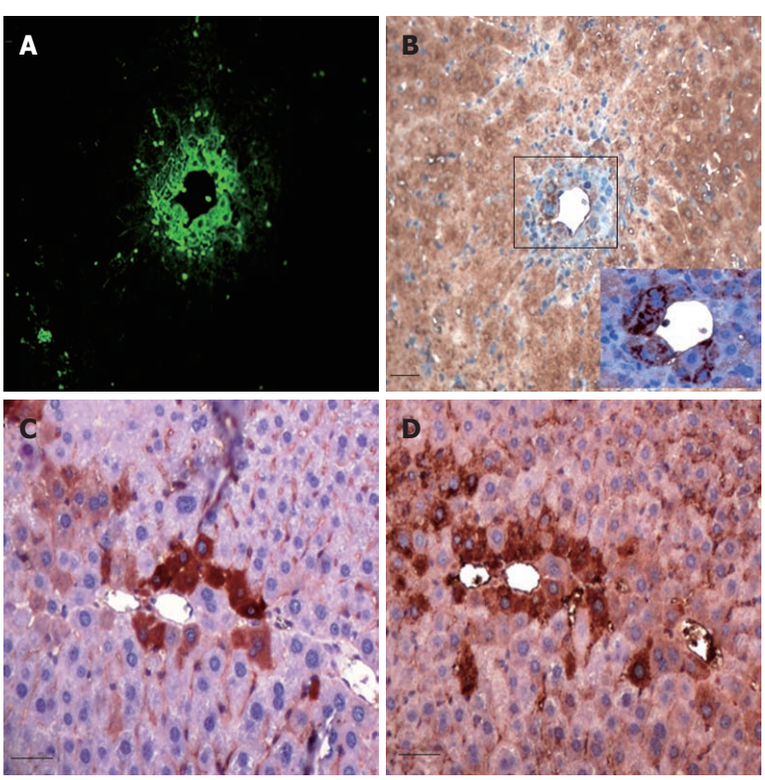

Figure 5 Serial sections examined for Green fluorescence protein and albumin expressions. Green fluorescence protein (GFP) +ve transplanted cells (A) showed very faint albumin expression at the cell periphery of dividing cells at 72 h (B), whereas areas stained with anti-GFP antibody (C) were positive for albumin (D) at 2 wk following cell therapy (scale bar = 100 μ).

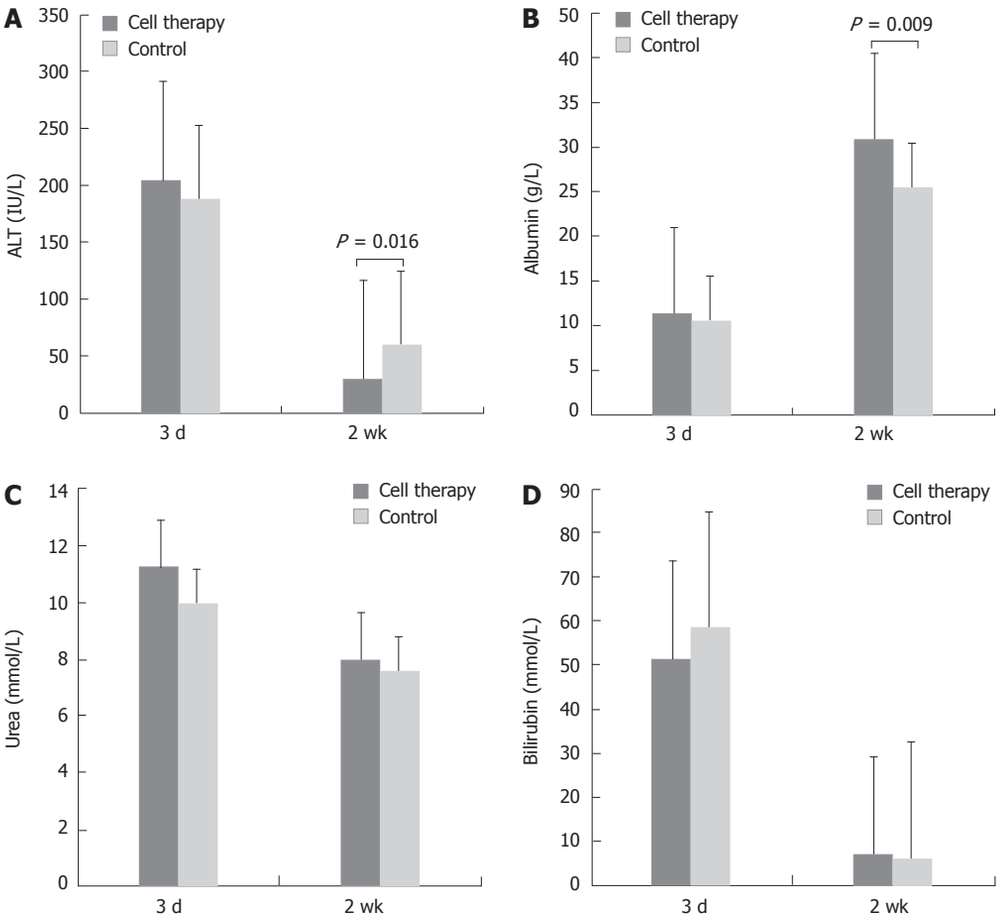

Figure 6 Serum levels of alanine aminotransferase, albumin, bilirubin and urea are shown (*n* = 21). A: The alanine aminotransferase (ALT) level significantly dropped in both groups at 2 wk when compared with the 72 h. When compared with the 72 h, there was a significant reduction in serum ALT level at 2 wk in the embryonic stem cell treatment group, but not in the control group; B: The albumin level also improved in both groups with the level being significantly higher in the cell therapy group when compared with the control group at 2 wk; C: The drop in urea levels was not significant in either group; D: Bilirubin levels dropped significantly from 72 h to 2 wk, with no significant differences between groups at similar time-points.

h (Figure 5A and B). However, when examined on serial sections, few cells that were positive for GFP were also strongly positive for albumin at 2 wk (Figure 5C and D).

There was a significant improvement in serum levels of ALT, albumin and bilirubin in both groups at 2 wk when compared with the 72 h time-point (Figure 6). Cell therapy itself had no effect on any of these parameters at the 72 h time point when compared with the control group. However, at 2 wk, serum ALT was significantly lower in the cell therapy group when compared to the control group (ALT: 29.58 ± 2.19 *vs* 60.38 ± 29.22, cell therapy *vs* control group respectively, Mann *U* Whitney test $P = 0.016$, *t*-test $P = 0.07$) (Figure 6A). The serum albumin level was also significantly higher in the cell therapy group (Albumin: 30.8 ± 1.27 *vs* 25.54 ± 2.29, cell therapy *vs* control group, respectively, $P = 0.009$) (Figure 6B). No significant changes occurred in serum bilirubin or urea levels between either group at 2 wk (Figure 6C and D).

DISCUSSION

In the present study we developed a novel model in which we were able to monitor both the immediate and late kinetics of transplanted ESC cells. In this way, we were able to track the cells over days in real-time after the injection and had a better understanding about the dynamics of the cells in an experimental model of ALF without the need to sacrifice animals.

In the present model, we used APAP to induce ALF. So far, most of the existing animal models look into the role of cell therapy on liver regeneration following partial hepatectomy or hepatocellular damage induced by CCl4[18-20]. In these models, the roles of cell therapy were not studied in a pathophysiological milieu reciprocating the clinical scenario of ALF[21]. For example, following liver resection, the liver bed reduces drastically and resection itself mobilizes the CD 133+ subset of cells from bone marrow into circulation, which may have played an independent role in liver regeneration[22]. Moreover, CCl4-induced liver damage builds up over time and does not produce a similar profound effect to that of ALF[21]. In this study, we used an ALF model induced by APAP at a relatively moderate dose of 300 mg/kg, and transplanted the undifferentiated ESCs 4 h following induction of injury so that most of the APAP would have been me-

tabolized and would not interfere with ESCs survival[15]. In order to track the cells *in vivo*, we used a reproducible imaging system for continuous real-time monitoring of the injected cells following transplantation. The IVIS is a relatively new optical imaging system that is being widely used in the fields of oncology and immunology, allowing non-invasive cell detection and migration[23]. Near infrared dyes have been previously used for monitoring cells *in vivo* with improved quality of signal detection by increasing the contrast between the signal and the background, which is comprised mainly of water, oxyhemoglobin and deoxyhemoglobin[24]. This has made it possible to track labeled cells located in deep-seated organs with minimal background fluorescence. To achieve that goal, we labeled the ESCs with a near infrared lipophilic tracer dye (DiR), which has the advantage of very low cell toxicity and laterally diffuses within the cell membrane, hence staining the whole cell. Very recently, Chois *et al*[25] used luciferase-transfected fetal hepatocyte cells for repopulating the liver in a monocrotaline-injected mice model and nicely showed the uptake of the cells by a CCD camera generated images. The advantages of the imaging we used in this study lies with the simplicity of the method. This technique is relatively cheap and easy to use without any necessity for genetic manipulation of the cells. There is also no necessity to inject any extra dye for visualization of the cells, which might interfere with body chemistry and prolong the anesthetic duration for the animals. The cells could be clearly seen migrating from the spleen to the liver (Figure 2). The signal intensity in the liver was highest between the second and third days post-transplantation, possibly because cell proliferation is highest at that time[26]. A rapid drop in the signal intensity was noticed after the third day and continued to fade until it completely disappeared at 2 wk post-transplantation. Similar to the DiR dye we used, the signal from firefly luciferase also dropped on day 10 following hepatocyte transplantation[25]. However, visualization and quantification of the transplanted cells was still possible at 2 wk by DiR imaging when the organs were extracted and imaged directly under the IVIS.

Since the ESCs were transfected with GFP, it was possible to observe the distribution of the transplanted cells on tissue sections directly under the fluorescent microscope or by immunohistochemistry using the anti-GFP antibody. Engraftment of the ESCs was confirmed on liver tissue sections in the post-transplantation period by direct visualization of GFP +ve cells, which appeared in the close vicinity of the central veins where the main brunt of the damage had occurred. The homed pericentral cells subsequently proliferated and spread throughout the liver parenchyma. The mechanism through which the ESCs integrate into the liver plate depends primarily on the disruption of the sinusoidal endothelial cells[27]. Although APAP overdose characteristically affects the centrilobular regions of the liver, causing extensive necrosis, there is also a direct toxic effect on the sinusoidal endothelial cells through glutathione depletion[28] and thus this may have played a role in the uptake of cells into the liver parenchyma, particularly since GFP +ve cells were also detected in the sinusoidal endothelial lining at 2 wk.

ESC transplantation did not improve either survival or liver functions at 72 h. At 2 wk some transplanted cells expressed albumin and morphologically resembled hepatocytes. There was an increase in serum albumin production at 2 wk in the cell therapy group when compared to the control group. It is unlikely that the differentiation of transplanted cells into hepatocytes could explain the improved liver functions at 2 wk in the cell therapy group, since the cells were few and we did not perform additional studies to confirm differentiation as this was not the purpose of the study. The paracrine effect of the transplanted cells, rather than direct differentiation, seems to be a more possible cause of improved liver functions. Mesenchymal stem cell conditioned medium has been shown to improve liver functions following induction of ALF in rats[29]. Proteins released from human undifferentiated ESCs were also shown to improve cardiomyocytes function[30].

ESC therapy has been riddled with several problems including allogenic rejection, ethical concerns and, most importantly, chances of malignant transformation of ESCs. Although Moriya *et al*[31] did not detect any teratoma formation following transplantation of undifferentiated ESCs in a liver cirrhosis model in mice; the transformation of undifferentiated ESCs into teratomas is very likely after a period of time. We used undifferentiated ESCs in this study to develop a suitable model to study the kinetics of transplanted cells in ALF; however, to study the therapeutic effect of ESCs in ALF, ideally we should have used differentiated ESCs, pluripotent stem cells or primary hepatocytes. Differentiation of ESCs *in vitro* into hepatocytes has been extensively studied by several groups and could be achieved by formation of embryoid bodies[32], or directly by adding growth factors to the ESCs in monolayer cultures[33]. However, full maturation of hepatocytes is not complete without the influence of the intrinsic environment[34]. Several studies have been conducted to simulate the inductive microenvironment *in vitro*, either through co-cultures with hepatocytes[35] or using conditioned media in *in vitro* cultures[36].

We conclude that serial longitudinal tracking of transplanted cells in a mouse model of ALF is possible using IVIS and that dual labeling would allow for both immediate and long-term tracking of the transplanted cells, which would in turn allow us to better understand their differentiation and fate.

COMMENTS

Background

Acute liver failure is a life-threatening condition. Several therapies have been designed to treat this condition with mixed results. Stem cells represent a promising therapeutic modality; however, in order to optimize cell therapy, it would be necessary to develop an accurate cell tracking method.

Research frontiers

We developed a novel imaging system for stem cell tracking using a dual

labeling fluorescent protocol. It was possible to track the cell dynamics *in vivo* without killing the animals, giving an insight into the cell biodistribution in different organs. This would allow real-time monitoring in the early phase following development of acute liver failure which would be very beneficial in optimizing cell therapy.

Innovations and breakthroughs

Other methods of cell monitoring rely either on early or late tracking of cells. Through dual labeling we could take advantage of the near infrared cell label, which is very efficient in localizing the cells *in vivo*, but has a short half-life. The authors could then track the green fluorescence protein label, which is not efficient for *in vivo* cell tracking, but could be used for localizing the cells in tissue sections either directly or indirectly even after a long period of time.

Application

Understanding cell dynamics in the acute phase of liver failure would allow for the optimizing of cell therapies according to the time-points when the cells engraft in the liver and could then serve as an alternative therapeutic option to liver transplantation.

Peer review

This is an interesting study about some non-invasive methods for tracking stem cells to evaluate the cell engraftment following acute liver failure by acetaminophen. The authors developed an interesting and novel model for *in vivo* tracking of embryonic stem cells, based in stained green fluorescence protein embryonic stem cells with the IVIS Lumina-2. Immunohistochemistry for albumin and green fluorescence protein were used to confirm liver embryonic stem cell nesting.

Abstract

AIM: To investigate the seroprevalence of *Helicobacter pylori* (*H. pylori*) and its relationship to nutritional factors in female Vietnamese immigrants to Korea.

METHODS: A total of 390 female immigrants from Vietnam and 206 Korean male spouses participated in the study. Blood samples from 321 female immigrants and 201 Korean male spouses were analyzed for *H. pylori* antibodies. Data on age, sex, alcohol consumption, smoking status, dietary nutritional factors and gastrointestinal symptoms were collected using questionnaires. The daily intakes of the following nutrients were estimated: energy, protein, niacin, lipid, fiber, calcium, iron, sodium, potassium, zinc, folate, cholesterol, and vitamins A, B1, B2, B6, C and E.

RESULTS: The prevalence of *H. pylori* positivity was lower in the immigrants than in age-matched Korean females (55.7% *vs* 71.4%, respectively; $P < 0.0001$) and the domestic population of Vietnam. The prevalence of *H. pylori* positivity among married couples was 31.7% for both spouses. There were no statistically significant differences in the incidence of smoking, amount of alcohol consumed, or nutritional factors between the *H. pylori*-positive and negative groups.

CONCLUSION: The prevalence of *H. pylori* positivity was lower among female Vietnamese immigrants than among Korean females. Nutritional factors did not differ between the *H. pylori*-positive and negative groups.

Key words: Vietnam; Immigration; South Korea; *Helicobacter pylori*; Diet

INTRODUCTION

Helicobacter pylori (*H. pylori*) infection is a major cause of gastric diseases such as chronic gastritis, peptic ulcer disease, and gastric malignancy[1]. *H. pylori* infection can be transmitted from mouth to mouth between family members[2]. Immigrants could be a source of *H. pylori* transmission.

In Korea, immigration has increased since 2000, and the number of marriages between young immigrant females and Korean males has increased rapidly. Official records show that there were 35 142 marriages between

immigrant females and Korean males in 2009[3]. Female Vietnamese immigrants are involved in 20.6% of marriages between immigrants and Koreans and are the second most common group of immigrant newlyweds after Chinese females. The number of marriages between immigrant Vietnamese females and Korean males increased by 42.5% in 2009[3]. Although the increase in the number of immigrants may have affected the prevalence of infectious and inherited diseases in Korea, a study on *H. pylori* infection of immigrants has not been conducted.

We conducted a serological study on the prevalence of *H. pylori* positivity and compared the prevalence of *H. pylori* infection among female Vietnamese immigrants with that of Korean females. We also evaluated the relationship between *H. pylori* infection and nutritional factors in female Vietnamese immigrants.

MATERIALS AND METHODS

Subjects

This survey involved 399 asymptomatic female Vietnamese immigrants and was conducted from March 2006 to August 2007 at the Ewha Mokdong University Hospital. In total, 321 immigrant females and 202 Korean male spouses were enrolled for serological testing for *H. pylori* antibodies. A total of 202 married couples were involved. Questionnaires were completed by the immigrant females with the help of a translator. Demographic data (age, sex, and past history of gastrointestinal disease) and lifestyle data (smoking, alcohol consumption, and dietary intakes) were obtained using the questionnaire. The same questionnaire was completed by the Korean spouses.

Serological analysis

A 5-mL blood sample was collected after an 8-h fast and centrifuged for 10 min at 3000 *g*, and the serum stored at -70 ℃. *H. pylori* infection was determined according to the presence of serum *H. pylori* immunoglobulin (IgG) antibodies using an enzyme-linked immunosorbent assay (ELISA) kit, Genedia® (Noksymja, Seoul, South Korea). The sensitivity and specificity of this assay were reported to be 93.2% and 83.5%, respectively[4]. The prevalence of *H. pylori* infection among the immigrants was compared with that determined from a national survey of *H. pylori* in Koreans. Associations between *H. pylori* prevalence and gastrointestinal symptoms, smoking, exercise, and alcohol consumption were analyzed.

Dietary survey

Trained dietitians interviewed the subjects using a quantitative food frequency questionnaire. The subjects were asked to recall their usual dietary intakes of foods. The energy and nutrient content of each food item were estimated using the Korean Foods and Nutrients Database[5]. The daily intakes of vitamins in the form of supplements were calculated according to their frequency of consumption, dosage, and vitamin content. The nutritional factors assessed were energy, protein, lipid, sugar, fiber, calcium, iron, sodium, potassium, zinc, folate, cholesterol, and vitamins A, B1, B2, B6, C and E. Associations between *H. pylori* prevalence and nutritional factors were analyzed.

Statistical analysis

The statistical significance of the difference in the prevalence of *H. pylori* between female Vietnamese immigrants and Korean females was evaluated. All data were analyzed using SAS version 9.1 (SAS institute, Cary, NC, United States) and SPSS version 10.0 (SPSS Inc, United States). A P value of less than 0.05 was considered significant.

RESULTS

General characteristics and H. pylori positivity in female Vietnamese immigrants

The mean age of female Vietnamese immigrants was 24.7 ± 6.4 years in the *H. pylori*-positive group and 25.0 ± 6.3 years in the *H. pylori*-negative group. The age of the female Vietnamese immigrants ranged from 18 to 60 years, and 40% had gastrointestinal symptoms. The most common symptom was epigastric pain (19.0%), followed by constipation (17.0%).

The incidence of *H. pylori* positivity was 55.7% among the 321 female Vietnamese immigrants, 57.7% among those aged 11-20 years, 57.8% among those aged 21-30 years, and 48.5% among those aged 31-50 years. *H. pylori* positivity did not increase markedly with age. The prevalence of *H. pylori* positivity was lower among female Vietnamese immigrants of all ages than among Korean females (55.7% *vs* 71.4%, respectively; $P < 0.0001$) and among Korean females aged 21-30 years (57.8% *vs* 85.2%, respectively; $P = 0.006$) and older than 30 years (48.6% *vs* 75.6%, respectively; $P < 0.0001$) (Table 1). The prevalence of H. pylori positivity was lower in female Vietnamese immigrants than in the corresponding age groups for Korean females.

Influence of lifestyle factors on H. pylori positivity

We analyzed whether *H. pylori* positivity was affected by smoking, exercise, history of gastrointestinal disease, or gastrointestinal symptoms (Table 2). The *H. pylori*-positive group had a lower incidence of history of gastrointestinal disease than that of the *H. pylori*-negative group (8.1% *vs* 15.1%, respectively; $P = 0.042$). Direct or indirect smoking, alcohol consumption, and frequency of exercise had no effect on *H. pylori* positivity.

H. pylori positivity in female Vietnamese immigrants and their spouses

The prevalence of *H. pylori* positivity among the male spouses of the immigrants was 64.3%. In the female Vietnamese immigrants, *H. pylori* positivity was highest at 21-30 years of age (57.8%), whereas in the Korean male spouses, it was highest at 31-50 years of age (64.8%) (Table 3). The mean *H. pylori* positivity for both spouses among the 202 married couples was 31.7%.

H. pylori positivity and its relationship to nutrition

None of the nutritional factors examined had a statisti-

cally significant effect on *H. pylori* positivity among female Vietnamese immigrants (Table 4). The consumption of vitamin C and vitamin E was higher in the *H. pylori*-positive group than in the *H. pylori*-negative group, but the difference was not statistically significant. Among the male spouses, fiber consumption was higher in the *H. pylori*-positive group than in the *H. pylori*-negative group ($P = 0.01$). The mean sodium intake was 3378.9 mg in the *H. pylori*-positive group. The mean sodium intake of the Korean spouses (4661.2 mg) was higher than that of the female Vietnamese immigrants.

DISCUSSION

The most important environmental factors implicated in the pathogenesis of gastric cancer are diet and *H. pylori* infection[1,6]. *H. pylori* infection is also correlated with gastrointestinal diseases such as gastric and duodenal ulcerations[7]. As immigration to Korea is increasing, *H. pylori*-infected immigrants could spread these diseases among the Korean community. Until now, no information has been available on the prevalence of *H. pylori* infection among female Vietnamese immigrants.

Detection of *H. pylori* antibody in serum is the simplest method of evaluating whether *H. pylori* infection is present. *H. pylori* IgG has been used as a prevalence index in epidemiological studies. Although the *H. pylori* IgG method has lower sensitivity and specificity for detecting *H. pylori* infection than the C*ampylobacter*-like organism (CLO) test, it is useful for the screening of asymptomatic patients and for health checkups[8]. The *H. pylori* IgG ELISA used in this study had 93.2% sensitivity and 83.5% specificity among Koreans[4], but its sensitivity and specificity differ among countries[9]. Vietnam and Korea are both in East Asia, and *H. pylori* variants in both countries have the same CagA3' motif (CAGTF/CAGJR, CAGJF/CAGTR)[10].

In Korea, the prevalence of *H. pylori* positivity was 46.6% among asymptomatic patients in 2000[4] and 62.4% among Korean females older than 16 years[4]. This estimate is lower than that reported by Song et al. in 1997 for a study involving 477 Korean females (72.5%)[11]. In the present study, the incidence of *H. pylori* positivity among the female Vietnamese immigrants was 55.7%, which is much lower than that recorded among Korean females (71.4%) ($P < 0.0001$) in the Korean national survey. The prevalence of *H. pylori* positivity was also much lower in immigrant females aged 21-30 years than in the corresponding age group for Korean females.

In Korea, the prevalence of *H. pylori* positivity in the domestic population increased with age and was highest (74%) at 30-40 years of age[4], but in female Vietnamese immigrants, it was higher at 20 years of age than at 30. In developing countries, the prevalence of *H. pylori* infection increased between 10 and 20 years of age and remained constant at about 80% thereafter[12]. In our study, the prevalence of *H. pylori* positivity among female Vietnamese immigrants did not increase between 10 and 20 years of age. The *H. pylori* positivity of the immigrants was lower than that of age-matched Korean females and that of the domestic population of Vietnam, which was 74.6%[13]. The prevalence of *H. pylori* infection showed differences between Vietnamese cities and was 78.8% in Hanoi, the capital of Vietnam, but in rural areas such as Hatay, it was as low as 69.2%[13]. The prevalence of H. pylori infection of female population was 79.4% in Hanoi and 72.8% in Hatay[13]. The region of origin of the female Vietnamese immigrants could have influenced the results of our study, but these data were not collected. The lower prevalence of *H. pylori* infection among female Vietnamese immigrants compared with that among Korean females was probably due to differences in race and local region of immigration origin.

The prevalence of simultaneous *H. pylori* positivity in female Vietnamese immigrants and their Korean male spouses was 31.7%, which is lower than that published for Korea (77%-88%)[14]. This discrepancy may have been because of differences in the sample populations used as the published data involved only 26 CLO-positive patients and their spouses. In a study of a Western population, *H. pylori* positivity was 83.3% among spouses with

Table 4 Analysis of the association between *Helicobacter pylori* positivity and nutritional factors in female Vietnamese immigrants and their male spouses

Cholesterol (mg)	330.5 (1393.0)	218.3 (214.0)	0.298	264.9 (191.0)	319.3 (299.9)	0.173

Data are presented as mean (SD). $^{1}P < 0.05$, *Helicobacter pylori* (*H. pylori*) positive group *vs Helicobacter pylori* negative group in Korean male spouses.

H. pylori-positive partners and 28.5% among spouses with *H. pylori*-negative partners[14].

Smoking and alcohol consumption were not significantly related to *H. pylori* positivity in our study, which is in agreement with the results of another study[15].

The *H. pylori*-negative group had a higher incidence of history of gastrointestinal disease than the *H. pylori*-positive group. The association between gastrointestinal disease and *H. pylori* infection is controversial[16]. The lower incidence of history of gastric disease among *H. pylori*-positive immigrant females should be verified using an objective endoscopic method. The incidence of gastrointestinal symptoms and *H. pylori* positivity was 60% and was similar in both *H. pylori*-positive and negative groups.

There were no statistically significant differences in the intakes of energy, protein, lipid, sugar, fiber or vitamins between the *H. pylori*-positive and negative groups. Another report showed that *H. pylori* positivity is higher among people who ingest roasted food more than twice daily than in people who ingest roasted food once daily or less[15]. However, the consumption of spices, dairy products, and fresh fruit and vegetables was not related to *H. pylori* positivity[15].

Nutritional factors were not related to *H. pylori* positivity among the female Vietnamese immigrants. The mean sodium intake was 3378.9 mg in the *H. pylori*-positive group. The mean sodium intake of the Korean spouses (4661.2 mg) was higher than that of the female Vietnamese immigrants. Koreans have a relatively high sodium intake, and patients with gastric cancer have a higher sodium intake than healthy subjects[17]. The female Vietnamese immigrants consumed less salt than the Koreans. Tsugane[18] reported that the incidence of gastric cancer among Japanese immigrants in the United States could be explained by the extent to which migrants continued to maintain a high consumption of salt. The incidence of gastric cancer among Vietnamese immigrants needs to be investigated.

Fiber intake was higher in the male spouses of the *H. pylori*-positive group ($P = 0.01$), and there was no statistically significant difference in vitamin C intake ($P = 0.086$). It has been reported that *H. pylori*-positive subjects had a low concentration of vitamin C in gastric juice and that vitamin C levels increased after eradication of *H. pylori*[19]. *H. pylori* positivity and the severity of gastritis were associated with the concentration of vitamin C level in gastric juice[19]. There was no significant relationship between *H. pylori* positivity and vitamin C intake in this study. Other studies have stated that the consumption of vitamin C increases serum and gastric juice concentrations of vitamin C, resulting in a lower prevalence of gastric cancer when combined with *H. pylori* eradication[20]. An analysis of dietary micronutrients (vitamin C, vitamin E, carotenoids, fiber, flavonoids, and selenium) commonly considered protective against gastric cancer yielded conflicting results[6]. *H. pylori* positivity was not affected by smoking, alcohol, or nutritional factors.

In conclusion, the prevalence of *H. pylori* positivity among the female Vietnamese immigrants was lower than that among Korean females, and nutritional fac-

tors showed no significant difference between the *H. pylori*-positive and negative groups. More studies on the transmission of *H. pylori* infection in immigrants are warranted.

COMMENTS

Background

Helicobacter pylori (*H. pylori*) infection is correlated with gastrointestinal diseases such as gastric cancer, gastric or duodenal ulcerations. As immigration to Korea is increasing, a difference in the prevalence of *H. pylori* infection between immigrants and the native population could affect the spread or prevalence of infectious disease.

Research frontiers

The prevalence of *H. pylori* positivity among female Vietnamese immigrants was lower than among Korean females, and nutritional factors showed no significant difference between *H. pylori*-positive and negative groups.

Innovations and breakthroughs

There have been few studies on the health or disease status of immigrants. Tsugane reported that the incidence of gastric cancer among Japanese immigrants in the United States could be explained by the extent to which migrants continued to maintain a high consumption of salt. There has been no report on the health of Vietnamese immigrants in Korea. The prevalence of *H. pylori* positivity was different between female Vietnamese immigrants and Korean females. Also, there were differences in the prevalence of *H. pylori* infection within Vietnam. The prevalence was lower in the female Vietnamese immigrants than in Korean females and the domestic female population of Vietnam. Nutritional factors did not show statistical differences related to *H. pylori* positivity.

Applications

H. pylori infection could be a source of infectious disease in family members. Investigation of *H. pylori* infection in immigrants could lead to further knowledge of gastric diseases such as gastric cancer or ulceration.

Peer review

This is an interesting comparison between two apparently relatively similar cohorts of females, who nevertheless have different infection rates with *H. pylori*. Interestingly, dietary factors do not appear to play a role-at least in adults. In view of this, it would be interesting to offer some speculation on the mode of infection with *H. pylori* in these cohorts of women!

Abstract

AIM: To assess the role of hyperpolarization-activated cyclic nucleotide-gated cation (HCN) channels in regulating the excitability of vagal and spinal gut afferents.

METHODS: The mechanosensory response of mesenteric afferent activity was measured in an *ex vivo* murine jejunum preparation. HCN channel activity was recorded through voltage and current clamp in acutely dissociated dorsal root ganglia (DRG) and nodose ganglia (NG) neurons retrogradely labeled from the small intestine through injection of a fluorescent marker (DiI). The isoforms of HCN channels expressed in DRG and NG neurons were examined by immunohistochemistry.

RESULTS: Ramp distension of the small intestine evoked biphasic increases in the afferent nerve activity, reflecting the activation of low- and high-threshold fibers. HCN blocker CsCl (5 mmol/L) preferentially inhibited the responses of low-threshold fibers to distension and showed no significant effects on the high-threshold responses. The effect of CsCl was mimicked by the more selective HCN blocker ZD7288 (10 μmol/L). In 71.4% of DiI labeled DRG neurons (n = 20) and 90.9% of DiI labeled NG neurons (n = 10), an inward current (I_h current) was evoked by hyperpolarization pulses which was fully eliminated by extracellular CsCl. In neurons expressing I_h current, a typical "sag" was observed upon injection of hyperpolarizing current pulses in current-clamp recordings. CsCl abolished the sag entirely. In some DiI labeled DRG neurons, the I_h current was potentiated by 8-Br-cAMP, which had no effect on the I_h current of DiI labeled NG neurons. Immunohistochemistry revealed differential expression of HCN isoforms in vagal and spinal afferents, and HCN_2 and HCN_3 seemed to be the dominant isoform in DRG and NG, respectively.

CONCLUSION: HCNs differentially regulate the excitability of vagal and spinal afferent of murine small intestine.

Key words: Hyperpolarization-activated cyclic nucleotide-gated cation; Vagal afferent; Spinal afferent; Gastrointestinal tract; CsCl

Hyperpolarization-activated cyclic nucleotide-gated cation channel subtypes differentially modulate the excitability of murine small intestinal afferents. *World J Gastroenterol* 2012; 18(6): 522-531 Available from: URL: http://www.wjgnet.com/1007-9327/full/v18/i6/522.htm DOI: http://dx.doi.org/10.3748/wjg.v18.i6.522

INTRODUCTION

The gastrointestinal tract is innervated by vagal and spinal afferent nerves, whose cell bodies lie in the dorsal root ganglion (DRG) and nodose ganglion (NG), respectively[1]. Previous studies have shown that vagal and spinal afferents differ in their responsiveness to a variety of stimuli and hence may play different roles in gastrointestinal (GI) physiology and pathophysiology. The mesenteric nerves (consisting of both vagal and spinal afferents) of the small intestine exhibited biphasic increases in afferent activity in response to ramp distension in the rat *in vivo* and in the *ex vivo* mouse or rat jejunum preparations, suggesting the presence of low- and high-threshold mechanoreceptors[2,3]. Booth *et al*[3] demonstrated that the low-threshold response in rats was markedly reduced following chronic vagotomy whereas the high-threshold response remained unaltered. These data were consistent with the notion that vagal mechanoreceptors are primarily low-threshold fibers that convey innocuous signals in the GI tract and contribute to the control of satiety and food intake as well as reflex regulation of motility, secretion and absorption[1]. The spinal afferents, on the other hand, are mainly composed of high-threshold and wide dynamic range fibers and may therefore encode nociceptive signals in the GI tract. There has been extensive evidence suggesting that altered sensitivity of vagal and spinal afferents may underlie some of the debilitating symptoms such as bloating and pain seen in functional GI diseases[4]. However, the molecular mechanisms of sensory dysfunction remain poorly understood.

Previous studies have identified a number of ion channels and G-protein coupled receptors that are involved in sensory transduction and modulation of the excitability of primary afferents including those innervating the GI tract. In mammals, the hyperpolarization-activated cyclic nucleotide-gated cation (HCN) channel family consists of 4 cation channels, named HCN_{1-4}. In cells expressing these channels, hyperpolarization of the membrane potential would activate HCN channels, resulting in a slow inward current. The kinetics of these channel activity are regulated by cyclic adenosine 3',5'-monophosphate (cAMP). Because these channels are activated near the resting membrane potential, they can modulate the membrane excitability. Several groups have explored the possible role of HCN channels in sensory processing. It has been shown that HCN channels are expressed in DRG and nodose neurons[5,6]. Importantly, it has been reported that HCN channels were up-regulated in DRG neurons following nerve injury and neuropathic pain was reversed by HCN blockers, suggesting that HCN channels have an excitatory influence on sensory neurons and may represent a potential therapeutic target in pain management. However, another study demonstrated that in nodose neurons and aortic baroreceptors, HCN blockers reduced the threshold for activation, indicating that HCN channels have an inhibitory influence on the excitability of nodose neurons and baroreceptors[5,7].

Matsuyoshi *et al*[8] examined the expression of HCN channels in bladder afferent neurons. Among HCN-1, HCN-2 and HCN-4, positive staining with HCN-2 antibodies was found in approximately 60% of small- and medium-sized bladder afferent neurons. However, the amplitude and current density of hyperpolarization-activated current (I_h) was significantly larger in medium-sized bladder afferent neurons than in small-sized bladder neurons, suggesting that I_h currents could control the excitability of mechanoceptive Aδ-fiber bladder afferent neurons[9]. HCN channels are also localized in enteric nervous system[10]. Linden and colleagues[11] found that the enhancement of afterhyperpolarization neuronal excitability in inflamed guinea pig colon involves an increase in I_h current. However, there has been little information regarding the potential role of HCN channels in the function of extrinsic afferents of the GI tract.

In the present study, we investigated the effect of HCN channel blockers on the mechanosensory responses of mesenteric afferent nerves of the murine jejunum *in vitro* and compared the I_h current in vagal and spinal primary afferent neurons retrogradely labeled from the small intestine.

MATERIALS AND METHODS

Animals

Male Kunming mice weighing 20-25 g were purchased from Shanghai Jiaotong University School of Medicine. The mice were allowed free access to normal laboratory food and tap water and were kept under conditions of constant temperature and humidity with a 12-h light/dark cycle. Mesenteric afferent nerve recording experiments were performed on 6 mice for CsCl and 3 mice for ZD-7288. Immunohistochemistry was performed on 3 DiI labeled mice and 3 as control. All procedures involving use of animals were approved by the Institutional Animal Care and Use Committee at Shanghai Jiaotong University.

Tissue preparation and afferent nerve recording

Mice were deeply anaesthetized with pentobarbital (80 mg/kg, ip) and then killed by cervical dislocation. A midline laparotomy was performed and sections of jejunum were rapidly removed[2]. One of the jejunum segments was placed in a recording chamber (10 mL) and superfused with oxygenated Krebs solution (composition in mmol/L: NaCl 113, KCl 5.9, $CaCl_2$ 1.25, $MgSO_4$ 1.2, NaH_2PO_4 1.2, $NaHCO_3$ 25, Glucose 11.5). Chamber temperature was kept at 34 ℃. The jejunum was cannulated at each end to allow intraluminal infusion (0.1 mL/min) and ramp distension of the gut. A branch of the mesenteric nerve was dissected and the electrical activity was recorded using a suction electrode connected to a Neurolog headstage (NL100, Digitimer Ltd., United Kingdom). The signal was amplified (NL104), filtered (NL 215, bandpass 300-3000Hz), digitized (Micro1401, CED, United Kingdom) and then captured by a computer with the Spike2 software (version 5.14, Cambridge Electronic Design, United Kingdom). The jejunum segment was distended

gradually to an intraluminal pressure of 60 mmHg by closing the outflow port to observe the mechanosensitivity of mesenteric nerves and this was repeated at an interval of 15 min. The effect of HCN channel blockers (5 mmol/L CsCl or 10 μmol/L ZD7288) on the mechanosensory responses was tested by switching the bath and intraluminal solution to one that contains one of the antagonists.

Retrograde labeling of DRG and NG neurons innervating the jejunum

DRG and NG neurons were retrogradely labeled by injecting the fluorescent dye, DiI (Molecular Probes, Eugene, OR)[12] into the gut wall. Briefly, mice were anaesthetized with 1% pentobarbital (40 mg/kg, ip). Under sterile conditions, a midline laparotomy was performed to expose the jejunum and 25 μL DiI (0.1% in DMSO) was injected at 15-20 sites into the smooth muscle layer. Incisions were sutured in layers and mice were allowed to recover for 1-2 wk to permit DiI to be transported to the cell soma.

Dissociation of neurons and patch-clamp recording

Mice were killed by an overdose of pentobarbital (100 mg/kg, ip). T_7-L_2 DRG and NG were quickly isolated under a dissecting microscope and transferred into ice cold Hanks' solution. The ganglia were minced with fine spring scissors after removing the connective tissue. The minced ganglia were placed in Hank's solution containing type Ⅱ collagenase (3 mg/mL) and trypsin (2.5 mg/mL) and incubated at 37 ℃ for 50 min, then washed 2-3 times in DMEM with 10% fetal calf serum, 100 U penicillin and 100 μg streptomycin. Cells were then dispersed by gentle titration with fire-polished Pasteur pipettes. The cell suspension was plated onto 35-mm culture dish coverslips precoated with 0.01% poly-lysine and incubated in 5% CO_2 at 37 ℃ overnight.

For patch-clamp recording, one of the coverslips was placed in the recording chamber (1 mL) and the cells were continuously perfused with extracellular solution (in mmol/L: NaCl 130, KCl 6, $MgCl_2$ 1.2, $CaCl_2$ 2.5, HEPES 10, Glucose 10, $BaCl_2$ 1) at room temperature (21-25 ℃). We added 1 mmol/L Ba^{2+} in the extracellular solution in order to block the inward-rectifier potassium current upon applying the hyperpolarizing voltage steps[13,14]. Whole cell recordings of the DiI-labelled cells were conducted using electrodes with a resistance of about 3-5 MΩ when filled with the internal solution (composition in mmol/L: K-gluconate 140, $MgCl_2$ 2, EGTA 1.1, HEPES 10).

Immunohistochemistry

Mice were killed by an overdose of pentobarbital and then perfused with saline followed by 4% paraformaldehyde in 0.1 mol/L sodium phosphate buffer with a pH of 7.4. T_7-L_2 DRG and NG were isolated and post-fixed in the same solution at 4 ℃ overnight and then transferred into 30% sucrose for 24 h at 4 ℃. The ganglia were then embedded in an Optimal Cutting Temperature compound and serially sectioned (10 μm) using a cryostat for immunofluorescent staining. Briefly, sections were treated with phosphate-buffered saline (PBS) containing 1% normal goat serum and 1% TritonX-100 at room temperature for 30 min twice followed by incubation with one of the primary antibodies at 4 ℃ overnight. The sections were rinsed in PBS for four times and then incubated with the secondary antibody at room temperature for 1 h. The primary antibodies used were rabbit polyclonal antibodies: 1:200 anti-HCN_1 (ab65706, Abcam), 1:200 anti-HCN_2 (ab65704, Abcam), 1:200 anti-HCN_3 (ab65705, Abcam) and 1:1000 anti-HCN_4 (ab65703, Abcam). The secondary antibody was a goat anti-rabbit Alexa Fluor 488 (Molecular Probes, Invitrogen) diluted in 10% NGS /PBS/Triton solution (1:1000).

Statistical analysis

Numerical data were expressed as mean ± SE. Statistical analysis of the data was performed using SPSS version 13.0 or Graphpad Prism version 5 (Graphpad software, San Diego, United States). The effect of CsCl on low- and high- threshold afferent responses were analyzed by paired Student's *t* test. The pressure-afferent nerve response curves were analyzed using linear regression and then compared using an analysis of covariance (ANCOVA). Amplitude, density and time constants of I_h current were compared between DRG and NG neurons by Wilcoxon rank sum test. Mean voltages of half activation ($V_{1/2}$) and slope factors (k) of I_h were acquired from the curves fitted by Boltzmann equation in Origin 6.0 (OriginLab, Northampton, Massachusetts, United States). The percentages of HCN-positive cells in DRG and NG were compared by the χ^2 test. $P < 0.05$ was considered statistically significant.

RESULTS

Effect of HCN channel blockers on the mechanosensory responses of small intestinal afferent nerves

Ramp distension of the jejunum segments typically evoked biphasic increases in mesenteric afferent nerve discharge (Figure 1), which is consistent with previous reports[2,15]. The first phase was a rapid increase in afferent activity when the intraluminal pressure started to rise and the nerve activity reached the first peak at an intraluminal pressure of approximately 5 mmHg and then plateaued or increased slowly as the intraluminal pressure continued to rise. The second phase was an accelerated increase in nerve discharge starting at an intraluminal pressure of 20 mmHg. This pattern of ramp distension-evoked afferent responses was due to the activation of three functional populations of afferent fibers, namely low-threshold fibers, wide dynamic range fibers and high-threshold fibers[2]. As is exemplified in Figure 1A, simultaneous bath and intraluminal application of the HCN channel blocker, CsCl (5 mmol/L), attenuated the initial phase of the nerve responses to ramp distension but seemed to render the second phase of the mechanosensory response unaffected. Figure 1B shows the average pressure-afferent response curves of the mesenteric nerves ($n = 6$) under the

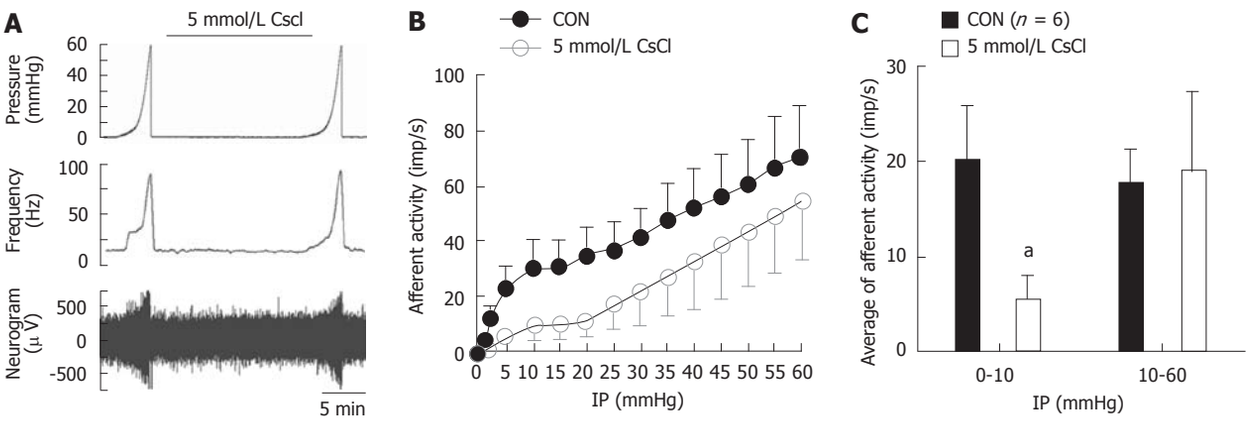

Figure 1 Effects of CsCl on the mechenosensory activity of small intestinal afferents. Figure 2 Effects of ZD-7288 on the mechanisensory responses of mesenteric afferent nerves. Note that the slopes of the average pressure-response curves in the pressure range of 10 mmHg - 60 mmHg were apparently similar with or without the hyperpolarization-activated cyclic nucleotide-gated cation channel blocker ZD-7288 (10 μmol/L). Data were pooled from 3 preparations.

control condition and in the presence of CsCl (5 mmol/L) (Figure 1B). For simplicity, each curve is divided into two parts (intraluminal pressure range, 0-10 mmHg and 10-60 mmHg) and analyzed using linear regression, reflecting the mechanosensitivity of low- and high-threshold fibers, respectively. Under the control condition, the initial part of the pressure-response curve had a slope of (2.95 ± 0.73) imp/s per mmHg and in the presence of 5 mmol/L CsCl, the slope was (0.90 ± 0.37) imp/s per mmHg, which was significantly smaller compared with the control curve ($P < 0.05$, ANCOVA, Figure 1B). The slope of the second part of the pressure-response curve (10-60 mmHg) in the presence of 5 mmol/L CsCl was not significantly different from that of the control curve [(0.86 ± 0.24) imp/s per mmHg *vs* (0.95 ± 0.27) imp/s per mmHg, $P > 0.05$, ANCOVA, Figure 1B]. Another way of addressing the responses of low- and high-threshold fibers is to calculate the changes in afferent discharge rate when the intraluminal pressure increased from the baseline to 10 mmHg (low-threshold response) and from 10 to 60 mmHg (high-threshold response). As shown in Figure 1C, 5 mmol/L CsCl attenuated the low-threshold response but rendered the high threshold response unaltered [0-10 mmHg: (19.91 ± 5.92) imp/s *vs* (5.65 ± 2.34) imp/s , paired *t* test, $t = 3.29$, $P < 0.05$; 10-60 mmHg: (17.48 ± 3.70) imp/s *vs* (18.83 ± 8.55) imp/s, paired *t* test, $P > 0.05$, Figure1C].

To confirm that CsCl-induced inhibition of the low-threshold mechanosensory response is due to the blockade of HCN channels, we observed the effects of ZD-7288, a more selective HCN channel blocker, on the responses of mesenteric nerves to ramp distension in 3 jejunum preparations. Indeed, 10 μmol/L ZD7288 mimicked the effects of CsCl in that it attenuated the low-threshold responses, but not significantly affected the high-threshold responses (Figure 2). These data clearly demonstrate that under the normal conditions, HCN channels exert a tonic facilitatory effect on the low-threshold mechanoreceptors but not on high-threshold mechanoreceptors.

Hyperpolarization-activated current in vagal and spinal primary afferent neurons projecting to the small intestine

We focused on DRG and NG neurons retrogradely labeled from the small intestine by patch-clamp recording of I_h current. I_h current was present in 71.4% (20/28) of DiI labeled DRG neurons (mean diameter, 35.67 ± 0.65 μm; mean capacitance, 45.83 ± 5.13 pF) and 90.9% (10/11) of NG neurons (mean diameter, 29.63 ± 1.20 μm; mean capacitance, 25.84 ± 2.60 pF). Figure 3 shows an example of DiI labeled DRG neurons viewed under the inverted fluorescence microscope, as well as the current and voltage traces obtained by whole cell recording. Under voltage-clamp recording, hyperpolarization pulses activated inward currents which were virtually abolished by 5 mmol/L CsCl. Under current-clamp recording, hyperpolarizing currents elicited hyperpolarization of the membrane potential which exhibited a "sag" (depolarization) that was also prevented by 5 mmol/L CsCl. These results show that both vagal and spinal primary afferent

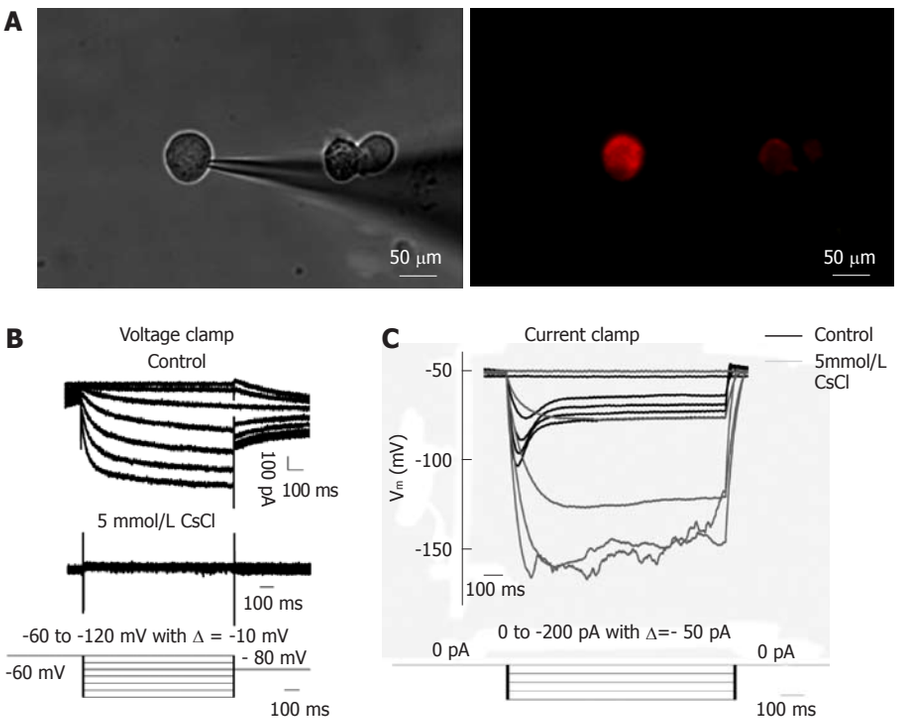

Figure 3 I_h recorded under whole-cell voltage and current clamp from DiI labeled dissociated dorsal root ganglia and nodose ganglia neurons innervating the jejunum. A: DiI labeled dissociated dorsal root ganglia neurons; B: Representative current traces of I_h current (top trace); Current recorded in the presence of 5 mmol/L CsCl (middle trace); voltage clamp protocal: I_h was induced from a holding potential of -60 mV in 1 s pulses from -60 mV to -120 mV in steps of 10 mV, followed by a final step to -80 mV to record the tail current (bottom trace); C: Voltage response to test current pulse before (black) and after (grey) application of 5 mmol/L CsCl (top trace); bottom trace shows the current clamp protocol, i.e., hyperpolarizing current pulses ranging from 0 pA to -200 pA in steps of 50 pA. Note that the current elicited an instantaneous hyperpolarization that was followed by depolarization (named "sag") of membrane potential. DRG: Dorsal root ganglia; NG: Nodose ganglia.

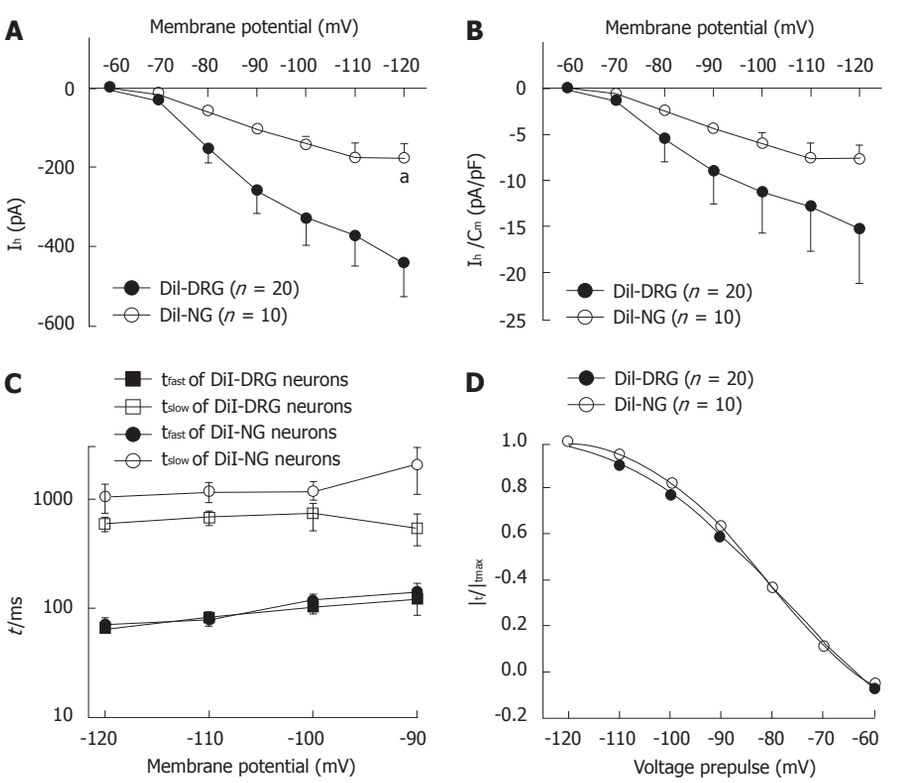

Figure 4 I_h steady-state parameters and activation kinetics in DiI-labeled DRG and NG neurons. A: I_h current-voltage relationship between DiI-labeled dissociated dorsal root ganglia (DRG) and nodose ganglia neurons (NG); B: I_h current density-voltage relationship between DiI-labeled DRG and NG neurons; C: The time constant of I_h current. I_h current traces were fitted with two exponentials according to the following equation: $I_h(t) = Af \exp(-t/\tau f) + As \exp(-t/\tau s)$, where $I_h(t)$ is the amplitude of the current at time t and Af and As are the initial amplitudes of the fast (τf) and slow (τs) activation time constant components, respectively. Time constants were obtained by fitting currents using pCLAMP; D: I_h current activation curves. Normalized activation curves were obtained from tail currents at -80 mV and fitted by Boltzmann function: $I_h/I_h(max) = 1/\{1+ \exp[(Vm - V_{1/2})/k]\}$, where I_h is the peak amplitude of the tail current recorded immediately after the pre-pulse, $I_h(max)$ is the maximal current recorded after the maximal prepulse of -120 mV, V_m is the membrane potential, $V_{1/2}$ is the membrane potential at which I_h conductance is half-activated, and k is a slope factor of the curve. Data were expressed as mean ± SE. [a]$P < 0.05$ *vs* DiI-labeled DRG neurons.

neurons projecting to the small intestine express functional HCN channels, which seemed to exert a facilitatory effect on the afferent excitability.

Hyperpolarization-activated currents in DiI-labeled DRG neurons were generally of larger amplitude than in NG neurons [-120 mV: (-439.08 ± 89.56) pA for DRG neurons and (-176.37 ± 36.96) pA for NG neurons, Wilcoxon rank sum test, $P < 0.05$, Figure 4A], although when normalized to the membrane capacitance, the difference in current density was not statistically significant between spinal and vagal afferents [-120 mV: (-15.22 ± 5.93) pA/pF for DRG neurons and (-7.64 ± 1.67) pA/pF for NG neurons, Wilcoxon rank sum test, $P > 0.05$, Figure 4B]. We compared the kinetics of I_h currents in these two populations. The time course of I_h activation was fitted by a two-exponential function (Figure 4C). There was no significant difference in the fast and slow time constant between DiI-labeled DRG and NG neurons [-120mV: (65.81 ± 6.89)

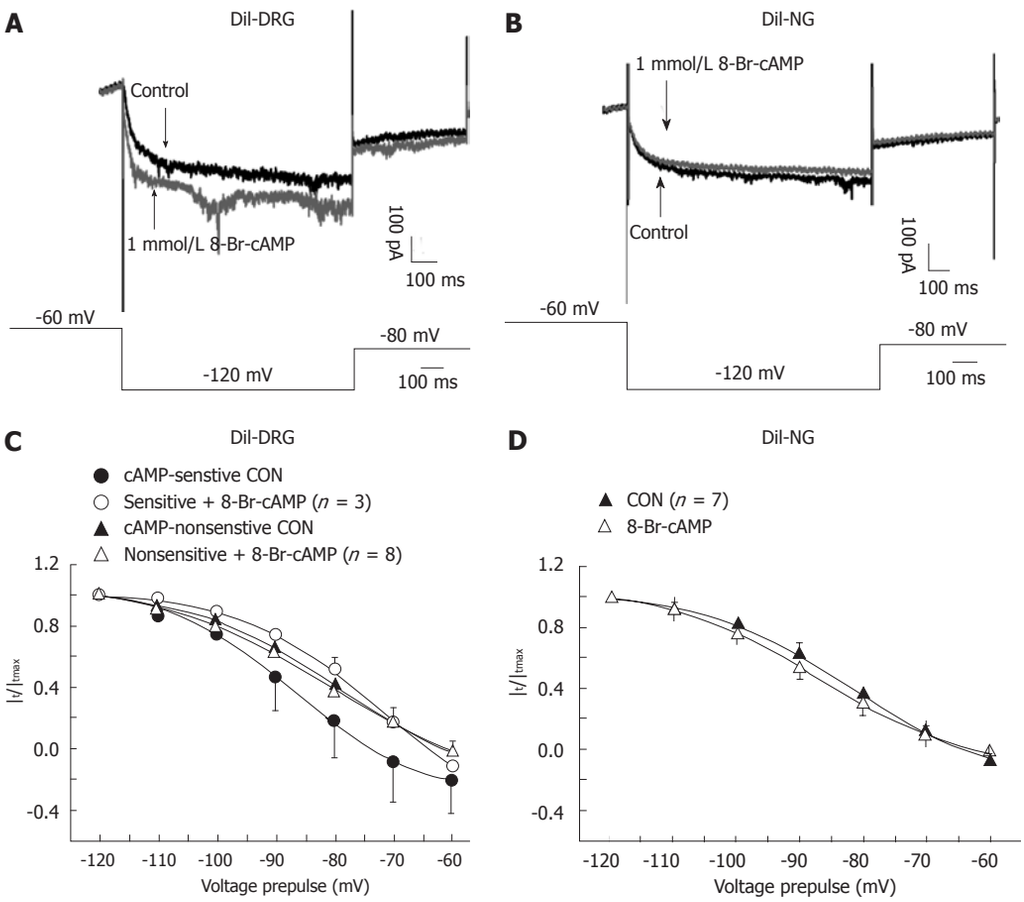

Figure 5 Effects of 8-Br-cAMP on the activation curves of I_h current in DiI-labeled dissociated dorsal root ganglia and nodose ganglia neurons. A and B: Overdraw of the I_h current traces elicited by a hyperpolarizing pulse (-120 mV) in control and in the presence of 8-Br-cAMP in DiI-labeled dissociated dorsal root ganglia (DRG) (A) and nodose neurons (B); C: Activation curves of cAMP-sensitive and cAMP-insensitive DiI-labeled DRG neurons before (black block symbols) and after treatment with 8-Br-cAMP (empty symbols); D: Activation curves of DiI-labeled nodose ganglia neurons before (black block triangle) and after treatment with 8-Br-cAMP (empty triangle). Data were expressed as mean ± SE.

ms and (590.57 ± 88.19) ms for DRG neurons, (70.12 ± 5.10) ms and (1044.54 ± 307.80) ms for NG neurons, respectively]. The activation parameters of I_h was $V_{1/2}$ (-77.86 ± 3.38) mV, slope factor 16.06 ± 2.96 for DiI-labeled DRG neurons and $V_{1/2}$ -81.31 ± 0.41 mV, slope factor 11.84 ± 0.40 for DiI-labeled NG neurons (Figure 4D).

We applied 8-Br-cAMP (a membrane permeable cAMP) to test the sensitivity of I_h currents in spinal and vagal afferent neurons to cAMP. In 3 of 11 DiI-labeled DRG neurons, I_h currents were augmented by 8-Br-cAMP, as is shown in Figure 5A. In these neurons, 8-Br-cAMP (1 mmol/L) caused a 14 mV depolarizing shift in the midpoint of voltage activation without marked effect on the slope factor [$V_{1/2}$ from (-86.49 ± 1.14) mV to (-72.16 ± 3.44) mV and slope factor from 10.59 ± 1.31 to 12.07 ± 2.04, Figure 5A and C]. I_h currents in the other 8 DRG neurons tested were not sensitive to 8-Br-cAMP [$V_{1/2}$ from (-79.45 ± 1.70) mV to (-80.43 ± 2.07) mV and slope factor from 12.17 ± 1.52 to 14.00 ± 2.03, Figure 5C]. Seven NG neurons were tested, but the I_h currents in these neurons were not altered in the presence of 8-Br-cAMP [$V_{1/2}$ from (-81.95 ± 0.78) mV to (-86.84 ± 0.29) mV and slope factor from 11.57 ± 0.78 to 11.98 ± 0.36, Figure 5B and D]. These data suggest that different isoforms of HCN channels may exist in subpopulations of spinal and vagal primary afferent neurons innervating the small intestine.

Immunohistochemical staining of HCN isoforms in DRG and NG neurons

There was no apparent immunofluorescent staining for HCN_1 in DRG or NG sections. HCN_2 immunostaining was detected in both ganglia. In DRG sections, 12.3% of DRG neurons and numerous afferent fibers were stained for HCN_2. In NG sections, HCN_2 immunostaining was less extensive in that only 2.3% of NG neurons ($P < 0.05$, χ^2 test, compared with DRG) and fewer fibers were stained for HCN_2. Weak HCN_3 immunoreactivity was detected in some DRG neurons. In contrast, moderate staining for HCN_3 appeared to be present in the majority of NG neurons. HCN_4 immunoreactivity was not detected in NG sections but was present in a minority of DRG neurons (Figure 6).

To determine the subtypes of HCN channels expressed in intestinal primary afferent neurons, we further observed the immunoreactivity of HCN_{1-4} in DRG and NG neurons retrogradely labeled from the small intestine

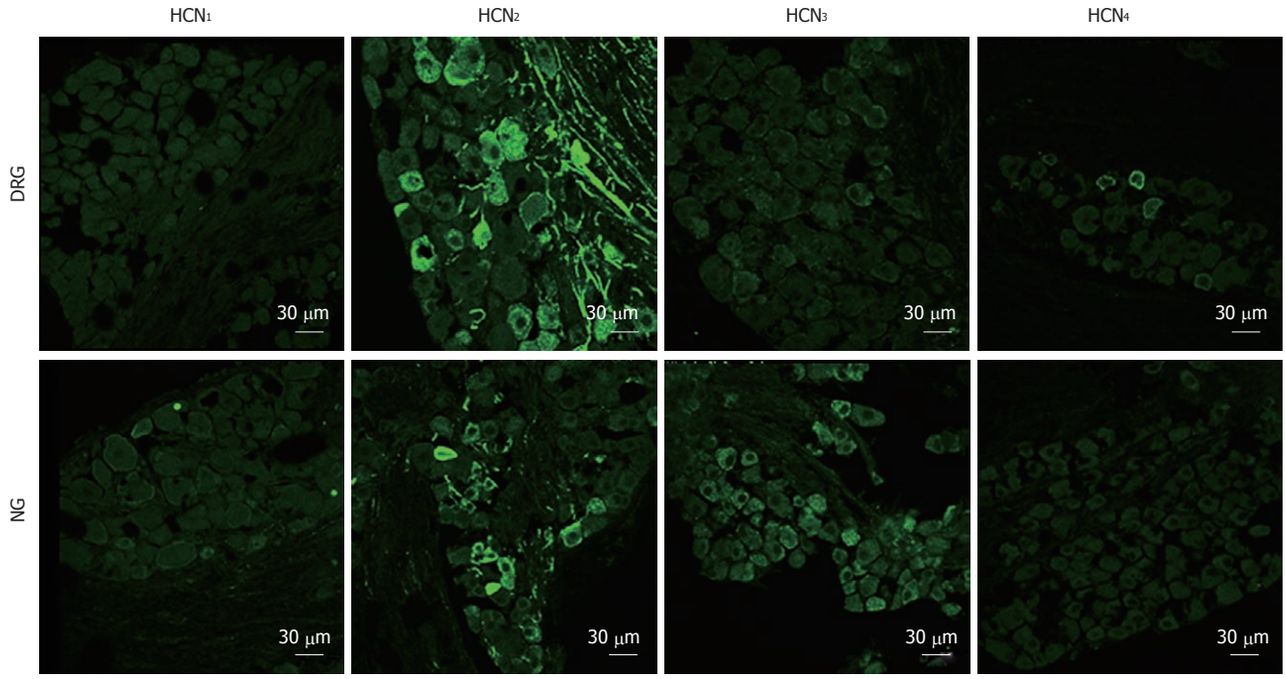

Figure 6 Immunostaining for hyperpolarization-activated cyclic nucleotide-gated cation isoforms in dorsal root ganglia and nodose ganglia sections. Hyperpolarization-activated cyclic nucleotide-gated cation channel 1 (HCN_1) immunoreactivity was not detectable in dorsal root ganglia (DRG) and nodose ganglia (NG) neurons. HCN_2 immunoreactivity was prominent in DRG (cell bodies and fibers) and was also present in some NG neurons and fibers. HCN_3 immunoreactivity was profuse in NG sections but was weaker in DRG sections. HCN_4 immunoreactivity was present in a minority of DRG neurons and was absent in NG.

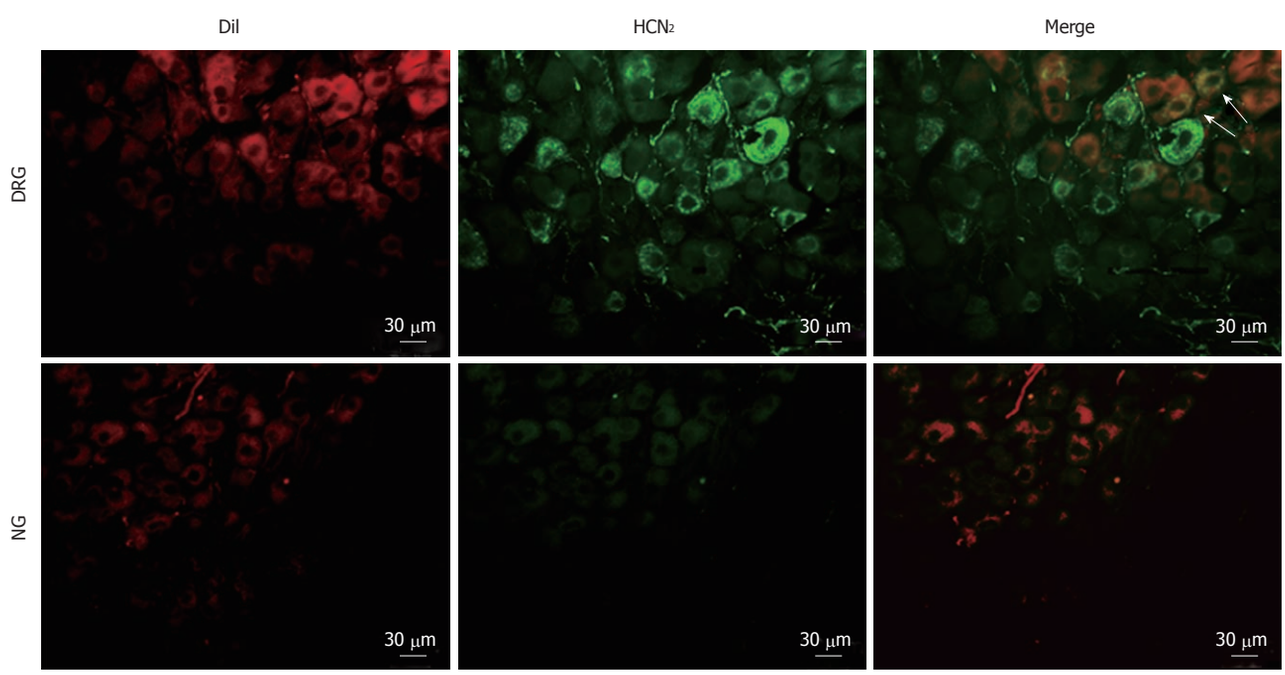

Figure 7 Immunostaining for hyperpolarization-activated cyclic nucleotide-gated cation channel 2 in intestinal primary afferent neurons. Spinal and vagal afferent neurons innervating the small intestine were labeled *via* injection of DiI (red) into the gut wall. Arrows indicate positive hyperpolarization-activated cyclic nucleotide-gated cation channel 2 (HCN_2) staining in DiI-labeled dorsal root ganglia neurons. DRG: Dissociated dorsal root ganglia; **NG**: Nodose ganglia.

via injection of DiI into the gut wall. As expected, HCN_1 immunoreactivity was not detected in any of the DiI-labeled DRG or NG neurons. HCN_2 immunoreactivity was present in some DiI-labeled DRG neurons but was not detected in DiI-labeled NG neurons (Figure 7). On the other hand, moderate HCN_3 immunoreactivity was apparently present in most DiI-labeled NG neurons. DiI-labeled DRG neurons, however, were only weakly immunoreactive to HCN_3 (Figure 8). HCN_4 immunoreactivity was not detected in DiI-labeled DRG or NG neurons.

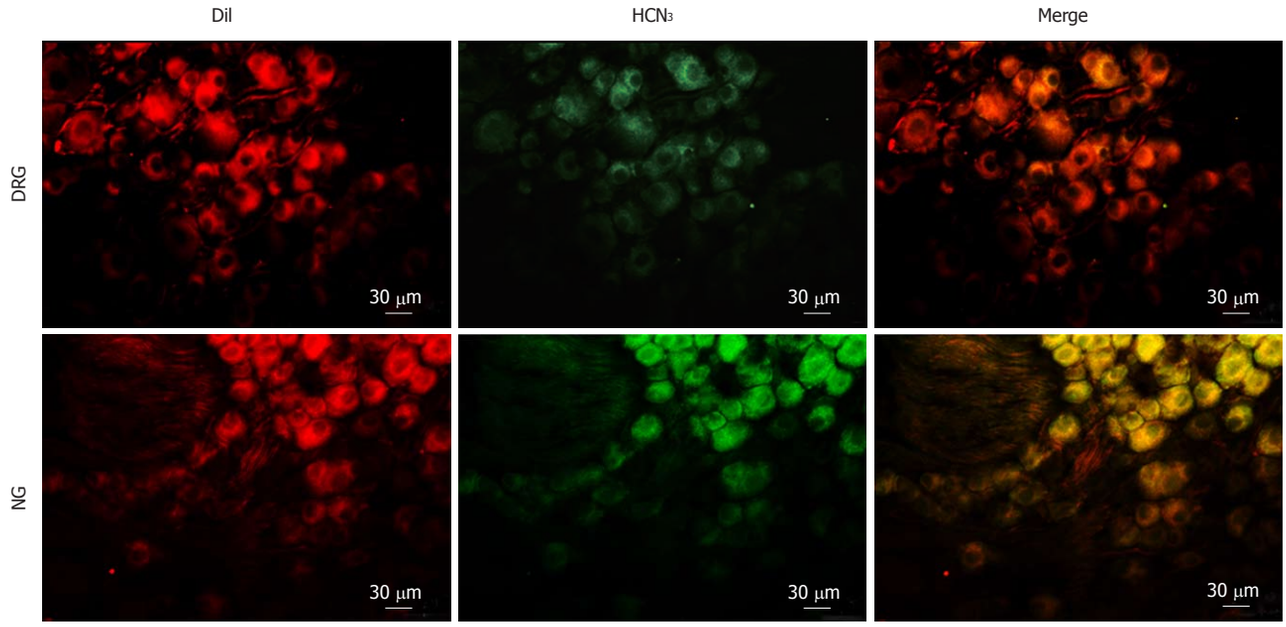

Figure 8 Immunostaining for hyperpolarization-activated cyclic nucleotide-gated cation channel 3 in intestinal primary afferent neurons. Intestinal afferents were labeled *via* injecting DiI into the gut wall. Note that weak hyperpolarization-activated cyclic nucleotide-gated cation channel 3 (HCN_3) immunoreactivity (green) was present in some DiI-labeled (red) dorsal root ganglia neurons. In contrast, most DiI-labeled nodose ganglia neurons were moderately stained for HCN_3.

DISCUSSION

Extrinsic afferent nerves play a major role in the control of GI function. Altered vagal and spinal afferent nerve sensitivity has been implicated in the pathophysiology of GI symptoms such as bloating, discomfort and pain. Previous studies have shown that there exist major differences in vagal and spinal primary afferent neurons in their sensitivity to mechanical and chemical stimulations. Delineating the molecular mechanisms that control the excitability of spinal and vagal afferents of the GI tract may potentially offer novel therapeutic targets. The present study provided evidence that HCN channels differentially regulate the excitability of spinal and vagal afferents innervating the small intestine.

In the first series of the study, we tested the effects of HCN channel blocker, CsCl, on the mechanosensory responses of mesenteric nerves of the jejunum. Consistent with previous reports, ramp distension of the jejunum evoked biphasic increases in mesenteric nerve discharge, which was due to the activation of three major types of afferent fibers: low-threshold fibers, wide dynamic range fibers and high-threshold fibers[2]. CsCl at 5 mmol/L was found to attenuate the first phase of the increase in afferent discharge (pressure rose by 10 mmHg from the baseline) and showed no significant effect on the second phase of the response (pressure rose from 10 to 60 mmHg). CsCl is a relatively weak HCN channel blocker and was non-selective among different HCN isoforms. We choose to test 5 mmol/L CsCl since this was the concentration used in many previous studies[7,16,17] and we noted in pilot experiments that the amplitude of action potential spikes was not altered, suggesting that conduction of nerve signals was not impaired in the presence of 5 mmol/L CsCl. To further exclude the possible off-target effects of 5 mmol/L CsCl, we tested a more potent HCN channel blocker ZD7288 (10 μmol/L) and found that it had a similar effect on the mechanosensory responses of mesenteric nerves. Thus, we could be relatively confident that the inhibitory effects of 5 mmol/L CsCl on the mechanosensory responses were due to blockade of HCN channels and that this set of data show certain HCN isoforms that exert a tonic facilitatory action on the excitability of low-threshold afferent fibers.

Booth *et al*[3] showed in rats that the low-threshold responses of mesenteric nerves to ramp distension of the jejunum diminished whilst the high- threshold responses remained intact following chronic vagotomy. Therefore, in the second series of the experiments, we tested the hypothesis that there were differences in the expression of functional HCN channels in vagal *vs* spinal primary afferent neurons. To this end, we conducted patch clamp recording of I_h in acutely dissociated DRG and NG neurons. I_h currents of varying amplitudes could be elicited by hyperpolarizing voltage pulses in approximately half of DRG and NG neurons. We then focused on DiI-labeled (intestinal) spinal and vagal sensory neurons. I_h current was present in 71.4% of DRG neurons and 90.9% of NG neurons. The I_h currents of DRG neurons were generally of greater amplitude than those of NG neurons, but the kinetics (fast and slow time constants and activation curves) of I_h currents in these two populations were not significantly different. At the present, subtype selective HCN blockers are not available, but different subtypes of HCN channels are known to show distinct cAMP sensitivity. HCN_2 and HCN_4 are strongly modulated by cAMP, whilst HCN_1 and HCN_3 show minimal or no sensitivity to cAMP[18]. We therefore tested the

sensitivity of I_h currents to cAMP in DiI-labeled DRG and NG neurons. In 3 of 11 DRG neurons tested, the I_h currents showed a significant sensitivity to 8-Br-cAMP with a significant depolarizing shift of the haft activation voltage. In the other 8 DRG neurons and all (7/7) DiI-labeled NG neurons, I_h currents were not altered by 8-Br-cAMP. Admittedly, the number of cells included in this study was small. Nevertheless, this set of data does suggest that subpopulations of spinal afferents of the small intestine might express cAMP-sensitive (HCN_2 or HCN_4) and cAMP-insensitive HCN isoforms (HCN_1 or HCN_3), whilst vagal afferents of the small intestine appeared to express the cAMP-insensitive HCN channels only.

In the final series of experiments, we detected the expression of HCN isoforms in spinal and vagal primary afferent neurons by means of immunohistochemistry. HCN_1 was not detected in DRG or NG sections. Intense HCN_2 immunoreactivity was present in 12.3% of unidentified DRG and 2.3% unidentified NG neurons, respectively. Conversely, HCN_3 was more abundant in NG than in DRG. HCN_4 was seen in a minority of DRG neurons but not in NG neurons. Furthermore, we found that DRG neurons retrogradely labeled from the small intestine were partially immunoreactive to HCN_2 and weakly stained for HCN_3, whereas NG neurons retrogradely labeled from the small intestine were virtually all immunoreactive to HCN_3 but not to HCN_2. Combined with the patch-clamp and the afferent nerve recording data, these results would suggest that the vagal primary afferent nerves of the small intestine express cAMP-insensitive HCN_3 channels. Since HCN blockers, CsCl and ZD7288, inhibited the low-threshold (i.e., vagal) mechanosensory responses of mesenteric nerves, it appears likely that HCN_3 channels exert a tonic facilitatory action on the excitability of vagal afferents.

The expression of HCN isoforms in sensory neurons has been investigated in several previous studies. For spinal primary afferent neurons, Tu *et al*[19] reported presence of HCN_1 immunoreactivity in large- and medium-sized neurons, HCN_2 in proportions of neurons of all sizes and absence of HCN_4 immunoreactivity in rat DRG (L_4-L_5). The distribution of immunoreactivity for HCN isoforms within the DRG found in the present study was consistent with the findings of Matsuyoshi *et al*[8], who demonstrated that HCN_2 was the dominant isoform in L_6-S_1 rat DRG. In that study, HCN_2 immunoreactivity was detected in 46.9%, 21.1% and 4.5% of small-, medium- and large-sized neurons, respectively; and there was no apparent staining for HCN_1 and scarce staining for HCN_4. For vagal afferent neurons, Tu *et al*[5] detected HCN_1, HCN_3, and HCN_4 in A-fiber neurons and HCN_2, HCN_3 and HCN_4 in C-fiber neurons in NG of rats using a double-staining technique. They further demonstrated that over-expression of HCN_{1-3} channels in nodose neurons contributed to the decreased excitability of vagal afferent neurons in diabetic rats. Li *et al*[7] also reported that over-expression of HCN_1 and HCN_2 was associated with the blunted excitability of A fiber aortic baroreceptor neurons in type-1 diabete rats. In the current study, most NG neurons were moderately stained for HCN_3 and minorities of NG neurons were stained for HCN_2, whilst HCN_1 and HCN_4 immunoreactivity was hardly detectable. It is likely that there exist subtle species differences in the distribution of HCN isoforms in vagal afferent neurons and that expression of HCN isoforms in vagal afferent neurons may be altered under certain pathological conditions.

Momin and colleagues demonstrated that I_h current had an important influence on action potential generation in sensory neurons[20]. We noted that CsCl and ZD7288 inhibited the low-threshold (vagal) mechanosenosry responses without significant effect on the high-threshold (presumably spinal) responses, although the patch-clamp and immunohistochemical data both showed that functional HCN channels were present in some spinal afferent neurons. It appears likely that under normal conditions, HCN channels expressed on spinal afferent neurons only have minimal effect on the excitability of afferent terminals. However, this does not preclude the possible contribution of HCN channels to the hyper-excitability of spinal afferents seen in pathological conditions such as inflammatory and non-inflammatory bowel diseases. In this regard, it is particularly interesting to note that a proportion of spinal afferents appeared to express HCN_2, which is sensitive to modulation by cAMP, a key intracellular second messenger for a variety of inflammatory mediators[18,21]. Conceivably, spinal afferents expressing HCN_2 may become hypersensitive due to the increased availability of inflammatory mediators such as bradykinin, ATP, 5-HT and prostaglandin E_2[22].

In summary, the data obtained in this study suggest that HCN_2 and HCN_3 are differentially expressed in vagal *vs* spinal primary afferents innervating the small intestine. HCN_2 is the major HCN isoforms in spinal afferents and HCN_3 is more abundant in vagal afferent neurons and seems to exert a tonic facilitatory modulation on the excitability of afferent terminals.

COMMENTS

Background

The gastrointestinal (GI) tract is innervated by vagal and spinal afferent nerves, which play important roles in the control of GI function. Altered vagal and spinal afferent nerve sensitivity has been implicated in the pathophysiology of GI symptoms such as bloating, discomfort and pain, but the molecular mechanisms are still not clear. Hyperpolarization-activated cyclic nucleotide-gated cation (HCN) channels underlie the pacemaker current in the heart and are also known to regulate CNS neuronal excitability. The current study investigated the possible role of HCN channels in the control of small intestinal afferent nerve sensitivity.

Research frontiers

Previous studies implicated HCN channels in neuropathic pain and in control of arterial baroreceptor and bladder afferent sensitivity. Linden and colleagues reported that enhanced I_h current contributes to the increased excitability of a subpopulation of enteric neurons in inflamed guinea pig colon. Until recently, little information is available regarding the potential role of HCN channels in the function of extrinsic afferents of the GI tract.

Innovations and breakthroughs

As reported in this study, HCN_2 and HCN_3 are differentially expressed in vagal *vs* spinal primary afferents innervating the small intestine. HCN_2 is the major

HCN isoform in spinal afferents whereas HCN_3 is more abundant in vagal afferent neurons. HCN_3 seems to exert a tonic facilitatory action on the excitability of vagal afferent terminals.

Applications

The current findings suggest that drugs targeting HCN_2 or HCN_3 may potentially reverse dysfunction of vagal and spinal afferents seen in functional and inflammatory GI diseases.

Terminology

HCN is a hyperpolarization-activated cyclic nucleotide-gated cation channel which mediates I_h current.

Peer review

The design of the study is correct and the findings are important, as these channels may redirect further research against bowel symptoms to other targeted drugs.

Abstract

AIM: To investigate the expression and methylation status of the secreted frizzled-related protein 2 (SFRP2) in esophageal squamous cell carcinoma (ESCC) and explore its role in ESCC carcinogenesis.

METHODS: Seven ESCC cell lines (KYSE 30, KYSE150, KYSE410, KYSE510, EC109, EC9706 and TE-1) and one immortalized human esophageal epithelial cell line (Het-1A), 20 ESCC tissue samples and 20 paired adjacent non-tumor esophageal epithelial tissues were analyzed in this study. Reverse-transcription polymerase chain reaction (RT-PCR) was employed to investigate the expression of SFRP2 in cell lines, primary ESCC tumor tissue, and paired adjacent normal tissue. Methylation status was evaluated by methylation-specific PCR and bisulfite sequencing. The correlation between expression and promoter methylation of the *SFRP2* gene was confirmed with treatment of 5-aza-2′-deoxycytidine. To assess the potential role of SFRP2 in ESCC, we established stable SFRP2-transfected cells and examined them with regard to cell proliferation, colony formation, apoptosis and cell cycle *in vivo* and *in vitro*.

RESULTS: SFRP2 mRNA was expressed in the immortalized normal esophageal epithelial cell line but not in seven ESCC cell lines. By methylation-specific PCR, complete methylation was detected in three cell lines with silenced SFRP2 expression, and extensive methylation was observed in the other four ESCC cell lines. 5-aza-2′-deoxycytidine could restore the expression of SFRP2 mRNA in the three ESCC cell lines lacking SFRP2 expression. SFRP2 mRNA expression was obviously lower in primary ESCC tissue than in adjacent normal tissue (0.939 ± 0.398 *vs* 1.51 ± 0.399, $P < 0.01$). SFRP2 methylation was higher in tumor tissue than in paired normal tissue (95% *vs* 65%, $P < 0.05$). The DNA methylation status of the SFRP2 correlated inversely with the SFRP2 expression. To assess the potential role of SFRP2 in ESCC, we established stable SFRP2 transfectants and control counterparts by introducing pcDNA3.1/v5 hisA -SFRP2 or pcDNA3.1/v5 hisA -empty vector into KYSE30 cells lacking SFRP2 expression. After transfection, the forced-expression of SFRP2 was confirmed by the RT-PCR. In comparison with the control groups, stably-expressed SFRP2 in KYSE 30 cells significantly reduced colony formation *in vitro* (47.17% ± 15.61% *vs* 17% ± 3.6%, $P = 0.031$) and tumor growth in nude mice (917.86 ± 249.35 mm^3 *vs* 337.23 ± 124.43 mm^3, $P < 0.05$). Using flow cytometry analysis, we found a significantly higher number of early apoptotic cells in SFRP2-transfected cells than in the control cells ($P = 0.025$). The mean cell number in the S and G2-M phases of the cell cycle was also significantly lower in SFRP2-transfected KYSE30 cells compared with mock transfected counterparts.

CONCLUSION: Silencing of SFRP2 expression through promoter hypermethylation may be a factor in ESCC carcinogenesis through loss of its tumor-suppressive activity.

INTRODUCTION

Esophageal cancer is the sixth leading cancer-related cause of death worldwide. Although esophageal adenocarcinoma is the most rapidly increasing cancer in Western countries, esophageal squamous cell carcinoma (ESCC) remains the predominant histological subtype in China[1]. Despite recent improvements in its diagnosis and treatment, the prognosis for patients with ESCC is still unsatisfactory[2]. Among the reasons cited for this situation are the lack of understanding of the carcinogenic mechanism of ESCC, and the lack of sensitive and specific molecular markers to detect these cancers at an early stage.

In addition to genetic changes, epigenetic modifications and in particular DNA methylation, are recognized as common molecular alteration in human tumors. Functional inactivation of tumor suppressor genes (*TSG*) through promoter methylation has been shown to be involved in the pathogenesis of various cancers, including ESCC[3-7]. Importantly, DNA methylation changes have been reported to occur not only in advanced cancers, but also in premalignant lesions[8,9]. DNA methylation changes are, therefore, potentially good early indicators for the clinical application of sensitive cancer detection.

Aberrant promoter methylation of secreted frizzled-related protein (*SFRP*) genes, a new group of tumor suppressor genes, has been documented in several human malignancies such as colorectal cancer[10], gastric cancer[11], and hepatocellular carcinoma[12]. SFRPs are a family of secreted glycoproteins that act as negative regulators of the Wnt signaling pathway. Every member in this family of genes contains a frizzled-like cysteine-rich domain through which they either interact with Wnt proteins to prevent them from binding to Fz proteins, or form nonfunctional complexes with Fz and then block the Wnt signaling pathway[13,14]. As the Wnt pathway plays a crucial role in various human carcinogenesis[15,16], its aberrant activation by epigenetic inactivation of SFRPs may induce tumorigenesis.

The aberrant hypermethylation of the SFRP2 promoter has been reported to be a good molecular marker in gastric and colorectal cancer[17,18], suggesting that SFRP2 is a tumor suppressor. However, other reports indicate that SFRP2 promotes tumor progression in glioma[19], renal cancer cells[20], and decreases apoptosis in breast cancer cells[21]. In spite of these studies, to our knowledge there have not yet been any reports describing the significance of epigenetic inactivation of the *SFRP2* gene in ESCC progression and its potential as a diagnostic and therapeutic target**.** We therefore analyzed the methylation and expression status, as well as the function, of this gene in ESCC.

Here, we first determine SFRP2 methylation and its expression level in 7 ESCC cell lines and 20 paired primary ESCC tissues. We then explore the functional significance of methylation-induced silencing of SFRP2 expression in ESCC cell lines both *in vitro* and *in vivo*.

MATERIALS AND METHODS

Cell lines and cell culture

A total of seven ESCC cell lines (KYSE 30, KYSE150, KYSE410, KYSE510, EC109, EC9706 and TE-1) were maintained in our laboratory. One human immortalized normal esophageal epithelial cell line (Het-1A), which was used as a "normal" control for ESCC cell lines, was purchased from the American Type Culture Collection (Manassas, VA, United States). ESCC cell lines were cultured in RPMI 1640 (Invitrogen, Carlsbad, CA, United States) supplemented with 10% fetal bovine serum (Hyclone, Logan, UT, United States) and antibiotics (100 U/mL penicillin G and 100 μg/mL streptomycin) at 5% CO2, 37 ℃, and 95% humidity. Het-1A cells were cultured in bronchial epithelial basal medium with growth supplements (Clonetics, San Diego, CA, United States).

Human esophageal tissue samples

Paired specimens of human ESCC and adjacent noncancerous esophageal squamous epithelium (n = 20) were obtained from patients who underwent resection for ESCC without chemotherapy or radiation therapy at the Beijing Friendship Hospital. Samples were stored in liquid nitrogen. All subjects gave informed consent for obtaining the study materials. The study was approved by the Ethics Committee of Beijing Friendship Hospital.

RNA extraction and reverse-transcription polymerase chain reaction

Total RNA was extracted from the 20 pairs of human tissue and eight cell lines by Trizol reagent (Invitrogen, Carlsbad, CA) according to the manufacturer's instructions. For semi-quantitative reverse-transcription polymerase chain reaction (RT-PCR), 2 μg of RNA was reversely transcribed using Superscript Ⅱ reverse transcriptase according to the manufacturer's protocol (Invitrogen).

SFRP2: Secreted frizzled-related protein 2; GAPDH: Glyceraldehyde-3-phosohate dehydrogenase; MSP: Methylation-specific.

The mRNA expression levels of the SFRP2 were determined by conventional RT-PCR with Taq polymerase (Takara, Dalian, China). Glyceraldehyde-3-phosohate dehydrogenase was used as an internal control of RNA integrity. The RT-PCR procedure consisted of 35 cycles with an annealing temperature of 56 ℃. The primers used are listed in Table 1.

Isolation and bisulfite modification of genomic DNA

Genomic DNA was obtained from esophageal tissues and cell lines by standard phenol-chloroform extraction. Genomic DNA was treated with sodium bisulfite using a Zymo DNA Modification kit (Zymo Research, Orange, CA). Bisulfite induces deamination of unmethylated cytosines, converting unmethylated CpG sites to UpG without modifying methylated sites. This allows their differentiation by methylation-specific PCR, or sequencing.

Demethylation with the DNA demethylating agent 5-aza-2-deoxycytidine

Three human ESCC cell lines (TE-1, KYSE-30 and KYSE -510) were treated with DNA demethylating agent 5-Aza-dC by addition of fresh medium containing 5-Aza-dC (10 μmol/L, Sigma) every day for 3 consecutive days. Cells were harvested for DNA and RNA extractions. Control cells received no drug treatment.

Methylation-specific polymerase chain reaction

The methylation status of the SFRP2 in esophageal tissues and cell lines was determined by MSP. Briefly, bisulfite-treated DNA was used as a template to amplify MSP using primers specific for methylated and unmethylated sequences of the gene. The PCR reaction was set up using 0.5 U hot-start Taq-polymerase (Takara) per reaction in a total volume of 20 μL and run for 40 cycles with an annealing temperature of 60 ℃. MSP primers are listed in Table 1.

Bisulfite genomic sequencing

For bisulfite genomic sequencing, a fragment of the SFRP2 promoter CpG islands that contained 34 CpG sites was amplified from the bisulfite-treated DNA using specific primers (Table 1). The PCR procedure consisted of 35 cycles with an annealing temperature of 54 ℃. The PCR products were then cloned into the pEasy-T1 vector (Transgene, Beijing, China). Eight to ten colonies were randomly chosen and sequenced.

Cloning of SFRP2 and construction of expression vector

Expression vectors containing the human full-length cDNA fragment of SFRP2 were generated by PCR cloning. Primers are listed in Table 1. Amplified PCR products were cloned into pEasy-T1 vector (Transgene), and the fragments verified by sequencing, then cut using *Eco*RI^{HF} and *Hin*dⅢ, and ligated into the *Eco*RI^{HF}/*Hin*dⅢ sites of pcDNA3.1/V5-HisA vector (Invitrogen).

Cell cycle analysis

Cell cycle analysis was carried out by flow cytometry. KYSE30 cells were transfected with 4 μg of pcDNA3.1/V5-HisA-SFRP2-expression vector or pcDNA3.1 V5-HisA empty vector using Lipofectamine2000 (Invitrogen). After 48 h, cells were harvested and fixed in 70% ethanol for 30 min. The samples were concentrated by removing the ethanol and treating with 10 μg/mL RNase (Roche). They were then stained with propidium iodine (Sigma) and analyzed for cell cycle distribution by DNA content analysis using flow cytometry.

Stable clone establishment

To prepare stable cell lines re-expressing SFRP2, we transfected KYSE30 cells with the pcDNA3.1/V5-HisA-SFRP2 expression vector encoding SFRP2 cDNA using Lipofectamine2000 (Invitrogen), according to the manufacturer's instructions. Cells transfected with pcDNA3.1 V5-HisA empty vector were used as controls. Transfected cells were selected by culturing with G418 (Merck, Darmstadt, Germany) at 300 μg/mL for 1 mo. Single colonies of stable transfectants were isolated and expanded for further analysis.

Detection of apoptosis by annexin V/FITC

KYSE30 cells stably transfected with pcDNA3.1/V5-HisA-SFRP2-expression vector or pcDNA3.1 V5-HisA empty vector were harvested, washed twice in phosphate buffered saline (PBS) (4 ℃), and re-suspended in 250 μL binding buffer. One hundred microliters of cells from each sample were aliquoted into FACS tubes and stained

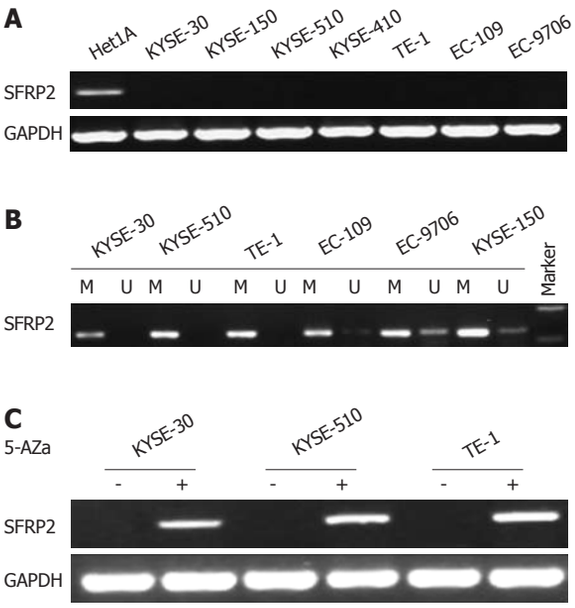

Figure 1 Expression and promoter methylation of secreted frizzled-related protein 2 in esophageal squamous cell carcinoma cell lines. A: Secreted frizzled-related protein 2 (SFRP2) mRNA expression as determined by reverse-transcription polymerase chain reaction (RT-PCR); B: The methylation status of the SFRP2 promoter as determined by methylation specific PCR; C: mRNA expression of SFRP2 (determined by RT-PCR) restored after treatment with the demethylation agent 5-Aza-dC in three esophageal squamous cell carcinoma cell lines. M: Methylated; U: Unmethylated.

with 5 μL annexin V/FITC and 10 μL of 20 μg/mL propidium iodine (Sigma). After gentle mixing, cells were incubated for 15 min at room temperature in the dark. Four hundred microliters of binding buffer was added immediately prior to analysis by flow cytometry.

Cell proliferation assay

Stable transfected KYSE30 cells with or without SFRP2 expression vector and parental cells were selected for measurement of cell proliferation. A quantity of 5×10^3 cells were reseeded in 96-well plates. After incubation, the medium was removed and 20 μL 3-(4,5-dimethyl-thiazol-2yl)-2,5-diphenyltetrazolium bromide (5 mg/mL, Gibco) was added to each well. DMSO was added and the optical density of each well was read at 490 nm. Each experiment was performed in triplicate.

Colony formation assay

A quantity of 2×10^3 KYSE30 cells transfected with either SFRP2 expression vector or empty vector were cultured in 60-mm plates with G418 (Merck, Darmstadt, Germany) at 0.3 mg/mL for 4 wk in regular culture medium. Colonies with cell numbers of more than 50 cells per colony were counted. Colonies were fixed with methanol for 15 min and stained with Giemsa. All the experiments were performed in triplicate wells in three independent experiments.

In vivo tumorigenicity

Stable KYSE30 cells transfected with either the SFRP2 expression vector or empty vector cells and parental cells (1.5×10^6 cells in 0.2 mL PBS) were inoculated subcutaneously into the dorsal flank of 5-wk-old male Balb/c nude mice. Each group was comprised of 5 mice, and all were maintained under sterile conditions. Tumor formation was observed 2 wk later. Tumor diameter was measured every 3 d for 5 wk, and tumor volume (mm^3) estimated by measuring the longest and shortest diameter of the tumor and calculating the volume as follows: volume = $(\text{shortest diameter})^2 \times (\text{longest diameter}) \times 0.5$. After 5 wk of observation, the mice were sacrificed. Tumors were excised, measured, and weighed. Care of animals and all experimental procedures were approved by the Animal Ethics Committee of Beijing Friendship Hospital, and were carried out in accordance the "Guideline for the Welfare of Animals in Experimental Neoplasia"[22].

Statistical analysis

All statistical analyses were conducted using SPSS 11.5 software (SPSS Inc, Chicago, IL, United States). Data were expressed as the mean ± SD. P values < 0.05 were considered statistically significant. Statistical comparison between two groups was performed using the non-parametric Mann-Whitney U-test or Student's t-test. For comparison of more than three groups, we used one-way analysis of variance, followed by Tukey's multiple comparison.

RESULTS

Frequent transcriptional silencing of SFRP2 in ESCC cell lines

We first examined mRNA expression of SFRP2 by means of reverse-transcription-PCR in seven ESCC cell lines (TE-1, KYSE-30, KYSE-150, KYSE-410, KYSE-510, EC-109 and EC-9706), and one immortalized normal esophageal epithelial cell line (Het-1A). RT-PCR showed that the SFRP2 transcript was silenced in all seven ESCC cell lines, but not in the immortalized normal esophageal epithelial cell line (Het-1A) (Figure 1A). We next examined the role of promoter methylation in the silencing of SFRP2. By methylation-specific PCR, complete methylation was detected in three cell lines with silenced SFRP2 expression, and extensive methylation was observed in the other four silenced cell lines (Figure 1B). We analyzed SFRP2 methylation in more detail using high-resolution bisulfite genomic sequencing analysis. Extensive methylation was detected in three ESCC cell lines (KYSE-30, KYSE-510 and TE-1) with silenced SFRP2 expression, whereas no methylated CpG site was detected in the immortalized normal esophageal epithelial cell lines (Het-1A) (Figure 2).

SFRP2 reactivation in ESCC cell lines treated with 5-Aaza-dC

Since we had established that the SFRP2 mRNA expression was related to its methylation status, we next investigated whether DNA demethylation could restore the expression of SFRP2 mRNA in the three ESCC cell lines lacking SFRP2 expression using 5-Aza-dC. 5-Aza-dC restored the

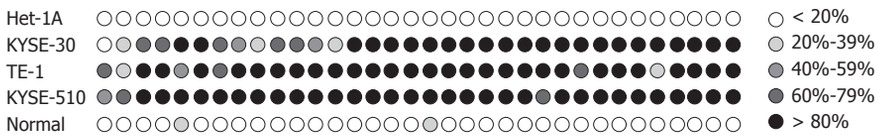

Figure 2 A representative picture of bisulfite genomic sequencing in the secreted frizzled-related protein 2 gene promoter. A-293bp region with 34 CpG site was analyzed. Each row of CpG site represents an individual allele of the secreted frizzled-related protein 2 promoter analyzed. Percentage methylation was determined as a percentage of methylated cytosine from 8 to 10 randomly sequenced colonies. Methylated and unmethylated CpG sites are indicated by black and white circles, respectively.

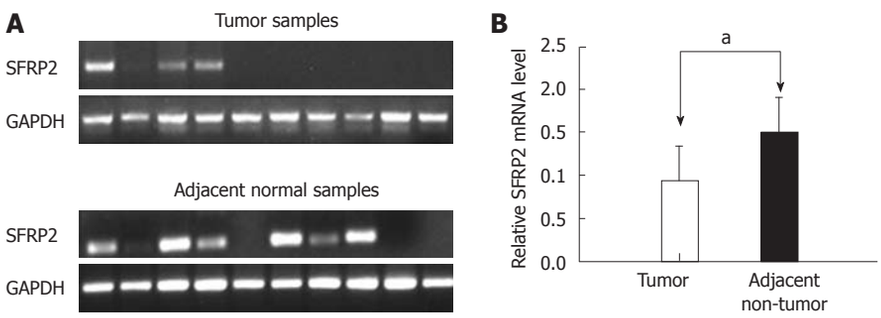

Figure 3 Expression of secreted frizzled-related protein 2 in esophageal squamous cell carcinoma and paired non-cancerous tissues. A: Reverse-transcription polymerase chain reaction (RT-PCR) analysis of secreted frizzled-related protein 2 (SFRP2) mRNA expression in 10 primary esophageal squamous cell carcinoma (ESCC) tissues and their adjacent non-cancerous tissues; B: The SFRP2 mRNA expression level normalized according to the glyceraldehyde-3-phosphate dehydrogenase (GAPDH) mRNA level. Data are expressed as mean ± SD. ESCC tissues *vs* adjacent non-tumor tissues ($^aP < 0.01$).

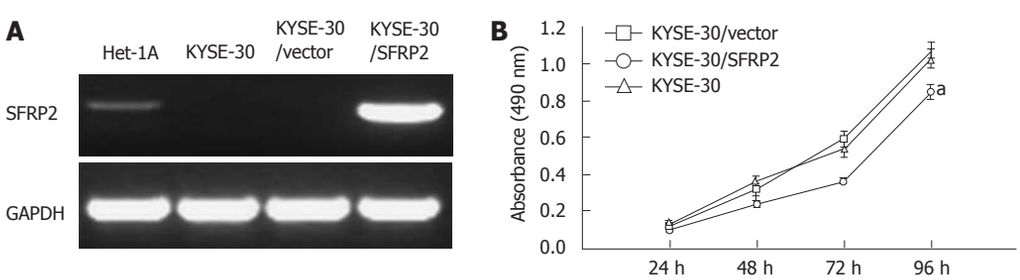

Figure 4 Effect of secreted frizzled-related protein 2 ectopic expression on cell proliferation. expression of SFRP2 in all of the cell lines (Figure 1C), further supporting the role of promoter methylation as a primary mechanism of SFRP2 inactivation.

Expression and methylation status of the SFRP2 in primary ESCC tumors

We determined the mRNA expression level of SFRP2 in 20 pairs of primary human ESCC tumors and adjacent non-cancerous tissues using RT-PCR. When compared with adjacent non-cancerous tissues, SFRP2 was found to be clearly down-regulated in primary ESCC tumor specimens (1.51 ± 0.399 *vs* 0.939 ± 0.398, $P < 0.001$) (Figure 3). SFRP2 promoter methylation was observed in 95% (19/20) of the ESCC tissues and 65% (13/20) of the paired normal esophageal epithelial tissues, as measured by methylation-specific PCR. The positive rate of methylation in ESCC tissue was significantly higher compared with that in the normal control ($P = 0.044$). Notably, using high-resolution bisulfite genomic sequencing analysis, no SFRP2 methylation was seen in normal esophageal epithelium specimens (Figure 2).

SFRP2 inhibits tumor cell proliferation and induces apoptosis

A cell proliferation assay was performed on stably transfected KYSE30 cells with or without the SFRP2 expression, and on parental cells. Re-expression of SFRP2 in the transfected KYSE30/SFRP2 cells was confirmed by reverse-transcription PCR (Figure 4A). Cells stably expressing SFRP2 grew significantly slower than the empty vector-transfected cells and parental cells ($P < 0.05$, Figure 4B). We carried out apoptosis and cell cycle analysis to investigate whether SFRP2 over-expression affects these parameters in ESCC cells. We found a significantly higher number of early apoptotic cells in SFRP2-transfected cells than in the control cells ($P = 0.025$, Figure 5). The mean cell number in the S and G2-M phases of the cell cycle was also significantly lower in SFRP2-

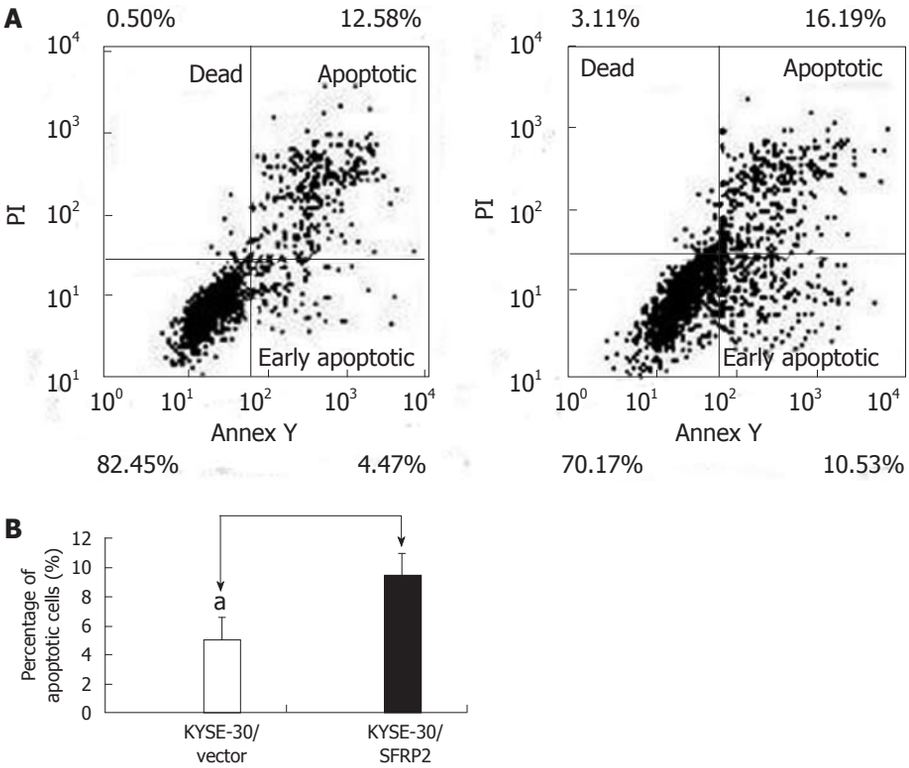

Figure 5 Ectopic expression of SFRP2 induces apoptosis in KYSE30 cells. A: The representative images of flow cytometry analysis; B: The data are the percentage of early apoptotic out of the total cell population of KYSE30 cells transfected with SFRP2 and cells with the empty vector.The early apoptotic cells in SFRP2-transfected cells were significantly higher than that in the control cells ($^aP < 0.05$).

Table 2 Effect of secreted frizzled-related protein 2 re-expression on the cell cycle distribution of KYSE30 cells (%)

Groups	G0/G1	S	G2/M
KYSE-30/vector	45.76 ± 3.74	48.64 ± 4.90	5.59 ± 5.18
KYSE-30/SFRP2	64.49 ± 6.11	30.52 ± 5.07	4.97 ± 6.60

transfected cells, suggesting SFRP2-induced G1 arrest in KYSE30 cells (Table 2).

SFRP2 suppresses colony formation of ESCC cell lines

Frequent silencing of SFRP2 by promoter methylation in ESCC cell lines, but not in the immortalized normal esophageal epithelial cell line, suggests a potential tumor-suppressor role of this gene. To test this speculation, we examined the effect of SFRP2 re-expression on growth characteristics of ESCC cells using colony formation assays. The colonies formed by SFRP2-transfected KYSE30 cells were significantly fewer in number (47.17% ± 15.61% *vs* 17% ± 3.6%, $P = 0.031$) and smaller in size than those in control cells (Figure 6), indicating that SFRP2 has a definite growth inhibitory effect.

SFRP2 inhibits tumor growth in nude mice

After studying the effect of SFRP2 on cell proliferation *in vitro*, the involvement of SFRP2 in carcinogenesis *in vivo* was investigated. SFRP2-transfected KYSE30 cells, control cells, and parental cells were injected into nude mice. The tumor growth curve of stably transfected KYSE30/SFRP2 expression vector and KYSE30/vector control in nude mice is shown in Figure 7. The tumor size was significantly lower in SFRP2 transfected nude mice than in the vector control mice (917.86 ± 249.35 mm^3 *vs* 337.23 ± 124.43 mm^3, $P < 0.05$); however, no difference was found between the weight and volume of tumors from parental cells and those from the control, suggesting that SFRP2 functions as a tumor suppressor in esophageal carcinogenesis.

DISCUSSION

The SFRPs are a group of negative modulators of the Wnt signaling pathway, of which five members (SFRP1-5) have been identified to date. Using microarray analysis, we previously confirmed that the expression of SFRP2 was 3.6-fold lower in ESCC tissues than in paired non-cancerous tissue samples, implying that down-regulation of SFRP2 may be involved in the carcinogenesis of ESCC. In this study, we extended our previous work on SFRP2 to ESCC and found that SFRP2 was silenced in seven ESCC cell lines, but not in an immortalized esophageal epithelial cell line. The silencing of expression was linked closely to promoter methylation, as confirmed by demethylation treatment and methylation analyses, suggesting that promoter methylation is the principal regulatory mechanism of SFRP2 inactivation in ESCC. There are unmethylated alleles in 4 ESCC cell lines with no expression of SFRP2 detected by reverse-transcription PCR, indicating the existence of other transcription regu-

latory mechanisms that repress SFRP2 expression, such as histone remodeling or transcriptional repressors.

Similar results were found in the experiments on primary ESCC tissues and adjacent non-tumor tissues. SFRP2 was clearly down-regulated in primary ESCC tumor tissues when compared to the paired non-cancerous tissues. MSP analysis of the SFRP2 promoter revealed a higher prevalence of CpG methylation in ESCC tissues than in adjacent non-tumorous tissues, suggesting that aberrant methylation of the SFRP2 promoter region is not a cell line-specific event and is frequent in ESCC carcinogenesis.

Functional inactivation of SFRP2 by promoter methylation, which resulted in tumor cell proliferation and invasion, has been confirmed in many human cancers[23-27], suggesting that SFRP2 functions as a tumor suppressor. In contrast to these results, others have found that SFRP2 reduced apoptosis and promotes tumor progression[19,21]. Yamamura *et al*[20] found that ectopic expression of SFRP2 in renal cancer cells reduced UV-induced apoptosis and increased the G2 phase of the cell cycle, significantly promoting the growth of xenografts in nude mice. However, there has been no detailed report thus far describing the functional significance of SFRP2 in ESCC. We therefore analyzed the functional role of SFRP2 in esophageal carcinogenesis by both *in vitro* and *in vivo* assays. Ectopic expression of SFRP2 in KYSE30 cells with no SFRP2 expression induced low cloning efficacy in colony formation assay, along with reduced tumor size in nude mice. FACScan analysis of SFRP2-re-expressed KYSE30 cells revealed a significant decrease in cell proliferation, and an increase in apoptotic cells. Taken together, these results confirmed the role of SFRP2 as a functional TSG through suppression of cell proliferation and induction of cell apoptosis in ESCC. Previous studies of other tumors, such as colorectal and gastric cancer, showed that SFRP2 functioned as tumor suppressor through attenuating the Wnt signaling pathway[10-12]. When it came to ESCC in the present study, although we confirmed that ectopic expression of SFRP2 significantly reduced the expression lever of c-myc and cyclinD1, which were downstream genes of the Wnt pathway (data not shown), further experiments such as immunofluorescence and luciferase reporter assay are necessary to reach a similar conclusion.

SFRP2 methylation was proven to be a highly promising predictive biomarker in many human cancers. Cheng *et al*[17] reported that methylated SFRP2 was detected in 66.7% of serum samples from cancer patients, but not in normal controls and the frequency of SFRP2 hypermethylation decreased from 73.3% in gastric cancer to 37.5%

in intestinal metaplasia and 20% in adjacent non-cancer tissues, indicating that SFRP2methylation may have the potential for identifying individuals at risk of further histological progression. Muller *et al*[28] proposed SFRP2 hypermethylation as a sensitive marker able to detect 77%-90% of colorectal cancers (CRC); Huang *et al*[18] reported that methylated SFRP2 occurred in 94.2%, 52.4%, 37.5% and 16.7% of patients with CRC, adenoma, hyperplastic polyp, and ulcerative colitis, respectively. However, the clinical impact of SFRP2 hypermethylation in ESCC is unknown. Further studies of clinical correlation of SFRP2 methylation are required to answer this question.

In summary, we have presented the first convincing evidence that the epigenetic silencing of SFRP2 is a frequent event in human ESCC, and that SFRP2 is a potent TSG with key roles in suppressing cell proliferation and inducing apoptosis in the development of esophageal cancer. Further studies should be conducted to assess whether SFRP2 methylation might serve as a useful bio-marker for early detection and a potential target for treatment of esophageal carcinoma through reversal of SFRP2 inactivation by demethylating agents.

COMMENTS

Background

Esophageal squamous cell carcinoma (ESCC) is one of the most frequent malignant neoplasms in China. Although the exact mechanisms remain unclear, several studies have indicated that functional inactivation of tumor suppressor genes (TSG) through promoter methylation were involved in the pathogenesis of ESCC. Secreted frizzled-related protein 2 (SFRP2) promoter methylation has been documented in several human malignancies. We therefore analyzed the methylation and expression status, as well as the function of this gene in ESCC.

Research frontiers

Aberrant promoter methylation of *SFRP2* gene has been documented in several human malignancies, such as colorectal cancer, gastric cancer, and breast cancer. This study investigated the role of SFRP2 in ESCC and showed for the first time that the hypermethylation of *SFRP2* gene promoter was the predominant mechanism for *SFRP2* gene silence in esophageal cancer.

Innovations and breakthroughs

The authors present the first convincing evidence that the epigenetic inactivation of SFRP2 is a frequent event in human ESCC, and that SFRP2 is a potent TSG with key roles in suppressing cell proliferation and inducing apoptosis in the development of ESCC.

Applications

SFRP2 methylation might serve as a useful bio-marker for early detection and a potential target for treatment of esophageal carcinoma.

Terminology

DNA methylation is an epigenetic modification that is important for normal development in higher organisms. Aberrant changes in methylation patterns play an important role in carcinogenesis, cancer progression and chemosensitivity.

Peer review

This is a study looking for the significance of epigenetic inactivation of SFRP2 in the development of ESCC. The data suggest that SFRP2 methylation might serve as a potential target for treatment of ESCC in the future. Overall ,this study is well designed and the data are convicing.

Abstract

AIM: To evaluate whether contrast enhanced ultrasound (CEUS) might also be used for response prediction and early response evaluation in patients receiving bevacizumab based chemotherapy for metastasized colorectal cancer.

METHODS: Thirty consecutive patients with non primary resectable liver metastases from colorectal cancer underwent CEUS before treatment (CEUS date 1) and before the second (CEUS date 2) and fourth (CEUS date 3) cycle of bevacizumab based chemotherapy. Three parameters [PEAK, Time to peak (TTP) and RISE RATE]were correlated with radiological response.

RESULTS: For neoadjuvant purpose a reduction of tumour mass was required to assume clinical response. Based on these response criteria there was a significant ($P < 0.001$) correlation in TTP between metastases of responders (9.08 s) and non-responders (14.76 s) archived on CEUS date 1. By calculating a standardized quotient (metastases divided by normal liver tissue) we were able to define a cut off, predicting response with a sensitivity of 92.3 % and a specificity of 100 %. To reflect a palliative intention only those patients with progressive disease were classified as non-responders. In this stetting TTP was also significantly ($P < 0.01$) different between responders and non-responders. In contrast, Peak and Rise rate did not show any significant difference between responder and non-responder.

CONCLUSION: CEUS might serve as a surrogate marker to predict treatment response in patients with metastasized colorectal cancer who receive antiangiogenic therapy.

Key words: Colorectal cancer; Liver metastases; Response prediction to chemotherapy; Contrast-enhanced ultrasound; Bevacizumab

INTRODUCTION

The liver is the most frequent site of colorectal cancer (CRC) metastases, with 15% to 25% of patients having liver metastases at diagnosis and further 30% developing liver metastases at a later point in the disease course[1-3]. While for decades prognosis for these patients was poor, introduction of multimodal management approaches such as highly active chemobiological therapy and innovative surgical techniques, have significantly improved both disease free and overall survival. Those patients who can have liver metastases resected even display 5-year survival rates of up to 40%, with 20% alive after 10 years[4]. Unfortunately, most patients initially present with unresectable disease. However, in some of these cases neoadjuvant treatment can reduce tumour load and allow secondary resections. Thus, the aim of systemic chemotherapy in patients with non primary respectable liver metastases has undergone a transition from a pure palliative to a neoadjuvant and thereby curative concept[5].

To improve anti-tumour activity, in clinical routine the vascular endothelial growth factor (VEGF)-antibody bevacizumab is often added to treatment[6-8]. While on the one hand such combination chemotherapies are associated with improved response rates, they are on the other hand related to high toxicity and costs, and it remains an unsolved problem to identify those patients that will benefit from therapy. Fluorodeoxyglucose positron emission tomography (FDG PET) demonstrated efficacy in early treatment monitoring of a variety of tumour diseases, however data supporting its use in patients with advanced colorectal cancer are conflicting[9,10]. A novel technique to improve response evaluation to anti-angiogenic agents represents contrast-enhanced ultrasound[11] with the opportunity to detect changes of tumour perfusion at early time-points after administration of chemotherapy.

In the present study we explore the use of CEUS for response prediction and early response evaluation in patients with liver metastases from CRC, which were treated with bevacizumab containing chemotherapy.

MATERIALS AND METHODS

Patients

Between October 2007 and October 2009, 30 consecutive patients with histological confirmed colorectal carcinoma and non primary resectable liver metastasis, according to the decision of our interdisciplinary tumour board, were enrolled. Five patients had metastatic rectal cancer and 25 patients had colonic cancer. The histological grading was in 13 cases G2 and in 17 cases G3. The number of individual liver metastases ranged from 4 to 25.

All eligible patients were > 18 years old and had no prior history of receiving chemo- or radiotherapy or major surgery within 28 d before initiation of study treatment. The protocol was approved by the institutional review board and carried out in accordance with the Declaration of Helsinki and local ethical and legal requirements.

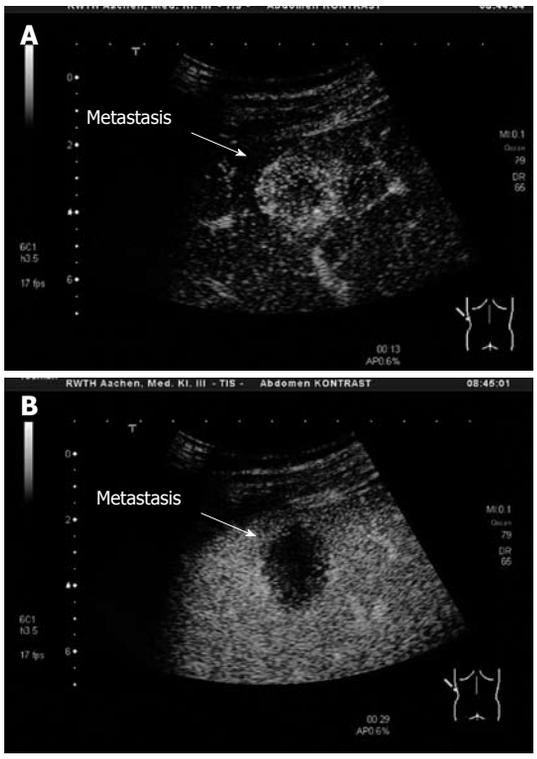

Figure 1 Contrast enhanced ultrasound. A: A representative liver metastasis after 13 s of contrast agent injection with early contrast enhancement; B: A representative liver metastasis after 29 s of contrast agent injection with lost of contrast enhancement.

Treatment

Chemotherapy consisted of Leucovorin (LV) 400 mg/m^2 per day as a 2 h infusion followed by bolus 5-Fluorouracil (5-FU) 400 mg/m^2 per day and a 46-h infusion of 5-FU 2400 mg/m^2 per day (simplified FOLFIRI). Bevacizumab was administered every two weeks at a dose of 5 mg per kg.

Contrast-enhanced ultrasound

Within 1 d before the first (day 1), second (day 15) and forth (day 43) application of chemotherapy a contrast enhanced ultrasound (CEUS) of one liver metastasis was performed (CEUS - date 1, 2 and 3). In case of multiple liver metastases, the metastasis which could be best positioned in the CEUS was selected. Ultrasound examinations were performed using the Aplio system (Toshiba Medical Systems Europe, Neuss, Germany). All patients were examined with a convex 3.5 MHz transducer as baseline US. The CEUS was performed using the contrast enhancer SonoVue® and predefined settings using the 3.5 MHz transducer. All patients were examined in wideband harmonic mode (pulse inversion) at low energy (low mechanical index) optimizing real-time detection of harmonic contrast response. The agent was injected as bolus in units of 2.4 mL through a peripheral venous catheter over 2 s, followed by bolus injection of 10 mL of 0.9% NaCl solution. Video documentation of all examination steps was obtained from the beginning of injection for a period of at least 2 min, allowing recording all steps of contrast enhancement characteristics (Figure 1).

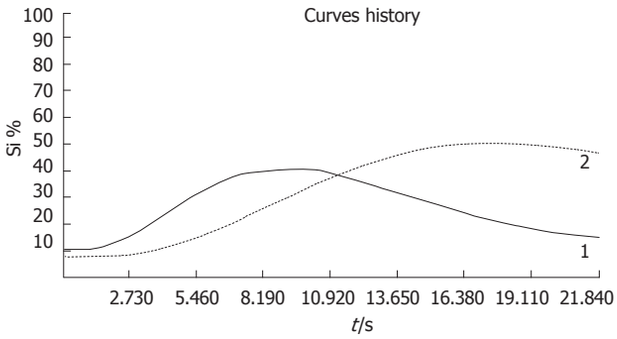

Figure 2 Curves of contrast behavior in a liver metastasis (solid line, 1) and normal liver tissue (dotted line, 2) over the time (s = seconds) and percent of contrast enhancement (Si %).

For quantitatively measuring vascularity in the metastasis and normal liver tissue by contrast dye characteristics we used the Bracco QONTRAST software (Version 4.00). This software is a specific sonographic quantification software, based on pixel by pixel signal intensity over time to obtain contrast-enhanced sonographic perfusion maps for each metastasis. In all cases, regions of interest (ROIs) were chosen over the whole area of the metastasis. Additionally we selected ROIs at least two centimetres lateral (same deepness) of the metastasis in a region with normal liver tissue. The first contrast enhancement seen in ROI determines the beginning of the measurement (Figure 2).

Three parameters were calculated including the PEAK (%; maximum peak of contrast intensity), the Time to peak (TTP) (s, time to reach the maximum peak of contrast intensity) and the RISE RATE (s-1), which is equal to contrast enhancement. The ultrasound exam was analyzed by two independent investigators blinded to the cases.

Response evaluation

All patients received before and after 3 mo of therapy a CT scan for response evaluation. Tumour response was defined by changes in diameter of target lesions on the basis of Multislice-CT results at baseline and after the first 3 mo of FOLFIRI-Avastin administration, according to published recommendations [Response Evaluation Criteria In Solid Tumors (RECIST) 1.1][12].

Statistical analysis

The multivariate analysis of variance model (MANOVA) was applied to test the within subject factors time (CEUS date 1, 2 and 3) and tissue (metastasis *vs* normal). Pair wise comparisons were performed with the paired *t*-test. The MANOVA was applied to test the between subject factor response (responder *vs* non-responder). For each separate date the unpaired *t*-test was used to compare the two groups. ROC curves were used to analyse the diagnostic power of the parameters. Cut points were chosen as to maximize the Youden index. Patients were classified as responder if the parameter is smaller or equal to the cut point.

RESULTS

Patients and response to chemotherapy

A total of 30 patients (8 women and 22 men) with a mean age of 62 (range: 50-78) were enrolled and received FOLFIRI supplemented by bevacizumab for metastasized colorectal cancer. All patients underwent radiological evaluation of tumour-load at baseline and after a period of 3 mo of treatment. According to RECIST criteria 1 patient showed a complete response (CR), 12 patients showed a partial response (PR), 8 patients had a stable disease (SD) and 9 patients had a progressive disease (PD). 4 of the 30 patients underwent resection of liver metastases within 4 mo after initiation of chemotherapy.

To reflect the clinical reality of patients with metastasized colorectal cancer, two distinct definitions of response were used: in a first scenario only those patients with PR and CR in radiological evaluation were classified as responders, while in a second scenario also patients with radiological SD were included in the group of responders.

Contrast-enhanced ultrasound

At baseline, all hepatic tumour sites were assessed by classical sonography. One metastasis was chosen as an index metastasis for further examination bei CEUS. The diameters of these selected lesions ranged from 1.9 cm to 15 cm (mean 2.7 cm). 26 lesions were classified as predominantly hypoechoic and 4 as hyperechoic according to B-mode ultrasound. In these lesions, all relevant quantitative parameters (TTP, PEAK and RISE RATE), were analyzed at baseline and during the course of treatment (CEUS-date 1, 2 and 3) by CEUS.

By applying the more strict criteria of the first scenario (neoadjuvant purpose), reflecting the need of tumour reduction in patients that could benefit from neoadjuvant therapy, we detected a significant ($P < 0.001$) difference of TTP in metastases between responders (9.08 s) and non-responders (14.76 s) already at baseline (CEUS date 1) shown in Table 1 and illustrated in Figure 3A. Furthermore in the group of the responders, a strong and continuous increase in TTP was observed during therapy and this reflects the effect of bevacizumab on tumour vascularisation. Strikingly no comparable therapy related increase in TTP was detectable within the group of non-responders. While on CEUS date 2 differences in TTP between responders and non-responders were still detectable, after 4 cycles (8 wk) of therapy identical TTP were detected in both groups. In contrast to these observations in metastatic tissue, no differences in TTP were found in normal liver tissue. To further standardize our data, a standard TTP-quotient was calculated by dividing the TTP measured in liver metastasis by TTP in the corresponding normal liver. Strikingly standardization of the described data did not change the described observations.

Chemobiological therapies are related to high toxicity. Response prediction would therefore allow restricting treatment to patients that will benefit from therapy. We therefore attempted to calculate a cut of point which

Table 1 Time to peak and to peak quotient in liver metastasis

	Date 1	Date 2	Date 3
Time to peak			
Responder (CR, PR)			
mean ± SD	9.1 ± 2.9	12.1 ± 2.3	14.6 ± 3.9
95% CI	7.3-10.8	10.7-13.6	12.2-17.0
Non-responder (SD[1],PD)			
mean ± SD	14.8 ± 3.7	16.7 ± 2.8	16.4 ± 2.6
95% CI	12.8-16.7	15.2-18.2	15.0-17.7
P value compared responder with non-responder	< 0.001	< 0.001	NS
Time to peak quotient			
Responder (CR, PR)			
mean ± SD	57.5 ± 11.8	80.5 ± 5.4	93.7 ± 9.2
95% CI	50.3-64.6	77.2-83.7	88.2-99.2
Non-responder (SD[1], PD)			
mean ± SD	98.7 ± 12.6	100.6 ± 13.3	96.9 ± 9.7
95% CI	92.2-105.2	93.8-107.5	91.9-101.9
P value compared responder with non-responder	< 0.001	< 0.001	NS

NS: Not significant; CR: Complete response; PR: Partial response; SD[1]: Stable disease; PD: Progressive disease; CI: Confidence interval.

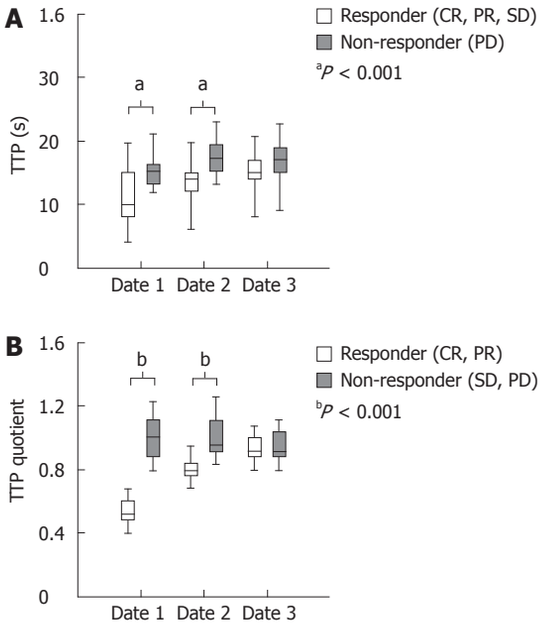

Figure 3 Time to peak parameters. A: Time to peak (TTP) values measured in the metastasis between responders and non-responders on contrast enhanced ultrasound (CEUS) date 1, date 2 and date 3 (responders with complete response (CR), partial response (PR) and stable disease (SD) (n = 21) *vs* non-responder with progressive disease (PD) (n = 9); B:The TTP quotient between responders and non-responders on CEUS date 1, date 2 and date 3 (CR and PR were classified as responders (n = 13) and patients with SD and PD as non-responders (n = 17).

predicted response with high specificity and sensitivity. According to our data, a TTP-quotient < 0.7 predicted a decrease of tumour load according to RECIST with a sensitivity of 92.3% and a specificity of 100% (Table 1 and Figure 3B).

In a second scenario we used less strict criteria for response definition, as patients with stable disease were also included in the group of responders, reflecting the clinical reality of patients in a palliative setting. Interestingly, also based on this response definition TTP and TTP-quotient were significantly lower in the group of the responders compared to non responders (Figure 3A). Here, a TTP quotient of 0.8 predicted response with a sensitivity of 61.9% and a specificity of 100%.

In contrast, the PEAK and RISE RATE parameter did not show any significant difference between responder and non-responder independent of response definition, use of the quotient or date of CEUS. In addition, there was no significant correlation between tumour response and differentiation of the tumour or the number, the location or the size of liver metastases (data not shown).

DISCUSSION

In the last years intensive efforts were conducted to identify surrogate markers that predict response to antiangiogenic combination chemotherapies. Previously a correlation between early metabolic response according to PET and patients outcome was demonstrated in patients receiving bevacizumab. However comparable data regarding colorectal cancer are insufficient. Indeed just recently two studies investigating the role of FDG-PET for treatment monitoring in patients with metastasized colorectal cancer revealed conflicting results[9,10]. Furthermore, despite these advances in monitoring of treatment, to our knowledge no data describing surrogate markers for prediction of response before starting the treatment are available.

In the present study we demonstrate that CEUS might evolve as an innovative tool in prediction of response and response evaluation in patients with metastasized colorectal cancer receiving bevacizumab based therapy. We clearly demonstrate that baseline TTP and TTP quotient are significantly lower in the group of the responders compared to the non-responders, meaning that low baseline TTP significantly correlates with tumor response according to RECIST. Furthermore, correlating to the antiangiogenic effect of bevacizumab we observed a strong increase in TTP and TTP quotient during chemotherapy, which was restricted to the group of the responders. In line with these data Varallyay *et al*[13] recently demonstrated a decrease in tumor perfusion after bevacizumab based chemotherapy by using dynamic MRI.

Chemobiological combination chemotherapies are associated with considerable toxicity and prediction of response could help to prevent non-responders from undesiderable side-effects. Based on the described perfusion analysis we established a cut off for TTP which predicted response with a specificity and sensitivity of up to 90%. To our knowledge we here for the fist time describe a parameter which reliably predicts tumor response even before starting therapy.

Despite these encouraging results, the present study has some limitations. The number of patients included is limited and at present the follow up is only 3 mo, so that

a conclusion on the use of CEUS for predicting survival is not possible. Additionally, we only included one index lesion that could be best positioned in the CEUS and thus it would be of interest to include different liver metastasis of one patient to further assess the power of this method.

In summary, our results indicate that CEUS might serve as a useful, noninvasive surrogate marker of early response in patients with liver metastases of a colorectal cancer receiving bevacizumab. However, larger trials with a longer follow-up are needed to clarify the clinical use of CEUS in this field.

COMMENTS

Background

In the last few years contrast enhanced ultrasound (CEUS) was established for differentiation between benign and malignant liver lesions. CEUS might also be used for response prediction and early response evaluation in patients receiving chemotherapy for metastasized colorectal cancer.

Research frontiers

In the present study we explore the use of CEUS for response prediction and early response evaluation in patients with liver metastases from CRC, which were treated with bevacizumab containing chemotherapy.

Innovations and breakthroughs

The results indicate that CEUS might serve as a useful, noninvasive surrogate marker of early response in patients with liver metastases of a colorectal cancer receiving bevacizumab.

Applications

CEUS for response evaluation may represent a future diagnostic pathway in the management of patients with liver metastases of a colorectal cancer.

Peer review

This is an interesting pilot study investigating the relevance of CEUS in metastatic colorectal cancer. For the first time a parameter, which reliably predicts tumor response even before starting therapy, was described.

Abstract

AIM: To investigate the morbidity, mortality, recurrence and technical aspects of two distinct surgical strategies that were implemented in successive periods.

METHODS: Ninty-two patients with 113 cysts underwent surgical procedures. The study was divided into 2 periods. Data from first period (P1) were compiled retrospectively. The surgical strategy was conservative surgery. The second period (P2) included a prospective study conducted according to a protocol following the criterion that radical procedures should be performed whenever it is technically feasible.

RESULTS: Patients of both periods showed no statistically significant differences in age, gender, cyst location or mortality. Among the P2 group, patients exhibited more preoperative jaundice, and cyst size was smaller ($P < 0.05$). Changes in surgical strategy increased the rate of radical surgery, decreases morbidity and in-hospital stay ($P < 0.001$). A negative result in P2 was the death of two old patients (4.8%) who had undergone conservative treatments. The rate of radical surgery in P2 was around 75%.

CONCLUSION: Radical surgery should be the technique of choice whenever it is feasible, because it diminishes morbidity and in-hospital stay. Conservative surgery must be employed only in selected cases.

Key words: Hydatid disease; Surgery; Morbidity; Liver

INTRODUCTION

The primary therapeutic objective in hydatid disease of the liver (HDL) is to completely eliminate the parasite and prevent recurrences with minimal morbidity and mortality[1-6]. Although several treatment options exist, the mainstay of therapy is surgery[1,2,4,6-14]. At present, no scientific evidence exists regarding which of two possible technical options, radical surgery (RS) or conservative surgery (CS), is most appropriate[4,7,11]. The main difference between the two surgical options is that the parasitic cyst is completely excised in RS, whereas only a variable percentage of the cyst is excised in CS, which makes complementary therapeutic measures for the residual cavity necessary[3,9,10]. We made an ambispective (retrospective and prospective) study to compare two consecutive

periods in our center in which the preferential surgical strategy for HDL changed from conservative surgery to radical surgery.

MATERIALS AND METHODS

The inclusion criterion was: patients with HDL who underwent scheduled surgery in our center in the study period (January 2001 to November 2010). A total of 92 patients with 113 cysts made up the study group. The exclusion criterion was emergency surgery for HDL.

RS was defined as complete open or closed cystectomy and/or hepatectomy. All other interventions (subtotal cystectomy, Lagrot surgery, marsupialization, and others) were categorized as CS[2,7,13,15]. Blood tests, liver tests, indirect anti-Echinococcus antibody hemagglutination, abdominal CT and ultrasonography were done in all patients. All patients had CE1, CE2 or CE3 type cysts (World Health Organization classification).

The study had two periods. The data from the first period (January 2001 to April 2007) (P1) were compiled retrospectively. The preferred surgical strategy was conservative surgery with insertion of a Kehr tube if preoperative jaundice, intracystic bile, or bile duct dilation was present. The period from May 2007 to January 2010 (P2) was a prospective study conducted according to protocol guided by the criterion the RS should be performed whenever it was technically feasible. The decision to perform total cystectomy or hepatectomy depended exclusively on cyst location and the relation between the cyst and vascular and biliary structures. A Kehr tube was not inserted unless required to resolve situations that arose intraoperatively. Systematic preoperative endoscopic retrograde cholangiopancreatography (ERCP) was performed if a frank intrabiliary rupture was present. Albendazole was administered only if conservative surgery is going to be performed for one month preoperatively and 3 mo postoperatively.

Morbidity and mortality were assessed according to the Dindo-Clavien classification[15,16]. Data were analyzed with the SPSS 16.0 program for Mac. Approval of ethics committee was obtained for P2.

RESULTS

General findings

In the 2001-2007 period (P1), 50 patients with 60 cysts were treated (Table 1). The patients were 56% men (28/50) and the median age of patients was 53 years (range: 11-77). Previously operated recurrent cysts were present in 22% (11/50) of patients. The usual clinical manifestation was abdominal pain (60%) (30/50); only 10% (5/50) of patients debuted with obstructive jaundice. The median number of cyst was one. The cyst locations were: 18 in left liver, 23 in right liver, and 9 bilobar. Median cyst size was 8.5 cm (2-20 cm) and 48.3% of cysts were larger than 10 cm. Only 2 patients (4%) had preoperative ERCP.

L: Left; R: Right; NS: No stastistical significance.

In the 2007-2010 period (P2), 42 patients with 53 cysts were treated. Seven patients (16.7%) were HDL cyst recurrence. The 59.6 % of patients (25/42) were men. The median age was 52 years (range: 23-83 years). Abdominal pain was the primary symptom in 29 patients (69%). The debut was as complicated HDL in 31% (13/42) of patients (8 cases of obstructive jaundice due to frank intrabiliary rupture, 2 cases of septic shock, 1 cutaneous hydatid fistula, 1 bilio-bronchial fistula, and 1 upper gastrointestinal hemorrhage due to esophageal varices originated by portal hypertension). The median cyst size was 6.5 cm (range: 3-20 cm) and 21.1% of cysts were more than 10 cm in diameter. The cyst locations were: 22 in left liver, 15 in right liver, 4 bilobar cysts, 2 in spleen, and 2 subcutaneous cysts. Preoperative ERCP was performed in 9 patients who debuted with obstructive jaundice (8 patients with obstructive jaundice and one patient with a bilio-bronchial fistula). Preoperative percutaneous drainage was done in the two patients with septic shock and were operated on later.

Technical aspects

In P1, RS was performed in 3 patients (6%) and 4 cysts (6.6%) and consisted of 4 total cystectomies. In 47 patients (94%) with 56 cysts (93.4%), CS was performed, consisting of 47 partial cystectomies, which were accompanied by cyst marsupialization in 10 cases. A Kehr tube was installed in 36 patients (72%). Some type of morbidity occurred in 21 patients (42%). Postoperative biliary fistulas developed in 17 cases, that occurred in patients

that were treated by CS, as well as one stenosis of the intrahepatic biliary tract, one gas embolism, and two cases of bleeding of the residual cystic cavity, one of which required a new laparotomy (19 Clavien Ⅲa, 2 Clavien Ⅳb). The mortality was 0%. The median hospital stay was 23 d (6-71 d). Four recurrences (6.7%) were detected during follow-up. The mean follow-up was 74 mo (range: 36-108 mo).

In P2, RS was performed in 31 patients (73.8%) and 39 cysts (73.6%). The operations performed were left lateral sectionectomy (11), left hepatectomy (5), right hepatectomy (2), total cystectomy (15), two of them by laparoscopic approach, and splenectomy (2). CS was performed in 11 patients with 14 cysts; cystectomy was almost complete in 8 of these patients. The Lagrot procedure with omentoplasty was performed in 2 patients and one marsupialization. The most frequent reason for not performing RS was the presence of more than 5 cm of contact surface with the inferior vena cava (8/11). Two Kehr tubes (5%) were inserted. Seven patients experienced morbidity (17%); 5 patients had a Clavien-Dindo Ⅲa morbidity consisting in postoperative biliary fistulas that were resolved by postoperative ERCP. The patients presenting biliary fistula three have been treated by CS and 2 by RS. The two patients treated by RS had hepatic hilar damage, which was managed by hepatectomy and reconstruction of the biliary tree. Two patients with Clavien-Dindo V pathology, an 81-year-old patient and an 83-year-old patient with complicated cysts, were treated by means of CS (bilio-bronchial fistula and septic shock due to an infected cyst). These patients developed numerous complications and died (mortality: 2/42, 4.8%). The median hospital stay was 7 d (range: 4-50 d; in the follow-up conducted (range: 1-36 mo), no recurrences were observed.

P1-P2 comparison

The patients of the two periods showed no statistically significant differences in age, gender, primary symptom, cyst location, previous surgery, mortality, or recurrence (Table 1). Among the P2 patients, patients had more preoperative jaundice, more preoperative ERCPs were performed, and cyst size was smaller ($P < 0.05$). In addition, the change in surgical strategy substantially increased the rate of radical surgery and diminished the number of Kehr tubes installed, morbidity, particularly biliary fistula, and the mean stay ($P < 0.001$). In P2, the death of two patients occurred (5%) who had been treated by means of CS.

DISCUSSION

HDL is still an endemic disease in certain areas of the planet[2-7,10,11,13,14]. No consensus exists in the international literature regarding the optimal treatment for HDL[10,13,17-19]. Possible therapeutic options are observation, anthelmintics, percutaneous aspiration, or surgery (conservative or radical). Surgery is considered the therapy of choice[2,3,8-11,17-19]. There are many studies for and against both surgical options[8,19]. Current evidence on which type of surgery is optimal for HDL is supported only by evidence level Ⅳ grade C[7,8,13].

The two technical options, CS and RS, have their respective advantages and disadvantages. Only a randomized study with a large number of patients can provide a methodologically valid response. The most important problem is the bias inherent to the fact that CS is universally applicable, whereas RS sometimes is not feasible.

The characteristics of the cyst (number, size and location), presence of complications related to the HDL, the patient's age and comorbidities, presence of new or recurrent disease, and the surgeon's experience in hepatic surgery condition decision-making with regard to selection of the technique[2-4,9-11,17,19]. CS offers acceptable results, is easily performed at any center and on any cyst by surgeons with little experience in hepatic surgery, and has a low mortality rate and an appreciable morbidity rate, particularly biliary morbidity and recurrence[1,4,10,12,17,19]. Since laparoscopy came into use for the treatment of HDL, CS has become popular again as the preferred method because laparoscopic RS is technically more challenging[11,14,19].

RS is safe and efficient, and produces less morbidity, especially in terms of postoperative biliary fistula and cavity infection. RS eliminates the possibility of untreated satellite lesions in CS and achieves a shorter hospital stay with fewer recurrences[1,4,7,8,10,11,14,17]. RS is generally criticized as associated with high morbidity and mortality that are considered disproportionate in the case of a benign pathology, although the benignity of HDL is questionable[1,8,10,14,17,19]. The only prospective comparative study of RS and CS concluded that RS is associated with less morbidity and mortality, fewer recurrences, and a shorter hospital stay[20]. The election of total cystectomy or anatomic resection depends on cyst location and the anatomic relations of the cyst(s)[10]. RS, despite the advantages mentioned, has not been generally accepted as the treatment of choice.

RS is not feasible in certain cases of extensive contact (> 5 cm) with the inferior vena cava[9]. In our series, this was the main contraindication for RS. A small number of combined resections of the inferior vena cava and hydatid cyst have been reported[21], but we believe that this procedure should be performed only in cases of serious complications (Budd-Chiari syndrome, hemorrhage or other) that justify exeresis.

Major hepatectomy, which was once unthinkable, has been demonstrated to achieve excellent results with very low morbidity, mortality and recurrence rates[17]. The 20% rate of major hepatectomy in our series was high compared to 3.3%-10% in other series[14]. Major hepatectomy was performed for biliary rupture at the hilar plate or the presence of several cysts that affected the entire hepatic lobe. The hepatic resection most frequently performed was left lateral sectionectomy for cysts that affected segments Ⅱ-Ⅲ[14].

Published series on surgery for HDL usually involve cases of CS or a combination of patients treated by CS and/or RS[3,4,6,9,10,17,19]. Few publications exist on patients treated exclusively by RS (22). The percentage of RS in mixed series varies widely and ranges from 15% to 80%[1-14,17-21], but a few series have reported as many as 75% of patients treated with RS, including our series[11,17,22]. The use of an ultrasonic bisturi, a more refined hepatic surgery technique, to treat patients with HDL in hepato-bilio-pancreatic units that have experience in treating this condition, and the surgical team's awareness of the advantages of RS, are the key to attaining this RS rate, with CS being restricted to very specific cases[23].

The literature overall morbidity of RS is 3.2% to 32% lower than the morbidity of CS (15.7%-54%)[2-6,9-11,13,17,19,22]. In the second period, in which the RS rate was high, there was a drastic decrease in morbidity.

The literature rate of postoperative biliary fistula in RS was 0% to 7.7%, compared to 11.3%-25.6% for CS[2,8,11,14,18,19]. Traditionally, when CS is performed, if bile is present in the cyst, the bile ducts are dilated, or preoperative cholangitis is observed, the bile ducts found inside the cystic cavity are sutured and a Kehr tube is inserted in the choledochus or a biliary derivation is performed[1,3,6,13,19]. The rate of Kehr tube use in series of patients treated by CS is 30% to 50%[4].

Performance of preoperative ERCP in patients who debut with obstructive jaundice due to a frank intrabiliary rupture, established by protocol in our unit, facilitates optimal bile duct cleaning and helps to eliminate the need for bile duct opening[2,3]. The combination of preoperative ERCP and RS drastically reduces the need for a Kehr tube, thus eliminating the morbidity associated with this procedure and shortening the mean hospital stay[3,6,14]. In series in which RS is the most frequently used technique, the Kehr tube is used in only 4% compared to 4.8% in our series. Patients with frank biliary rupture into the cyst are at the highest risk of postoperative biliary fistula, so we consider them to be a sub-group of patients who may benefit especially from RS.

Infection of the residual cystic cavity is an exclusive complication of CS[1,2]. The frequency of abscess formation in the residual cavity ranges from 5.5% to 37%[1,8,10,12,19]. Several techniques exist to diminish this complication, including omentoplasty, introflection, capitonnage, external drainage, *etc.*[4]. In P2, a patient who debuted with cyst infection and septic shock in which CS with omentoplasty was practiced presented infection of the cystic cavity. Omentoplasty seems to be accompanied by less morbidity than other techniques[4,6,7,12]. In patients in whom RS is performed, an intra-abdominal abscess can develop in the dead space remaining after the hepatic parenchyma is resected, although the rate of this complication is lower (3%) than the rate of intracystic cavity infection[2,8] and we did not observe it in our series. An added problem of CS is the difficulty of conducting postoperative follow-up using imaging techniques, since it is complicated to assess residual cavities and differentiate between a residual cavity with disease recurrence and one without recurrence[24].

The recurrence rate after surgery for HDL is 0% to 25%. The recurrence rate differs between RS (0%-6.4%) and CS (6%-25%)[2,4,6,8-11,14,17,18]. However, although recurrence after RS is much less frequent than after CS, RS is not suitable for all patients[18]. Cases of HDL recurrence should be treated by RS if this is technically feasible[2,9]. Our recurrence rate was 6% in the first period, when patients were treated preferentially by CS. The follow-up of patients in the second period is too short to draw conclusions yet.

Mortality due to surgery for HDL is low and differs between patients treated by CS (0%-2.1%) and by RS, which has a slightly higher mortality (0%-2.9%)[2-4,6,9,10,13,14,17-19,22]. Higher mortality rates (4.5%) have been reported in series limited to cysts that communicate with the biliary tract, all treated by CS[2,25]. In our series, the two deaths that occurred in the second period were patients over 80 who had complicated cysts (septic shock due to an infected cyst and bilio-bronchial fistula) treated by means of CS. No deaths occurred in the patients of the RS group.

Despite the methodologic limitations of an ambispective study, we believe that radical surgery should be performed in HDL because it reduces morbidity, especially biliary complications, the duration of the hospital stay and, according to published series, has a lower recurrence rate. Conservative surgery is useful in certain extreme cases in which the risk is extremely high[8,11].

COMMENTS

Background

No evidence medicine data about best surgical option for liver hydatidosis exist. We have performed an ambispective study divided in 2 periods, first period we performed as first option conservative surgery, in second radical surgery. We compare morbidity, relapse and feasibility of radical surgery.

Research frontiers

The research hotspot is how to completely eliminate hydatid disease of the liver and prevent recurrences with minimal morbidity and mortality. But, which of two possible technical options, radical surgery or conservative surgery, is most appropriate? In this study, the authors attempt to answer this question.

Innovations and breakthroughs

Very few ambipective of liver hydatidosis exist. Randomized trial comparing radical and conservative surgery are scarce.

Applications

Radical surgery is the best surgical therapy but not always is feasible.

Peer review

Morbidity, relapse and hospital stay is reduced with radical surgery but these techniques are not always feasible. Preoperative endoscopic retrograde cholangiopancreatography in jaundiced patients is recommended.

Abstract

AIM: To describe a modified technique for placement of a tracheobronchial self-expanding plastic stent (SEPS) in patients with benign refractory hypopharyngeal strictures in order to improve dysphagia and allow stricture remodeling.

METHODS: A case series of four consecutive patients with complex hypopharyngeal strictures after combined therapy for laryngeal cancer, previously submitted to multiple sessions of dilation without lasting improvement, is presented. All patients underwent placement of a small diameter and unflared tracheobronchial SEPS. Main outcome measurements were improvement of dysphagia and avoiding of repeated dilation.

RESULTS: The modified introducer system allowed an easy and technically successful deployment of the tracheobronchial Polyflex stent through the stricture. All four patients developed complications related to stent placement. Two patients had stent migration (one proximal and one distal), two patients developed pharyngocutaneous fistulas and all patients with stents in situ for more than 8 wk had hyperplastic tissue growth at the upper end of the stent. Stricture recurrence was observed at 4 wk follow-up after stent removal in all patients

CONCLUSION: Although technically feasible, placement of a tracheobronchial SEPS is associated with a high risk of complications. Small diameter stents must be kept in place for longer than 3 mo to allow adequate time for stricture remodeling.

Key words: Larynx neoplasms; Hypopharynx; Strictures; Dilation; Stents

INTRODUCTION

Total laryngectomy or pharyngolaryngectomy combined with postoperative radiation therapy is the standard treatment for advanced laryngeal cancer. After therapy, the majority of patients will develop some degree of swallowing dysfunction because of the altered swallowing dynamics of the neopharynx[1]. Differential diagnosis between functional dysphagia, benign strictures and newly developing tumors is essential because of the different therapeutic approach and prognosis. Moreover, late onset dysphagia, usually due to hypopharyngeal or upper esophageal strictures, may occur in up to 58% of patients and can become a devastating complication compromising nutritional status and deteriorating quality of life[2]. These strictures are typically complex with an angulated, irregular and severely narrowed lumen that results from mucosal scarring (healing by secondary intention) after radiation induced mucositis and ischemia[3]. Although they can usually be dilated with bougies, most are difficult to treat and cannot be dilated to an adequate diameter for relief of dysphagia despite repeated sessions or tend to require multiple dilations due to recurrence of dysphagia. Furthermore, deployment of a self-expanding metal or plastic stent is not easy because they are placed very high in the pharynx with the upper flange of the stent at less than 12 cm from the dental arcade. Thereby, nutrition through feeding tubes, nasogastric or percutaneous gastrostomy, is often required.

We developed a modified introducer system for placement of a tracheobronchial self-expanding plastic stent (SEPS) (Polyflex™, Willy Rüsch GmbH/Boston Scientific Corporation, Natick, MA, United States) in patients with refractory and complex hypopharyngeal strictures after surgery and radiotherapy. The purpose was to alleviate dysphagia as well as to allow for hypopharynx conditioning, resulting in a less stenotic lumen. This report describes the technical aspects of the modified introducer system and evaluates the safety and efficacy of this stent in this group of patients.

MATERIALS AND METHODS

Four patients with refractory hypopharyngeal strictures after total laryngectomy followed by radiation therapy for laryngeal cancer were included. Before stent placement, all patients had been submitted to several sessions of dilations with Savary-Gilliard polyvinyl bougies over a spring-tip stainless steel guidewire (Cook Medical) or a 0.038 in × 260 cm Jagwire (Boston Scientific) under fluoroscopic guidance. Because of the rigidity of the stricture, it was not possible to introduce dilators larger than 12.8-15 mm even with sessions performed every 2 to 3 wk. Successive recurrence of the stricture was observed in all patients, with consequent dysphagia to semisolid foods. Each patient signed an informed consent form before the endoscopic procedure.

The tracheobronchial Polyflex™ stent used in this study is a SEPS made of silicone with a polyester mesh.

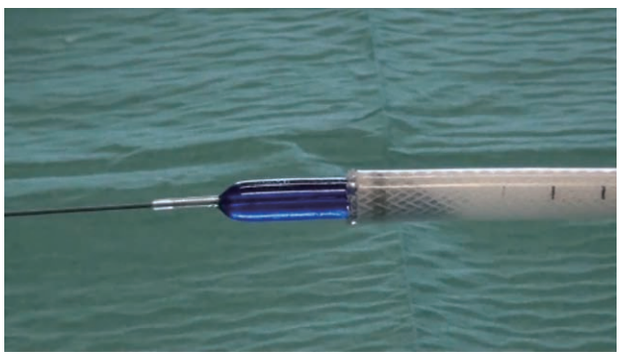

Figure 1 Tracheobronquial Polyflex stent with an esophageal wire-guided balloon inserted through the delivery system with the tip protruding from the introducer by 2 to 3 cm.

While this mesh structure on the outer surface reduces dislocation risk, the silicone coating throughout the stent prevents ingrowth of granulation tissue. The latter, along with the reduction of its cross-section when stretched lengthwise, would have the advantage of allowing easy removal or change of the stent without the usual difficulty associated with self-expanding metal stents. The stent is impregnated with markers at both ends to assist fluoroscopic visualization and endoscopic placement. Since strictures were very narrow and non-compliant and stents would be positioned very high in the hypopharynx, we used a tracheobronchial stent because this was the only available stent of small diameter and without flared ends. However, the Polyflex™ airway stent delivery system, unlike the esophageal one, is somewhat inflexible and stiff and has a blunt edge, making it difficult to transverse the angulation of the oropharynx and to position it through the area of stenosis. To overcome this difficulty we modified the introducer system, cutting both the basket of the stent loader and the opposite end and making the system hollow. An 8-10 mm controlled radial expansion (CRE) balloon dilation catheter (Boston Scientific) without the guidewire was then inserted through the delivery system with the tip protruding from the introducer by 2 to 3 cm and then inflated, resulting in a tapered edge with only a small indentation between the balloon and the delivery tube (Figure 1). The system was then threaded over a 0.035 in × 450 cm Jagwire (Boston Scientific) previously placed under fluoroscopy through the stricture into the esophagus, allowing easy and atraumatic passage and positioning of the stent delivery system (Figure 2). Subsequent stent deployment was performed under simultaneous fluoroscopic guidance and direct vision, with an ultra-thin videoendoscope passed alongside the introducer shaft.

RESULTS

Patient 1

A 71-year-old man with T3N0M0 laryngeal cancer underwent total laryngectomy followed by chemoradiation therapy 2 years previously. Three months after completing therapy, the patient developed dysphagia with solids

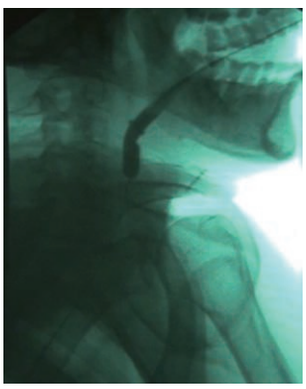

Figure 2 Passage of the stent delivery system through the stricture under fluoroscopic guidance.

Figure 3 Endoscopic view of the uvula and the stent deployed in the hypopharynx.

which progressively worsened. Upper gastrointestinal endoscopy revealed a 4 cm regular stricture with a 4 mm lumen at 12 cm from the incisors. A percutaneous endoscopic gastrostomy tube was placed. The patient underwent 8 sessions of dilation for 6 mo with little improvement. At the time of tracheobronchial Polyflex™ stent placement, lumen dilation was performed from 7 to 11 mm, and a 14 mm × 6 cm stent was deployed (Figure 3). There was improvement in the dysphagia score and the patient was able to take solid meals until 2 mo later when he complained of recurrent symptoms. Endoscopy showed 1 cm distal stent migration with tissue overgrowth at the proximal end. Repositioning of the stent into the stricture was performed using an alligator jaw grasping forceps, with resolution of symptoms. However, 6 wk later the patient was readmitted with dysphagia for liquids due to complete obstruction of the upper end of the stent with granulomatous tissue. The stent was removed and no other treatment was performed since the gastroscope could easily be introduced into the stomach. Nevertheless, dysphagia relapsed after 1 mo, with recurrence of the stricture, requiring multiple sessions of dilation during the 5 mo follow-up.

Patient 2

A 54-year-old man with T4N1M0 laryngeal cancer underwent total laryngectomy followed by radiation therapy 7 years previously. Progressive dysphagia occurred 4 years later. Endoscopy revealed a 3 cm regular stricture with a 3 mm lumen at 10 cm from the dental arcade. The patient underwent 3 endoscopic dilations over 2 mo to 12.8 mm, with symptom relief. However, dysphagia relapsed 2 years later and endoscopic bougienage was restarted with dilations performed every 3-4 wk for 10 mo. At this time, it was still not possible to introduce a Savary-Gilliard dilator larger than 12.8 mm, and a 14 mm × 4 cm tracheobronchial Polyflex™ stent was successfully placed across the stricture. Two days after the procedure and subsequent to a coughing attack, the patient developed sudden total dysphagia. Endoscopic examination showed proximal stent migration with impaction in the oropharynx. The stent was therefore removed

Figure 4 Cervical X-ray to assess adequate positioning and expansion of the stent.

and replaced by a same diameter but 2 cm longer Polyflex™ stent (Figure 4). The patient was able to tolerate a solid diet until 3 mo later when he complained of only being able to swallow liquids. Hyperplastic tissue growth with stricture formation at the upper end of the stent was observed. After dilation with a 13.5 mm CRE balloon catheter, we used a two-channel therapeutic scope and two alligator jaw forceps grasping at opposite sites to remove the plastic stent. At 4 wk post-procedure the patient had relapse of the stricture and additional dilations were required during the 3 mo follow-up to maintain lumen patency and oral feeding.

Patient 3

A 44-year-old man with T3N2M0 laryngeal cancer who had been treated with total laryngectomy followed by chemoradiation therapy developed progressive dysphagia 2 years after completion of the treatment. Endoscopy revealed a 2 cm long stricture with a 3 mm lumen at 13 cm from the incisors, and dilations were carried out monthly (7 sessions). Despite the stricture allowed passage of a 15 mm dilator, there was only brief relief of the dysphagia due to the inability to maintain lumen diameter. In view of the recurrence of the stricture, a 16 mm × 4 cm tracheobronchial Polyflex™ stent was deployed. There was improvement in the dysphagia score and the patient

Figure 5 View of the lower end of the stent through the pharyngocutaneous fistula.

was able to take solid meals. In the meantime, cervicothoracic computed tomography demonstrated a large pulmonary mass suspected to be a second primary tumor, and chemotherapy was started. Two months after stent placement, though the patient had no dysphagia, he was readmitted with a pharyngocutaneous fistula with purulent drainage at the level of the lower end of the stent (Figure 5). Intravenous antibiotic therapy was started and the stent removed and replaced 3 d later with a same diameter but 2 cm longer Polyflex™ stent, so that it could occlude the fistula orifice. Although cicatrization was observed within 2 wk, reopening after each course of chemotherapy was necessary. Two months later the patient noted recurrence of dysphagia complicated by the constant leakage of saliva, ingested food and liquids through the fistula. After removal of the stent, a percutaneous endoscopic gastrostomy tube was placed for nutritional support. Even though the patient was given nothing *per os* for 2 wk, this was not successful in closing the fistula and ultimately a partially covered self-expanding metal stent was used to seal the leakage.

Patient 4

A 56-year-old man with a T3N3M0 carcinoma of the supraglottic larynx was treated by neoadjuvant chemotherapy followed by total laryngectomy and radiation therapy. Four months later the patient was referred to our unit with food impaction. Upper gastrointestinal endoscopy showed a tight 3 cm long stricture at 13 cm from the incisors. Four sessions of dilation at 3 wk intervals offered only a slight improvement and so a decision was made to introduce a 14 mm × 6 cm tracheobronchial Polyflex™ stent. However, 24 h after the procedure and despite a normal water-soluble contrast swallow, the patient complained of total dysphagia with pharyngonasal regurgitation. The stent was therefore removed and the patient discharged. One week later, the patient was readmitted with fever, productive cough and a pharyngocutaneous fistula with purulent drainage. The patient was treated with intravenous antibiotics and percutaneous gastrostomy tube placement, with resolution of the respiratory symptoms and spontaneous closure of the fistula track 6 wk later.

DISCUSSION

Hypopharyngeal stricture is a serious complication that may occur after total laryngectomy and radiotherapy. Contributing factors include continued alcohol and tobacco abuse, the dose-volume relationship of the radiotherapy, and normal tissue damage from the tumor and the treatment[4]. Endoscopic dilation is the mainstay of treatment for hypopharyngeal strictures. However, these strictures are usually complex, and even complete lumen obliteration requiring a transgastric endoscopic retrograde approach has been previously reported[5]. When strictures fail to respond to endoscopic dilations, they are defined as refractory. In addition to providing significant physical discomfort, ongoing dilation therapy in these patients carries a risk of perforation and mortality as high as 5% has been reported[6]. Although the use of intralesional steroid injection and electrocautery incisions have been considered for peptic and anastomotic strictures, respectively, no significant benefit has been established for this indication[7,8].

The use of self-expanding stents is another possibility to achieve tissue remodeling needed to promote longer lasting stricture resolution. The rationale is to offer a continuous and stable dilation that might prevent the scarring process and avoid the adhesion of damaged areas. Self-expanding metal stents are currently considered the most effective and widely used method of palliation of malignant dysphagia. However, several limitations preclude their routine use in the management of benign esophageal strictures. Actually, these stents can become embedded into the granulation tissue ingrowth through the mesh of the uncovered part of the stent, resulting in recurrent obstruction and difficult removal. To overcome these disadvantages, a SEPS Polyflex™, designed to induce less tissue ingrowth and to be easily removed, was developed by Boston Scientific Corporation and has been commercially available since 2003. This stent is made of a polyester mesh completely covered by a silicone layer with a smooth inner surface and a structured outer surface. Initial studies on the use of Polyflex™ stents in benign refractory strictures were favorable, with improvement of symptoms and few complications. Repici *et al*[9] reported 15 patients with caustic, post-radiation, anastomotic and peptic strictures. Stent placement was successful in all patients and long-term resolution of dysphagia after 23 mo follow-up was achieved in 80% of patients. Evrard *et al*[10] reported 21 patients, of whom 17 had hyperplastic (after metallic stent placement), caustic, peptic, anastomotic and post-radiation strictures, with 81% of patients remaining dysphagia-free during a mean follow-up of 21 mo. However, less encouraging results have since been reported, with a lower success rate and a high incidence of complications. Overall, for benign esophageal strictures, the success rates of SEPSs in the published literature range from 17% to 95%, with 6% being major complications[11].

In the current literature, there are only two small series evaluating the efficacy and safety of stents in the treat-

ment of benign refractory hypopharyngeal strictures. Conio *et al*[12] developed a modified fully covered self-expanding Niti-S stent with a body diameter of 10 mm, 12 mm or 14 mm and a flared 2 mm wider upper end. Although it effectively improved dysphagia in all patients, six of the seven patients developed complications requiring stent exchange 3 mo after previous stent placement. Due to the stricture recurrence observed after stent removal, prolonged stent placement with periodic stent exchange was necessary. Somani *et al*[13] described four patients who underwent temporary esophageal Polyflex™ stenting for 3 mo. Although three of the four patients remained symptom-free after a median follow-up of 14 mo, they were able to pre-dilate the strictures up to 15 mm to allow the passage of the stiff 13 mm introducer system and the deployment of a 20 mm body with 23 mm flare plastic stent. While the use of such a large stent can explain the good results, that would not be possible in the tight and rigid strictures observed either in the first study or in our group of patients.

In the present study, the modified introducer system for placement of tracheobronchial Polyflex™ stents allowed an easy and technically successful deployment of the stent through the stricture. The use of small diameter and unflared upper end stents can explain the absence of significant pain or a foreign body sensation in the throat. Nevertheless, all patients developed complications as stent migration, a pharyngocutaneous fistula, and hyperplastic tissue growth with stent obstruction. Actually, although migration is likely to occur with this type of stent, they may be easily recovered or repositioned with an alligator jaw forceps. Moreover, the features of these stents reduce the risk of intestinal complications that may occur after migration of larger or flared stents. Fistula formation can also occur spontaneously after chemoradiation for head and neck cancer, or be precipitated by concurrent chemotherapy or infection. However, there is little doubt that in these patients the high radial expansive force and relative inflexibility of the Polyflex™ stent could have played an important role in the development of the pharyngocutaneous fistulas. Hyperplastic tissue growth with fibrous stricture formation at the upper end of the stent was observed in all patients who had their stents *in situ* for more than 8 wk, requiring stent removal. This has been previously reported to occur with the Polyflex™ stent in only a small number of patients in the literature and may be related to the stimulation of the underlying pathologic process by the upper edge of the stent, with ongoing obliterative endarteritis and ischemia after radiation injury[14]. Finally, stricture recurrence with dysphagia was observed in all patients at 4 wk follow-up after stent removal indicating that, in strictures with this etiology, small diameter stents must be kept in place for longer than 3 mo to allow adequate time for stricture remodeling.

In conclusion, these results suggest that Polyflex™ stents have limited efficacy in benign hypopharyngeal stricture resolution. New smaller diameter stents are needed to manage these narrow and non-compliant refractory strictures and to provide an alternative approach to continued serial dilation and feeding tube nutrition.

COMMENTS

Background

The management of patients who have benign refractory hypopharyngeal strictures after surgery combined with chemoradiation therapy is often unsatisfactory and disappointing. Repeated dilation therapy or long-term feeding through a nasogastric tube or percutaneous gastrostomy is frequently required.

Research frontiers

The authors aimed to evaluate the efficacy and safety of a tracheobronchial self-expanding plastic stent (SEPS) (Polyflex™) placed with modified technique in the treatment of refractory hypopharyngeal strictures after combined therapy for laryngeal cancer.

Innovations and breakthroughs

This case series has shown the technical feasibility of tracheobronchial Polyflex stent insertion for hypopharyngeal strictures. The modification of the stiff delivery system, with insertion of a balloon dilation catheter through the introducer resulting in a wire-guided tapered edge, allowed an easy and atraumatic transverse of the oropharynx and stricture. However, the results suggest that these stents have limited efficacy in stricture remodeling and have a high incidence of side effects.

Applications

Placement of SEPSs is associated with early hyperplastic tissue growth requiring short term stent replacement. New smaller diameter stents are needed to manage these narrow and refractory hypopharyngeal strictures.

Peer review

Although the use of temporary SEPS is a well recognized option for treatment of refractory stenosis of gastrointestinal tract, both benign or malignant, this report is interesting because it describes a personal modification of the introducer that should be effectively used for some more complex strictures.

Abstract

AIM: To investigate the expressions of leptin and peroxisome proliferator-activated receptor γ (PPARG) in relation to body mass index (BMI).

METHODS: We evaluated leptin and PPARG expression in 30 adenomas over 1 cm in size by immunohistochemical staining. In addition, clinicopathologic features including BMI were assessed.

RESULTS: PPARG and leptin expression showed a strong positive correlation (P = 0.035). The average BMI of the leptin-positive group was higher than that of the leptin-negative group (25.4 ± 3.4 kg/m^2 *vs* 22.6 ± 2.4 kg/m^2, P = 0.018), and leptin expression was significantly correlated with high BMI (P = 0.024). Leptin expression was more frequently observed in intermediate/high grade dysplasia than in low grade dysplasia (P = 0.030). However, PPARG expression was not correlated with BMI and grade of dysplasia.

CONCLUSION: BMI has influenced on the leptin expression of colorectal adenoma. The exact mechanism underlies the strong correlation between leptin and PPARG expression needs further study.

Key words: Leptin; Peroxisome proliferator-activated receptor γ; Obesity; Body mass index; Colorectal adenoma

INTRODUCTION

Colorectal cancer is a major cause of cancer-related mortality and morbidity[1]. Many Asian countries, including South Korea, China, Japan, and Singapore, have experienced an increase of 2 to 4 times in the incidence of colorectal cancer during the past few decades[2]. Obesity is a risk factor of colorectal cancer and colorectal adenoma, and is an independent poor prognostic variable in colorectal cancer survivors[3-5]. Although mechanism by which obesity increases the risk of colorectal cancer is not clearly understood, obesity-induced changes in hormonal metabolism are known to distort the normal balance between cell proliferation, differentiation, and apop-

tosis[3]. Circulating levels of insulin, insulin-like growth factor, and leptin are increased in obesity and may mediate the increased risk of colorectal cancer[6,7]. Leptin plays a central role in mammalian feeding behavior and energy expenditure[8]. In addition to its neurohormonal action in the brain, several *in vitro* studies have shown that leptin can act as a mitogenic, antiapoptotic, and tumorigenic factor for different cancer cell lines[9,10]. Moreover, leptin is overexpressed in human colorectal cancer[11], and its expression gradually increases during the transition from normal adenoma to adenocarcinoma, suggesting that it is associated with colorectal carcinogenesis[12]. Interestingly, however, high leptin expression in colorectal cancer is an indicator of favorable tumor features and better survival in colorectal cancer patients[12]. One interesting fact revealed in our previous study was that there was a linear trend between leptin expression of colorectal adenomas and patients' body mass index (BMI)[13]. This suggests that obesity postulated from high BMI can affect tumorigenesis through local leptin activity.

Peroxisome proliferator-activated receptor γ (PPARG) is a member of the nuclear hormone receptor PPAR superfamily[14]. PPARG plays an important role in adipose cell differentiation, modulation of metabolism, modulation of the inflammatory response, and cellular apoptosis[15,16]. Unlike leptin, PPARG is involved in cell cycle regulation and cellular differentiation in colonic epithelium, supporting its antineoplastic effect[15,17,18]. Therefore, some researchers have tried to use PPARG agonists as chemotherapeutic agents for malignancy[19]. Moreover, the overexpression of PPARG in colorectal cancer is independently correlated with longer survival of patients, so PPARG expression appears to mark an indolent subset of colorectal cancers as dose leptin expression[20].

Despite the antagonistic effects on the development of neoplasm, the expressions of PPARG and leptin are related with favorable prognosis respectively[12,20]. This phenomenon led us consider the possible interaction of PPARG and leptin in the development of colon cancer and adenoma. Colorectal adenoma is the well known premalignant lesion of colorectal cancer, and remove of it is accepted as a most effective prevention of colorectal cancer. However, there are only few studies regarding leptin and PPARG expression in colorectal adenoma[12]. Moreover, there has been no report about the correlation between leptin expression and PPARG expression. Therefore, we aimed to investigate leptin and PPARG expression in colorectal adenomas in relation to BMI. We also investigated whether the detailed characteristics of adenomas such as dysplasia grade, number, and location, are correlated with leptin or PPARG expression. Finally, we aimed to establish whether the expression of leptin is correlated with that of PPARG in colorectal adenomas.

MATERIALS AND METHODS

Patients and specimens

Thirty patients with colorectal adenomas of over 1 cm in size were enrolled in this study. All patients, less than 55 years old, were diagnosed and treated by polypectomy or endoscopic mucosal resection at the Seoul Paik Hospital (Seoul, South Korea) between August 2007 and August 2008. We excluded adenomas, which had carcinomatous components. All tissue samples were formalin fixed and paraffin embedded. Hematoxylin and eosin (HE) slides, pathologic reports, and medical records were retrospectively reviewed to confirm the diagnosis and clinicopathologic parameters including age, gender, BMI, adenoma location, adenoma size, pathologic type, and dysplasia grade. We followed the guidelines for human studies and animal welfare regulations. Subjects had given their informed consent, and the study protocol had been approved by the institutional review board on human research.

Tissue microarray construction

The most representative area of each adenoma was carefully selected and marked on a HE stained slide. Core tissue biopsies (2 mm in diameter) were taken from the corresponding donor blocks and arranged in a new recipient paraffin block (tissue array block) using a trephine apparatus (SuperBioChips Laboratories, Seoul, South Korea). Duplicate tissue cores were taken from each donor block to minimize the limitations of identifying a representative area of the tumor.

Immunohistochemical staining

Serial 4-μm thick sections of tissue array blocks were examined immunohistochemically. Sections were deparaffinized, and antigen retrieval was performed in 10 mmol/L sodium citrate buffer (pH 6.0) for 15 min at 95 ℃ using a microwave oven. Endogenous peroxidase was blocked for 10 min with 30 mL/L H_2O_2 and slides were labeled with a mouse monoclonal antibody to PPARG (E-8, 1/50 dilutions; Santa Cruz Biotechnology, Santa Cruz, CA, United States) or a rabbit polyclonal antibody to leptin (A-20, 1/100 dilution; Santa Cruz Biotechnology) for 1 h. After washing with phosphate-buffered saline, a chromogen reaction was carried out using an Ultravision LP kit (Labvision, Fremont, CA, United States). Briefly, sections were incubated with primary antibody enhancer for 20 min and horseradish peroxidase for 30 min. 3, 3'-diaminobenzidine tetrahydrochloride was used as a chromogen and Mayer's hematoxylin counterstain was applied. Negative controls without primary antibody were run simultaneously. The expressions of both proteins were evaluated based on the intensity and extent of the staining. Staining intensity was scored as 0 (negative), 1 (weak), or 2 (strong). Extent of staining was scored as 0 (0%), 1 (1%-20%), 2 (20%-50%), or 3 (50%-100%). PPARG positivity was defined as the presence of weak nuclear staining in at least 20% of adenoma cells, or the presence of strong nuclear staining (Figure 1A and B). Leptin positivity was defined as the presence of weak cytoplasmic staining in at least 20% of adenoma cells, or the presence of strong cytoplasmic staining (Figure 1C and D).

Table 1 Baseline characteristics of subjects

Baseline characteristics	Value
Total patients	30
Sex (male) *n* (%)	23 (77)
Age, year	44.6 ± 6.5
BMI (kg/m^2)	24.2 ± 3.83
Polyp size (cm)	1.2 ± 0.3
Polyp number	2.2 ± 1.4
Location[1] *n* (%)	
Left colon	17 (56.7)
Right colon	13 (43.3)
Dysplasia grade *n* (%)	
Low	13 (43.3)
Intermediate/high	17 (56.7)
Pathology *n* (%)	
Tubular	25 (83.0)
Villotubular	5 (17.0)

[1]Left colon consists of transverse, descending and sigmoid colon and rectum, and right colon is composed of cecum and ascending colon. BMI: Body mass index.

Statistical analysis

Statistical analysis was performed using the Statistical Package for the Social Sciences (SPSS) software (version 12.0, SPSS, Chicago, IL, United States). The relationship between PPARG and leptin was evaluated using the Fisher's exact test. The relationships of PPARG or leptin with clinicopathologic features were investigated by the Fisher's exact test and *t* test. Two tailed *P* values less than 0.05 were regarded as statistically significant.

RESULTS

The study sample included 23 male and 7 female patients. Patient age ranged from 29 to 53 years (44.6 ± 6.5 years). Tumors consisted of 25 tubular adenomas and 5 villotubular adenomas. Seventeen adenomas located in the left colon: transverse, descending and sigmoid colon and rectum, and 13 adenomas located in the right colon: cecum and ascending colon. The sizes of adenomas ranged from 1 to 2.5 cm (1.2 ± 0.3 cm). The number of polyps ranged from 1 to 5 (2.2 ± 1.4). Thirteen adenomas showed low grade dysplasia. Seventeen adenomas had intermediate grade dysplasia or high grade dysplasia. There were no polyps containing carcinoma-*in-situ*. These results were described in Table 1.

In colorectal adenomas, 22 of 30 cases (73.3%) showed PPARG expression, and 17 cases (56.7%) showed leptin expression (Table 2; representative photomicrographs in Figure 1). PPARG and leptin expression showed significant correlation each other ($P = 0.035$).

The BMI of the leptin positive group (25.4 ± 3.4 kg/m^2) was significantly higher than that of the leptin negative group (22.6 ± 2.4 kg/m^2, $P = 0.018$, Figure 2A), and leptin expression was significantly correlated with high BMI (≥ 25 kg/m^2, $P = 0.024$, Table 2). In contrast, PPARG expression was not correlated with BMI ($P = 0.162$, Figure 2B).

Leptin expression was observed more frequently in the intermediate/high grade dysplasia group than in the low ($P = 0.030$, Table 2). However, PPARG expression was not

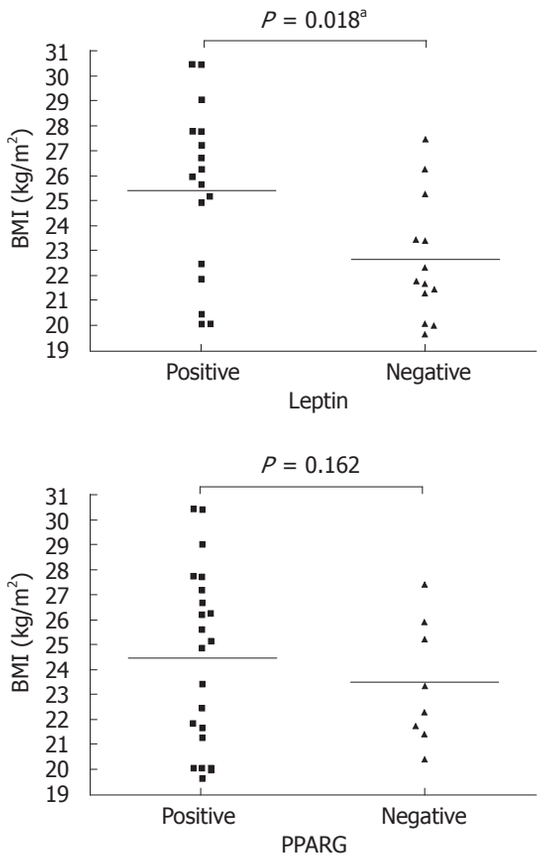

Figure 2 Leptin and peroxisome-proliferator-activated receptor γ expression in colorectal adenomas and body mass index. A: The body mass index (BMI) of leptin positive group (25.4 ± 3.4 kg/m^2) was significantly higher than the BMI of leptin negative group (22.6 ± 2.4 kg/m^2, P = 0.018); B: There is no significant difference between the BMI of peroxisome-proliferator-activated receptor γ (PPARG) positive group (24.47 ± 0.75 kg/m^2) and PPARG negative group (23.52 ± 0.87 kg/m^2, P = 0.162).

correlated with dysplasia grade (P = 0.295, Table 2). Neither leptin nor PPARG expression were correlated with the location or pathologic types of adenomas (Table 2).

Table 2 Leptin expression in colorectal adenomas and clinicopathologic characteristics of patients *n* (%)

Clinicopathologic features	Leptin expression			PPARG expression		
	Positive	Negative	*P* value	Positive	Negative	*P* value
	17 (56.7)	13 (43.3)		22 (73.3)	8 (26.7)	
BMI						
⩾ 25 kg/m^2	11 (36.7)	3 (5.0)	0.024	11 (36.7)	3 (9.9)	0.689
< 25 kg/m^2	6 (20.0)	10 (33.3)		11 (36.7)	5 (16.7)	
Dysplasia grade						
Low	5 (16.7)	9 (30.0)	0.03	9 (29.7)	5 (16.7)	0.295
Intermediate/high	12 (40.0)	4 (13.3)		13 (43.7)	3 (9.9)	
Location[1]						
Left colon	11 (36.7)	6 (20.0)	0.794	8 (26.7)	3 (9.9)	0.954
Right colon	6 (20.0)	4 (13.3)		14 (46.7)	5 (16.7)	
Histological type						
Tubular	14 (46.7)	11 (36.7)	0.869	12 (40.0)	13 (43.4)	0.743

[1]Left colon consists of transverse, descending and sigmoid colon and rectum, and right colon is composed of cecum and ascending colon. BMI: Body mass index; PPARG: Peroxisome proliferator-activated receptor γ.

DISCUSSION

Our study revealed a strong correlation between leptin expression in colorectal adenomas and high BMI. Although BMI is just one measure of obesity, the strong correlation between high BMI and leptin expression nonetheless suggests that obesity may influence leptin expression in adenomas. In our previous study, we found a trend between leptin expression and BMI[13]. However, when we enrolled colorectal adenoma lager than 1 cm size in this study, we could observe the strong correlation between high BMI and leptin expression in colorectal adenomas.

Several studies of leptin expression in cancers have suggested that local rather than endocrine leptin might play a significant role in breast tumorigenesis[21]. More specifically, both leptin and leptin receptor were found in breast tumors, indicating that leptin could influence cancer cells through autocrine or paracrine mechanisms[21-23]. However, given the induction of leptin overexpression by obesity-related stimuli, it is reasonable to also consider systemic effects on leptin expression[23].

Several studies have suggested that leptin expression is related to local hypoxia. Indeed, in several cellular systems, including breast cancer cells, leptin mRNA expression is induced by hypoxia, and the leptin gene promoter is regulated by hypoxia-inducible factor-1α[23-25]. However, we would argue that high BMI is a more likely potential marker for leptin expression than hypoxia in colorectal adenomas, for the following 2 reasons. First, previous studies regarding leptin expression and hypoxia dealt with cancers rather than adenomas. It is reasonable to accept that leptin is induced under the effect of hypoxia in cancers due to their large mass, but colorectal adenomas are much smaller than typical cancers. Furthermore, PPARG expression was strongly correlated with leptin expression in our study. PPARG levels are known to be reduced by hypoxia[26], so the strong correlation between leptin and PPARG further suggests that leptin expression is probably not caused by hypoxia in colorectal adenomas.

When we divided adenomas into low and intermediate/high dysplasia grade groups, leptin was expressed more frequently in the intermediate/high grade dysplasia group. Interestingly, the ratio of overexpressed leptin was gradually increased from normal mucosa, to adenoma, to carcinoma[11,12]. Therefore, increased leptin expression ratio from low grade to intermediate/high grade dysplasia appears to follow the pattern of increased leptin expression from normal mucosa to adenoma, to carcinoma by stages. Moreover, this may connote that as dysplasia progresses, autocrine or paracrine mechanisms of leptin may thus be progressively enhanced in colorectal adenomas.

In our study, PPARG expression was positively correlated with leptin expression in colorectal adenomas, but was not correlated with high BMI or adenoma dysplasia grade. PPARG and leptin functionally intersect *via* the Ja-

nus-activated kinase/signal transducers and activators of transcription (JAK/STAT) pathway. Leptin signaling is transmitted mainly by the JAK/STAT pathway[27] and terminated by the induction of suppressor of cytokine signaling-3[28]. In contrast to leptin, PPARG agonists inhibit cytokine-induced activation of the JAK-STAT pathway[29] and STAT-3[30]. These findings show that leptin and PPARG clearly affect the JAK/STAT pathway in different ways and possibly interact each other by unrevealed feedback mechanisms[31]. Regarding 2 molecules, several recent studies revealed that leptin might exert an inhibitory effect on PPARG protein expression. Zhou *et al*[32] suggested leptin induced extracellular signal-regulated kinases (ERK) 1/2 activation, which cause the subsequent decline in PPARG expression in hepatic stellate cells. In addition, leptin could inhibit the PPARG expression in TallyHo/Jng mouse[33]. On the other hands, PPARG ligands has the inhibitory effect on leptin induced hepatic stellate cells proliferation through the reversion of ERK 1/2 activation[33,34]. However, molecules may interact *via* different mechanism or interact with each other differently depend on cells or organs. Therefore, to clarify the exact mechanism between leptin and PPARG in colorectal adenomas, we think that additional in vitro studies are needed.

There were several limitations in our study. First of all, enrolled numbers in this study was relatively small. We wanted exclude the age factor which strongly influence on development of colorectal adenoma and carcinoma. Indeed, the prevalence of colorectal adenoma in Korea revealed that most colorectal adenomas were detected in aged group[35]. To determine the pure effect of obesity on leptin and PPARG expression in colorectal adenomas, we enrolled the patients who were under age of 55. However, information from 30 cases was enough to generate appropriate statistical values. Second, limitation was that we were able to investigate the only one indicator of obesity, BMI. Other variables accessing obesity such as wait circumference and waist-hip ratio were not investigated due to lack of information. Third, we did not investigate a control group. If we had evaluated leptin and PPARG expression in hyperplastic polyps or normal mucosa, we would establish specific criteria for the overexpression of 2 molecules in the present study. Fourth, there was no in vitro study about the interaction of PPARG and leptin. These two molecules may affect the JAK/STAT or ERK 1/2 pathways in different ways and possibly interact each other by unrevealed mechanisms. In this study, however, we did not evaluate the mechanism regarding the relationship of leptin and PPARG expression in the development of colorectal adenoma. Our study suggested the correlation between PPRAG and leptin expression but could not explain the causal relationship. For understanding the causal relationship, in vitro study should be performed in the near future.

In summary, our study is the first to evaluate simultaneous leptin and PPARG expression in colorectal adenomas in relation to BMI and characteristics of adenomas. Based on the strong correlation between leptin expression and high BMI, we postulated that energy accumulation might induce overproduction of leptin in colorectal adenomas. The known positive correlation between leptin expression and dysplasia grade further strengthens the possibility that leptin might contribute to the sequential progression of carcinogenesis from low grade dysplasia to colorectal carcinoma and through high grade dysplasia[11,12]. In contrast, PPARG expression showed no correlation with high BMI or dysplasia grade in colorectal adenomas. The correlation between leptin and PPARG expression suggests that a possible interaction between these 2 molecules during the development of adenomas, likely mediated by the JAK/STAT or ERK 1/2 pathway.

COMMENTS

Background

Colorectal cancer is a major cause of cancer-related mortality and morbidity. Leptin regarded to be associated with colorectal carcinogenesis. Unlike leptin, peroxisome-proliferator-activated receptor γ (PPARG) is involved in antineoplastic effect. Despite the antagonistic effects on the development of neoplasm, the expressions of PPARG and leptin are related with favorable prognosis respectively. This phenomenon suggests that the possible interaction of PPARG and leptin in the development of colon cancer and adenoma.

Research frontiers

Mechanism of leptin expression was one imperative issue in the research field related to the article. Obesity, expressed as body mass index (BMI), can be related with leptin expression in colorectal adenomas. Second issue was the relationship between PPARG expression and leptin expression in colorectal adenomas because these two molecules behave antagonistically.

Innovations and breakthroughs

The study is the first to evaluate simultaneous leptin and PPARG expression in colorectal adenomas in relation to BMI and characteristics of adenomas. Based on the strong correlation between leptin expression and high BMI, we postulated that energy accumulation might induce overproduction of leptin in colorectal adenomas. The correlation between leptin and PPARG expression suggests a possible interaction between these 2 molecules during the development of adenomas, likely mediated by the janus-activated kinase / signal transducers and activators of transcription or extracellular signal-regulated kinase 1/2 pathway.

Applications

Present study showed the first step to widen our understating about the interaction of PPARG and leptin in the development of colorectal adenomas. New findings about this molecular interaction can be applicable in the prevention of colorectal adenomas, premalignant lesion of colorectal cancer, and can provide pivotal hint for chemotherapy for colorectal cancer.

Peer review

The paper demonstrated interesting findings. Strong correlation between leptin and PPARG expression in colorectal adenomas, correlation between leptin expression and high BMI, and Leptin expression was more frequently observed in intermediate/high grade dysplasia than in low grade dysplasia, while PPARG expression was not correlated with BMI or grade of dysplasia.

Abstract

AIM: To explore the potential risk factors related to gastrointestinal cancer in northern China.

METHODS: A total of 3314 cases of gastrointestinal cancer (esophageal, gastric, pancreatic and biliary) and 2223 controls (including healthy individuals, glioma and thyroid cancer) were analyzed by case-control study. Multivariable logistic regression analysis was applied to evaluate the association between different cancers and hepatitis B surface antigen, sex, age, blood type, diabetes, or family history of cancer.

RESULTS: Type 2 diabetes was significantly associated with gastric, biliary and pancreatic cancer with an OR of 2.0-3.0. Blood type B was significantly associated with esophageal cancer [odd ratio (OR) = 1.53, 95% confidence interval (CI) = 1.10-2.14] and biliary cancer (OR = 1.49, 95% CI = 1.09-2.05). The prevalence of type 2 diabetes was significantly higher in gastric, biliary and pancreatic cancers compared with other groups, with ORs ranging between 2.0 and 3.0. Family history of cancer was strongly associated with gastrointestinal compared with other cancers.

CONCLUSION: Blood type B individuals are susceptible to esophageal and biliary cancer. Type 2 diabetes is significantly associated with gastric, biliary and especially pancreatic cancer.

Key words: Blood type; Type 2 diabetes; Gastric cancer; Esophageal cancer; Pancreatic cancer

INTRODUCTION

The incidence and mortality of gastrointestinal cancers (e.g., esophagus, stomach, pancreas, and biliary tract) are higher in China compared with Western countries, but the reason remains unclear.

In contrast to most Western countries, esophageal squamous cell cancer is common in many areas of China[1].

Gastric cancer ranks as the third most common cancer in China for both men and women, with 5-year survival rate < 20%[2]. Pancreatic cancer is the sixth leading cause of death among malignant diseases in China, with an overall cumulative 5-year survival rate of only 1%-3%[3].

A recent seroepidemiological study conducted in mainland China showed that hepatitis B surface antigen (HBsAg) prevalence was 7.2% in the general population and 1.1% in children under 5 years of age[4]. Hepatitis B virus (HBV) is considered to be hepatotropic and is significantly associated with end-stage chronic liver diseases, including hepatocellular carcinoma (HCC) and cholangiocarcinoma[5]. HBV may travel through the bloodstream and deposit in other organs[6]. The possible relationship between HBV and pancreatic or bile duct cancer has been reported[7,8], but the inverse relationship has been reported by others[9].

The most common type of diabetes mellitus, type 2, seems to be associated with cancers of the biliary tract and pancreas. It is significant that the greatest risk of cancer in diabetic patients is to the organs in which concentrations of endogenous insulin reach particularly high levels (i.e., liver and pancreas)[10]. Meta-analyses have indicated that diabetes mellitus is associated with a 1.7-fold increased risk of pancreatic cancer and a 2.5-fold increased risk of HCC[11].

Studies conducted several decades ago have suggested a link between inherited human blood group antigens and the risk of various malignancies[12]. Human blood antigens are glycoproteins expressed on the surface of red blood cells and a few other cell types, including cells from the gastrointestinal tract. The sugar residues of these glycoproteins are attached to a protein backbone, the H antigen, by a glycosyltransferase that is encoded by the *ABO* gene[13]. Alterations of surface glycoconjugates may lead to modifications and could be related to tumor development and spread.

Recently, Wolpin *et al*[14] have found that ABO blood type is significantly associated with the risk of pancreatic cancer. Hassan *et al*[7] have reported a higher risk of pancreatic cancer in HBV carriers.

Although it seems reasonable that ABO blood type, HBsAg, and type 2 diabetes may have a close relationship with gastrointestinal tract tumors in Western countries, to the best of our knowledge, no previous studies have been conducted to investigate the possible association between these factors and the risk of gastrointestinal cancers in China. Therefore, we embarked on the present large case-control study to evaluate whether ABO blood type, HBsAg, sex, age, type 2 diabetes, and family history of cancer are associated with gastrointestinal cancer in northern China.

MATERIALS AND METHODS

Study population

This study is a retrospective hospital-based, case-control investigation conducted in Beijing, China, at the Chinese PLA General Hospital. A total of 3314 cases and 2223 controls were recruited from January 2004 to November 2008. Cases were patients with newly diagnosed gastrointestinal tract tumors, who were evaluated and treated at the Chinese PLA General Hospital. The population mainly came from northern China and the majority was Han people. The inclusion criteria for cases were as follows: pathologically confirmed diagnosis of gastrointestinal tract cancer; laboratory data available for ABO blood type, HBsAg, and diabetes screening; and detailed record of disease course and history. The exclusion criteria were the presence of other types of digestive disease (such as neuroendocrine tumors, adenomas, cysts or unknown primary tumors) and the absence of laboratory data on blood types, HBsAg and plasma glucose.

Controls were healthy cohorts (undergoing physical examination in Chinese PLA Hospital, mainly from northern China) or patients with other cancers (such as glioma and thyroid cancer). The inclusion criteria for controls were the same as those for cases, except for the cancer diagnosis. The cases and controls were selected at the same period, with integrated laboratory data on blood types, HBsAg and plasma glucose to reduce the bias inherent in retrospective studies. The research proposal was approved by the hospital institutional review board and ethics committee.

Sampling and subject recruitment

The fasting blood samples were collected from patients and controls. Plasma samples were separated and tested for the presence of HBsAg using a third-generation ELISA or chemiluminescence assay, venous glucose by enzyme methods, and blood type by immune assay. The laboratory researcher running these assays was blinded to the disease status (cases or controls) of the subjects' blood samples. Patients whose fasting glucose was > 7.8 mmol/L at least twice were diagnosed as having diabetes. The blood type was ABO. Family history of cancer was defined as any of the first-degree relatives (parents, brother or sister, children) with a tumor history.

Sample size and statistical methods

Cases were comprised of a total of 855 esophageal, 824 gastric, 809 pancreatic and 826 biliary cancer patients. Controls included 674 glioma and 798 thyroid cancer patients, as well as 751 healthy controls. Stata software version 10 (http://www.stata.com/stata10/) was used for data management and statistical analysis. We compared the proportions of potential risk factors among cases and controls. Student's *t* test was used to compare mean age between cases and controls. The χ^2 test was used to compare proportions. We performed multivariable unconditional logistic regression analyses using all variables significant at $P < 0.05$ in the single factor analyses. For each factor, we calculated the adjusted odds ratio and 95% CI using maximum likelihood estimation.

RESULTS

Association of sex, age, family history of cancer, HBsAg and diabetes with gastrointestinal cancer

To determine whether sex, age, family history of cancer,

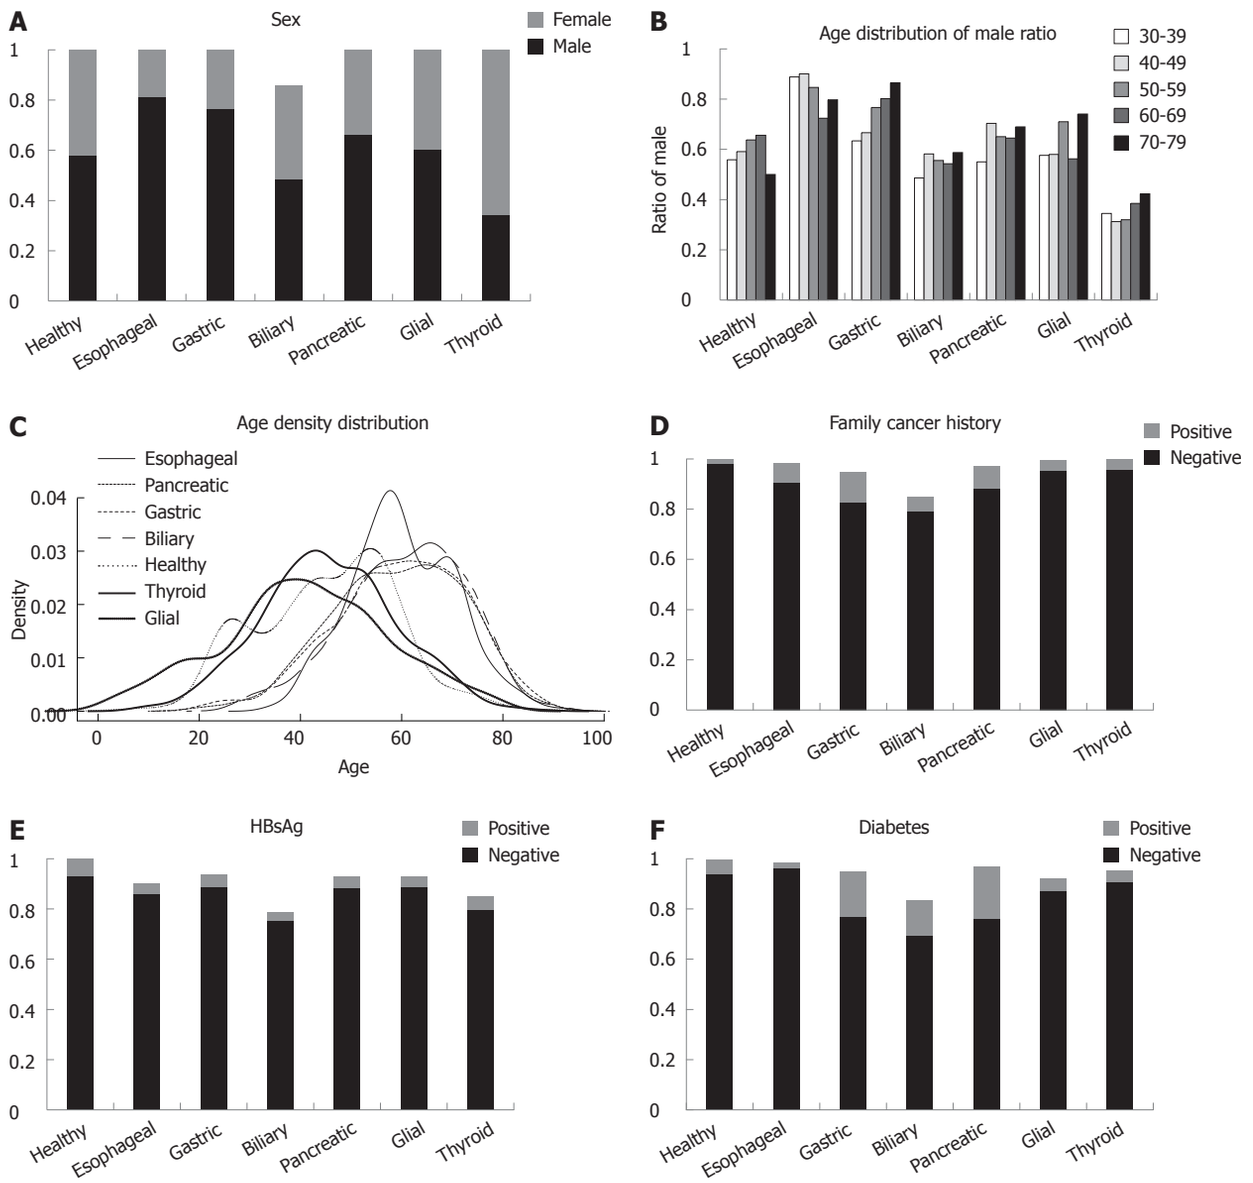

Figure 1 Distributions of clinical traits among different patient groups. A: Sex distribution in different patient groups. Blank areas in this figure represent missing values. Y axis represents sex composition. Grey color represents female individuals, black color represents male individuals; B: Proportion of male patients in different age groups with various cancers, and in healthy controls. Different colors represent different age groups. Y axis represents male ratio; C: Age distribution of different patient groups; D: Frequency of family cancer history (positive or negative) among different population groups; E: Proportion of population with HBsAg among different population groups. Grey color represents HBsAg-positive groups. Black color represents HBsAg-negative groups; F: Proportion of patients with diabetes among different population groups. Grey color represents diabetes-positive groups. Black color represents diabetes-negative groups.

Table 1 Number of cancer patients and healthy individuals in this study

Population	Number
Healthy controls	751
Esophageal cancer	855
Gastric cancer	824
Biliary cancer	826
Pancreatic cancer	809
Glioma	674
Thyroid cancer	798

HBsAg and diabetes were associated with gastrointestinal cancer, we evaluated the distribution of these clinical traits among the healthy controls, and patients with digestive system and other system cancers (Figure 1A), and calculated the OR to measure the association of each trait with gastrointestinal or other cancers, compared with healthy controls (Table 1), using multivariable logistic regression (Table 2).

Sex: The esophageal and gastric cancer groups were dominated by male patients, whereas female patients comprised the majority in the thyroid cancer group (Figure 1). Therefore, thyroid cancer showed a protective effect of male sex (OR = 0.37, 95% CI = 0.30-0.47, Table 2), whereas all other cancers were positively associated with male sex compared with healthy controls (Table 2).

Table 2 Associations between different risk factors and cancer types

Cancer type	Sex		Age		Family history		HBsAg		Diabetes	
	OR[1]	95% CI	OR	95% CI	OR	95% CI	OR	95% CI	OR	95% CI
Esophageal	3.22	[2.42–4.28]	1.12	[1.10–1.13]	6.20	[3.03–12.68]	0.66	[0.39–1.11]	0.29	[0.15–0.54]
Gastric	1.80	[1.38–2.35]	1.08	[1.07–1.09]	9.61	[5.07–18.22]	0.72	[0.43–1.19]	2.07	[1.40–3.08]
Biliary	0.86	[0.67–1.10]	1.10	[1.09–1.11]	5.27	[2.58–10.75]	0.94	[0.56–1.58]	2.13	[1.43–3.17]
Pancreatic	1.21	[0.94–1.55]	1.08	[1.07–1.09]	6.18	[3.22–11.86]	0.72	[0.43–1.19]	2.87	[1.97–4.19]
Glioma	1.17	[0.93–1.47]	0.98	[0.97–0.99]	2.83	[1.42–5.64]	0.68	[0.42–1.09]	1.06	[0.65–1.72]
Thyroid	0.37	[0.30–0.47]	1.00	[1.00–1.01]	2.46	[1.24–4.88]	0.95	[0.61–1.47]	0.89	[0.54–1.45]

[1]OR > 1 means males are more susceptible than females to cancers. Odd ratios (ORs) and respective 95% confidence intervals (CIs) were calculated using multivariable logistic regression. For each cancer, regression analysis was performed *vs* healthy controls. Factors including HBsAg and diabetes, as well as sex, age and family history of cancer were considered.

Table 3 Association between blood types and cancer types

Cancer type	Control	Type A		Type B		Type AB		Type O	
		OR[1]	95% CI	OR	95% CI	OR	95% CI	OR	95% CI
Esophageal	Type O	0.99	[0.70–1.40]	1.53	[1.10–2.14]	1.25	[0.76–2.08]	–	–
	All others	0.80	[0.60–1.05]	1.49	[1.12–1.97]	1.11	[0.71–1.74]	0.80	[0.60–1.07]
Gastric	Type O	0.99	[0.71–1.37]	1.03	[0.74–1.46]	1.28	[0.78–2.10]	–	–
	All others	0.93	[0.71–1.23]	1.03	[0.78–1.37]	1.24	[0.79–1.93]	0.96	[0.73–1.26]
Biliary	Type O	0.78	[0.56–1.08]	1.49	[1.09–2.05]	0.95	[0.57–1.57]	–	–
	All others	0.65	[0.49–0.86]	1.66	[1.27–2.17]	0.91	[0.58–1.43]	0.92	[0.70–1.21]
Pancreatic	Type O	1.05	[0.76–1.44]	1.26	[0.91–1.75]	1.44	[0.89–2.31]	–	–
	All others	0.88	[0.67–1.15]	1.20	[0.92–1.57]	1.28	[0.84–1.95]	0.86	[0.65–1.12]
Glioma	Type O	0.83	[0.62–1.12]	1.15	[0.86–1.54]	1.22	[0.81–1.84]	–	–
	All others	0.77	[0.60–0.98]	1.21	[0.95–1.56]	1.21	[0.84–1.76]	0.99	[0.78–1.26]
Thyroid	Type O	0.74	[0.56–0.99]	1.16	[0.87–1.55]	1.01	[0.66–1.54]	–	–
	All others	0.70	[0.54–0.89]	1.30	[1.02–1.66]	1.07	[0.73–1.57]	1.07	[0.84–1.35]

[1]Only Odd ratios (ORs) for blood type are shown here, ORs for other factors are similar to Table 2. Here HBsAg, diabetes, sex, age and family history of cancer were excluded. ORs and respective 95% confidence intervals were calculated using logistic regression. For each cancer, every blood type group was compared with type O group and all the other groups separately.

The age peak of cancer occurrence was different among various cancers, therefore, we calculated sex ratios within different age groups to ensure the distribution was not skewed by any particular age group. Sex ratios were largely consistent among different age groups (Figure 1B). Thus, the association of sex with thyroid, esophageal and gastric cancers seems to be independent of age.

Age: The age distribution of patients with gastrointestinal cancers (esophageal, gastric, biliary and pancreatic) was similar, whereas that of healthy controls and patients with other cancers (glial and thyroid) had relatively younger age profiles (Figure 1C). These different age distributions suggested that older individuals were more susceptible to gastrointestinal cancer. Only glioma had a weak negative association with increasing age compared with healthy controls (OR = 0.98, 95% CI = 0.97-0.99). All the other cancers analyzed here showed weak positive association with age (Table 2).

Family history of cancer: The prevalence of a positive family history of cancer seemed to be much higher in the cases compared with controls (Figure 1D). Association analysis also revealed stronger associations of family cancer history with gastrointestinal cancer compared with other cancers (Table 2), although the two other cancers (glioma and thyroid) were also significantly associated with cancer family history when compared with healthy controls (OR = 2.83, 95% CI = 1.42-5.64; OR = 2.46, 95% CI = 1.24-4.88, respectively).

HBsAg: There were no associations found between HBsAg and any of the different patient groups (Figure 1E and Table 2).

Diabetes: Type 1 diabetes mellitus is relatively rare in most populations and cancer risk investigations have been scarce. Our study indicates that the prevalence of type 2 diabetes was significantly higher in gastric, biliary and pancreatic cancers compared with other groups (Figure 1F), with ORs ranging between 2.0 and 3.0 (Table 2). However, esophageal cancer was strongly inversely associated with type 2 diabetes compared with healthy controls (OR = 0.29, 95% CI = 0.15-0.54).

Association of ABO blood types with gastrointestinal cancer

The risk of thyroid cancer was lower in blood type A than in type O (OR = 0.74, 95% CI = 0.56-0.99). The risk of esophageal cancer (OR = 1.53, 95% CI = 1.10-2.14) and

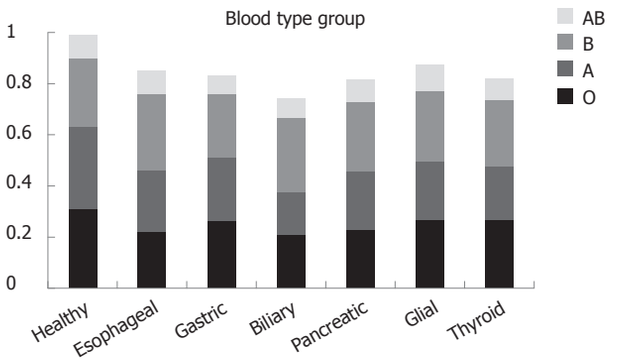

Figure 2 Fraction of each blood type with different population groups. Different colors represent different blood types (AB, A, B, or O), Blank areas in this figure represent missing values.

biliary cancer (OR = 1.49, 95% CI = 1.09-2.05) (Table 3) was significantly associated with blood type B. These were confirmed by comparison of each blood type with a combination of all the other blood types (Table 3, Figure 2). In addition, the risk of thyroid cancer in blood type B was significantly higher when compared with the combination of all the other blood types (OR = 1.30, 95% CI = 1.02-1.66). The risk of biliary cancer and glioma was significantly lower in blood type A when compared with combination of all the other blood types (OR = 0.65, 95% CI = 0.49-0.86; OR = 0.77, 95% CI = 0.60-0.98).

No significant associations of cancer risk were found with blood type AB. This may have been caused by the small number of patients with this blood type in this study.

DISCUSSION

This was a retrospective study on the risk factors (including ABO blood type, HBsAg, diabetes, sex, age and family history of cancer) associated with digestive system cancer in northern China. To reduce the bias, we tried to enlarge our samples, and the cases and controls were selected using the same criteria and in the same period. The association of type 2 diabetes with gastric, biliary and pancreatic cancers was significant, and blood type B was significantly associated with esophageal and biliary cancers.

The ABO blood groups are defined by carbohydrate moieties displayed on the surface of red blood cells and attached to a protein backbone, known as the H antigen. Three variant alleles (A, B and O) of a single gene on chromosomes 9q34, the *A, B* or *O* gene, determine a person's blood type by encoding three glycosyltransferases with different substrate specificities. In addition to their expression on the surface of red blood cells, the A, B and O antigens are highly expressed on the surface of epithelial cells of the gastrointestinal, bronchopulmonary, and urogenital tracts.

One hospital-based case-control study has shown some evidence of a positive association between blood type A and risk of pancreatic cancer[15]. Another study has demonstrated an increased prevalence of pancreatic cancer among patients with blood group B and a decreased prevalence in patients with blood group O[16]. Wolpin *et al*[14] have found that ABO blood type is significantly associated with the risk of pancreatic cancer. Compared with blood group O, patients with groups A, AB and B were more likely to develop pancreatic cancer (adjusted hazard ratios for incidence of pancreatic cancer were 1.32, 95% CI = 1.02-1.72; 1.51, 95% CI = 1.02-2.23; and 1.72, 95% CI = 1.25-2.38, respectively). However, in our study, no significant associations between A, B and O blood types and pancreatic cancer were found. Environmental and dietary factors may play an important role in pancreatic cancer. However, a lower risk of biliary cancer associated with blood type A was found in our study, whereas patients with blood type B were more susceptible to esophageal and biliary cancers.

The functional significance of ABO blood group distribution might be associated with biological characteristics such as differentiation, mean size of the tumor, venous invasion, and TNM stages of esophageal squamous cell cancer[17]. A previous study from China has shown that blood group B is associated with the incidence of upper esophageal squamous cell cancer in men[18]. Our results are consistent with these findings.

Previous studies have reported an association between hepatitis B and pancreatic and biliary cancers. Hassan *et al*[7] have reported a higher risk of pancreatic cancer in HBV carriers. Meanwhile, a case-control study in China has reported that HBV infection and hepatolithiasis are risk factors in the development of cholangiocarcinoma[8]. In Shanghai, chronic HBV infection was associated with a 2.4-fold increased risk of extrahepatic bile duct cancer[19]. However, no association was found between HBsAg and pancreatic or biliary cancer in our study. However, there were some limitations to this study for evaluation of HBV infection. We only acquired HBsAg data, and not data from occult HBV infection. Occult HBV infection has been described in patients who are negative for HBsAg, and who have been previously exposed to HBV and have recovered from acute or chronic infection[20,21]. Currently, it is generally accepted that occult HBV infection among patients without any serological evidence for infection is a risk factor for HCC development[22-24]. For biliary cancer, we did not separate our cases by extrahepatic and intrahepatic origin although most cases were extrahepatic in origin.

Diabetes has been found in previous studies to be associated with a number of cancers. Recent studies among Japanese men and women have shown that a past/present history of diabetes is associated with cancer risk for all sites in both sexes (OR = 1.44, 95% CI = 1.28-1.62; OR = 1.39, 95% CI = 1.19-1.62, respectively). A significantly increased risk was found for cancers of the pharynx, esophagus, colorectum, liver, pancreas, and lung among men, and the stomach, liver, lung and uterine cervix among women[25,26]. Diabetes mellitus and hyperglycemia have also been found to increase the risk of gastric cancer associated with *Helicobacter pylori* infection[27]. The relationship between diabetes mellitus and esophageal

cancer has also been investigated in a Danish study that has shown a 30% increase in risk for esophageal cancer among men with diabetes. No increased risk was seen in women[28].

Diabetes often precedes pancreatic cancer and is thus regarded as a potential risk factor for malignancy. Conversely, pancreatic cancer may secrete diabetogenic factors. Given these findings, there is increasing interest in whether close monitoring of the glycemic profile may help with early detection of pancreatic cancer[29]. The success of a strategy using new-onset hyperglycemia and diabetes as a screening tool to identify people with a high likelihood of asymptomatic pancreatic cancer will depend largely on our ability to differentiate pancreatic-cancer-associated diabetes from the more common type 2 diabetes, by use of a serological biomarker[30].

The risk from diabetes varies according to tumor site, and in our study, diabetes had the strongest association with pancreatic cancer, a moderately increased risk for gastric and biliary cancers, and a decreased risk for esophageal cancer. Given the food intake difficulties of patients with advanced esophageal cancer, the inverse association of diabetes with esophageal cancer could be an effect of diet restriction. Substantial public investment in preventing diabetes mellitus is important to have a major impact on its adverse health effects including cancer.

In conclusion, we found that blood type A was associated with a lower risk of biliary cancer, glioma and thyroid cancer, while those with blood type B were more susceptible to esophageal, biliary and thyroid cancers. Patients with type 2 diabetes were at high risk of pancreatic cancer, moderate risk for gastric and biliary cancers, and decreased risk for esophageal cancer. We did not find any association between HBsAg and the four gastrointestinal cancers in the Chinese population that we studied here.

COMMENTS

Background

The incidence and mortality of gastrointestinal cancer (such as cancer of the esophagus, stomach, pancreas, and biliary tract) are higher in China compared with Western countries, but the reason remains unclear.

Research frontiers

Although it seems reasonable that ABO blood type, hepatitis B surface antigen (HBsAg), and type 2 diabetes have a close relationship with gastrointestinal tract tumors in Western countries, to the best of our knowledge, no previous studies have been conducted to investigate the possible association between these factors and the risk of gastrointestinal cancer in China.

Innovations and breakthroughs

This was a retrospective study on the risk factors (including ABO blood type, HBsAg, diabetes, sex, age and family history of cancer) associated with digestive system cancer in northern China. The association of type 2 diabetes with gastric, biliary and pancreatic cancer was significant, and blood type B was significantly associated with esophageal and biliary cancers.

Applications

It is important for early cancer detection and prevention that type 2 diabetes is related to gastric, biliary, and particularly pancreatic cancers.

Peer review

This study describes a very large case-control study of risk factors (age, sex, ABO blood type, diabetes, hepatitis B virus, and family cancer history) for gastrointestinal cancers in northern China. ABO blood group and type 2 diabetes are correlated with gastrointestinal cancer in northern China, and the family history findings are important. The study design is good and the methods are standard and reliable.

Abstract

AIM: To screen the differential expressed genes in colorectal cancer and polyp tissue samples.

METHODS: Tissue specimens containing 16 cases of colorectal adenocarcinoma and colorectal polyp *vs* normal mucosae were collected and subjected to cDNA microarray and bioinformatical analyses. Quantitative reverse transcription-polymerase chain reaction (qRT-PCR) was used to confirm some of the cDNA microarray data.

RESULTS: The experimental data showed that eight genes were differentially expressed, most of which were upregulated in adenomatous polyp lesions. Forty-six genes expressions were altered in colorectal cancers, of which 29 were upregulated and 17 downregulated, as compared to the normal mucosae. In addition, 18 genes were similarly altered in both adenomatous polyps and colorectal cancer. qRT-PCR analyses confirmed the cDNA microarray data for four of those 18 genes: *MTA1*, *PDCD4*, *TSC1* and *PDGFRA*.

CONCLUSION: These differentially expressed genes likely represent biomarkers for early detection of colorectal cancer and may be potential therapeutic targets after confirmed by further studies.

INTRODUCTION

Colorectal polyp (CRP) is considered as a premalignant lesion for development of colorectal cancer (CRC)[1]. Although the mechanism underlying colorectal cancer de-

velopment remains to be defined, a series of genetic and epigenetic events are thought to play important roles in colorectal carcinogenesis, including oncogene activation and tumor suppressor gene inactivation[2,3].

By attaining a detailed understanding of the altered gene expression profile of colorectal cancer novel strategies may be developed for earlier detection and more effective prevention and treatment, thereby reducing colorectal cancer incidence and increasing survival rates.

In this study, we performed a cDNA microarray analysis to profile differential gene expressions in tissue specimens of polyps and colorectal carcinoma and compared the expression profiles to that in corresponding normal tissues. We chose the genes with marked differential expressions for verification by quantitative reverse transcription-polymerase chain reaction (qRT-PCR). These data provide insightful information into the genetic mechanisms of colorectal cancer and identify genes that may be useful as biomarkers for early disease detection.

Table 1 Clinical characteristics of patients with colorectal cancer or polyps

Case	Sex	Age	Size in cm/*n*		Differentiation	Depth	Dukes

MATERIALS AND METHODS

Ethics

This study was carried out in accordance with the Declaration of Helsinki (2000) of the World Medical Association and approved by the Medical Ethics Committee of Fujian Province, China. All patients read and signed an informed consent form prior to surgery and sample collection.

Patient tissue

A total of 16 patients with colorectal adenocarcinoma and adenomatous polyp lesions were collected from The 174th Hospital of the Chinese PLA between May 2006 and December 2010. Diagnosis of these patients was confirmed by surgical pathology. None of the patients received any pre-surgical chemo- or radiation-therapy. All tissue specimens were immediately taken from the operation room upon excision from the patient, snap frozen in liquid nitrogen, and stored at -80 ℃ until use. The tissue specimens from these patients were divided into two groups: adenomatous polyp lesions *vs* proximal non-cancerous colorectal mucosae (Group A) or colorectal cancer *vs* proximal non-cancerous colorectal mucosae (Group B). The clinicopathological characteristics of these patients are summarized Table 1.

RNA isolation and cDNA microarray analysis

Total cellular RNA was extracted from the tissue samples by using the Trizol reagent (Sigma-Aldrich Inc., Germany)[2,4]. mRNA isolation was then carried out with Qiagen Oligotex beads, (Valencia, CA, United States) according to the manufacturer's instructions. The final concentration of mRNA was measured by spectrophotometer.

Next, the mRNAs from colorectal cancer or adenomatous polyp lesions were reverse transcribed into cDNA by means of Cy5-dUTP labeling, while the mRNAs from the normal mucosae were processed with Cy3-dUTP labeling by following the manufacturer's protocols (NEN Company, Boston, MA, United States). The labeled probes were then hybridized to the cDNA microarray (Chipscreen, Shenzhen, China), which contained 8064 human genes.

Microarray scanning and data analysis

Hybridized cDNA microarrays were scanned using a Gene PIX 4000 microarray fluorescence scanner (Axon Instruments, Foster City, CA, United States). Accompanying bioinformatical software was used convert the output images to data form and perform analysis. Ratios of Cy5: Cy3 were normalized to the median ratio value of all the microarray spots detected. Spots with intensities in both channels that were 0.5 to 2.0-fold higher than the local background were excluded from further analysis. SPSS v13.0 statistical software (Chicago, IL, United States) was used to carry out Student's *t*-test statistical analysis to determine significant intergroup differences of gene expression. *P*-values < 0.05 were considered statistically significant.

Quantitative reverse transcription-polymerase chain reaction

Differentially expressed genes between the adenomatous polyp lesions and colorectal cancer samples detected by the cDNA microarray, as compared to non-cancerous tissues, were verified by using qRT-PCR. The primers for these mRNAs used for qRT-PCR is listed in Table 2.

RESULTS

Qualification of the isolated total RNA and mRNA from the tissue samples

Quality of the isolated total RNA and mRNA from the tissue samples was found to have high correlation coefficients (Figure 1). The fluorescence signal was consistent

Table 2 Primers used for quantitative reverse transcription polymerase chain reaction analysis

Gene tag	Sequences	Tm (℃)	Cycle	Product (bp)
MTA1	5′-AGCCGTGCTTCGGTATCTT-3′ 5′-CCCGTTGTGCTGCTCGTA-3′	57	30	580
PDCD4	5′-GCTGAATTCGGATGGATG-TAGAAAATGAGCAGA-3′ 5′-CTGCTCGAGTCAG-TAGCTCTCTGGTTTAAGA-3′	54	27	470
TSC1	5′-ATCGCCTTTATGGAATGT-3′ 5′-GCTTGTGGTGGTTCAGTT-3′	49	29	510
PDGFRA	5′-ACCATAAGGCTCTTACTCT-3′ 5′-TTCTGGCACTTACCTACA-3′	45	31	490

with the expectations and standards (Figure 2); for example, the good 28S to 18S RNA subunit ratio in these samples indicated that there was no significant degradation (data not shown).

Identification of differential gene expression profile between colorectal cancer and adenomatous polyp lesions

cDNA microarray analysis of these tissue mRNAs revealed that eight genes were differentially expressed between adenomatous polyp lesions and the normal mucosae, and most of these were upregulated in the polyps (Table 3, $P < 0.05$). Meanwhile, 46 genes were differentially expressed between colorectal cancer and normal tissues, of which 29 were up-regulated in the cancer samples (Table 3, $P < 0.05$). A total of 18 genes were found to be similarly altered in both adenomatous polyp lesions and colorectal cancer samples (Table 4). qRT-PCR confirmed the observed patter for four of those 18 genes: *MTA1*, *PDCD4*, *TSC1* and *PDGFRA* (Table 5).

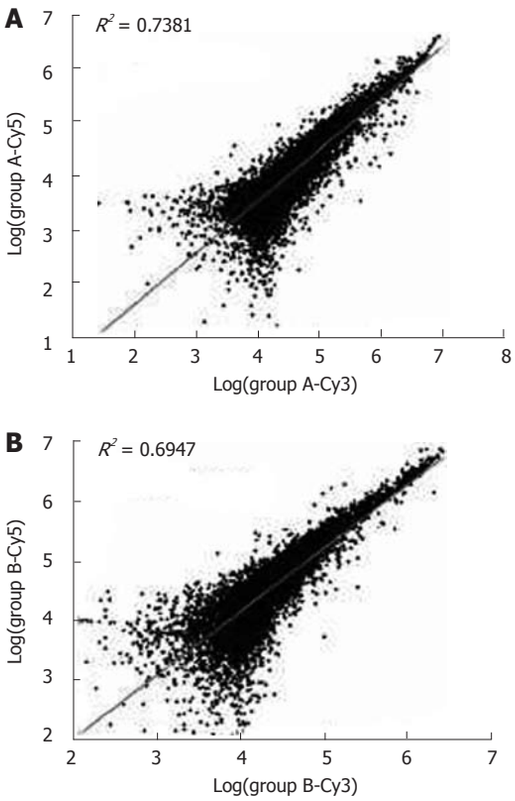

Figure 1 Correlation of CY5/CY3 hybridization signal intensity of all gene spots in Group A (polyps *vs* normal) and B (colorectal cancer *vs* normal) (*R* = 0.8591 and 0.8335, respectively). For visualization of these gene distributions, dispersion plots containing the log2 (normal tissues) and log2 (polyps or colorectal cancer) values were constructed.

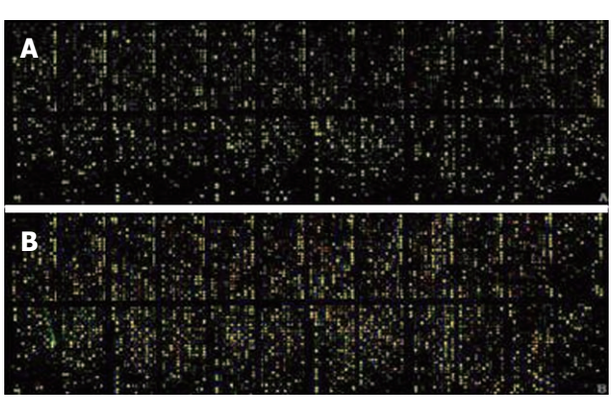

Figure 2 Microarray scanned data from Group A and B.

DISCUSSION

Colorectal carcinoma is a major cause of cancer-related deaths in China[5,6]. Unfortunately, little is known about the gene expression profiles between colorectal cancer and adenomatous polyp lesions. Genes that are differentially expressed in adenomatous polyp lesions may represent useful biomarkers for risk of colorectal cancer development, while altered genes in cancerous tissues may be used as therapeutic targets for colorectal cancer treatment[7].

Adenomatous polyp is the premalignant lesion of colorectal cancer[8-12]. Therefore, we conducted the current study to profile the differential gene expressions between normal mucosae and adenomatous polyp lesions, between normal mucosae and colorectal cancer, and between adenomatous polyp lesions and colorectal cancer. We found that eight genes were differentially expressed in adenomatous polyp lesions, as compared to normal mucosae. In addition, 46 genes were differentially expressed in colorectal cancer, as compared to the normal mucosae; twenty-nine of which were up-regulated. A total of 18 genes were significantly upregulated in both colorectal cancer and adenomatous polyp lesions, further indicating that adenomatous polyp is a precancerous lesion. However, some genes were downregulated in adenomatous polyp lesions (such as *MGST1* and *PDGFRA*) or upregulated in colorectal cancers only (*PLAGL1*). These genes encode proteins that are known to be involved in cell growth, apoptosis, and metastasis and are likely to contribute to colorectal carcinogenesis, as purported by previous studies[13,14].

The *MGST1* gene is located in 12p13.1-13.2 and was previously considered to be a "housekeeping" gene[15].

However, it has been frequently observed as upregulated in various cancers. A recent *in vitro* study has implicated the role of MGST1 in development of multiple drug resistance during breast cancer chemotherapy with several cytostatic drugs (such as cisplatin)[16]. Polymorphisms in MGST1 have also been associated with colorectal cancer risk in Chinese[17]. In this study, we found that MGST1 mRNA levels were upregulated in colorectal cancer, as compared to those detected in normal mucosae (2.90 ± 0.16). Intriguingly, MGST1 was down-regulated in adenomatous polyps, as compared to the normal mucosae (2.14 ± 0.23), but further study is necessary to fully understand the implications of this finding.

PDGFRA gene mutation is commonly observed in tissues of gastrointestinal stromal tumors[18]. Mutated PDGFRA proteins demonstrate constitutively elevated tyrosine

kinase activity and possess transforming ability, which can be reversed through PDGFR blockade[19]. Thus, mutants of PDGFRA protein behave as oncogenes, as has been demonstrated in glioma samples[20]. Here, we observed high expression of PDGFRA in colorectal cancers, as compared to that in normal tissues (4.81 ± 0.14). This observation suggests that PDGFRA may contribute to cancer development or maintenance of the tumor phenotype, possibly by supporting properties of tumor cell growth and invasiveness. However, to the reason why PDGFRA was down-regulated in adenomatous polyps remains unclear.

Finally, *PLAGL1*, a tumor suppressor gene, is localized on the chromosome 6q24-25 and is the target of several types of chromosomal rearrangement, including one identified in pleomorphic adenomas and malignant tumors. PLAGL1 is ubiquitously expressed in many human tissues where it regulates normal physiological functions; however, it has also been demonstrated to functionally contribute to complex pathologies such as cancer[21-23]. Our current study showed that PLAGL1 mRNA was down-regulated in colorectal cancer, as compared to adenomatous polyps, suggesting that PLAGL1 protein may also play a role in suppressing colorectal cancer development.

The functional roles for each of these genes in colorectal tumorigenesis remain to be verified. Nonetheless, our data provide insightful information into their potential roles in this complex and diverse disease[24]. Future studies will aim to verify these differentially expressed genes as biomarkers for early detection and/or therapeutic targets for treatment of colorectal cancers.

COMMENTS

Background

The mechanism of colorectal carcinogenesis remains to be defined and this study aims to obtain the gene expression profiles between colorectal cancer and adenomatous polyp lesions.

Research frontiers

Many researchs on genetic and epigenetic events which are thought to play important roles in colorectal carcinogenesis, such as oncogene activation and tumor suppressor gene inactivation.

Innovations and breakthroughs

The study firstly screened the differential expressed genes in colorectal adenocarcinoma and colorectal polyp *vs* normal mucosae.

Applications

These differentially expressed genes maybe as biomarkers for early detection and/or therapeutic targets for treatment of colorectal cancers.

Peer review

Study was well designed and performed methodologically.

Abstract

AIM: To investigate the promoter region methylation status of retinoblastoma protein-interacting zinc finger gene 1 (RIZ1) in the human esophageal squamous cell carcinoma (ESCC) cell lines and tissues and verify the relationship between methylation of RIZ1 and oncogenesis, tumor progression and metastasis etc of ESCC.

METHODS: Methylation-specific polymerase chain reaction (MSP) was used to investigate the promoter region methylation status of RIZ1 in 6 ESCC cell lines. One cell line where RIZ1 promoter region methylation was detected was selected for the next study, where the cell line was treated with 5-aza-CdR. Real-time polymerase chain reaction was used to investigate its influence on the transcription of RIZ1. Experiments using frozen pathological specimens from 47 ESCC patients were performed using the same MSP methodology.

RESULTS: Promoter methylation of *RIZ1* gene was detected in TE13, CaEs17 and EC109 cell lines and the cell line TE13 was chosen for further study. The expression of RIZ1 mRNA in TE-13 was up-regulated after treatment with 5-aza-CdR. The rate of methylation in carcinomas tissues was significantly higher than those in matched neighboring normal and distal ending normal tissue, and the deviation of data was statistically significant (χ^2 = 24.136, P < 0.01). Analysis of the gender, age familial history, tumour deviation, tumour saturation, lymph gland displacement and clinical staging of 47 samples from ESCC patients showed that the fluctuation of data was not statistically significant.

CONCLUSION: Promoter methylation may play an important role in the epigenetic silencing of *RIZ1* gene expression in human ESCC. RIZ1 is considered to be a potential tumor suppressor gene and may be a biological parameter for testing early stage human ESCC.

INTRODUCTION

Esophageal cancer is one of the most aggressive malignancies with poor prognosis in the world. Esophageal squamous cell carcinoma (ESCC) is a major histological form of the disease, especially in the Northern part of China[1], which is different from Europe and America. Like other types of solid tumors, the development of ESCC is due to the accumulation of the abnormal expression of oncogenes and tumor suppressor genes (*TSG*). Several genetic alterations have been associated with the development of ESCC including p53 and p16 mutations, amplification of cyclin D, c-myc, and EGFR, and allelic loss on chromosomes[2-5]. In mammalian development, DNA methylation has an essential regulatory function which suppresses gene activity by changing chromatin structure[6,7]. It has become apparent that aberrant DNA methylation of promoter region CpG islands may serve as an alternate mechanism to genetic defects in the inactivation of TSG in human malignancies[8,9].

In recent years, researchers found that the retinoblastoma protein-interacting zinc finger gene (*RIZ*) maps to the distal short arm of human chromosome 1 (1p36), a region thought to harbor TSG for a variety of human cancers. The *RIZ* gene normally produces two protein products of different length, RIZ1 and RIZ2. RIZ1 contains the positive regulatory (positive regulatory domain I binding factor 1 and RIZ) domain, but RIZ2 lacks this domain[10]. In many human cancers, RIZ1 is considered a TSG because RIZ1 can induce G2-M arrest and apoptosis. Moreover, a knockout study showed that RIZ1 is a tumor susceptibility gene in mice[11]. The expression of RIZ1 is frequently silenced in many human malignant tumours, including carcinomas of the breast, prostate, and thyroid gland[12-14]. Recently, methylation of RIZ1 promoter CpG islands has been proposed as a common mechanism in inactivating RIZ1. Increasing clinical evidence reveals a positive correlation of reduced RIZ1 expression with increased risk for metastasis, indicating that RIZ1 may be a potential new TSG[12-14]. Although RIZ1 is a putative tumor suppressor in several cancer types, for instance breast cancer[15], gastric cancer[16], lung cancer[17] and so on, the role of RIZ1 in human ESCC has not been reported. In this study, we analyzed methylation status of the RIZ1 promoter and its relationship with RIZ1 mRNA expression in human ESCC cell lines. In addition, the study examined the relationship between methylation of the *RIZ1* gene in the promoter region, oncogenesis, tumor progression, metastasis and hereditary factors etc of ESCC.

MATERIALS AND METHODS

Cell lines and tissues

The human ESCC cell lines KYSE150, KYSE510, TE13, EC9706, CaEs17 and EC109 were provided by the Institute of Cellula Nervosa in Tianjin Huanhu Hospital and were cultured in recommended media RPMI1640 (GIBCO, HEPES 4.76 g/$NaCO_3$ 2.0 g/RPMI-1640 10.4 g/ddH_2O 1000 mL) supplemented with 10% newborn bovine serum (GIBCO), 1 × L-glutamine and 1 × penicillin-streptomycin. Cells were maintained at 37 ℃ in a humidified environment with 5% CO_2.

Carcinoma, matched adjacent normal (> 2 cm from the tumor) and distal ending normal (> 5 cm from the tumor) tissues were obtained in our department during surgical excision from 47 patients with ESCC. All specimens were placed in liquid nitrogen immediately after resection and stored at -80 ℃ until RNA or genomic DNA (gDNA) extraction. No patient had received chemotherapy or radiation therapy prior to surgery. All patients were confirmed to have ESCC by pathologic test.

DNA extraction, purification and bisulfite modification

gDNA from cell lines or ESCC frozen tissues was extracted by using a Dneasy kit (Biomiga). All extracted genomic DNA was treated with sodium bisulfite (Sigma) as reported previously. Briefly, 2 μg gDNA was denatured by 5.5 μL of 3 mol fresh NaOH (final concentration 0.3 mol/L) for 10 min at 37 ℃. 30 μL of 10 mmol/L hydroquinone (Sigma) and 520 μL of 3 mol/L sodium bisulfite (pH 5.0) were added, away from light. The mixture was inverted, added to 200 μL liquid paraffin to prevent water evaporation and reagent oxidation, then incubated at 50 ℃ for 16 h. The modified DNA was purified using the Wizard DNA clean-up system (Promega). The purified DNA was treated again with NaOH and precipitated. DNA was resuspended in 20 μL of LoTE, 2 μL of which were subjected to polymerase chain reaction (PCR) amplification.

Methylation-specific polymerase chain reaction and sequencing

Methylation-specific primers were designed to cover 23 CpG dinucleotides numbered -124--103 (forward) and 32-52 (reverse). Similarly, unmethylation-specific primers were designed to cover 23 CpG dinucleotides numbered -123--103 (forward) and 32-52 (reverse). Primers specific for methylated DNA (forward 5'-GTGGTGGTTATTGGGCGACGGC-3'; reverse 5'-GCTATTTCGCCGACCCCGACG-3') and unmethylated DNA (forward 5'-TGGTGGTTATTGGGTGATGGT-3'; reverse 5'-ACTATTTCACCAACCCCAAGA-3') were added to the reaction and expected to generate 177-bp and 175-bp products, respectively. PCR conditions were 40 cycles of denaturation at 94 ℃ for 30 s, annealing at 68 ℃ for methylation-specific amplification or at 60 ℃ for unmethylation-specific amplification for 45 s and extension at 72 ℃ for 60 s, then sequencing of PCR products.

Reexpression of RIZ1 through 5-aza-CdR treatment

2×10^5 TE13 cancer cells were seeded into 6-well plates and treated with 10 μmol/L special DNA methyltransferase (DNMT) 5-aza-CdR (Sigma) for 3 d. The drug liquid was replaced every day, reagent was wiped out and

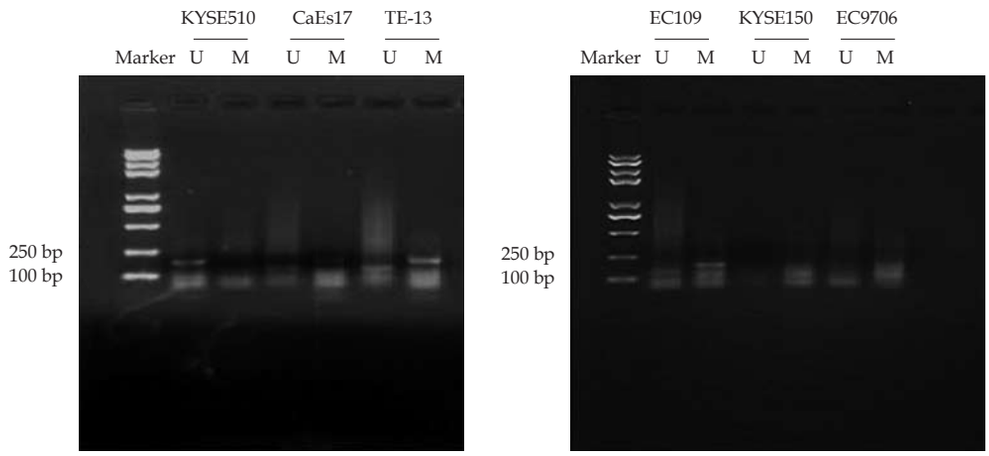

Figure 1 Methylation-specific polymerase chain reaction analyses of retinoblastoma protein-interacting zinc finger 1 promoter methylation status using genomic DNA extracted from 6 human esophageal squamous cell carcinoma cell lines, products of 177 bp and 175 bp were expected for methylated (M) and unmethylated (U) DNA. M: Methylation-specific amplification (177 bp); U: Unmethylation-specific amplification (175 bp).

incubation was continued routinely for 5 d. RNA was isolated, and real-time PCR was performed as described previously.

RNA extraction and reverse transcription reaction

Total cellular and tissue RNA was isolated by Trizol (Invitrogen) reagent according to the manufacturer's recommendations. Cellular RNA was isolated from 5×10^6 to 1×10^7 cells by 1 mL Trizol decomposition and tissues samples were ground into a fine powder using a mortar and pestle, and incubated in Trizol solution (100 g/L) for 15 min. Then 1/5 volume of chloroform was added. After vigorous agitation standing for 5 min, the inorganic phase was separated by centrifugation at 12000 *g* for 15 min at 4 ℃; RNA was then precipitated in the presence of equivolume isopropanol and centrifuged at 12000 *g* for 10 min at 4 ℃. RNA pellets were washed with 1 mL 75% ice-cold ethanol [diethypyrocarbonate (DEPC) treated] and centrifuged at 8000 *g* for 5 min at 4 ℃ then dissolved in DEPC-treated H_2O. Total RNA was quantified and concentration determined using ultraviolet (UV) spectrophotometry (Beckman Coulter) by absorbency at 260/280 nm and 1.2% denaturing agarose gel. For real-time polymerase chain reaction (real-time quantitative PCR) analysis, 2 μg RNA was reverse transcribed using reverse transcriptase M-MLV (Takara), Ribonuclease inhibitor (Takara) and dNTP mixture (Takara), according to the manufacturer's protocol; the cDNA templates were subjected to PCR amplification.

RT-PCR, sequencing and Real-time PCR

One μL cDNA from the TE13 cell line treated or not by 5-aza-CdR was used as the template to amplify specific fragments in 25 mL reaction mixture (10 × easy taq buffer 2.5 μL, 2 mol/L dNTP 2.5 μL, F primer 1 μL, R primer 1 μL, cDNA 1 μL, Easy taq 0.3 μL, ddH_2O 16.7 μL) under the following conditions: denaturation at 94 ℃ for 3 min, 35 cycles at 94 ℃ for 30 s, at 56 ℃ for 30 s, at 72 ℃ for 20 s, then extensions at 72 ℃ for 10 min. The primer (10 μmol/L) sets were: RIZ1, forward 5'-TCTGCTGTTGACAAGACCC-3', reverse 5'-GCATCAATGCACATCCATC-3'. The RIZ1 primer set yielded a band at 167 bp. 12 mL RT-PCR reaction product was analyzed by electrophoresis on a 12 g/L agarose gel. The electrophoresis images were scanned by UV spectrophotometer (Beckman Coulter). Sequencing of 0.75 μL of the resultant cDNA from TE13, which was mixed with 2 × SYBR Premix Ex Taq™ (Takara), was then performed. The primer (10 μmol/L) sets used were: RIZ1, forward 5'-TCTGCTGTTGACAAGACCC-3', reverse 5'-GCATCAATGCACATCCATC -3'; GAPDH, forward 5'-GAAGGTGAAGGTCGGAGTC-3', reverse 5'-GGGTGGAATCATATTGGAAC -3'. The amplifications were performed in LightCycler (Roche) real-time PCR system according to the manufacturer's protocol. Each sample was run in triplicate for each gene. An initial denaturation step at 94 ℃ for 5 min was followed by 45 cycles of denaturation at 95 ℃ for 5 s, annealing at 59 ℃ for 20 s, extension at 72 ℃ for 10 s, then the solubility temperature curve assay was performed.

Statistical analysis

t-test was used to compare the measurement data, for instance the RIZ1 mRNA expression levels with primary ESCC and the adjacent and distal ending normal tissues by Real-time PCR. The relative quantitative results were analyzed by comparison of $2^{-\text{average}\Delta\Delta CT} \times 100\%$. χ^2 test was also used to estimate the enumeration data, for example the results. P values < 0.05 were considered statistically significant.

RESULTS

Methylation status detecting of RIZ1 in human ESCC cell lines

MSP analyses of RIZ1 promoter methylation status using genomic DNA extracted from 6 human ESCC cell lines, products of 177 bp and 175 bp were expected for methylated (M) and unmethylated (U) DNA. Promoter methylation of *RIZ1* gene was detected in TE13, CaEs17, EC109

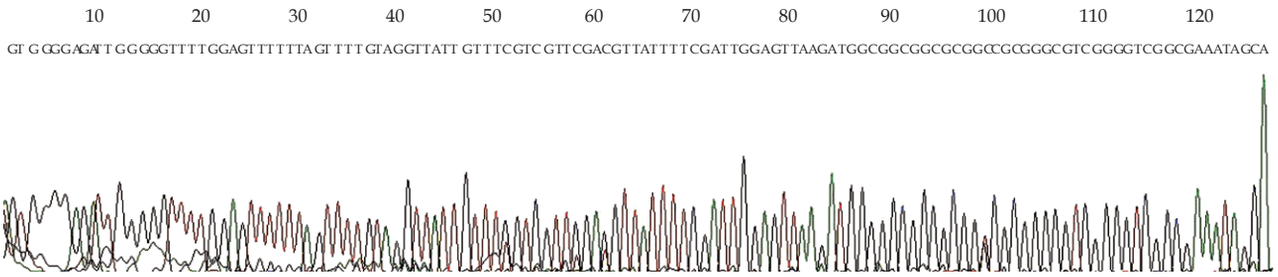

Figure 2 Sequencing analysis of methylated (M) polymerase chain reaction products of methylation-specific polymerase chain reaction from TE13

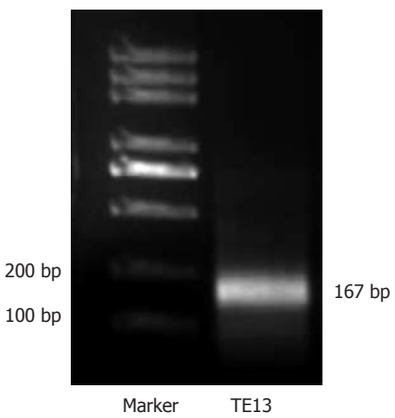

Figure 3 Reverse transcription-polymerase chain reaction for RIZ1 expression in TE13 treated or not by 5-aza-CdR.

but not KYSE510, KYSE150 and EC9706 (Figure 1).

All cytosines were changed to thymines, except cytosines in CpG dinucleotide in M-sequences obtained from amplification using M-primer (Figure 2).

RIZ1 mRNA expression of treated TE13 by DNMT compared with expression in untreated TE13

The expression of RIZ1 was higher after use of 5-aza-CdR than before its use ($P < 0.01$) (Figures 3-5).

Methylation of RIZ1 gene in promoter region of ESCC tissues

Among 47 nonselective ESCC patients and matched adjacent normal and distal ending normal esophageal tissue, 26, 3 and 0 cases, respectively, exhibited methylation in the CpG island of the RIZ1 promoter. The corresponding methylation ratios were 55.3%, 6.4% and 0.0%. The rate of methylation in carcinomas tissues was significantly higher than that in matched adjacent normal and distal ending normal tissues, and the deviation of data was statistically significant ($P < 0.01$). The difference in methylation rates between matched adjacent normal and distal ending normal tissues possesses no statistical significance ($P > 0.05$). In the 3 samples where methylation was positive in matched neighbouring normal tissues, methylation also existed in the corresponding carcinoma tissues. MSP electrophoresis of ESCC patients with RIZ1 methylation positive amplification in both carcinomas and matched normal tissues is illustrated in Figure 6A, while that with RIZ1 methylation positive amplification only in carcinomas tissues but not in matched normal tissues is shown in Figure 6B.

The relation between analysis of the methylation state of the CpG island in the *RIZ1* gene promoter by χ^2 verification and the clinical information of the 47 sufferers of the ESCC is illustrated in Table 1. It can be seen that there was no correlation between the methylation state of the CpG island in the *RIZ1* gene promoter of the 47 samples and the sufferers' gender, age, familial history, tumour deviation, tumour saturation, lymph gland displacement and clinical stages, respectively. The fluctuation of data was not statistically significant ($P > 0.05$ in all groups) (Table 1).

DISCUSSION

Among the numerous genes that are known to be silenced in human cancers, for example p53, Syk, APC, BRCA1, *etc.*[18-20], RIZ1 is one of the few with a proven role in causing cancer as demonstrated. Whereas previous studies demonstrate reduced *RIZ1* gene expression to be common in cancers, this study confirms that RIZ1 is commonly silenced by DNA methylation. The RIZ1 promoter has been demonstrated to have the characteristics of a CpG island, which suggests that RIZ1 is a target of inactivation by epigenetic mechanisms[21]. In prostate cancer, 42.6% of cancer cases were reported to have RIZ1 methylation, and was more frequent in patients with a high-grade malignancy[13]. In gastric adenocarcinoma, hypermethylation of RIZ1 was found in 69% of cancer tissues and in 21% of corresponding non-neoplastic mucosa[22]. In thyroid carcinoma Lal *et al*[14] reported that all of the 31 cancerous cases were methylated, and methylation was significantly frequent compared with normal thyroid tissues (33%). Du *et al*[21] reported that methylation of RIZ1 was detected in 44% (11/25) of breast cancer specimens and 62% (20/32) of liver cancer specimens. However, RIZ1 mutation has not been detected in these cancers[23]. Thus, DNA methylation may represent the preferred mechanism of RIZ1 inactivation in these cancers. Furthermore, because many types of human cancer cell lines exhibit reduced RIZ1 expression, we predict that *RIZ1* gene methylation will be commonly found in many types of human cancer tissue. In a previous study, we found that, compared with normal tissues, the expres-

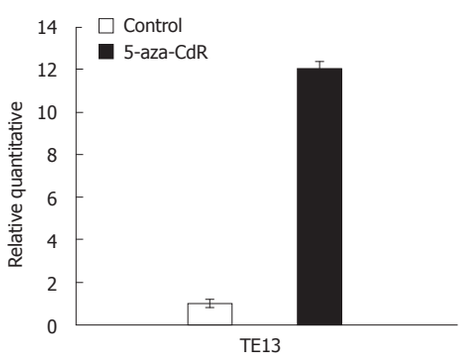

Figure 5 The expression of retinoblastoma protein-interacting zinc finger 1 when the drug 5-aza-CdR is used.

sion of RIZ1 mRNA was significantly lower in cancer tissues than in the adjacent non-cancerous tissues ($P < 0.01$). But in this study there was no significant difference between cancer tissues and the adjacent non-cancerous tissues ($P = 0.067$). No RIZ1 protein expression was observed in the cancer tissues, as it was 0% (0/12), while the expression level in the normal tissues was 66.67% (8/12). There was a statistically significant difference between RIZ1 mRNA and protein expression ($P < 0.05$) which indicates that RIZ1 expression may reduce the occurrence of ESCC. RIZ1 may be a candidate tumor suppressor in ESCC.

In this paper, we explored DNA methylation of RIZ1 in the promoter region among human ESCC cell lines, malignant human ESCC, its matched adjacent normal and distal ending normal tissues. MSP was used to detect

the promoter region methylation status of *RIZ1* gene in human ESCC cell lines including KYSE150, KYSE510, TE13, EC9706, CaEs17 and EC109. Promoter methylation of *RIZ1* gene was detected in TE13, CaEs17 and EC109. TE13 was chosen for further research and treated with 5-aza-CdR. Real-time PCR shows us that the expression of RIZ1 mRNA in TE-13 was up-regulated after treatment by the drug. The results of study using ESCC pathological frozen specimens illustrate that the R1Z1 gene promoter of the ESCC possesses a 55.3% methylation positive ratio (26/47). RIZ1 methylation positive amplification was seen in 26 sets of carcinoma tissue from 47 sufferers and unmethylation positive amplification was seen in 21. In matched neighboring normal esophageal tissues, the RIZ1 methylation positive amplification appeared in 3 cases, while unmethylation positive amplification was found in 44 cases. Furthermore, in distal ending normal esophageal tissues, the methylation positive amplification did not exist, i.e., all 47 studied cases possessed unmethylation positive amplification. Among those 3 sufferers with RIZ1 methylation positive amplification in matched neighbouring normal esophageal tissues, the corresponding carcinoma tissue also contained RIZ1 methylation positive amplification. In the 47 sufferers of ESCC, 3 possessed methylation in carcinoma tissue and matched neighbouring normal tissue but possessed unmethylation in distal ending normal tissue. Twenty three sufferers showed methylation in carcinoma tissues, but unmethylation in matched neighbouring normal tissue and distal ending normal tissue. Twenty one sufferers possessed unmethylation in carcinoma, matched neighbouring normal and distal ending normal tissues. The rate of methylation of RIZ1 promoter in ESCC was higher than that of adjacent normal tissues ($\chi^2 = 24.1$, $P < 0.01$).

DNA methylation in the promoter region may play an important role in the epigenetic silencing of *RIZ1* gene expression. However, the test to determine *RIZ1* gene promoter methylation shows there is no methylation found in 2 other human ESCC cell lines. This means that dimunition of RIZ1 expression is not always triggered by promoter methylation. One such potential mechanism is that RIZ1 silencing could be caused by a defect in a certain transcription factor that normally activates the RIZ1 promoter. Another potential mechanism is mutation in the RIZ1 promoter. However, given the prevalence of DNA methylation, these other mechanisms are not likely to be commonly involved, and further research is required to find out the true mechanism. Furthermore, we did not observe any significant correlation between RIZ1 methylation and tumour grade. This may be attributable to a relatively small sample size and the complexity of the unselected patient population. Additional detailed studies using a patient cohort should be done needed to examine the value of RIZ1 methylation as a diagnostic or prognostic marker. Another explanation is that gene methylation exists in the early stage of ESCC, but not in the middle and late stages. Hence, there is a statistically insignificant discrepancy during the development of tumour and the displacement of lymph gland. We guess that the methylation of the CpG island in RIZ1 may be an important molecular mechanism during the appearance and development of ESCC in the early stage, and may become a biological parameter for testing early stage of ESCC.

The vital importance of the epigenetic changes on the generation and development of tumours has been thoroughly realized by human beings. Nowadays, there exists an expert database of DNA methylation for researchers (www.methdb.de). The DNA methylation abnormality of malignancy characterizes significantly according to: specifics of the tumour, specifics and reversibility of genes and tissues, *etc*. Methylation testing techniques possess high sensibility and specificity. Thereinto, the MSP technique can be applied for testing some small quantity of tissues sections, phlegm and urine, *etc*., as well as for clinical follow-up through quantitative analysis of relevant genes. Therefore, further research on the mechanisms of the tumour suppressor gene *RIZ1* on esophageal cancer may show some new parameters of early diagnosis and prognosis evaluation for esophageal cancer. The DNMT, 5-aza-CdR, has been clinically applied for curing some solid tumors and some hematological diseases, such as myelodysplastic syndrome, acute myeloid leukemia, etc. A new therapy target for esophageal cancer may be found by strengthening the research on DNA methylation of the genes and the significance of application of 5-aza-CdR.

COMMENTS

Background

Recently, methylation of the *retinoblastoma protein-interacting zinc finger* gene (*RIZ1*) promoter CpG islands has been proposed as a common mechanism in inactivating RIZ1. Increasing clinical evidence reveals a positive correlation of reduced RIZ1 expression with increased risk for metastasis, indicating that RIZ1 may be a potential new tumour suppressor gene (*TSG*). However, although RIZ1 is a putative tumour suppressor in several cancer types, for instance breast cancer, gastric cancer, lung cancer, the role of RIZ1 in human esophageal squamous cell carcinoma (ESCC) has not been reported.

Research frontiers

In mammalian development, DNA methylation has an essential regulatory function of suppressing gene activity by changing chromatin structure. It has become apparent that aberrant DNA methylation of promoter region CpG islands may serve as an alternate mechanism to genetic defects in the inactivation of TSG in human malignancies.

Innovations and breakthroughs

China is a country with a high incidence of ESCC, and the pathological type is mainly squamous cell carcinoma, which is different from adenocarcinoma reported in other countries. The present study aimed to discover the effect and mechanism of the anti-cancer gene *RIZ1* on ESCC. The results illustrate that low expression of RIZ1 in ESCC is relevant to promoter methylation. Methylation takes place in the early stage of carcinogenesis, and it may become a molecular biological parameter for early diagnosis.

Applications

The methylation of RIZ1 is the major reason for the low expression in ESCC. This could take place in early stages of ESCC, and is expected to be a molecular biological parameter for early diagnosis.

Peer review

This paper reports RIZ1 promoter methylation in esophageal cancer in a usual way.

Abstract

Acute pancreatitis is an inflammatory disease characterized by local tissue injury which can trigger a systemic inflammatory response. So vascular complications of pancreatitis are a major cause of morbidity and mortality. Pulmonary embolism in acute pancreatitis has been reported to be very rare. We reported a case of pulmonary embolism with acute pancreatitis. A 38-year-old woman broke out upper abdomen pain without definite inducement. She had no nausea and vomiting, fever, dyspnea, cough and expectoration, chest pain. The patient had been diagnosed with acute pancreatitis in local hospital. The patient was treated with antibiotics and proton pump inhibitors, and the abdomen pain was alleviated slightly. But the patient came forth cough and expectoration with a little blood, progressive dyspnea. A computed tomographic scan of the abdomen revealed pancreatitis. Subsequent computer tomography angiography of chest revealed pulmonary embolism (both down pulmonary arteries, left pulmonary artery and branch of right pulmonary artery). Dyspnea of the patient got well with thrombolytic treatment and anticoagulation therapy. Pulmonary embolism is a rare but potentially lethal complication of pancreatitis. Familiarity with this complication will aid in its early diagnosis, therapy and prevent pulmonary embolism, a rare but catastrophic phenomenon.

Key words: Pulmonary embolism; Pancreatitis

INTRODUCTION

Pulmonary embolism (PE) is a blockage of the main artery of the lung or one of its branches by a substance that has travelled from elsewhere in the body through the bloodstream (embolism). Usually this is due to embolism of a thrombus (blood clot) from the deep veins in the legs, a process termed venous thromboembolism. A small proportion is due to the embolization of air, fat, talc in

drugs of intravenous drug abusers or amniotic fluid. Untreated, PE has a mortality rate of approximately 30%.

Vascular complications of pancreatitis are a major cause of morbidity and mortality and are related to haemorrhage resulting from arterial erosion or pseudoaneurysms, ischaemic complications (either "local" or related to remote vascular events) and venous or arterial complications - specifically splanchnic thrombosis and associated varices[1-3]. The frequency of pulmonary embolism in acute pancreatitis has been reported to be very rare. The thrombohemorrhagic complications in pancreatitis are playing a tremendous part in the development of its most severe forms and fatal outcome. So we described a case of pulmonary embolism with acute pancreatitis and reviewed the literature for the occurrence of this complication.

CASE REPORT

A 38-year-old woman broke out upper abdomen pain after engorgement. She had no nausea and vomiting, fever, dyspnea, cough and expectoration, chest pain. The patient had been diagnosed with acute pancreatitis in local hospital. The relevant laboratory findings on admission were: white blood cell (WBC) 12.71 × 10^9/L, red blood cell 3.65 × 10^{12}/L, hemoglobin 109 g/L, platelets 100 × 10^9/L, blood amylase 1130 U/L, alanine aminotransferase 261 U/L, total bilirubin 33.9 μmol/L, lactate dehydrogenase 614 U/L, urea nitrogen 10.26 mmol/L, serum creatinine 149.3 mmol/L, serum potassium 3.9 mmol/L, serum calcium 1.89 mmol/L, fasting blood glucose 12.1 mmol/L, c-reactive protein 162 mg/L. The patient was treated with antibiotics and proton pump inhibitors, and the abdomen pain was alleviated slightly. But the patient came forth cough and expectoration with a little blood, progressive dyspnea. So the patient was transferred to our institution. We found the following signs with physical examination: The temperature was 36 ℃, the breath rate was 30 breaths per minute, the heart rate was 120 beats per minute, the blood pressure was 90/60 mmHg. The patient had cyanopathy of lip, breathed rapidly. Coarse breath sounds were heard in whole lung, breath sounds were decreased in the bilateral low lung fields, moist rales were heard in bilateral lung. Cardiac examination revealed tachycardia of 120 beats per minute without pathological murmur. Abdomen was flat and soft. Tenderness was obvious in upper abdomen. There was no rebound tenderness on abdomen. Liver and spleen were untouched below the costal margin. Shifting dullness was negative. The remainder of the examination was unremarkable, with no clinical evidence of deep venous thrombosis.

Oxygen saturation of blood was 78% on room air, 82% on 4 L/min oxygen nasal cannula, and 89% with noninvasive ventilator. Laboratory evaluation showed a WBC count of 13.4 × 10^9/L, with otherwise normal complete blood count; normal basic metabolic panel results; and arterial blood gas measurements showed a pH of 7.30, PCO_2 43.6 mmHg, PO_2 68.4 mmHg, and bicarbonate 20.8 mEq/L on oxygen flow rate of 6 L/min face mask. Plasma dimerized plasmin fragment D (D-dimer) assay was > 500 μg/L. blood amylase was 850 U/L.

Electrocardiogram of the patient showed the sinus tachycardia and T-wave change. Doppler echocardiography revealed that right atrial was enlarged. There were no signs of celiac and pelvic vein thrombosis or proximal leg deep venous thrombosis with venous ultrasonography. A computed tomographic (CT) scan of the abdomen revealed pancreatitis (Figure 1). A CT scan of the chest revealed bilateral pleural effusion, lung infection and pulmonary hypertension (Figure 2). Subsequent computer tomography angiography of chest revealed pulmonary embolism (both down pulmonary arteries, left pulmonary artery and branch of right pulmonary artery) (Figure 3). Dyspnea of the patient got well with thrombolytic treatment and anticoagulation therapy.

DISCUSSION

Acute pancreatitis is an inflammatory disease characterized by local tissue injury which can trigger a systemic inflammatory response. There is increasing evidence that endothelial dysfunction is one of the critical pathophysiologic manifestations in patients with severe form of acute pancreatitis[1-4]. In keeping with this, we report the case of pulmonary embolism with acute pancreatitis. The case was reported for the reason: because pulmonary thrombus is a rare complication of pancreatitis.

Pulmonary embolism is a rare complication of pancreatitis, and there have been very few descriptions of it. Vascular thrombosis and hypercoagulable states complicating pancreatitis are thought to due to release of proteolytic enzymes from the pancreas and direct vasculitis. So some researchers consider the mechanism of formation of the pulmonary thrombus in the present case to be as follows: (1) a cyst communicating with the pancreatic duct penetrates into the vascular; (2) pancreatic juice enters the vascular and triggers the formation of a thrombus secondary to vasculitis; (3) hypercoagulability complicates pancreatitis and is thought due to a combination of hepatic dysfunction and hypertrypsinaemia (resulting in raised fibrinogen and Factor Ⅷ concentrations) and cachexia; (4) vascular changes, due to proteolytic damage or inflammation, may also play a significant part; and (5) the acute pancreatitis provokes deleterious effects in endothelium-dependent relaxing response for ACh in isolated mesenteric rings that were strongly associated with high plasma NO_x-levels as consequence of intense inflammatory responses. Furthermore, the subsensitivity of contractile response to phenylephrine in both mesenteric and pulmonary rings might be due to the complications of this pathological condition in the early stage of pancreatitis[5-7].

Pulmonary thromboembolism is a dreadful complication of vascular thrombosis in acute pancreatitis. Symptoms of pulmonary embolism include difficulty breathing, chest pain on inspiration, and palpitations.

Figure 1 A computed tomographic scan of the abdomen revealed pancreatitis. A: Plain computed tomographic (CT) scan; B: Enhanced CT scan.

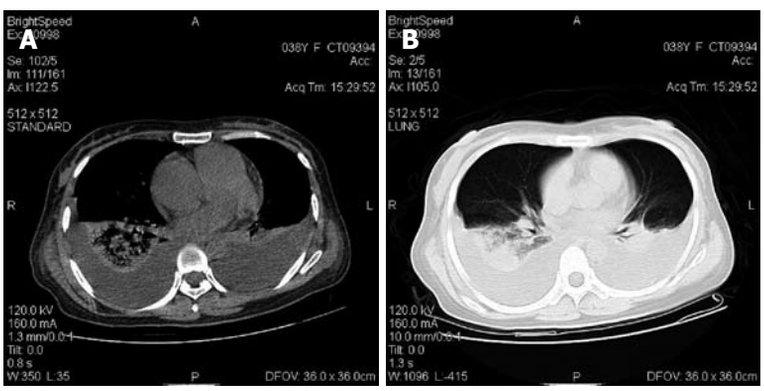

Figure 2 A computed tomographic scan of the chest revealed both sides pleural effusion, lung infection and pulmonary hypertension. A: Mediastinal window; B: Lung window.

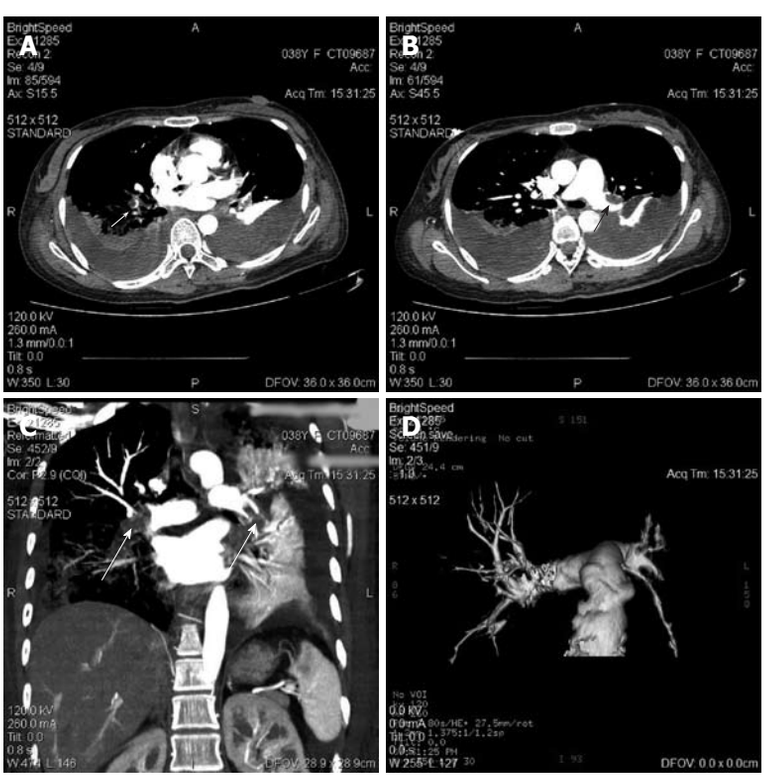

Figure 3 A Computer Tomography angiography of chest revealed pulmonary embolism (both down pulmonary arteries, left pulmonary artery and branch of right pulmonary artery). A: Embolism of rihgt down pulmonary artery (arrow); B:Embolism of left down pulmonary artery (arrow); C: Embolism of left pulmonary artery and branch of right pulmonary artery in coronal view of chest-3D slab image (arrows); D: 3D reconstruction of pulmonary arteries.

Clinical signs include low blood oxygen saturation and cyanosis, rapid breathing, and a rapid heart rate. Severe cases of PE can lead to collapse, abnormally low blood pressure, and sudden death. Diagnosis is based on these clinical findings in combination with laboratory tests (such as the D-dimer test) and imaging studies. So virtually all radiological modalities have been applied to the diagnosis of vascular thrombosis in acute pancreatitis. Contrast venography, ultrasonography, contrast-enhanced CT scan and magnetic resonance imaging (MRI) all have defined roles in the diagnosis of vascular thrombosis. Radionuclide 99mTc-venography and lung perfusion scintigraphy

are useful in diagnosing pulmonary thromboembolism secondary to vascular thrombosis in pancreatitis, showing abnormal large hot spots at the level of the pancreas and pulmonary embolism[2,8,9].

Early recognition and investigation of thromboembolism is imperative because accurate diagnosis and timely radiological interventional procedures can reduce mortality. Early treatment with intravenous heparin is effective. A vascular filter is sometimes used in the management of vascular thrombosis in acute pancreatitis to prevent pulmonary thromboembolism[10-13].

This case report describes a rare complication of acute pancreatitis. Familiarity with this complication will aid in its early diagnosis, therapy and prevent pulmonary embolism, a rare but catastrophic phenomenon.

In conclusions, pulmonary thrombosis is a rare but potentially lethal complication of pancreatitis. Where the patient developing acute shortness of breath, or leg edema, superficial thrombophlebitis or thromboembolic events arouse clinical suspicion of vascular thrombosis, evaluation by CT scanning, MRI, radionuclide 99mTc-venography and lung perfusion scintigraphy is required. Early recognition and investigation of thromboembolism is imperative because accurate diagnosis and timely radiological interventional procedures can reduce mortality. Early treatment with intravenous heparin or thrombolysis is effective. Vascular filter insertion may be a life-saving measure for such patients.

Abstract

The difference between stages Ⅰ and Ⅲ of gastric gastrointestinal stromal tumor depends principally on the number of mitosis. According with TNM classification, the presence in the tumor of high mitotic rate determines the upgrading. Many studies exposed different count techniques in evaluating the number of mitosis. An international standardized method to assess mitotic rate is needed.

Key words: Gastrointestinal stromal tumor; Mitosis; Classification; Gastroesophageal; Enucleation

Peer reviewer: Justin MM Cates, MD, PhD, Department of Pathology, Vanderbilt University Medical Center, Medical Center North, C-3322, 1161 21st Avenue South, Nashville, TN 37232, United States

TO THE EDITOR

We read with great interest the comment to our article[1] by Peparini *et al*[2]. They posed the attention on the new TNM (Tumor, Node, Metastasis) classification[3] which included the gastrointestinal stromal tumors (GISTs). They particularly stressed the attention on the staging differences and the consequential therapeutic approach of the Ⅰ and Ⅲa stage of gastric GIST. The difference between these two stages depends principally on the number of mitosis. In fact, according with TNM classification, the presence in the tumor of high mitotic rate determines the upgrading, with a major risk and the proposed necessity of a more aggressive therapeutical behaviour. High mitotic rate for TNM classification is defined as more than 5 mitosis in 50 high-power fields (HPF) using the 40X magnification objective (total area 5 square mm in 50 fields)[3]. TNM classification states that stringent criteria have to be followed when defining mitosis: pyknotic or dyskaryotic nuclei must not be counted as mitoses[3].

On one hand we agree with the comment of Peparini *et al*[2] about the necessity to be carefull in deciding which surgical and target therapeutic strategy should be adopted, on the other hand however we consider mandatory to stress the possible bias in evaluating the number of mitosis.

Many studies in fact exposed different count techniques in evaluating the number of mitosis, which could lead to a different staging and consequentially to a different surgical and target therapeutic approach for the same lesion[4]. The number of different staging systems[4] and the uncertain behaviour of the GISTs, especially those of the upper gastrointestinal tract, which seem to be less aggressive than those of the lower tract, left uncertain the best treatment for the gasto-esophageal junction GISTs. In fact, it has been demonstrated as the gastric GISTs differentiated one from each other depending on the localization (gastoesophageal junction and body *vs* distal antrum)[5]. Moreover high intratumoral discrepancies in mitotic rate have been reported[6].

The anatomical site and the peculiar charachteristics of the tumor impose to be extremely careful to the risk-

benefit balace. Lastly, the urgent need for an international standardized method to assess mitotic rate which define the spectrum of mitotic figures, the total field area of 50 HPF and the best tumor area to be used for the count is emphasized from the present interesting correspondence.

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1361 experts in gastroenterology and hepatology from 64 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systemically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensuses and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing
Statistical review is performed after peer review. We invite an expert in Biomedical Statistics from to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Ridit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc*. The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

Conflict-of-interest statement
In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent
Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights
When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www.clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://www.wjgnet.com/1007-9327office. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no less than 256 words) and structured abstracts (no less than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no less than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections.

AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/…"; MATERIALS AND METHODS (no less than 140 words); RESULTS (no less than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 *vs* 3.61 ± 1.67, $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: …*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of *P* values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of *P* values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that...".

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed and http://www.crossref.org/SimpleTextQuery/, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in boldfaced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in boldfaced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*

Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*

Biology: *H. pylori*, *E coli*, *etc.*

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be re-submitted online (http://www.wjgnet.com/1007-9327office/). The author should send the copyright transfer letter, responses to the reviewers, English language Grade B certificate (for non-native speakers of English) and final manuscript checklist to wjg@wjgnet.com.

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

WJG is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1300 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.

Abstract

Irritable bowel syndrome (IBS) is a functional gut disorder with high prevalence. Because of various factors involved in its pathophysiology and disappointing results from conventional IBS medications, the treatment of IBS is challenging and use of complementary and alternative medicines especially herbal therapies is increasing. In this paper, electronic databases including PubMed, Scopus, and Cochrane library were searched to obtain any *in vitro*, *in vivo* or human studies evaluating single or compound herbal preparations in the management of IBS. One *in vitro*, 3 *in vivo* and 23 human studies were included and systematically reviewed. The majority of studies are about essential oil of Menta piperita as a single preparation and STW 5 as a compound preparation. Some evaluated herbs such as Curcuma xanthorriza and Fumaria officinalis did not demonstrate any benefits in IBS. However, it seems there are many other herbal preparations such as those proposed in traditional medicine of different countries that could be studied and investigated for their efficacy in management of IBS.

Key words: Herbal medicines; Irritable bowel syndrome; Systematic review

Peer reviewer: Mauro Bortolotti, MD, Professor, Department of Internal Medicine and Gastroenterology, University of Bologna, Via Massarenti 48, Bologna 40138, Italy

Rahimi R, Abdollahi M. Herbal medicines for the management of irritable bowel syndrome: A comprehensive review. *World J Gastroenterol* 2012; 18(7): 589-600 Available from: URL: http://www.wjgnet.com/1007-9327/full/v18/i7/589.htm DOI: http://dx.doi.org/10.3748/wjg.v18.i7.589

INTRODUCTION

Irritable bowel syndrome (IBS) is a functional gut disorder characterized by abdominal pain or discomfort, bloating, and bowel disturbances[1] with a higher prevalence ratio of women to men (ratio of 2:1)[2]. Studies from Asia suggest higher prevalence of IBS in more developed countries such as Singapore (8.6%) and Japan (9.8%) compared with India with the lowest prevalence (4.2%)[3]. The pathophysiology of IBS is most likely multifactorial involving visceral hypersensitivity, abnormal gut motility, intestinal microbiota, inflammation and immune disturbance, genetic factors, abnormal gas handling, psychosocial factors, intestinal infections, central nervous system, and serotonin[1,4,5]. Pharmacological treatment of IBS varies from antidepressants including tricyclic antidepressants[6] and selective serotonin reuptake inhibitors[7], to antispasmodics[8,9], 5-hydroxytryptamine-3 receptor (5-HT3) antagonists[10], 5-HT4 agonists[11], antibiotics[12], probiotics[13], and melatonin[14]. But involvement of numerous factors in pathophysiology and a very significant

placebo effect[15] cause therapy of this disease to be more complex. Due to disappointing results with conventional IBS treatments, complementary and alternative medicines are becoming attractive options for many patients[16].

In the present paper, management of IBS by herbal medicines and their modes of action have been evaluated in detail. For this purpose, electronic databases including PubMed, Scopus, and Cochrane library were searched to obtain studies giving any *in vitro*, *in vivo*, or human evidence of the efficacy of herbs in the treatment of IBS. Data were collected for the years 1966 to 2011 (up to February). The search terms were: "complementary and alternative medicine", "plant", or "herb" and "irritable bowel syndrome". Reference lists of the retrieved articles were also reviewed for additional applicable studies. The title and abstract of each article were examined to eliminate duplicates, reviews, studies examining functional bowel diseases other than IBS, and studies assessing complementary and alternative medicines other than herbs. Figure 1 shows a flow diagram of the study selection process.

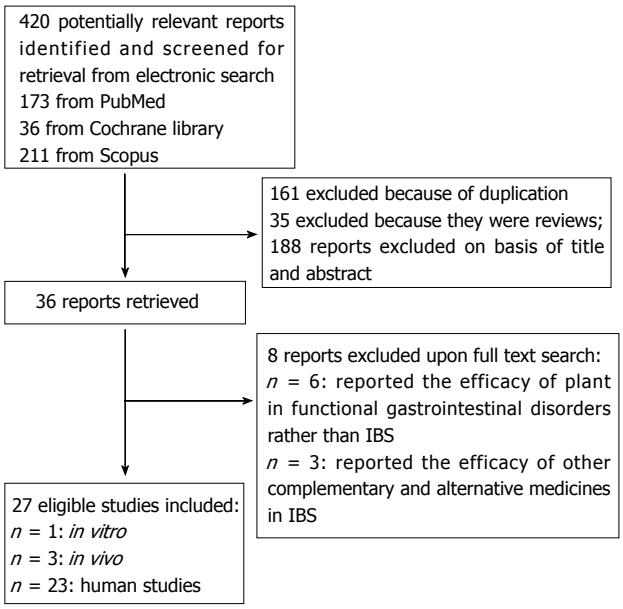

Figure 1 Flow diagram of the study selection process. IBS: Irritable bowel syndrome.

INVESTIGATED HERBAL PREPARATIONS IN IBS

Single preparations

Preparations containing only one herb and investigated in IBS are discussed below and also in Table 1.

Aloe vera

Fifty-eight patients with IBS were randomized to receive *Aloe vera* or matching placebo for a month but no significant difference was found between Aloe and placebo groups[17].

Curcuma species

Eight-week treatment of IBS patients with Curcuma longa extract tablet decreased IBS prevalence and abdominal pain/discomfort score significantly between baseline and after treatment. There were significant improvements in the IBS quality of life (QOL) scales. Approximately two thirds of all subjects reported an improvement in symptoms after treatment, and there was a favorable shift in self-reported bowel pattern[18]. In a randomized, double-blind, placebo-controlled trial, IBS patients were randomly assigned to receive Curcuma xanthorriza or placebo. IBS-related pain increased in the Curcuma group and decreased in the placebo group. IBS-related distension showed a greater reduction in the placebo group compared to the curcuma group. Additionally, the global assessment of changes in IBS symptoms and psychological stress due to IBS did not differ significantly among the two treatment groups. Thus, Curcuma xanthorriza did not show any therapeutic benefit over placebo in patients with IBS[19]. Thus, the species of Curcuma used is an important factor in determining its efficacy in IBS. The efficacy of Curcuma in IBS may be due to bactericidal[20], anti-inflammatory[21], and spasmolytic[22] activities.

Cynara scolymus

Cynara scolymus was demonstrated to have both preventive and curative roles in IBS. The leaf extract of Cynara scolymus was evaluated in healthy volunteers suffering concomitant dyspepsia and showed a 26.4% fall in IBS incidence after treatment. A significant shift in self-reported usual bowel pattern away from "alternating constipation/diarrhea" toward "normal" was observed. The nepean dyspepsia index (NDI) total symptom score significantly decreased by 41% after treatment. Similarly, there was 20% improvement in the NDI total QOL score in the subset after treatment[23]. When the leaf extract of Cynara scolymus was administered to patients with IBS for 6 wk, a significant reduction in the severity of symptoms was observed. Ninety-six percent of patients rated this extract better than or at least equal to previous therapies administered for their symptoms. Furthermore, the tolerability of Cynara scolymus extract was very good[24]. It was reported that Cynara scolymus affects intestinal microbiota[25] and has antispasmodic activity[26].

Fumaria officinalis

The efficacy of Fumaria officinalis, because of its antispasmodic activity, has been investigated in IBS patients. In the randomized, double-blind, placebo-controlled trial, IBS-related pain decreased more in the fumitory group compared to the placebo group. IBS-related distension decreased in the placebo group and increased in the fumitory group. Additionally, the global assessment of changes in IBS symptoms and psychological stress due to IBS did not differ significantly among the two treatment groups[19].

Table 1 Single herbs used for treatment of irritable bowel syndrome

Scientific name	Part	Type of study	Model	Concomitant drugs	Duration of study	Results	Ref.
Aloe vera	Gel	Placebo-controlled double-blind trial	IBS patients	-	1 mo	No difference between treatment and placebo groups in response to treatment at 1 mo diarrhea-predominant patients showed a trend towards a response to treatment at 1 mo	[17]
Curcuma longa	Rhizome	Partially blinded, randomized, two-dose, pilot study	IBS patients	-	8 wk	↓Abdominal pain/discomfort score Significant improvements in IBS QOL scales Approximately two thirds of all subjects reported an improvement in symptoms after treatment	[18]
Curcuma xanthorrhiza	Rhizome	Randomized, double-blind, placebo-controlled trial	IBS patients	-	18 wk	↑IBS-related pain ↓IBS-related distension but more decrease was seen in placebo The global assessment of changes in IBS symptoms and psychological stress due to IBS did not differ significantly among groups	[19]
Cynara scolymus	Aqueous-alcohol extract of leaf	Postmarketing surveillance study	IBS patients	-	6 wk	↓Severity of symptoms reported by both physicians and patients 96% of patients rated this drug as better than or at least equal to previous therapies Very good tolerability	[24]
	Aqueous extract of leaf	Dose-ranging, open, postal study	IBS patients	-	2 mo	↓IBS incidence by 26.4% A significant shift in self-reported usual bowel pattern away from "alternating constipation/diarrhea" toward "normal" ↓NDI total symptom score by 41% 20% improvement in the NDI total QOL score	[23]
Fumaria officinalis	Whole plant	Randomized, double-blind, placebo-controlled trial	IBS patients	-	18 wk	↓IBS-related pain ↑IBS-related distension The global assessment of changes in IBS symptoms and psychological stress due to IBS did not differ significantly among group	[19]
Hypericum perforatum	Aerial parts	Randomized, double-blind, placebo-controlled trial	IBS patients	-	12 wk	↓Overall BSS in both groups with the placebo arm having significantly lower scores at 12 wk compared with Hypericum group A similar proportion of subjects in each treatment group believed that the study drug they received decreased IBS life interferences	[28]
		Open-label, uncontrolled trial	IBS women	-	8 wk	↓autonomic nervous system to different stressor Improvement of Gastrointestinal symptoms of IBS	[29]
Iberis amara	Whole plant extract	Double-blind, randomized, placebo-controlled, multicentre trial	IBS patients	-	4 wk	Significant improvement in IBS symptom scale and abdominal pain scale in Iberis group compared with placebo	[44]
Maranta arundinacea	Root	Uncontrolled	Diarrhea predominant- IBS patients	-	1 mo	↓Diarrhoea ↓Abdominal pain	[30]
Menthe piperita	Essence	Prospective double blind placebo-controlled randomized trial	IBS patients	-	4 wk	75% of the patients in the treatment group showed a > 50% reduction of basal total IBS symptoms score compared with 38% in the placebo group ($P < 0.009$) a statistically significant reduction of the total IBS symptoms score in treatment group compared with T (0), while no change was found with the placebo	[34]
		Randomized double-blind placebo-controlled study	IBS patients	-	8 wk	The number of subjects free from abdominal pain or discomfort changed from 0 at wk 0 to 14 at wk 8 in the treatment group and from 0 to 6 in controls ($P < 0.001$). ↓Severity of abdominal pain significantly in the drug group as compared to controls Improvement in the QOL in the treatment group There was no significant adverse reaction	[33]
		Randomized, double-blind controlled trial	IBS patients	-	2 wk	76% of the patients receiving peppermint oil reported changes in the severity of symptom scale at the end of trial compared with 19% receiving placebo Improvements in the change of symptom scale in 71% of the patients receiving peppermint oil compared with 43% receiving placebo	[35]

			IBS patients	-	1 mo	No significant differences between groups in the Gastrointestinal Symptom Rating Scale No changes in symptoms such as abdominal rumbling, abdominal distention, belching, gas, and heartburn in treatment group compared with placebo Mean severity of pain symptoms in the treatment group was significantly lower than that in the placebo Significant reduction in the abdominal pain, abdominal distension, stool frequency, borborygmi, flatulence in the treatment group compared to placebo Symptom improvements after essence therapy were significantly better than after placebo No significant changes in liver function test results.	[32]
Paeonia lactiflora	Paeoniflorin; Active principle of root	*In vivo*	Neonatal maternal separation-induced visceral hyperalgesia in rats	-	Single dose	A dose-dependent analgesic effect Blockage of analgesic effect of Paeoniflorin by norbinaltorphimine, dl-α-methyltyrosine, and yohimbine. Analgesic effect may be mediated by kappa-opioid receptors and α(2)-adrenoceptors in the central nervous system	[39]
Plantago psyllium	Seed	Randomized placebo controlled trial	IBs patients	-	12 wk	Significantly greater proportion of responders in the psyllium group than in the placebo group ↓Symptom severity significantly in the psyllium group compared with the placebo No differences in QOL	[40]

IBS: Irritable bowel syndrome; QOL: Quality of life; NDI: Nepean dyspepsia index; BSS: Bowel symptom score.

Hypericum perforatum

Hypericum perforatum is a popular herbal medicine for the treatment of depression and it may be beneficial in the management of IBS by modulating psychological stress and serotonin[27]. The efficacy of Hypericum perforatum (St John's wort) was evaluated in IBS patients during a 12-wk randomized, double-blind, placebo-controlled trial. The overall bowel symptom score (BSS) from baseline was decreased both in Hypericum and placebo groups whereas the placebo arm showed significantly lower scores at the end of treatment. Individual BSS for diarrhea (D-BSS), constipation (C-BSS), pain or discomfort, and bloating, adequate relief (AR) of IBS of at least 50% during the last 4 wk of therapy and IBS quality-of-life score showed greater improvement in the placebo group when compared with the Hypericum group. Thus Hypericum perforatum showed lower efficacy for treatment of IBS than placebo[28]. Another study showed that Hypericum perforatum can improve the psychologic symptoms and the ANS reactivity to stress and relieve intestinal symptoms in women with IBS. In patients with IBS, intestinal symptoms of IBS were also relieved significantly[29].

Maranta arundinacea

The efficacy of powdered root of Maranta arundinacea (Arrowroot) was assessed in patients with diarrhea predominant-IBS. It reduced diarrhea with a long-term effect on constipation. It also reduced abdominal pain[30].

Mentha × piperita

The evidence for the efficacy of essential oil of Mentha × piperita (peppermint oil) in IBS seems to be more than other herbal preparations[9,31]. In a prospective, randomized, double-blind, placebo-controlled clinical study, the efficacy of an enteric-coated peppermint oil formulation was evaluated in outpatients with IBS. Seventy-nine percent of patients on Mentha capsule experienced an alleviation of the severity of abdominal pain, 83% had less abdominal distension, 83% showed a reduced stool frequency, 73% had fewer borborygmi, and 79% less flatulence. Corresponding figures for the placebo group were: 43% with reduced pain, 29% with reduced distension, 32% with reduced stool frequency, 31% with fewer borborygmi, and 22% with less flatulence. Symptom improvements after Mentha capsule were significantly better than after placebo. No significant side effect was seen in the Mentha group and peppermint oil was well tolerated[32]. In another randomized, double-blind, placebo-controlled study conducted on outpatients with IBS, the number of subjects free from abdominal pain or discomfort changed from 0 at week 0 to 14 at week 8 in the peppermint oil group and from 0 to 6 in the placebo group. The severity of abdominal pain was reduced significantly in the peppermint group as compared to the placebo group. Furthermore, peppermint oil capsule significantly improved the QOL. No significant adverse reaction was reported from peppermint oil capsule[33]. In another study, the effectiveness of an enteric-coated peppermint oil capsule was evaluated in patients with IBS in whom small intestinal bacterial overgrowth, lactose intolerance and celiac disease were excluded. The symptoms evaluated were: abdominal bloating, abdominal pain or discomfort, diarrhea, constipation, feeling of incomplete evacuation, pain at defecation, passage of gas or mucus and urgency at defecation. The number of patients who

showed reduction of the basal total IBS symptoms score in the peppermint oil group was greater than that in the placebo group[34]. In a randomized, double-blind controlled trial of children with IBS, 75% of those receiving peppermint oil showed a reduced severity of pain associated with IBS. At the end of the trial, the peppermint oil group reported a more significant improvement in the change of symptom scale than the placebo group. Symptoms such as changes in abdominal rumbling, abdominal distention, belching, gas, and heartburn exhibited no changes when peppermint oil was compared with placebo. The most predominant effect of peppermint oil was reduction in the severity of abdominal pain. No side effects were reported by either the investigator or patients during the 2-week study period[35]. Mentha was shown to have antimicrobial[36] and antispasmodic[37] activity and cause reduction in gastric motility[38].

Paeonia lactiflora

The root of Paeonia lactiflora is used in many herbal preparations for IBS. Paeoniflorin (PF) is one of the principle active ingredients of the root of Paeonia lactiflora. A dose-dependent analgesic effect was produced by both intraperitoneal and central administration of PF on visceral pain in rats with neonatal maternal separation. Further investigation showed that this effect may be mediated by kappa-opioid receptors and α (2)-adrenoceptors in the central nervous system[39].

Plantago psyllium

The efficacy of seed from Plantago psyllium in IBS was determined during a randomized controlled trial. The proportion of responders was significantly greater in the Plantago group than in the placebo group during the first month and the second month of treatment. After three months of treatment, symptom severity in the Plantago group was reduced by 90 points, compared with 49 points in the placebo group. No differences were found with respect to QOL[40].

COMPOUND PREPARATIONS

Preparations containing more than one herb are discussed below and summarized in Table 2.

Carmint

Carmint is an Iranian herbal medicine containing total extracts of Melissa officinalis, Mentha spicata, and Coriandrum sativum. Thirty-two IBS patients randomly received either carmint or placebo, plus loperamide or psyllium (based on their predominant bowel function), for 8 wk. The severity and frequency of abdominal pain/discomfort were significantly lower in the carmint group than the placebo group at the end of the treatment according to severity and frequency of bloating[41].

A Chinese herbal medicine

A randomized, double-blind, placebo-controlled trial was conducted to determine whether a Chinese herbal medicine (CHM) is of any benefit in the treatment of IBS. This formulation composed of 20 different herbs (Table 2). Compared with patients in the placebo group, patients in the CHM groups showed a significant improvement in bowel symptom and global improvement scores as rated by patients and by gastroenterologists. Patients reported that treatment significantly reduced the degree of interference with life caused by IBS symptoms[42].

Padma Lax

Padma Lax, a complex Tibetan herbal formula (Table 2), was evaluated for safety and effectiveness in treating constipation-predominant IBS in a 3-mo double-blind randomized pilot study. Significant improvement was demonstrated after 3 mo in the Padma Lax group compared to placebo in constipation, severity of abdominal pain, daily activities, incomplete evacuation, abdominal distension and flatus/flatulence. Significantly more Padma Lax patients than placebo patients rated the current treatment superior to previous therapies tried for IBS. Laboratory parameters displayed no clinically significant changes. The primary side effect of Padma Lax was loose stools which improved by lowering dose[43].

STW 5

STW 5 (Iberogast), a formula composed of hydroethanolic extracts of nine herbs, has been prepared for functional gastrointestinal disorders like IBS and its efficacy and mechanisms of action were investigated in several studies. It was significantly better than placebo in reducing the total abdominal pain and the IBS symptom scores. In a double-blind, placebo-controlled, multicentre trial, STW 5-Ⅱ, another formula composed of 6 of 9 herbal extracts used in STW 5, and a preparation containing only one of 9 herbal extracts (extract of Iberis amara) were compared with placebo. STW 5-Ⅱ like STW 5 showed more significant reduction in the total abdominal pain and the IBS symptom scores compared with placebo. There were no statistically significant differences between the mono-extract group and the placebo group[44]. Different mechanisms have been proposed for the efficacy of STW 5 in IBS. A study evaluating STW 5 effects on mucosal secretion in human intestinal mucosa/submucosa preparations and in the human epithelial cell line T84 suggested that this herbal preparation is a secretogogue in the human intestine by direct epithelial actions and through activation of enteric neurons. The prosecretory effect is due to increased epithelial chloride fluxes via cystic fibrosis transmembrane conductance regulator and calcium dependent chloride channels[45]. STW 5 was studied *in vitro* for binding affinities to serotonin (5-HT3 and 5-HT4) and muscarinic (M3) receptors of the intestine that play central roles in the etiology of IBS. STW 5 showed binding affinity to 5-HT4, M3 and to a lesser degree 5-HT3[46]. STW 5 has also controlled visceral hypersensitivity by reducing intestinal afferent sensitivity to mechanical and chemical stimuli in the upper gastrointestinal

Table 2 Combination herbal therapies used for irritable bowel syndrome

Name of preparation	Composition (part)	Type of study	Model	Concomitant drugs	Duration of study	Results	Ref.
Carmint	Mentha piperita (leaf) Melissa officinalis (leaf) Coriandrum sativum (fruit)	Double-blind, randomized, placebo-controlled, multicenter clinical trial	IBS patients	Loperamide or psyllium (based on their predominant bowel function)	8 wk	Severity and frequency of abdominal pain/discomfort were significantly lower in the Carmint group than the placebo group	[41]
CHM	Codonopsis pilosulae (root) Agastaches seu pogostemi (whole plant) Ledebouriella sesloidis (root) Coicis lachryma-jobi (seed) Bupleurum chinensis (whole plant) Artemisia capillaries (whole plant) Atractylodis macrocephalae (rhizome) Magnolia officinalis (bark) Citrus reticulata (pericarp) Zingiber officinale (rhizome) Fraxinus spp. (bark) Poria cocos (sclerotium) Angelica dahurica (root) Plantago spp. (seed) Phellodendron spp. (bark) Glycyrrhiza uralensis (root) Paeonia lactiflora (root) Saussurea lappa (root) Coptidis spp. (rhizome) Schisandra spp. (fruit)	Randomized, double-blind, placebo-controlled trial	IBS patients	-	16 wk	Significant improvement in bowel symptom scores as rated by patients and by gastroenterologists Significant global improvement as rated by patients and by gastroenterologists Patients reported that treatment significantly ↓ the degree of interference with life caused by IBS symptoms	[42]
C-IBS formula	Lactulose Ulmus fulva (bark) Glycyrrhiza glabra (root) Avena sativa (bran)	A two arm, open-label, uncontrolled pilot study	Constipation-predominant IBS	-	2 wk	A 20% increase in bowel movement frequency ↓ in straining, abdominal pain, bloating, and global IBS symptom severity improvements in stool consistency well-tolerated	[54]
DA-IBS formula	Vaccinium myrtillus (fruit) Ulmus fulva (bark) Cinnamomum zeylanicum (bark) Agrimonia eupatoria (aerial part)	A two arm, open-label, uncontrolled pilot study	Diarrhea-predominant and alternating bowel habit IBS patients	-	2 wk	a small, but significant increase in bowel movement frequency ↓ in straining, abdominal pain, bloating, flatulence, and global IBS symptoms well-tolerated	[54]

Iberogast (STW 5)	Iberis amara (whole plant) Chelidonium majus (root) Silybum marianum (fruit) Melissa officinalis (leaf) Carum carvi (fruit) Glycyrrhiza glabra (root)	*In vitro*	Human intestinal mucosa/submucosa preparations human epithelial cell line T84 human enteric neurons			A dose-dependent increase in ion secretion in human tissue and T84 cells evoke an increased spike discharge in 51% of human submucous neurons	[45]
	Angelica sinensis (root) Matricaria recutita (flower) Mentha piperita (leaf)	*In vivo*	Wistar rats	-	Single dose	↑Afferent discharge to 5-HT and bradykinin dose-dependently	[47]
		Double-blind, randomized, placebo-controlled, multicentre trial	IBS patients	-	4 wk	Significant improvement in IBS symptom scale and abdominal pain scale in STW 5 group compared with placebo	[44]
STW 5-Ⅱ	Iberis amara (whole plant) Melissa officinalis (leaf) Carum carvi (fruit) Glycyrrhiza glabra (root) Matricaria recutita (flower) Mentha piperita (leaf)	Double-blind, randomized, placebo-controlled, multicentre trial	IBS patients	-	4 wk	Significant improvement in IBS symptom scale and abdominal pain scale in STW 5-Ⅱ group compared with placebo	[44]
Padma Lax	Aloe barbadensis A. ferox (extract) Jateorhiza palmata (root) Marsdenia condurango (bark), Rhamnus frangula (bark) Gentiana lutea (root) Inula helenium (rhizome) Terminalia chebula (fruit) Piper longum (fruit) Rhamnus purshiana. (bark) Rheum palmatum (root) Strychnos nux-vomica (seed) Zingiber officinale (root)	Randomized, double-blind, placebo-controlled trial	Constipation predominant-IBS patients	-	3 mo	Significant improvement compared to placebo in constipation, severity of abdominal pain, incomplete evacuation, abdominal distension and flatus/flatulence Significantly more Padma Lax patients compared to placebo rated the current treatment superior to previous therapies tried for IBS Laboratory parameters displayed no clinically significant changes	[43]
TXNG	Paeonia lactiflora (root) Atractylodes macrocephala (rhizome) Citrus reticulate (green unripe exocarp)	Prospective, randomized, double-blind, placebo-controlled trial	Diarrhea predominant-IBS patients	-	3 wk	↓IBS-related pain in the TXNG group compared with the placebo ↓Frequency and the duration of abdominal pain between the TXNG group and the placebo Improvement of IBS-related stool in form or appearance in the TXNG group in comparison with the placebo	[52]

	Allium macrostemon (bulb)					↓Stool frequency in the TXNG group compared with the placebo Improvement of stool passage (urgency or Feeling of incomplete rectal emptying) in the TXNG group compared with the placebo. Improvement in IBS-related diarrhea in the TXNG group compared to placebo No statistical difference in either the effective time of IBS-related pain or the effective time of IBS-related diarrhea between the two groups ↓IBS-related pain alleviation time and the IBS-related diarrhea alleviation time in the TXNG group compared to those in the placebo group	
TXYF	Atractylodes macrocephala (rhizome)	*In vivo*	Maternal separation-induced visceral hypersensitivity rats	-	2 wk	↓Pain threshold pressure and abdominal withdrawal reflex scores in a dose-dependent manner	[54]
	Paeonia lactiflora (root) Citrus sinensis (dried old peel) Ledebouriella divaricata (root)					↓ 5-HT levels in serum ↓Corticotrophin releasing factor concentrations in the brain Visceral hypersensitivity alleviation was dependent on the substance P expression in the colon mucosa	
		Randomized placebo-controlled trial	Diarrhea predominant-IBS patients	Miyarisan	4 wk	No significant difference between two groups in terms of the total efficacy or the scores of symptoms before and after treatment ↓The number of activated mast cells in the intervention	[53]
TCM	Atractylodes macrocephala (rhizome)	Randomized placebo-controlled trial	Diarrhea predominant-IBS patients	-	16 wk (8 wk drug administration +8 wk follow up)	No significant difference in the proportion of patients with global symptom improvement between the TCM and placebo groups at week 8 and at week 16	[51]
	Astragalus membranaceus (root) Paeonia lactiflora (peeled root, fried) Atractylodes chinensis (rhizome) Bupleurum chinense (root) Citrus reticulata (peel) Saposhnikovia divaricata (root) Paniculata (twigs) Punica granatum (rind) Portulaca oleracea (above-ground parts) Coptis chinensis (rhizome)					No difference in individual symptom scores and the quality-of-life assessment between the two groups at all time points	

CHM: Chinese herbal medicine; TXNG: Tong-xie-ning; TXYF: Tong-Xie-Yao-Fang; TCM: Traditional Chinese Medicine; 5-HT: Serotonin; spp.: Schisandra chinensis.

tract in male Wistar rats. Following the different doses of serotonin and bradykinin, the peak in afferent nerve discharge was always reduced after pretreatment with STW 5 compared to controls. The ramp distension of the intestinal loop stimulated a rise in intestinal afferent nerve discharge that was lower in the STW 5 pretreated group compared to controls[47]. STW 5 decreased acetylcholine- and histamine-induced contraction of guinea pig ileum. This was also true for extracts of some constituents of this compound formula including Mentha piperita leaf, Matricaria recutita flower and Glycyrrhiza uralensis root. Extract from Iberis amara, however, showed no spasmolytic action; on the contrary, it increased the basal resting tone and contraction of atonic ileal segments. These data may explain, at least in part, the clinically observed therapeutic efficacy of STW 5 in both hypotonic and spastic

dysmotility symptoms of IBS[48]. Another study on STW 5 and its components showed that STW 5 evoked a relaxation of the proximal stomach but increased antral motility whereas both effects are myogenic. The extracts of Angelica sinensis root, Matricaria recutita flower and Glycyrrhiza uralensis root mimicked the inhibitory effects in the proximal stomach whereas the extracts of Chelidonium majus, Melissa officinalis leaf, Carum carvi fruit and Iberis amara increased motility of the proximal stomach. All extracts increased motility in the antrum comparable to the effects of STW 5[49]. These data justify the differential effect of STW 5 which is a result of the combined actions of its individual components explaining the clinically observed therapeutic efficacy of STW 5 in both hypotonic and spastic dysmotility symptoms of IBS. Moreover, STW 5 reduced inflammation-induced alterations in ileum/jejunum segments. The effects were associated with a restoration of the disturbed acetylcholine-induced contraction, pathohistological protection and inhibition of tumor necrosis factor (TNF)-α[50].

A traditional Chinese medicine

Therapeutic efficacy of a traditional Chinese medicine (TCM) (Table 2) was investigated in patients with diarrhea-predominant IBS. There was no significant difference in the proportion of patients with global symptom improvement between the TCM and placebo groups. Moreover, there was no difference in individual symptom scores and the quality-of-life assessment between the two groups[51].

Tong-xie-ning

Tong-xie-ning (TXNG) is a traditional Chinese medicine composed of four different herbs. The efficacy of this preparation was evaluated in diarrhea predominant-IBS patients by a prospective, randomized, double-blind, placebo-controlled trial. IBS-related pain measured by the numeric pain intensity scale in the TXNG group, significantly decreased as compared with the placebo group. A total of 82.7% of the patients reported a reduction in IBS-related pain in the TXNG group compared with 39.3% in the placebo group. Furthermore, there was a significant reduction in the frequency and the duration of abdominal pain between the TXNG group and the placebo group. In addition, IBS-related stools improved in form or appearance in the TXNG group in comparison to the placebo group. The stool frequency was significantly decreased in the TXNG group compared with the placebo group. Moreover, stool passage (urgency or feeling of incomplete rectal emptying) in the TXNG group was significantly improved when compared with the placebo group. There was a 20.7% and 42.9% loss of appetite in the TXNG and placebo groups, respectively. An observable improvement in IBS-related diarrhea was seen in 86.2% of subjects in the TXNG group and 42.9% of subjects in the placebo group. There was no statistical difference in either the effective time of IBS-related pain or the effective time of IBS-related diarrhea between the two groups. However, the IBS-related pain alleviation time and the IBS-related diarrhea alleviation time in the TXNG group were markedly shorter than those in the placebo group[52].

Tong-Xie-Yao-Fang

Tong-Xie-Yao-Fang (TXYF) is a prescription in TCM, prepared from four herbs (Table 2). A study was done to compare the efficacy of this formulation with Myarisan, a probiotic formulation, in treating diarrhea-predominant IBS. No significant difference between the two groups in terms of the total efficacy or the scores of symptoms before and after treatment was found. In this study, the number of activated mast cells was decreased in the TXYF group after treatment, showing a significant difference as compared with that before treatment as well as with that in the Myarisan group after treatment. This result suggested that the mechanism of action of TXYF might be through adjustment of mast cells activation to decrease visceral hypersensitivity[53]. This product has been investigated in experimental visceral hypersensitivity models that showed a dose-dependent analgesic effect. It significantly decreased serotonin levels in serum and CRF concentrations in the brain. Moreover, it was found that visceral hypersensitivity alleviation by TXYF was dependent on substance P (SP) expression in the colon mucosa[54].

C-IBS and DA-IBS formulations

The efficacy and tolerability of C-IBS (Table 2), a formula designed to treat constipation-predominant IBS, and DA-IBS, a formula designed to treat diarrhea-predominant and alternating bowel habit IBS, were evaluated in an uncontrolled study. Ingestion of the DA-IBS formula was associated with a small, but significant, increase in bowel movement frequency. Reductions in straining, abdominal pain, bloating, flatulence, and global IBS symptoms were also demonstrated in patients using this formula. Subjects in the C-IBS group experienced a 20% increase in bowel movement frequency and significant reductions in straining, abdominal pain, bloating, and global IBS symptom severity, as well as improvements in stool consistency. Both formulas were well-tolerated[55].

CONCLUSION

In this paper, different herbal preparations investigated for the management of IBS and their possible mechanisms of action were reviewed. Among the single preparations, the most evidence for efficacy in IBS patients was found for essential oil of Mentha piperita. Some single preparations including Aloe vera, Curcuma xanthorriza, Fumaria officinalis showed no benefit in IBS. There are conflicting results for the efficacy of Hypericum perforatum in IBS. Among compound preparations, most studies had been performed with STW 5, a formula containing hydroethanolic extract of 9 herbs. Hopeful results come from the efficacy of this herbal preparation

in the management of IBS with different mechanisms of action such as anti-inflammatory, prosecretory activity, and affecting gastrointestinal motility. Because of multifactorial nature of the pathophysiology of IBS, it seems that compound preparations can be more efficacious than single ones. Despite the wide prevalence of IBS, there are few studies on the use of herbal medicine in IBS and most studies in this area have focused on the use of peppermint oil and STW 5; while it seems that more effective herbal preparations can be found. For example, in traditional Iranian medicine (TIM) many single and compound herbal preparations have been introduced for the management of various gut disorders such as IBS[56]. Among the herbal contents of this preparations, oleogumresin from Boswellia carterii, fruit of Trachyspermum amum, flower of Eugenia caryophyllata, gall of Quercus infectoria, seed of Nigella sativa, fruit of Cuminum cyminum, tabasheer (a hard, whitish, translucent substance extracted from the joints of different Bambusa species), and fruit of Cucurbita pepo can be stated[57-59]. There is evidence in modern phytotherapy for the beneficial effects of these plants in IBS. Boswellia carterii has shown anti-inflammatory[60,61] and immunomodulatory activity[62]. An *in vitro* study demonstrated that Trachyspermum copticum has a beneficial effect on intestinal microbiota by inhibiting the growth of potential pathogens[63]. Eugenia caryophyllata has anti-inflammatory[64], immunomodulatory[65], and antimicrobial[66] properties. Gall of Quercus infectoria possesses anti-inflammatory[67] and antibacterial[68] activity. Nigella sativa showed anti-inflammatory, antimicrobial, and immunomodulatory activity[69]. Antimicrobial properties were reported for Cuminum cyminum[70] and Cucurbita pepo[71]. However, more studies are required to get more conclusive results about the efficacy of these herbs in IBS.

Abstract

Epithelial-to-mesenchymal and mesenchymal-to-epithelial transitions are well established biological events which have an important role in not just normal tissue and organ development, but in the pathogenesis of diseases. Increasing evidence has established their presence in the human colon during colorectal carcinogenesis and cancer invasion, chronic inflammation-related fibrosis and in the course of mucosal healing. A large body of evidence supports the role for transforming growth factor-β and its downstream Smad signaling, the phosphatidylinositol 3'-kinase/Akt/mTOR axis, the Ras-mitogen-activated protein kinase/Snail/Slug and FOXC2 pathway, and Hedgehog signaling and microRNAs in the development of colorectal cancers *via* epithelial-to-mesenchymal transition. C-met and Frizzled-7, among others, seem to be the principle effectors of mesenchymal-to-epithelial transition, hence have a role not just in mucosal regeneration but in the progression of colonic wall fibrosis. Here we discuss a role for these pathways in the initiation and development of the transition events. A better understanding of their induction and regulation may lead to the identification of pathways and factors that could be potent therapeutic targets. The inhibition of epithelial-to-mesenchymal transition using mTOR kinase inhibitors targeting the ATP binding pocket and which inhibit both mTORC1 and mTORC2, RNA aptamers or peptide mimetics, such as a Wnt5A-mimetic, may all be useful in both cancer treatment and delaying fibrosis, while the induction of mesenchymal-to-epithelial transition in induced pluripotent stem cells may enhance epithelial healing in the case of severe mucosal damage. The preliminary results of the current studies are promising, but more clinical investigations are needed to develop new and safe therapeutic strategies for diseases of the colon.

Key words: Epithelial-to-mesenchymal transition; Mesenchymal-to-epithelial transition; Colorectal cancer; Fibrosis; Mucosal healing

INTRODUCTION

Human colonic diseases are some of the most common diseases worldwide, and their incidence is increasing[1,2]. Although the diversity of the etiologic and pathophysiologic factors of colonic diseases is very wide, there exist two biological processes whose presence is indispensable in the progression or healing phase of these conditions.

One of these processes is the epithelial-to-mesenchymal transition (EMT), which has a significant role in the

development of the human body. EMT is also involved in the initial step, acquisition of migratory and invasive capability of colorectal cancer (CRC), and even has an important role in tissue fibrosis[3].

The other process is a reverse phenomenon, namely the mesenchymal-to-epithelial transition (MET). MET is also essential for normal tissue and organ development, but it is also involved in colorectal carcinogenesis, and it seems to have an important role in colonic mucosal regeneration[4,5].

The induction and regulation of these complex, reversible biological programs are not fully understood. Therapeutically, the influence of EMT and MET is recognized, but, unfortunately, the exact description of these biological phenomena is still missing. As the understanding of the steps of EMT and MET is of great clinical importance, and, at the same time, data about their complex induction and regulation, as well as their role in the pathogenesis of colonic diseases are scarce in the scientific literature, we aimed to summarize the current knowledge in this review.

EPITHELIAL-TO-MESENCHYMAL TRANSITION

EMT is a physiological mechanism which is present during development, including mesoderm formation and neural tube formation, and is also encountered in several pathological situations, such as renal interstitial fibrosis, endometrial adhesion, and cancer metastasis[3].

Cells that undergo EMT exhibit dramatic shape changes during which they can lose many of their epithelial characteristics, such as the loss of apico-basal polarity and cell adhesion, the repression of E-cadherin, occludin, tight junction protein 1, or cytokeratin expression, and increased cell mobility[6]. At the same time, elevated expression of tyrosine kinases or their activation, upregulation of N-cadherin, vimentin, fibronectin, zinc-finger domain proteins (SNAI1/SAIL, SNAI2/SLUG, ZEB2/SIP1), and matrix metalloproteinases, as well as basic helix-loop-helix domain protein Twist1 expression are often linked to a mesenchymal-like phenotype[7,8].

EMT INDUCTION AND REGULATION

Several oncogenic pathways (i.e., peptide growth factors, Src, Ras, integrin, Wnt/β-catenin, Notch) may induce EMT (Figure 1).

Transforming growth factor-β (TGF-β) is a potent inducer of EMT. TGF-β directly activates the expression of transcription factors such as SNAI1/2, Twist and ZEB1/2. These factors are the key regulators of the EMT program[9].

The Src SH3 and SH2 domains cooperate with extracellular signal-regulated kinase (ERK), MEK (ERK kinase), myosin light chain kinase (MLCK), and Rho-dependent protein kinase (ROCK) signaling to accumulate phosphomyosin at the colon cancer cell periphery and promote a mesenchymal-like phenotype[6]. It was recently shown that actomyosin contractility is a key determinant of EMT[6].

Ras-mitogen-activated protein kinase has been shown to activate two related transcription factors, namely Snail and Slug, both of which are transcriptional repressors of E-cadherin, and their expression induces EMT[10].

Recently, activation of the phosphatidylinositol 3'-kinase (PI3K)/Akt axis has emerged as a central feature of EMT[11]. Activation of PI3K/Akt signaling is associated with growth and progression of CRC. It was reported that the mTOR kinase, a downstream effector of PI3K/Akt signaling, regulates tumorigenesis in CRC[12,13]. Increased expression of mTOR, Raptor, and Rictor mRNA was noted with advanced stages of CRC, suggesting that mTOR signaling may be associated with CRC progression and metastasis[14]. Gulhati *et al*[14] showed that the inhibition of mTORC1 and mTORC2 attenuated migration and invasion of colon cancer cells concomitant with altered cytoskeletal rearrangement and decreased activation of RhoA and Rac1. The inhibition of mTORC1 and mTORC2 induces changes reminiscent of mesenchymal-to-epithelial transition, and it was also shown that the establishment of metastasis *in vivo* was completely abolished upon targeted inhibition of mTORC1 and mTORC2. Based on these results, one may propose that mTORC1 and mTORC2 regulate motility of colon cancer cells *via* RhoA and Rac1 signaling[11]. Twist, another transcription factor, has been shown to possibly induce EMT too, and is also implicated in the regulation of metastasis[7,8].

Expression of FOXC2, an important element of embryonic development is supposed to induce EMT and regulate metastasis. In addition, the expression of FOXC2 is induced when epithelial cells undergo EMT by Snail, Twist, Goosecoid, and TGF-β1[15-17].

The majority of human colon cancers carry mutations that lead to the activation of Wnt signaling, a pathway that also has a pivotal role in intestinal stem cell biology[18]. Despite the underlying genetic background, cells within individual tumors display differential Wnt signaling, suggesting further regulation by the microenvironment. A local loss of basement membrane at the invasive edge has been suggested to expose cancer cells to a different microenvironment, which promotes Wnt signaling (nuclear β-catenin expression), EMT-like changes and loss of differentiation[19]. Type 1 collagen is a known component of the microenvironment at the host–tumor interface in CRC[20], and is more highly expressed in tumors displaying infiltrative growth compared with those with expansive growth[21]. Type 1 collagen also reduces CDX2 expression, an early marker of epithelial commitment, in human CRC cell lines *in vitro*[20], and enhances tumorigenicity in human CRC cells in xenografts[22]. Integrin α1β2 has a central role in type 1 collagen-induced EMT[23].

Hedgehog signaling cascade cross-talks with Wnt, epithelial growth factor/fibroblast growth factor, and TGFβ/Activin/Nodal/bone morphogenic protein signaling cascades, which are implicated in EMT through

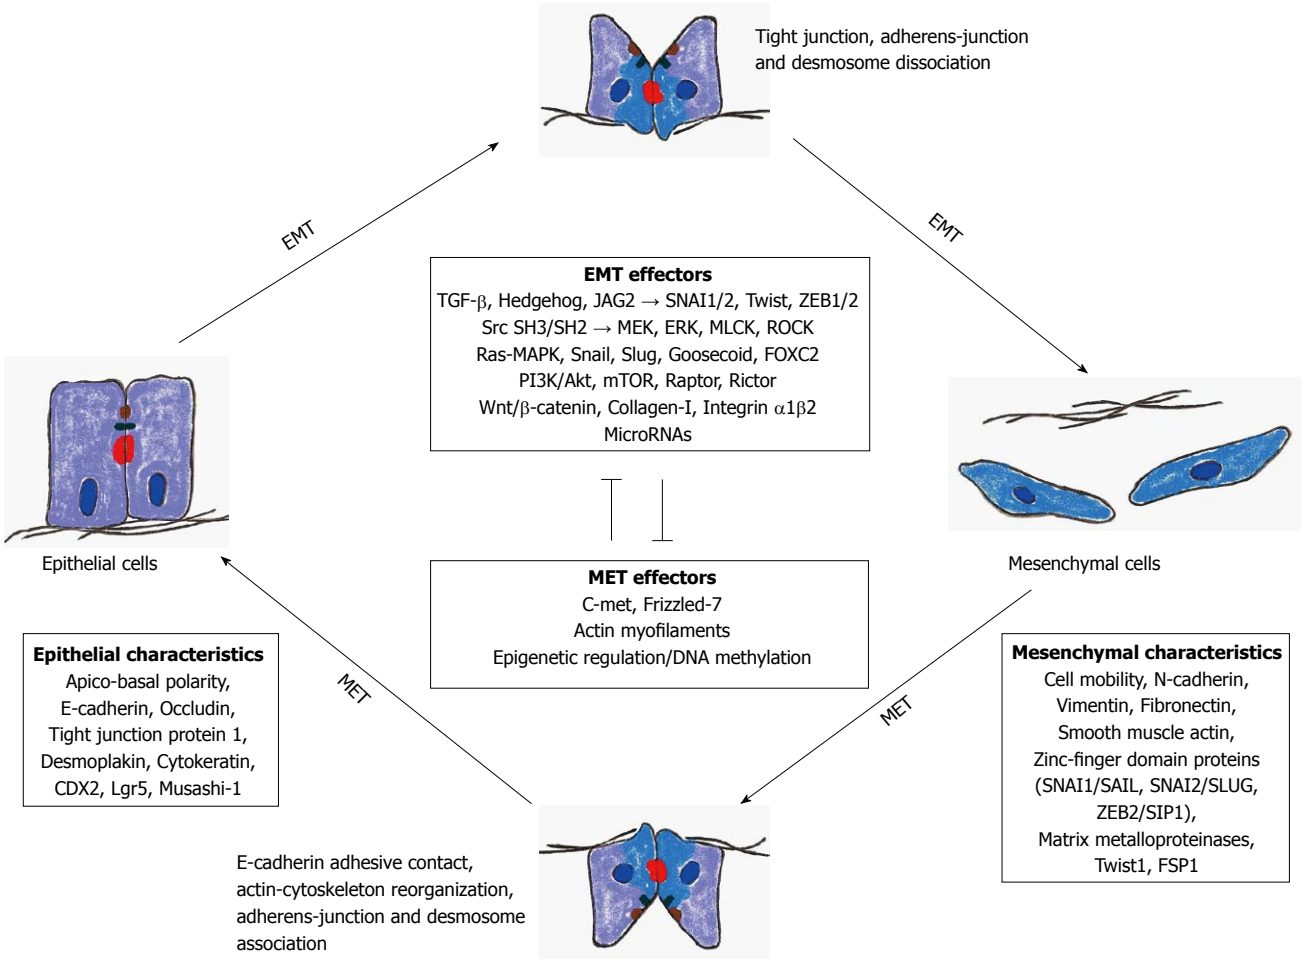

Figure 1 Schematic view of the effector pathways associated with epithelial-to-mesenchymal transition and mesenchymal-to-epithelial transition. EMT: Epithelial-to-mesenchymal transition; MET: Mesenchymal-to-epithelial transition; TGF-β: Transforming growth factor-β; MAPK: Mitogen-activated protein kinase; ERK: Extracellular signal-regulated kinase; MEK: MAPK/ERK kinase; MLCK: Myosin light chain kinase; ROCK: Rho-dependent protein kinase.

E-cadherin repression[8,24,25]. Although the Hedgehog signaling cascade induces the SNAI1 upregulation, there is no evidence for its direct SNAI1 transcriptional activation. On the other hand, Hedgehog signals induce JAG2 upregulation, and TGF-β1 secretion to promote motility and invasiveness of cancer cells[26]. JAG2 signaling induces transition of the Notch receptor to the Notch intracellular domain (NICD). NICD is then associated with the CSL transcription factor in the nucleus to induce SNAI1 upregulation[27]. TGF-β1 activates the TGF-β receptor for nuclear factor-κB-mediated transcriptional upregulation of ZEB1 and ZEB2 (zinc-finger transcription factors)[28], and also for the SMAD-Sp1-mediated transcriptional upregulation of mesenchymal markers, such as vimentin. Together these facts indicate that the Hedgehog signals indirectly induce EMT through the upregulation of multiple EMT regulators *via* Notch and TGF-β signaling cascades[29].

The 20-22 bp nucleotide noncoding RNAs, the microRNAs (miRNAs), regulate gene expression at post-transcriptional levels. Earlier profiling experiments have identified cohorts of miRNAs whose levels undergo significant changes upon TGF-β induced EMT, suggesting possible involvements of miRNAs in this process[30]. The miR 200 family has been linked to inhibition of EMT (promotion of the epithelial phenotype) through inhibition of ZEB1/2, known transcriptional repressors of the human E-cadherin gene[31].

In LIM 1863 colon carcinoma cells, the upregulation of miR-21 and miR-31 had been reported during EMT[32]. Overexpression as well as inhibition experiments support the contributions of both miR-21 and miR-31 not only in the TGF-β-induced morphological changes, but also in cell motility and invasion. It was also shown that T lymphoma and metastasis gene 1 (*TLAM1*) is a direct target of both miR-21 and miR-31, and that the suppression of *TLAM1* is important for the pro-migration and invasion activities of miR-21 and miR-31. Based on these results, miR-21 and miR-31 were indentified as positive regulators of the EMT in colon carcinoma cells[32].

Interestingly, it was recently shown[33] that nicotine enhanced the expression level of fibronectin, an important EMT-related maker, in a dose-dependent manner. Furthermore, an α7-nicotinic acetylcholine receptor antagonist and siRNA reversed the nicotine-enhanced fibronectin expression in both SW480 and DLD-1 cells[33].

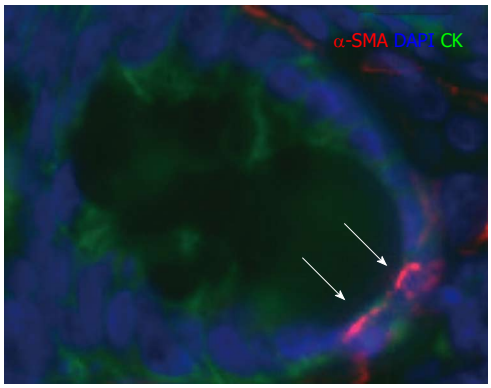

Figure 2 Chronic, fibrotizing phase of inflammatory bowel disease. The arrowed cytokeratin (CK) positive epithelial cells in a colonic crypt show α-smooth muscle actin (α-SMA) positivity. The initiation of the epithelial-to-mesenchymal transition is possible. (α-SMA: Red; CK: Green; nuclear counter-staining: Blue; fluorescence immunohistochemistry, taken by virtual microscope). DAPI: 4',6'-diamidino-2-phenylindole hydrochloride.

ROLE OF EMT IN PATHOLOGICAL CIRCUMSTANCES

The switch between epithelial and mesenchymal phenotypes occurs during the advanced stages of cancer development. As a general rule, epithelial cancer cells that have undergone EMT are thought of as being more migratory, which may contribute to the invasive or metastatic phenotype.

In adult organisms, it has been proposed that restrictive mechanisms repress EMT and MET[34]. During tumor development, these mechanisms appear to fail, allowing EMT as described in metastasis generation[35]. Colonic stroma tissue, including subepithelial lymphoid aggregates surrounding the cancer cells, plays an important role in both EMT regulation and tumor behavior. Mesker *et al*[36] analyzed the expression of markers involved in pathways related to stroma production and EMT (β-catenin, TGF-β-R2, Smad4) in high-risk CRC patients, and found that patients with high stroma and Smad4 loss are at high risk. The anti-EMT effect of Smad4 was also proven in colon carcinoma cells[37].

Besides colon cancer cell migration and invasion, EMT is also involved in organ fibrosis. The epithelium has been proposed to be a significant source of matrix-producing fibroblasts and of myofibroblasts[38]. Tissue accumulation of myofibroblasts shows strong correlation with the severity and progression of colonic fibrosis[39]. TGF-β1 has been long known as the chief inducer not just of EMT, but fibrosis, and myofibroblast generation. Accordingly, receptor Smads (Smad2 and particularly Smad3), the direct targets of the activated TGF-β receptor have been implicated as critical mediators in fibrogenesis and EMT[40,41] (Figure 2).

THERAPEUTIC ASPECTS OF EMT

Inhibition of EMT would be an ideal choice for the treatment of CRC, as well as colonic fibrosis developed on the basis of chronic inflammation. Despite the incontrovertible rationale for treating diseases belonging to PI3K/Akt/mTOR signaling with rapamycin, clinical results have been disappointing. One proposed mechanism of resistance to rapamycin arises from its inability to inhibit mTORC2[14,42]. The findings of Gulhati *et al*[11] support a role for elevated mTORC1 and mTORC2 activity in regulating EMT and metastasis of CRC. Taken together with previous results, showing that both mTORC1 and mTORC2 contribute to CRC tumorigenesis[14], it may be hypothesized that the inherent redundancy in functions of both complexes may allow mTORC2 to compensate for loss of mTORC1 activity upon rapamycin treatment, thereby leading to rapamycin resistance. Based on these data, Gulhati *et al*[11] provides the rationale for including mTOR kinase inhibitors targeting the ATP binding pocket, which inhibit both mTORC1 and mTORC2 more completely, as part of the therapeutic regimen for treating CRC patients.

miRNAs targeted to mRNAs, encoding stem cell signaling components or EMT regulators, are also potent drug targets. miRNAs inducing proliferative, anti-apoptotic, pro-angiogenic, or pro-metastatic effects on tumor cells could be downregulated for cancer therapy, while those with proapoptotic, anti-angiogenic, or anti-metastatic effects could be applied for synthetic miRNA[43,44]. An RNA aptamer is a short RNA oligonucleotide with a stable 3D structure[44]. RNA aptamers binding to the extracellular region of Patched1 could be utilized for drug delivery to cancer cells with Hedgehog signaling activation. RNA aptamers binding to the cytoplasmic region of Smoothened, and those binding to Fused or GLI1 could be utilized as Hedgehog signaling inhibitors. Peptide mimetics, resembling Wnt and fibroblast growth factor family members, have been developed[45,46]. Because Wnt5A is involved in the non-canonical signaling cascade for the induction of EMT partly through SNAI1 upregulation[47-50], a Wnt5A mimetic is able to suppress invasion and metastasis of cancer cells. On the other hand, great care should be taken before clinical application of these technologies, as the miRNA and siRNA off-target effects are serious problems.

MESENCHYMAL-TO-EPITHELIAL TRANSITION

Mesenchymal-to-epithelial transition is a reversible biological process that involves the transition from motile, multipolar or spindle-shaped mesenchymal cells to polarized epithelial cells. MET, just like EMT, also takes place during normal development in processes such as somitogenesis, kidney development, cardiogenesis, hepatogenesis and celomic cavity formation[4,51,52], moreover MET occurs in cancer metastasis, induced pluripotent stem cell reprogramming and mucosal healing[5].

While the mechanism in which MET occurs during each organ morphogenesis is similar, in that epithelium-associated genes are upregulated and mesenchymal ones

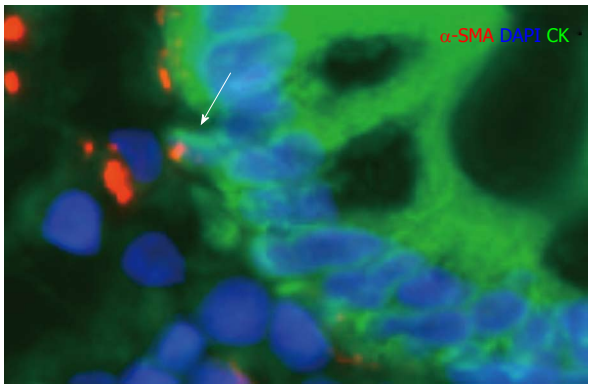

Figure 3 Regenerative phase of ulcerative colitis. The arrowed α-SMA positive pericryptic cell shows cytokeratin (CK) expression. The presence of the mesenchymal-to-epithelial transition is possible. (α-SMA: Red; CK: Green; nuclear counter-staining: Blue; fluorescence immunohistochemistry, taken by virtual microscope). DAPI: 4',6'-diamidino-2-phenylindole hydrochloride.

are downregulated, each process has a unique signaling pathway to induce MET and related changes in gene expression.

Though our knowledge about the mechanism and regulation of EMT in the colon is increasing nowadays, the reverse phenomenon, MET, is still not a well understood mechanism (Figure 1).

MET INDUCTION AND REGULATION

MET during carcinogenesis has been shown to be induced by the c-met proto-oncogene[53-55]. C-met, also known as hepatocyte growth factor receptor, is a receptor tyrosine kinase for hepatocyte growth factor and its increased expression leads to epithelial differentiation[56,57]. In addition to epithelial specification by C-met, 5-azacytidine, a DNA methyltransferase inhibitor with broad spectrum epigenetic effects, has been used to induce MET *in vitro*[58]. Recent research on the transcription factor Snail has been linked to aberrant DNA methylation of the epithelial specific E-cadherin promoter in association with EMT, and stable RNA interference of Snail expression in carcinoma cell lines induced a complete MET[59-61].

Frizzled-7 (FZD7) is necessary for MET in the LIM1863-Mph CRC model. The loss of FZD7 in cancer cells results in the persistence of a mesenchymal state (increased SNAI2/decreased E-cadherin)[62]. Moreover, FZD7 is also required for migration of the LIM1863-Mph monolayer cells. This suggests that FZD7 induced either migratory or epithelialization events depending on the context.

The role of DNA methylation in MET induction and induced pluripotent stem (iPS) cell reprogramming had been also highlighted[63].

In the inflamed colon, signs of MET can be detected in the subepithelial lymphoid follicles[64-66]. These data suggest that migrating stem cells undergoing MET may be sensitive to the chemokine/cytokine milieu of the inflammatory environment.

ROLE OF MET IN PATHOLOGICAL CIRCUMSTANCES

Regarding the colon, the need for MET is high when severe mucosal damage is present. In inflammation, MET can also be altered because mesenchymal stem cells are mobilized to the site of injury and consequently subjected to the inflammatory response[67]. Bone marrow-derived stem cells could differentiate into mature-appearing epithelial cells in response to tissue damage[68]. It was recently published that versican, a large chondroitin sulfate proteoglycan, mediates MET[69]. The results of Hirose *et al*[70] indicate that versican can bind specific chemokines through its chondroitin sulfate chains and by doing so, it tends to downregulate the chemokine function. This raises the possibility that versican is a potent regenerative factor in the colonic mucosa.

In the inflamed colon, the presence of CDX2- and cytokeratin-positive subepithelial cells in the marginal zone of subepithelial lymphoid follicles also suggests that MET may have a role in colonic mucosal regeneration[64]. Presumably the mesenchymal cells committed to an epithelial fate are sensitive for the regeneration-associated paracrine cytokine and chemokine environment in the inflammatory stroma (Figure 3).

THERAPEUTIC ASPECTS OF MET

Induced pluripotent stem cells can be derived from somatic cells by the induction of a small number of genes, like POU5F1, MYC, KLF4 and SOX2[71-74]. Originating from an individual's own tissue, iPS cells offer considerable therapeutic promise, avoiding both immunologic and ethical barriers to their use. Upon induction, mouse fibroblasts must undergo MET to successfully begin the initiation phase of reprogramming. Epithelial-associated genes (i.e., *E-cadherin*, *Claudin-3*, *-4*, *-7*, *-11*, *occludin*, epithelial cell adhesion molecule, *Crumbs homolog 3*) were all upregulated before the turning on of Nanog, a key transcription factor in maintaining pluripotency. Additionally, mesenchymal-associated genes like Snail, Slug, Zeb-1/2, and N-cadherin were downregulated[75].

Epigenetic changes, DNA methylation, seems to be also involved in MET regulation, which may also have therapeutic significance[63].

CONCLUSION

According to our current knowledge, both EMT and MET are highly significant biological events, not just in physiological, but in pathological circumstances. A better understanding of their induction and regulation may lead to the identification of pathways and factors that can be potent therapeutic targets.

The inhibition of EMT seems to be a useful technique to avoid CRC cell invasion and metastasis genera-

tion, and chronic inflammation-related colonic wall fibrosis may be also delayed, or even reversed.

The induction of MET is also of major clinical importance. In the case of severe mucosal damage, the time for complete epithelial regeneration may be reduced by enhancing the phenotype change of mesenchymal stem cells to epithelial cells.

The preliminary results of ongoing studies are promising, but more investigations are needed to develop new therapeutic strategies that can be safely used in the near future.

Abstract

Adamantiades-Behcet's disease (ABD) is a chronic, relapsing, systemic vasculitis of unknown etiology. It is more prevalent in populations along the ancient Silk Road from Eastern Asia to the Mediterranean Basin, and most frequently affects young adults between the second and fourth decades of life. ABD-complicated gastroenteropathy is a significant cause of morbidity and mortality, with abdominal pain as the most common symptom. The ileocecal region is affected predominantly, with ulcerations that may lead to penetration and/or perforation, whereas other parts of the gastrointestinal system including the esophagus and stomach can also be affected. Endoscopy is useful to locate the site and extent of the lesions, and tissue biopsy is often warranted to examine the histopathology that is often suggestive of underlying vasculitis of small veins/venules or, alternatively in some cases, nonspecific inflammation. Bowel wall thickening is the most common finding on computed tomography scan. Treatment is largely empirical since well-controlled studies are difficult to conduct due to the heterogeneity of the disease, and the unpredictable course with exacerbation and remission. Corticosteroids with or without other immunosuppressive drugs, such as cyclophosphamide, azathioprine, sulfasalazine, tumor necrosis factor α antagonist or thalidomide should be applied before surgery, except in emergency.

Key words: Adamantiades-Behcet's disease; Gastroenteropathy; Ulceration; Vasculitis

INTRODUCTION

Adamantiades-Behcet's disease (ABD) is a systemic inflammatory vasculitis of unknown etiology, characterized by relapsing episode of oral aphthous ulcers, genital ulcers, cutaneous and ocular lesions and other manifestations, including vascular, neurological and gastrointestinal involvements[1].

ABD usually occurs between the second and fourth decades of life. Recent epidemiological surveys indicate that male and female are equally affected in ABD[2-4]. ABD is particularly prevalent in ancient "Silk Route" populations from Far East to Middle East to Mediterranean, albeit it has global distribution. The marked geographic predilection of ABD can be explained by its genetics background and/or environmental triggers[1].

ABD-complicated gastroenteropathy (ABD-GE) varies in different populations, being much more frequent in the Far East than in the Middle East and Mediterranean. Several nationwide surveys and large-scale case series

show that ABD-GE is frequent in Japan (16%)[5], Germany (12%)[6], Iran (7.4%)[7], Korea (7.3%)[8] and China (6.5%)[9], but rare in Turkey (1.4%)[10].

The clinical manifestation of ABD-GE may also vary greatly, from mild symptom to life-threatening complications, including perforation, infarction, and massive bleeding resulting from vasculitis and/or thrombosis. Prompt treatment with corticosteroid plus immunosuppressive agents rather than surgery can alleviate the clinical symptoms and improve prognosis of ABD-GE patients. According to the International Study Group Criteria for ABD, diagnosis of ABD requires the presence of recurrent oral ulcers and two of the followings: Genital ulcers, typical eye lesions, typical skin lesions, and positive pathergy test[11]. However, in clinical practice, it is often challenging to make prompt and correct diagnosis when gastroenteropathy is presented as the initial or predominant manifestation in ABD patients, and sometimes is misdiagnosed as inflammatory bowel disease or other disorders. This paper systematically reviews the clinical manifestation and treatment of ABD-GE for the purpose of better managing this life-threatening complication.

MANIFESTATIONS OF GASTROINTESTINAL COMPLICATION

Among the 136 reported gastrointestinal (GI) endoscope cases in the Japanese patients with ABD who required surgery, abdominal pain was found in 92%, abdominal mass in 21%, and melena in 17%[12]. Almost all Japanese juvenile ABD-GE manifested with abdominal pain, bloody stool, high fever, and anal lesions[13]. The main manifestations of ABD-GE are described as follows (Table 1).

Mouth lesions

Almost all patients have recurrent oral ulceration. This is often the first symptom and occurs long before other manifestations appear. Minor aphthous ulcer (< 10 mm in diameter) is the most common type (85%), whereas major (> 10 mm in diameter) and herpetiform ulcers are less frequent. Lesions are usually painful, occur as single ulcer or in crops, with a round or oval appearance with erythematous border (pouched out), covered with grayish-white pseudo-membrane or a central yellowish fibrinous base. They usually heal without scarring. The most commonly involved sites are gingival and buccal mucosa, tongue and lips, although ulcers can also appear in the soft and hard palate, pharynx and tonsils. Histological findings suggest vasculitis with monocyte and lymphocyte infiltration at the early stage of the disease and neutrophils at later stage. Other disorders such as fibrinoid necrosis, endothelial swelling, and perivascular infiltration can also occur in ABD. Although aphthae is often multiple and occurs more frequently in ABD, they are indistinguishable from those of recurrent oral ulcers due to other causes, such as malnutrition, viral infections, inflammatory bowel disease, and Reiter's syndrome[14].

Esophageal lesions

Symptomatic esophageal involvement is considered very rare[15,16], usually associated with other GI manifestations[15-19]. Only 45 retrospective case reports of esophageal involvement in ABD were found in literature. Most of the patients had symptoms severe enough to warrant upper gastrointestinal endoscopic examination[20]. The middle or lower part of the esophagus is often involved, causing substernal pain, dysphagia, and in rare case, hematemesis. Morphological findings include erosion, aphthous, linear or perforating ulcer (Figure 1), and widely distributed esophagitis[15,16]. Occasionally, there may be perforation, dissection, penetration, fistula formation, or pharyngeal stenosis causing dysphagia and dyspnea[21-25]. Esophageal varices may occur in association with superior vena cava obstruction, and portal hypertension due to portal or hepatic vein thrombosis[26]. Although some prospective studies suggest that the prevalence of asymptomatic esophageal involvement in ABD is rather high, it does not lead to severe abnormalities, and esophagogastro-duodenoscopy is recommended only in those with clinical symptoms[20,25]. Histological findings reveal nonspecific inflammation with lymphocytic or neutrophilic infiltration rather than vasculitis. The esophageal lesions in ABD often respond to corticosteroid instead of treatment with a proton pump inhibitor[27,28]. Viral or candida esophagitis should be excluded before initiation of corticosteroid.

Gastric and duodenal lesions

The stomach is the least frequently involved part of ABD, and aphthous ulcers are the most common findings. It was reported that 45% of Taiwanese patients with ABD had gastric and/or duodenal ulcers[29]. There may be pyloric stenosis due to edematous hypertrophy of pyloric ring[30,31] or Dieulafoy's ulcer[32]. ABD patients with gastric and/or duodenal lesions usually present with epigastric pain. Duodenal ulcers may be resistant to antiulcer medications[31], but whether corticosteroid should be used is unclear. Such ulcers can resolve spontaneously, and corticosteroid may inhibit its healing process, so that the effect of corticosteroid is uncertain[33]. There was also report suggesting that *Helicobacter pylori* treatment could diminish the oral and genital ulcers of ABD patients[34].

Small and large intestinal lesions

There are two forms of intestinal involvement: small vessel disease with mucosal inflammation causing ulcer (Figure 2) and large vessel disease resulting in intestinal ischemia and infarction. Mucosal ulceration is most commonly seen in the ileocecal region, and it was found in 88% patients in a study[35], usually on the antimesenteric side[36], followed by involvement of other part of colon, but rarely rectum or anus. The ulcers may be aphthous or, alternatively, deep and round with pouched-out appearance. Longitudinal ulcers are rare. The ulcers may penetrate the intestinal wall, resulting in perforation (often at multiple sites), fistula formation, or bleeding. Ulcers may resolve with medical therapy, but recur later[37]. In

Table 1 Summary of major gastrointestinal manifestations of Adamantiades-Behcet's disease reported in the literatures

Ref.	Type of manifestation	Symptom	Frequency	Complication	Therapy	Outcome
Zhang *et al*[9] Tursen *et al*[10]	Recurrent oral ulcer	Painful ulcer	Almost 100%	Rare	Topical measures	Excellent
Mori *et al*[15] Yi *et al*[16]	Esophageal ulcer/ esophagitis	Substernal pain, dysphagia	Very rare	Very rare	Corticosteroid	Excellent
Ning-Sheng *et al*[29]	Gastric ulcer and/or duodenal ulcer	Epigastric pain	Variable (very rare to 45%)	Very rare	Uncertain	Excellent
Choi *et al*[35] Köklü *et al*[45]	Small and/or large intestinal ulcer	Abdominal pain, hematochezia	Variable (1.4% up to 16%)	Rare (perforation, massive bleeding)	Sulfalazzine, corticosteroid azathioprine, tumor necrosis factor α antagonist, thalidomide	Good
Bayraktar *et al*[53] Chubachi *et al*[54]	Large artery aneurysm/thrombosis in abdomen	Infarction, ischemia	Very rare	Very rare	Corticosteroid azathioprine, cyclophosphamide	Poor
Bismuth *et al*[56]	Large vein thrombosis in abdomen	Budd-Chiari syndrome	Very rare	Very rare	Corticosteroid azathioprine	Poor

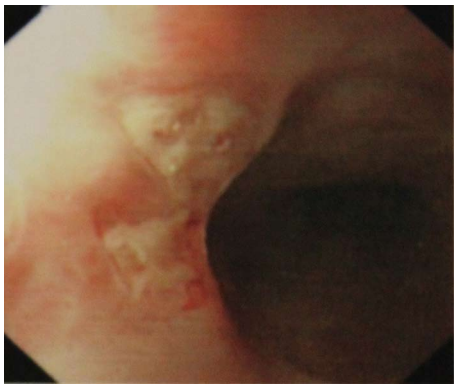

Figure 1 Esophageal involvement of Adamantiades-Behcet's disease. Endoscopic examination reveals two small punched-out, active ulcerations in the middle esophagus of the patient.

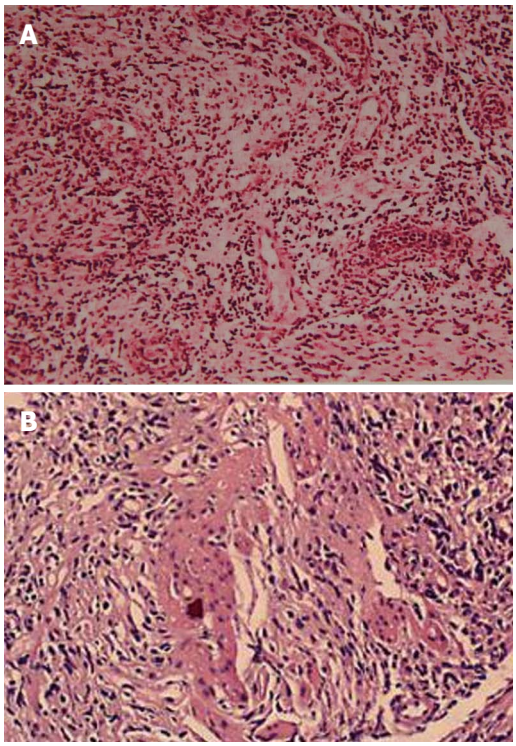

Figure 2 Ileum biopsy reveals lymphocyte-predominant inflammatory cells infiltration (A: HE, × 150) and fibrinoid vasculitis (B: HE, × 200). HE: Hematoxylin and eosin.

those ABD patients who underwent surgery while their disease was still active, the lesions tended to recur at the anastomotic site, especially along the ileal side of ileocolic anastomoses[38]. Although it is rare, there are also case reports of toxic megacolon without any precipitating factors[39] and severe proctitis with rectovaginal fistula[40].

Barium studies demonstrate single or multiple discrete ulcers with considerable thickening of the surrounding mucosal folds[18,38]. Other nonspecific findings include cecal contraction, widening of the ileocecal valve, fold thickening in the terminal ileum, and an apparent ileocecal mass with ulceration[41,42]. Barium study is a noninvasive and helpful examination to locate the GI lesions of ABD, but has limitations in defining the characteristics of lesions, and may not be applied to some cases of intestinal ABD that are inclined to penetrate the intestinal wall. In such situation, computed tomography (CT) scan and magnetic resonance imaging (MRI) will yield valuable information. CT scan shows concentric or uneven bowel wall thickening that remarkably enhances after administration of contrast agent[18,38]. This enhancement suggests stasis of blood due to vasculitis or perivasculitis affecting mainly the veins and venules of the ulcerous submucosa[38], which is supported by histopathological findings with diffuse vascular dilatation and perivascular lymphocyte infiltration. Polypoid lesions, sometimes with central ulceration, should be differentiated from malignancy by their marked contrast enhancement and involvement of both the terminal ileum and cecum. Complications such as bowel perforation and peritonitis, occur more frequently in those with a thickened bowel wall and severe perienteric infiltration than in those with polypoid lesions. MRI is helpful in revealing bowel wall thickening and increased contrast enhancement as well as extraluminal manifestations such as mesenteric infiltration around the involved bowel[43].

Colonoscopy is usually warranted for patients with clinical symptoms. The most common colonoscopic findings are localized single or multiple ulcers in the ileocecal

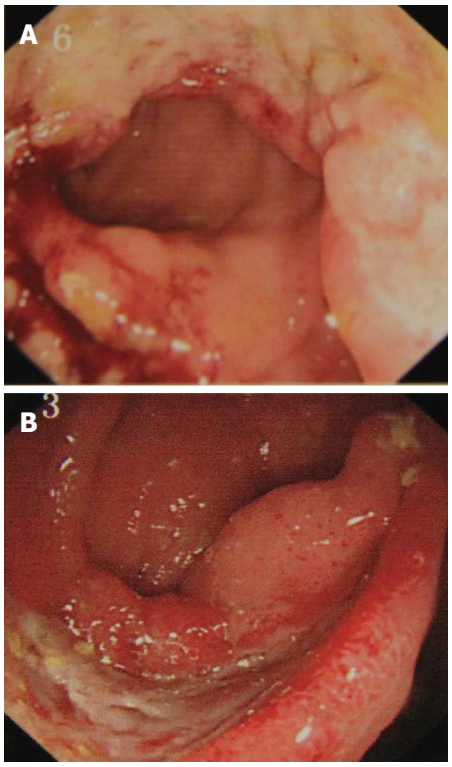

Figure 3 Typical colonoscopic findings of intestinal Behçet's disease. A: A single, large, and oval-shaped ulceration in the ileocecal region; B: A single annular-shaped ulcer in the ileum.

region (Figure 3), and only 4% has a diffuse distribution of lesions[44,45]. The characteristics of ileocecal ulcer of ABD also vary in different regions, with multiple superficial ulcers localized prominently in the terminal ileum in Turkish patients[46], and single deep ulcer with distinct borders in the Far East[44,45]. The colonic ulcers have been classified as volcano, geographic, and aphthous types. Volcano-type ulcers are defined as well-demarcated penetrating ulcers with nodular margins, converging folds, or pseudopolyps. Geographic-type ulcers are defined as shallow ulcers with sharp edges, and aphthous-type ulcers are small, pouched-out shallow ulcers similar to oral aphthous ulceration. Volcano-type ulcers have the least favorable response to medical treatment, and are at more frequent requisition for surgery, and are more likely to recur than the other two types[47]. Therefore, volcano-type ulcers should be treated vigorously and followed up closely. In rare cases, there are vesicular lesions or single rectal ulcers with otherwise normal mucosa[48].

Wireless capsule endoscopy is also useful in the investigation of gastrointestinal symptoms in ABD. It is particularly helpful for those patients in whom conventional investigations (such as esophago-gastro-duodenoscopy, colonoscopy, and barium study) are normal or fail to account for symptoms and signs[49,50].

The diagnosis of ABD is mainly based on the typical clinical findings, no specific serum markers or pathological features are available. Diagnosis of ABD-GE can be made if there is a typical oval-shaped large ulcer in the terminal ileum, or there are ulcerations or inflammation in the small or large intestines, and clinical findings meet the diagnostic criteria of ABD. Crohn's disease (CD), tuberculosis, vasculitis and other diseases that mimic ABD-GE should be excluded before diagnosis of ABD-GE is established[51]. Like CD, ABD-GE manifests as discrete ulcers and discontinuous bowel involvement with relative sparing of the rectum. The two diseases share extraintestinal manifestations, such as uveitis and arthritis. Unlike CD, ABD-GE is characterized by vasculitis of the small veins and venules with deep ulcerations, generally without granulomas or cobblestoning. However, both diseases may have chronic nonspecific inflammation with normal intervening mucosa. Perforation is more common in ABD-GE than in CD since the latter is characterized by intense fibrosis. Scalloping, ulceronodular patterns, and abscess formation are not observed in ABD-GE[46]. Unlike ulcerative colitis, colonic ABD consists of multiple aphthous ulcers with preservation of haustra and involvement primarily of the terminal ileum and proximal colon. Both intestinal tuberculosis and ABD-GE mainly manifest ulcerations in the ileocolonic region. Unlike ABD-GE, intestinal tuberculosis is characterized by granuloma with positive acid-fasting staining. Systemic lupus erythematosus (SLE) and ABD also share some common features, such as oral ulcerations, arthritis, and central nervous system involvement. Unlike ABD, SLE presents serum markers, such as anti-nuclear antibody, anti-ds-DNA and anti-Sm antibodies.

Vascular lesions in abdomen

ABD abdominal vasculitis is more likely to affect small veins and venules than arteries or arterioles. There can be intense inflammation around the vasa vasorum, resulting in destruction of the media and fibrous thickening of the intima and adventitia[52]. Pseudoaneurysms are the most common arterial manifestation, mainly involving the aorta, the pulmonary, and the femoral arteries. Thrombosis of the superficial and deep veins is more common than thrombosis and aneurysms of the large arteries in the abdominal cavity in ABD[53], albeit there was case report showing ABD patient manifested with a large aneurysm of the superior mesenteric artery causing occlusion and ischemic enteritis[54]. Mesenteric ischemia and infarction may be due to large vessel occlusion or to mucosal disease secondary to vasculitis of the small vessels[52].

Large vessel thrombosis occurs in 11% of ABD cases, of which 26% have hepatic vein or the inferior vena cava (IVC) thrombosis. In fact, ABD is the most common cause of Budd-Chiari syndrome in Turkey, especially in young male patients[55]. It may present with hepatomegaly, ascites, and involvement of other large vessels, mostly venous. Obstruction of the IVC due to extension of the thrombus to the ostium of the hepatic veins was found in most ABD patients with Budd-Chiari[56]. It could lead to acute hepatic failure and rapid death in one-third of the patients in one series. The major predicting factor for survival was the extent of vascular thrombosis in the IVC. ABD may also contribute to development of cavernous transformation of the portal vein[57], portal vein

thrombosis with splenomegaly, and superior vena cava thrombosis[58].

Other rare lesions

Hepatobiliary complications include fatty liver or congestion, acute and chronic hepatitis, cholelithiasis and cholecystitis, primary biliary cirrhosis, and hepatic abscesses[59-61]. The liver alkaline phosphatase level was elevated in 11% of ABD patients and correlated with disease activity[61]. Splenic involvement occurred in 37 of 170 autopsies in Japanese ABD patients with splenitis, splenomegaly, hemosiderosis, infarction, and auto-splenectomy, and pancreatic involvement was found in 2.9% of the ABD cases[60].

Acute ABD pancreatitis responded to treatment with corticosteroids[62]. Chronic pancreatitis was reported in an ABD patient with an alcohol history[63]. Due to the rarity of pancreatitis in ABD, other causes such as gallstone disease should be excluded.

Other rare complications include hepatic artery aneurysm causing hemobilia[64] as well as pylephlebitis and septic thrombophlebitis of the portal vein[65]. Type AA amyloidosis can also complicate with ABD, manifesting as diarrhea and malabsorption. It can also affect the kidneys with proteinuria and progress to nephrosis and renal failure. It has a 50% mortality rate after an average duration of 3.4 years[66-68].

TREATMENT AND PROGNOSIS

Treatment is largely empirical since well-controlled studies are difficult to conduct due to the heterogeneity of the disease, and the unpredictable course with exacerbation and remission. Therefore, there lacks evidence-based treatment recommended for the management of ABD-GE. Agents such as corticosteroids, sulfasalazine, azathioprine, cyclophosphamide, TNFα antagonist or thalidomide should be tried first before surgery, except in emergency[69,70]. Retrospective studies suggest that corticosteroids, sulfasalazine and azathioprine are effective in achieving remission without the need for surgery in a large proportion of patients. One study reported that azathioprine could decrease re-surgery rates and suggested that it should be used as maintenance therapy in patients whose gastrointestinal complication requires emergent surgery. Mesalazine may reduce the total dose of corticosteroids required to treat intestinal disease and esophageal ulcers[71,72]. Anti-TNFα therapy such as infliximab and thalidomide were also reported useful in treating intestinal lesions in case studies[22,73], which highlighted the role of large amounts of TNFα secreted by γδ T cells in ABD patients[74].

ABD-GE can sometimes resolve spontaneously, making it difficult to precisely evaluate the effectiveness of the therapy[33,36]. On the other hand, corticosteroids may prolong the healing process, provoke colonic perforation, and worsen the pancreatitis[33,75]. In one report, perforation was noted in 41% of patients who received corticosteroids and 33% of those who did not[12].

There is also no firm evidence to guide the management of major abdominal vessel disease in ABD. For the treatment of acute deep vein thrombosis in ABD, immunosuppressive agents such as corticosteroids, azathioprine, cyclophosphamide, or cyclosporine A are recommended[69,70]. For management of arterial aneurysms, cyclophosphamide and corticosteroids are recommended[69,70]. There is no evidence that anticoagulation is beneficial and it may in fact lead to fatal pulmonary hemorrhage in those with pulmonary arteritis and aneurysm formation[76].

Patients who have a history of intestinal perforation or fistula formation have a high probability of recurrence after surgery[35]. The recommended length of resection is controversial. Some advocate wide surgical margins, while others recommend removal of only the grossly affected bowel[12,35,77]. In one report, the incidence of recurrence was 18% with resection of the right colon and 35% with resection of just the ileocecal region[12]. In another report, the length of resection did not affect the rate of recurrence or reoperation[35]. Intraoperative endoscopy, especially of the small bowel, can help determine the length of resection during surgery. Follow-up endoscopy and barium studies should be done to evaluate the anastomotic site.

ABD usually has a chronic, unpredictable course with exacerbation and remission which decrease in frequency and severity over time. Death is mainly due to major vessel disease and neurological involvement. The prognosis is worst among young males[78]. Complete remission was achieved in 38% of ABD patients with gastrointestinal involvement after 8 wk of medical treatment[35]. The rate of recurrence after surgery has been reported to be 40%-56%[12,42]. Recurrence was found in 49% of patients at 5 years, especially in those with intestinal perforation or fistula formation[35]. Recurrent lesions were at or near the anastomosis in 81% of patients. Of those who underwent surgery, 75% recurred within 2 years and were associated with a higher rate of complications such as ocular and ileal lesions than the nonsurgical group[79]. The incidence of postoperative recurrence was lower in those with normal intraoperative endoscopy than in those with observed lesions[80].

Abstract

From a pure motor disorder of the bowel, in the past few years, irritable bowel syndrome (IBS) has become a multifactorial disease that implies visceral hypersensitivity, alterations at the level of nervous and humoral communications between the enteric nervous system and the central nervous system, alteration of the gut microflora, an increased intestinal permeability and minimum intestinal inflammation. Psychological and social factors can interfere with the communication between the central and enteric nervous systems, and there is proof that they are involved in the onset of IBS and influence the response to treatment and outcome. There is evidence that abuse history and stressful life events are involved in the onset of functional gastrointestinal disorders. In order to explain clustering of IBS in families, genetic factors and social learning mechanisms have been proposed. The psychological features, such as anxiety, depression as well as the comorbid psychiatric disorders, health beliefs and coping of patients with IBS are discussed in relation to the symptoms and outcome.

Key words: Anxiety; Depressive symptoms; Irritable bowel syndrome; Personality; Psychosocial factors; Sexual abuse; Stressful events

INTRODUCTION

Irritable bowel syndrome (IBS) is a frequent diagnosis in clinical practice for gastroenterologists and primary care physicians. It is a burden to society through total direct costs, reduced social functioning and quality of life impairment. IBS has a multifactorial etiology, involving altered gut reactivity and motility, altered pain perception, and alteration of the brain-gut axis. In addition, psychological and social factors can influence digestive function, symptom perception, illness behavior and outcome[1]. Psychological distress and major life events are frequently present in IBS, and are responsible, at least in part, for some outcomes. Whether they are also risk factors for IBS, is still uncertain. Since the biopsychosocial model of IBS was developed[2,3] the number of papers on IBS has skyrocketed. Accordingly, there has been a constant growing interest on the influences of psychosocial factors on the pathogenesis, course, severity and outcome in IBS. This review will highlight the place of environmental and psychosocial stressors in the biopsychosocial model of

IBS, and their role in the onset and course of symptoms.

BIOPSYCHOSOCIAL MODEL OF IRRITABLE BOWEL SYNDROME

The idea that emotions may influence the sensorimotor function of the gastrointestinal tract emerged at the beginning of the 19th century, and a lot of the evidence from research during that period is still valid[4]. Nevertheless, the vivid part of the history of IBS began only three decades ago, when the concept of the biopsychosocial model of illness and disease was developed[5]. This model integrates all possible accountable factors for the pathogenesis and clinical expression in IBS. The biopsychosocial approach allows for symptoms to be both determined and modified by psychological and social influences[3]. The link between psychosocial factors and gastrointestinal function (motility, sensation, inflammation) is through the brain-gut axis. This implies a bidirectional connection system between the gastrointestinal tract and the brain, through neural, neuroimmune and neuroendocrine pathways[6].

Psychosocial factors influence every component of the biopsychosocial model (Figure 1). Early in life, genetics and environmental factors (e.g., family influences, abuse, major losses), may affect one's psychosocial development (psychological state, coping skills) and/or the development of gut dysfunction. Gut dysfunction and dysregulation of the brain-gut axis can lead to IBS. During life, psychosocial factors (stressful life events, psychological distress), may influence digestive function, symptom perception, illness behavior, and consequently health outcome, daily function and quality of life[3]. Conversely, visceral pain can affect central pain perception, mood and behavior[7]. The psychological and social factors which may influence IBS are listed in Table 1.

ENVIRONMENTAL INFLUENCES IN IBS

Patients with IBS frequently report a positive family history of IBS, ranging from 33%[8] to 42%[9]. A constant research question is whether the clustering of IBS in families is due to common environmental risk factors or due to a common IBS specific set of genes.

Familial aggregation of IBS and twin studies showed that the concordance for IBS in monozygotic twins is significantly higher than in dizygotic twins, supporting the role of genetics in the etiology of IBS[10]. In the last decade, a lot of genetic studies looked for associations between gene functions (such as IL-10, the serotonin transporter, α-2 adrenergic receptors, and G protein) and gastrointestinal and colonic physiology in IBS patients, and searched for interactions between genotype and phenotypes[11]. So far, a definitive disease-causing gene or set of genes for IBS hasnot been identified.

There is a higher prevalence of IBS among subjects who have a family member with a history of abdominal pain, bowel dysfunction[12] or inflammatory bowel disease (IBD)[13]. An interesting fact is that subjects whose spouses had abdominal complaints did not report IBS symptoms more often than controls[12]. Only 5.4% of IBD patients' spouses reported IBS symptoms, *vs* 10.8% of first

Table 1 Psychological and social factors in irritable bowel syndrome

Environmental factors
Early life events
Upbringing environment
Incentives
Family function
Abuse history
Psychosocial stressors
Life events (divorce, unemployment, death of a close relative)
Daily hassles
Personality traits
Neuroticism, agreeableness, conscientiousness
Alexithymia
Health beliefs
Hypochondriacal beliefs
Illness representation
Perceived susceptibility
Coping strategies
Maladaptive coping (catastrophyzing, self-blame, substance abuse)
Negative emotions and psychiatric disorders
Mood disorders (major depression and dysthymic disorder)
Anxiety disorders (generalized anxiety disorder, panic disorder, post-traumatic stress disorder)
Somatization and somatoform disorders
Neurasthenia

degree relatives of IBD patients. Even if these observations support the idea that the inherited pathophysiological mechanisms are more important in IBS clustering in families, the effects of the common environment cannot be excluded.

Prenatal traumatic events may contribute to the development of IBS[14]. For example, exposure to severe wartime conditions in early life (in the first two years of life) was associated with an increased risk of developing IBS. To what extent this is attributable to the stressful environment of war, to severe undernutrition, or to the increased prevalence of infectious diseases is, however, unclear[15]. A large Norwegian population-based twin study[10] (on 12 700 twins) assessed the influence of nutrition in fetal life on the development of IBS, using birth weight as an indicator. The twins with a birth weight below 1500 g were significantly more likely to develop IBS. In addition, weight below 1500 g influenced the age at onset: IBSappeared 7.7 years earlier than in higher weight groups.

A recent study on children who had pyloric stenosis suggested that early stressful life events, such as gastric surgery, and perioperative nasogastric tube placement represent risk factors in the development of chronic abdominal pain in children at long-term follow-up[16].

The role of environmental factors in IBS was studied in a pediatric population in China. Adolescents and children who lived in a single-parent household, children exposed to low temperature environmental conditions, had a higher prevalence of IBS. Dietary habits (such as excessive intake of pepper and cold food) and personal habits (like alcohol consumption and smoking) were also associated with higher rates of IBS symptoms among children and adolescents[17]. On the other hand, two studies reported that an affluent childhood social class was associated with an increased risk of IBS[18,19]. One study concluded that privileged childhood living conditions (childhood living density < 1 person per room) was an important risk factor for IBS[18]. Howell *et al*[19] showed that there is a linear decrease in the odds of IBS across decreasing levels of social class.

Data regarding the effects of family environment are scarce. One study reported that by the age of 15 years, in 333 IBS patients, 31% had lost a parent through death, divorce or separation; 19% had an alcoholic parent, and 61% reported unsatisfactory relationships with, or between their parents[20]. Therefore, childhood deprivation may have an important influence on the etiology of IBS.

The clustering of IBS in families could partially be the result of social learning during childhood. The children of mothers with IBS have more non-gastrointestinal (GI) as well as GI symptoms (especially stomach aches), more school absences, and more physician visits for GI symptoms than children of non-IBS mothers[21]. In addition, children whose mothers made solicitous responses to illness complaints reported more severe stomach aches and they also had more school absences for stomach aches. Thus, children may learn abnormal illness behavior from their parents through social learning from parental reactions to symptom complaints[14].

ABUSE HISTORY

The role of abuse (especially childhood abuse) in IBS patients is still unclear. So far, authors have tried to determine (1) whether abuse is a risk factor for IBS; (2) whether there is a higher prevalence of abuse among IBS patients compared with other gastrointestinal diseases or healthy controls; (3) the effects of abuse on clinical outcome; and (4) the relationship between abuse and psychological distress, as a possible explanation of abuse-IBS association.

The prevalence of abuse history among patients with functional gastrointestinal disorders (FGIDs) varies widely. When comparing different data, we should consider at least three aspects: cultural differences which can lead to lower or higher self-report rates; the measurement methods of abuse used in different studies; and the type of abuse considered: physical, emotional/verbal or sexual. Also, the type of sexual act that is considered abusive varies from exhibitionism, fondling or contact abuse, to penetration or rape[22]. Given these facts, the prevalence of sexual and emotional abuse in IBS varies from 26%[23] to 50.8%[24], but lower values have also been reported. In other studies only 17% of abused patients had reported the abuse[25], therefore, the actual prevalence of abuse is usually higher.

In our experience, of 125 female patients with IBS, only one admitted she had "an undesired sexual contact", leading to a less than 1% reported frequency of sexual abuse. On the other hand, of 15 abused children from a specialized care center, seven met Rome Ⅲ criteria for IBS. We consider that the cultural differences between Romania and Western European countries are responsible for this under-recognition of abuse in female IBS patients[26].

There are studies which show that the prevalence of abuse history in patients with functional bowel disorders is greater than that in patients with organic bowel disorders and healthy control subjects[25,27,28]. Other studies failed to reinforce this observation[29]. Nevertheless, a constant finding is that abused individuals express higher levels of psychological distress[28,29] and higher levels of somatization[25,30], suggesting that previous abuse experience might lead to psychiatric disorders. There are significant data showing that anxiety disorders, depression[31] and somatization[32], are risk factors for IBS.

Two recent studies concluded that a lifetime history of a broad range of trauma and abuse, either in childhood or in adult life are independently associated with an increased IBS risk[30,33]. In a study that included women veterans[33], who are at increased risk of occupational trauma, including sexual trauma, the prevalence of IBS was 33.5%, and the most frequently reported trauma was sexual assault (38.9%). Even when depression and post-traumatic stress disorder were significantly more com-

Table 2 Environmental factors associated with irritable bowel syndrome

Prenatal traumatic events (e.g., nutrition in fetal life)
Early stressful life events (surgery, emotional, physical or sexual abuse)
Upbringing environment (low temperature, affluent childhood social class)
Family function (divorce, death of a parent)
Family history of abdominal pain, bowel dysfunction, inflammatory bowel diseases
Social learning (modeling)
Abuse history either in childhood or during adult life

mon in IBS cases than controls, neither explained the association between trauma and increased IBS risk.

Even if the role of abuse in IBS remains unclear, it was proven that abuse leads to increased psychological distress. Most probably, as a consequence, abuse is associated with greater impairment of functioning in daily lives, more visits to the doctor[25] and a poorer health outcome[34].

There are more and more data supporting the inherited component of IBS, but at the same time, the influences of the upbringing environment cannot be disregarded. IBS remains a multifactorial, complex disorder, caused by both environmental (Table 2) and genetic risk factors[9,11].

PSYCHOSOCIAL STRESSORS

Lazarus[35] divided stressors into life events and daily hassles. Life events refer to major events such as divorce, unemployment, or death of a close relative. Daily hassles are events which everybody experiences daily and frequently[36]. His assumption is that "(daily) hassles appear to be better predictors of health outcomes than life events". The results of a recent prospective study support this theory: there was a significant increase in stressor score (daily hassles) just before progression from IBS non-patient to IBS patient[37]. The majority of the subjects in this study however, were young college students, so factors rated as relatively stressful life events, were not very common.

The current data regarding the role of life events in the onset of IBS are the result of observations from the 80s. For example, Creed *et al*[38] showed that the most frequent events reported by patients with functional abdominal pain (FAP) (including IBS patients) during 38 wk prior to onset of symptoms, were a major disruption of close relationships, a marital separation, a family member leaving home, or break-up of a serious girl/boyfriend relationship. In addition, marked personal relationship difficulties such as severe marital problems or extreme family or household tensions, were much more frequently recorded among the FAP patients than in the organic GI diseases group (such as ulcer disease) or community subjects.

Recent data support the role of major life events in IBS. Childhood trauma was associated with an increased

Table 3 Psychosocial stressors and their relation to irritable bowel syndrome

Daily hassles, major life events (divorce, unemployment, or death of a close relative), and major social events (surviving holocaust, revolution, social changes) determine the onset of irritable bowel syndrome symptoms in susceptible individuals
Psychosocial stressors determine symptom exacerbation and health care seeking

vulnerability for multiple somatic symptoms of which IBS is one subset[30]. The items reported significantly more frequently in IBS than in healthy controls were: seeing someone being murdered, death or illness of a parent, failing to be understood by parents and having someone in the family with a psychiatric illness.

Holocaust survivors are another example of the impact of stressful life events on the development of IBS. The prevalence of IBS, duration of suffering, and frequency of GI symptoms were significantly higher in Holocaust survivors[39], when compared to controls with the same demographic background, but who had not been exposed to extreme mental and physical hardships during the war. From our personal experience[40], the stress developed by dramatic events presented live on television, during the uprising in Romania in 1989, led to an increased number of IBS symptoms within the first month.

Sometimes, what is considered to be a major life event is difficult to determine. For instance, a sudden cultural change (such as moving from a rural to an urban area) increased the prevalence of IBS in one study[41].

The experience of stressful life events can also determine symptom exacerbation among adults with IBS and frequent health-care seeking[7,42]. Thus, the severity of abdominal pain was higher in patients exposed to emotional stress[43], and stress exacerbated abdominal distension in one third of IBS patients[44]. In addition, recent data showed that environmental factors and psychosocial stressors (for example history of being psychologically abused, less than 6 h of sleep and irregular diet) influenced the progression from an IBS non-consulter to an IBS patient[37].

Based on these data we can say that psychosocial stressors, either during childhood or later in life are involved in the onset of IBS symptoms in susceptible individuals, and these factors influence the clinical course of IBS (Table 3).

PERSONALITY TRAITS

Personality is also considered to play a role in the etiology of IBS and in the decision to seek medical help. Personality traits have been defined as a "dynamic organization, inside the person (…) that create a person's characteristic patterns of behavior, thoughts and feelings"[45]. There are still debates regarding the major determinants of personality, and which personality traits should be included in psychometric questionnaires. However, very often,

Table 4 Personality traits and irritable bowel syndrome

Neuroticism and alexithymia are common in irritable bowel syndrome patients
Neuroticism is a predictor of illness perception and influences coping strategies
Examples of measurement tools: Toronto Alexithymia Scale (TAS-20), Neuroticism Extraversion Openness Personality Inventory[46]

personality is assessed based on five dimensions: extraversion (talkativeness, assertiveness, activity *vs* silence, passivity and reserve); agreeableness (kindness, trust, and warmth *vs* selfishness and distrust); conscientiousness (organization, thoroughness, and reliability *vs* carelessness, negligence and unreliability); neuroticism (tendency to experience negative emotions, such as anger, anxiety, or depression; also called emotional instability); and openness to experience (imagination, curiosity, and creativity *vs* shallowness and imperceptiveness)[46,47].

The majority of studies on this topic supports the idea that IBS patients have higher levels of neuroticism both when compared with the general population[48], and with patients with similar GI complaints (IBD patients)[49]. Neuroticism might influence coping strategies, being associated with escaping the problem or blaming oneself[50]. Neuroticism is also a significant predictor of illness perception and treatment beliefs in IBS[49].

Data are sometimes discordant with regard to the other dimensions of personality. The level of conscientiousness in IBS patients was high in some studies[48], while only average when compared with FD in other studies[51]. The differences may come from the fact that in some studies patients with comorbid psychiatric disorders were excluded[48].

Alexithymia is a stable personality trait, which is also frequently observed in IBS patients. Alexithymia is defined as a difficulty in identifying feelings and distinguishing between feelings and bodily sensations, difficulty describing feelings to other people, a markedly constricted imaginative process, and externally oriented thinking[52,53]. The Toronto Alexithymia Scale (TAS-20)[54] is the most widely used questionnaire to measure a person's alexithymia level. Subjects with a TAS-20 score > 61 (the score ranges from 20 to 100) are considered alexithymic. In the general population, less than 10% of patients are alexithymic[55]. In an Italian study, IBS patients had higher TAS-20 scores than healthy controls (59.1 *vs* 40.5). In addition, 43% of IBS patients had a TAS-20 score > 61, while only 2% of healthy subjects were alexithymic[56]. Our personal data on a female IBS population showed similar results[57]. Alexithymic individuals may misinterpret the somatic sensations associated with emotional arousal as symptoms of disease. It follows that, alexithymia is often associated with somatization, also a frequent finding in IBS patients[58]. Table 4 summarizes the association between personality traits and IBS.

HEALTH BELIEFS AND COPING WITH STRESS

A lot of patients with IBS believe that their chronic gut symptoms indicate a serious illness or even cancer. In addition, patients describe IBS not only as symptoms but mainly as it affects daily function, thoughts, feelings and behaviors. Patients report the sense of losing freedom, spontaneity and social contacts, as well as feelings of fearfulness, shame, and embarrassment. All these could lead to changes in their behavior such as avoidance of activities and many adaptations in routine in an effort for patients to gain control[59].

The most extreme form of preoccupation with an illness is hypochondriasis, included in the group of somatoform disorders. Hypochondriasis is the excessive fear of a serious illness, despite medical testing and reassurance to the contrary[60]. In a study from the 90s, patients with IBS expressed more hypochondriacal attitudes when compared with healthy subjects or patients with organic GI diseases. Patients with IBS had high scores on bodily preoccupation, hypochondriacal beliefs and disease phobia[61]. No other data on this subject are available. We cannot recommend screening for hypochondriacal attitudes, but in everyday practice, we can encounter IBS patients with excessive illness-related fear. The presence of hypochondriacal attitudes can be measured using the Illness Attitudes Scales (IAS) questionnaire. This questionnaire was developed in 1986[62], but even now remains a valid tool[63].

Psychological assessment of IBS patients revealed that there are differences regarding how individuals with IBS respond to their illness. In other words, IBS patients do adopt different coping strategies compared with patients with organic diseases or healthy controls. Coping is defined as "constantly changing cognitive and behavioral efforts to manage specific external and/or internal demands that are appraised as taxing or exceeding the resources of the person"[36]. The authors divided coping strategies into two main categories: problem-focused coping targeting directly the causes of stress, such as information seeking, constructive way of reducing/solving the problem and planning, and emotion-focused coping used to handle negative emotions evoked by the situation (such as an avoiding feeling, trying to escape the problem or blaming oneself).

There are a number of questionnaires which assess coping strategies, such as the Ways of Coping Questionnaire (WCQ)[64], Coping Strategies Questionnaire (CSQ)[65] and Coping Inventory for Stressful Situation (CISS)[66]. All of these include the main coping strategies mentioned. The CISS has proved so far to have very good psychometric properties and was validated in several languages[67].

Using WCQ, Drossman *et al*[50] showed that patients with IBS and other FGIDs, didnot use positive reap-

Table 5 Health beliefs and coping with stress in relation to irritable bowel syndrome

Health beliefs in IBS may be irrational, leading to hypochondriacal attitudes
Coping strategies can be inefficient in IBS patients, patients often adopt maladaptive coping strategies such as catastrophyzing
Patients with a high degree of catastrophyzing report more severe pain
Measurement methods: CSQ, CISS, WCQ

IBS: Irritable bowel syndrome; CSQ: Coping strategies questionnaire; CISS: Coping inventory for stressful situation; WCQ: Ways of coping questionnaire.

praisal as often as patients with organic disorders (such as IBD, acid peptic disease, pancreatico-biliary diseases). In a polish study, IBS patients had a high emotional-oriented coping style[51].

The CSQ focuses primarily on coping in response to painful conditions. The interest in using the CSQ in patients with IBS is related to the subscale measuring catastrophyzing (e.g., "When I am in pain, I feel I can't stand it anymore" or "it's awful and I feel it overwhelms me"). Catastrophyzing is a maladaptive coping strategy defined as "a negative cognitive process of exaggerated negative rumination and worry"[68]. Patients with IBS are more likely to catastrophize than patients with organic disorders[50]. In addition, catastrophyzing mediates the relationship between depression and pain severity. This relationship was suggested by the following observations: patients with IBS and a high degree of catastrophyzing have a tendency to report more severe pain; catastrophyzing and depression are associated[69]; depression did not predict symptom severity[70]. Patients with IBS who experience higher levels of depression engage in more catastrophic thinking, and partly through this thinking style experience more intense pain and greater activity limitations due to pain[69].

The CSQ also measures the overall effectiveness of coping strategies (the amount of control over symptoms and self-perceived ability to decrease symptoms). IBS patients were less likely to feel in control of symptoms and to feel able to decrease symptoms than patients with organic disorders[50], suggesting that coping strategies are not very efficient in IBS patients.

When speaking about coping styles in IBS patients it is difficult to draw a general conclusion. The studies mentioned above used different questionnaires to assess coping strategies in IBS. The results are not contradictory, but at the same time didnot point out a specific coping strategy in IBS patients (see also the summary in Table 5). Further research is necessary to establish the role of coping in symptom perception and control, and clinical outcome in IBS patients.

NEGATIVE EMOTIONS AND COMORBID PSYCHIATRIC DIAGNOSIS

Psychiatric symptoms and psychiatric disorders are more common in patients seen in referral practices than primary care or in the community of nonconsulters. The most frequent psychiatric diagnosis in IBS is mood disorders (major depression and dysthymic disorder), anxiety disorders and somatoform disorders[7].

Depression is the most common psychiatric diagnosis in IBS patients[71,72]. Patients with IBS have higher scores of depression than healthy controls[73,74], but lower than the psychiatric population[7,73]. However, depressive disorders are more common in clinic patients with IBS compared to patients with similar symptoms and organic GI diseases and compared to healthy controls[72,75]. In the study by Whitehead *et al*[72], the prevalence of depression in IBS was 31.4%, 21.4% in IBD and 17.5% in controls. Another study reported a lower prevalence of depression in IBS than in patients with chronic C hepatitis[76]. An interesting fact is that the number of self-reported depressive symptoms is not significantly higher in patients who seek medical care for their GI complaints compared with those who do not consult[75].

Anxiety and anxiety disorders, such as panic disorder (PD), generalized anxiety disorder (GAD) and posttraumatic stress disorder (PTSD) are also often observed in IBS patients. Anxiety tends to precede IBS onset, particularly if diarrhea predominates. This indicates that the psychiatric disorder cannot be regarded as a response to the functional GI disorder. It seems more likely that the psychiatric symptoms, especially anxiety, play a role in the development of IBS[31].

Anxiety is more common in IBS patients than in the general population[77,74]. In a community study, GAD was found in 16.5% of subjects with IBS symptoms, while in the group of subjects without these symptoms the prevalence was 3.3%[77]. Whitehead *et al*[72]reported similar results (15.8%) regarding the frequency of anxiety among IBS patients. However, other studies reported higher values. For example, 47% of patients with IBS met Hospital Anxiety and Depression Scale (HADS) screening criteria for anxiety in a South Australian study[76].

This significant difference in prevalence may have at least two causes. The first one refers to the sample of subjects taken into account-some studies were conducted on samples of patients seeking medical care, mostly in tertiary care settings; other studies investigated community subjects. The second explanation may be that the authors used different scales or criteria to establish the presence of anxiety. Lee *et al*[77] used the diagnosis criteria for GAD according to the Diagnostic and Statistical Manual of Mental Disorders[60]. HADS is a widely used instrument developed as a screening tool for detecting states of depression and anxiety in hospital settings[78]. Studies have also shown that HADS is valid when used in community settings and primary care medical practice[79]. HADS should be used only to estimate the likely prevalence of anxiety and depression, and not to establish a firm diagnosis. The latter can only be made by a psychologist or a psychiatrist using a structured interview based on the Diagnostic and Statistical Manual of Mental

Disorders (DSM)-Ⅳ.

Anxiety related to GI sensations, symptoms or the context in which these may occur is referred to as gastrointestinal specific anxiety (GSA). GSA influences symptom severity and quality of life in patients with IBS[80]. Patients with IBS have more severe GSA when compared with healthy subjects. In addition, IBS patients with severe GI symptoms have more severe GSA scores[81]. GSA can be assessed using The Visceral Sensitivity Index (VSI), a 15-item scale developed for this purpose[80]. The main information from measuring GSA, is related to the fact that the GSA score predicts GI symptom severity[81].

Data regarding the frequency of PD in IBS are scarce. Panic disorder is characterized by repeated, unexpected panic attacks, and is more common in women. Sufferers experience unexpected episodes of intense fear and associated cardiorespiratory, GI, neurological, and cognitive symptoms[60]. A study conducted in several secondary and tertiary gastroenterology clinics, reported that 12% of IBS patients had PD, 14% had GAD and 29% had depressive disorder[71]. The frequency of GAD and depressive disorder are similar to those mentioned above, even if the criteria used for the diagnosis of psychiatric disorders were different. Studies in female veterans, showed that IBS is more common in patients with PTSD, and PTSD represents an independent risk factor for IBS[33,82].

Somatization disorder (SD) is included, according to DSM-Ⅳ, in the larger group of somatoform disorders. SD is defined as a chronic condition in which "the individual experiences physical symptoms that suggest the presence of a general medical condition, but a medical workup cannot establish an etiological general medical condition that adequately explains the problem"[60]. Several studies conducted on tertiary care IBS patients reported an excessive somatization tendency in patients with IBS, the prevalence of SD reaching 25%[83,84]. However, a review on SD, mentioned that in primary care and in population-based samples, SD is very rare, with a lifetime prevalence of only 0.1% to 0.2%[85].

High scores on somatization questionnaires in patients with functional gastrointestinal disorders (FGIDs) were observed both in population-based studies and in clinical studies[86]. Somatization is frequently associated with anxiety and depression, and explains the frequent "extra-gastrointestinal symptoms" such as musculoskeletal complaints, urinary symptoms, sexual symptoms, headaches, and constant fatigue observed in patients with IBS[84,87]. It is also associated with a poor health-related quality of life, and predicts a poor response to treatment[88-90].

Recent data endorse these assumptions and also suggest that somatization is a risk factor for IBS. In a study conducted in a tertiary care setting on functional dyspepsia patients, somatization was found to be a common risk factor for co-morbid IBS and chronic fatigue-like symptoms[32]. A community-based prospective study[91], showed that psychosocial factors indicative of somatization (such as illness behavior scores, anxiety, sleep problems and somatic symptoms) are independent risk markers for the development of IBS, in a group of subjects previously free of IBS. After one year follow-up, 3.5% of the followed subjects developed IBS. Those who reported all four of these markers at baseline were six times more likely to report IBS when compared to those who were exposed to none or one marker.

Those who have SD use health services frequently, and have twice the annual medical care cost of people without SD[92]. This finding is also true for IBS patients, as patients with IBS and SD have a significantly greater number of medical consultations, telephone calls to physicians, urgent care visits, medication changes, missed work days and benzodiazepine use[84]. In addition, IBS patients with probable or definite somatization report more abnormal illness behaviors than those without SD[83].

Neurasthenia is also frequently reported in IBS patients, up to 35% in severe IBS patients[71]. It is very similar to chronic fatigue syndrome, being characterized by persistent and distressing fatigue after mental or physical effort associated with muscular aches, dizziness, sleep disturbance, irritability and mild depressive symptoms[60,93]. This entity is currently contested by some authors[93]. It is still included in the World Health Organization's International Classification of Diseases, but not in DSM-Ⅳ, due to its overlap with anxiety and depression.

Patients with IBS very often have more than one psychiatric disorder, and this finding is more common in severe IBS. For example in 74 patients with depressive disorder and severe IBS[71], 16 had PD, 6 had hypochondriasis and 41 had neurasthenia. Other psychiatric diagnoses reported in this study were dysthymia (7%), phobias (15%), undifferentiated somatoform disorder (9%) and drug or alcohol problems (8%).

Psychological distress is seen more often in IBS patients than in the general population. It also holds true that in patients with psychiatric disorders, IBS symptoms are more frequently reported than in the general population. In a community study, IBS was 4.7 times more common among patients with GAD than in the general population (22% *vs* 4.7%)[77]. Frequent abdominal pain, diarrhea, constipation, dyspepsia or IBS were present in 54% of subjects with depressive symptoms and in only 29% of non-depressed controls[86]. Patients with PD also have high rates of IBS symptoms[94-96], varying from 26.3%[96] to 46.3%[94], most probably due to different diagnostic criteria for IBS.

Numerous instruments have been developed to assess the presence of psychiatric symptoms or specific psychiatric disorders in IBS patients. The complexity of these questionnaires is clearly related to the purpose, which can either be screening or diagnosis, or research. One can obtain a general idea about a patient's psychological distress in IBS using the Symptom Checklist-90-Revised (SCL-90-R), developed by Derogatis[97]. The SCL-90-R has 9 subscales, including subscales for somatization, depression and anxiety, and provides an overview of symptom intensity at a specific point in time. From the three global indices determined, the Global Severity Index (GSI) mea-

Table 6 Comorbid psychiatric diagnoses and their relation to irritable bowel syndrome

Psychiatric symptoms and psychiatric diseases are frequent in IBS, especially in severe forms
Depression is the most common psychiatric disorder in IBS (approximately 30% of patients)
Generalized anxiety disorder is present in about 15% of patients
High gastrointestinal specific anxiety predicts symptom severity
High levels of somatization determine frequent use of health care services, a poor response to treatment and a poor health-related quality of life
Other psychiatric disorders in IBS patients: posttraumatic stress disorder, panic disorder, hypochondriasis, dysthymia, phobias, undifferentiated somatoform disorder, drug or alcohol problems
Patients with severe IBS may have more than one psychiatric disorder
Measurement methods: Symptom checklist-90-revised for overall psychological distress; state-trait anxiety inventory, beck depression Inventory

IBS: Irritable bowel syndrome.

sures overall psychological distress. The State-trait anxiety inventory[98] (STAI) and the Beck depression inventory[99] are another two questionnaires commonly used to assess the presence of anxiety and depression in IBS patients.

In the general population, half of patients with presumed IBS have psychiatric symptoms compared with one third in controls[100]. In several systematic reviews published at the beginning of the 2000's, the proportion of patients who met the criteria for any psychiatric diagnosis ranged from 40% to 94%[42,101,102]. We should take into account that some data are the results of studies conducted on tertiary care patients who are likely to be more distressed than other patients. Some studies did not evaluate the prevalence of psychiatric disorders in other chronic GI diseases, in the same setting. In addition, the criteria used to diagnose psychiatric disorders differed from one study to another. In a study by Creed *et al*[103] in severe IBS patients, 42% of patients had a concurrent psychiatric disorder (depressive, panic or generalized anxiety disorder). Even if this study didnot purposely determine the frequency of psychiatric disorders in IBS patients, it showed that even in the most severe IBS patients, a comorbid psychiatric disorder is found in less than half of the patients. In summary (Table 6), half or more IBS patients commonly have psychiatric symptoms or psychiatric disorders and their frequency is higher than for other medical patients in the same clinics.

CONCLUSION

Environmental and psychosocial factors are an important part of the biopsychosocial model of IBS, being involved in dysregulation of the brain-gut axis, leading to the onset of IBS, persistence of symptoms or abnormal illness behavior. There is a wide range of environmental and psychosocial stressors, acting at different moments in one's life; a number of people submit to these factors, but only susceptible individuals will develop IBS. Other major elements of the biopsychosocial model such as personality traits and psychiatric disorders are probably the elements which make one susceptible to the development of IBS.

Abstract

AIM: To characterize the influence of diet-induced changes in body fat on colitis severity in SMAD3-/- mice.

METHODS: SMAD3-/- mice (6-8 wk of age) were randomly assigned to receive a calorie restricted (30% of control; CR), control (CON), or high fat (HF) diet for 20 wk and were gavaged with sterile broth or with *Helicobacter hepaticus* (*H. hepaticus*) to induce colitis. Four weeks after infection, mice were sacrificed and the cecum and colons were processed for histological evaluation.

RESULTS: Dietary treatment significantly influenced body composition prior to infection ($P < 0.05$), with CR mice having less (14% ± 2%) and HF-fed mice more body fat (32% ± 7%) compared to controls (22% ± 4%). Differences in body composition were associated with alterations in plasma levels of leptin (HF > CON > CR) and adiponectin (CON > HF ⩾ CR) ($P < 0.05$). There were no significant differences in colitis scores between CON and HF-fed mice 4 wk post-infection. Consistent with this, differences in proliferation and inflammation markers (COX-2, iNOS), and infiltrating cell types ($CD3^+$ T lymphocytes, macrophages) were not observed. Unexpectedly, only 40% of CR mice survived infection with *H. hepaticus*, with mortality observed as early as 1 wk following induction of colitis.

CONCLUSION: Increased adiposity does not influence colitis severity in SMAD3-/- mice. Importantly, caloric restriction negatively impacts survival following pathogen challenge, potentially due to an impaired immune response.

Key words: SMAD3; Colitis; Adipokine; Obesity; Calorie restriction

INTRODUCTION

Adipose tissue (AT) is increasingly recognized as an active endocrine organ modulating a number of physiological processes. AT is a key regulator of insulin resistance[1,2]

and contributes to systemic inflammation through production of a variety of proteins, hormones and cytokines collectively referred to as adipokines[3,4]. Many of these secretory products play important roles in energy homeostasis and the immune response[5]. Several pro-inflammatory cytokines, including interleukin (IL)-6, C-reactive protein (CRP) and leptin, are released from AT even in the absence of acute injury or inflammation, and their production is increased in proportion to AT mass[6-10]. Such altered production of these cytokines contributes to a number of pathophysiological processes including peripheral insulin resistance, inflammation, vascular disease, and immune dysfunction commonly observed in obesity[2,11].

Inflammatory bowel diseases (IBD), including Crohn's disease (CD) and ulcerative colitis (UC), are chronic conditions characterized by remittent inflammation resulting in extensive damage to the gastrointestinal tract[12-14]. CD can affect any part of the intestine[12], whereas UC is confined to the colon[14]. Although certain clinical features differ between these two conditions[13], both are thought to result from a dysregulated immune response in susceptible individuals[15].

Altered local and systemic levels of cytokines including tumor necrosis factor (TNF)-α, leptin, and adiponectin have been observed in individuals with IBD and are suggested to contribute to the disease pathogenesis[16]. Leptin is a 16-kDa product of the ob gene and is produced primarily by adipocytes[17]. Circulating levels of leptin are increased in obesity and show a positive correlation to body mass index[18,19]. Although leptin regulates energy metabolism by inhibiting food intake and increasing energy expenditure[20], it also has important immunomodulatory roles[21-23]. Increases in leptin levels in the serum[24], mesenteric AT[25], and in the colonic lumen[26] have been reported during the active stage of IBD. Leptin is also associated with susceptibility to experimental colitis in mice[27]. Colonocytes express the leptin receptor, and luminal administration of leptin induces epithelial wall damage and neutrophil infiltration, suggesting a local pro-inflammatory role for this protein[26].

Adiponectin is a high molecular weight protein secreted by AT that contributes to glucose homeostasis by increasing peripheral insulin sensitivity and reducing hepatic gluconeogenesis[28]. Pro-inflammatory mediators, including TNF-α and IL-6, suppress adiponectin secretion and serum levels are markedly reduced in obese individuals[29-31]. Adiponectin is generally considered anti-inflammatory due to antagonistic effects on cytokine signaling[32-34]. However, increased levels have been detected in serum and hypertrophied mesenteric AT in patients with active IBD[35,36]. A direct role for adiponectin during experimental colitis in animals has produced inconsistent results[37-39].

There is currently insufficient evidence to support a causal relationship between obesity and IBD; however, the conditions share similar inflammatory characteristics. Recent studies indicate that the constant low-grade inflammation associated with excess AT, including elevated serum levels of CRP, IL-6 and TNF-α, may contribute to the severity of IBD[40]. Additionally, overweight and/or obese individuals with CD were found to have more complications and more frequent disease relapses than normal weight individuals[41], providing a potential link between excessive AT and pathogenesis of IBD.

In the current study we evaluated the influence of adiposity on colitis severity in SMAD3-/- mice. SMAD3-/- mice have defective transforming growth factor (TGF)-β signaling and develop mild colitis within 4 wk following infection with *Helicobacter spp*. Dysfunctions in TGF-β signaling are commonly observed in human IBD and during colon cancer development. Maggio-Price *et al*[42] demonstrated that SMAD3-/-, but not SMAD3+/- mice develop chronic colitis and colon cancer in response to a bacterial infection. In the SMAD3-/- mouse model of colon cancer, initiation and progression is induced by a bacterial infection *Helicobacter hepaticus* (*H. hepaticus*). The bacterium colonizes the cecum and proximal colon persistently, low grade inflammation and immune cell infiltration observed eventually lead to mucinous adenocarcinoma formation at 15-30 wk post infection[42]. Importantly, these lesions are flatter, more aggressive and harder to diagnose in humans. It is widely hypothesized that chronic low levels of inflammation, whether induced by a pathogen or not, leads to cancer promotion and progression. Therefore, this model is highly relevant to the process of human colon carcinogenesis. Specifically, the SMAD model is very similar to the development of specific human cancers where a pathogen is necessary (but not sufficient) to cause dysplasia and tumor formation. Examples include hepatitis and liver cancer, *Helicobacter pylori* and stomach cancer, and human papillomavirus and cervical cancer. The contribution of this research was to understand how energy balance differentially modulates promotion/progression of inflammation and pathogen-induced cancers.

Mice were submitted to one of three dietary treatments (control, 30% caloric restriction, or high fat diet) to induce differing levels of adiposity after 20 wk, and were then infected with *H. hepaticus* to induce colitis. Plasma leptin and adiponectin were measured pre-infection and histological scoring was performed on cecum and colon tissue 4 wk post-infection.

MATERIALS AND METHODS

Animal husbandry

Mice (129-*Smad3*^{tm1Par}/J, referred to hereafter as SMAD3-/-) were generously donated by Lillian Maggio-Price at the University of Washington. The mouse colony was developed by pairing SMAD3-/- males with SMAD3+/- females. Weaning and genotyping of subsequent litters was performed as described below at approximately 21 d after birth; only SMAD3-/- mice were used in this study. All mice were housed in 60 square inch plastic cages with micro-isolator lids and maintained in temperature and humidity controlled rooms with a 12-h light-dark cycle. Harlan Teklad 22/5 Rodent Diet 8640 (22% crude protein, 5% crude fat) was given *ad libitum* prior to the start

of the study. All mouse procedures were approved by the Michigan State University Institutional Animal Care and Use Committee.

Genotyping

Ear tissue samples were obtained and DNA extracted with REDExtract-N-Amp™ Tissue PCR Kit (Sigma-Aldrich, St. Louis, MO) according to manufacturer's recommendations. Four primers were used for polymerase chain reaction: 1271 (GGATGGTCGGCTGCAGGTGTCC) and 1272 (TGTTGAAGGCAAACTCACAGAGC) to recognize SMAD sequences and give a 130 bp product, and 506 (CGGCGAGGATCTCGTCGTGACCCA) and 507 (GCGATACCGTAAAGCACGAGGAAG) to recognize vector sequences. Thermal cycling of the samples was conducted with an initial denaturation at 94 ℃ for 3 min, 40 cycles of denaturation-annealing-extension (respectively 20 s at 94 ℃, 30 s at 58 ℃, and 1 min at 72 ℃), and a final extension of 72 ℃ for 3 min. Polymerase chain reaction products were then evaluated on a 2% agarose gel and visualized under UV transillumination.

Helicobacter hepaticus culture

Isolates of *H. hepaticus* (strain 3B1, ATCC 51449) were kindly donated by Vince Young at University of Michigan. Bacteria were streaked onto sheep blood agar plates and incubated at 36 ℃ for 24-48 h under anaerobic conditions using GasPak™ pouch systems (BD, Franklin Lakes, NJ). After incubation, cultures were collected by the addition of Bacto™ Tryptic Soy Broth (BD, Franklin Lakes, NJ) and the optical density was assessed using a Bio-Tek Synergy HT multi-mode microplate reader (Bio-Tek, Winooski, VT) to ensure a constant bacterial population ($\geqslant$ 1.8 at 600 nm wavelength).

Dietary treatments and experimental procedures

SMAD3-/- mice (6-8 wk of age) were randomly assigned to one of three Open Source diets (Research Diets Inc, New Brunswick, NJ): control (CON; formula D12450B: 20% protein, 70% carbohydrate, 10% fat), 30% calorie-restricted (CR; formula D03020702B: 27% protein, 54% carbohydrate, 6% fat) or high fat (HF; formula D12492: 20% protein, 20% carbohydrate, 60% fat) to induce differing levels of adiposity as previously described[43]. Mice were weighed weekly to assess body weight changes. Body composition was also assessed after 20 wk using an EchoMRI-100™ quantitative nuclear magnetic resonance machine (Echo Medical Systems, Houston, TX).

In a pilot study (data not shown; n = 73 mice), weight differences between dietary treatments were found to be maximal around 20 wk, therefore this time frame was chosen for induction of colitis. Mice were thus fed diets (n = 37 CON, 19 CR, and 36 HF) for 20 wk and then gavaged with 0.3 mL dosages of either bacteria-free control Tryptic Soy Broth or *H. hepaticus*, one dosage per day on two consecutive days. Continued weight monitoring was conducted on the gavaged mice and any animal that exhibited a weight loss of > 20% from one week to the next was euthanized. Four weeks after infection, mice were euthanized *via* carbon dioxide asphyxiation. Terminal bleeds were performed *via* cardiac puncture and blood was collected in a heparin-coated syringe. Blood samples were centrifuged at 12 000 × g for 15 min at 4 ℃, and plasma was collected and frozen at -80 ℃ until further use.

Histopathology

The entire lower gastrointestinal tract was isolated and removed. Ceca were incised and cleared of fecal material with ice-cold phosphate buffered saline (PBS). Colons were similarly cleared, rinsed with PBS and sectioned. Cecum and colon samples were fixed for 24 h in a 10% formalin solution and then processed, stained, and scored by a board certified pathologist (Dr. Ingeborg Langohr) blinded to treatment for degree of colitis and dysplasia[44]. Grades were on a 1 to 4 scale both for inflammation (1, no inflammation; 2, mild inflammation; 3, moderate inflammation; 4, marked inflammation) and dysplasia (1, no dysplasia; 2, low grade dysplasia; 3, high grade dysplasia; 4, high grade dysplasia with invasion/adenocarcinoma). Briefly, low-grade dysplasia was characterized by thickened mucosa with elongated crypts with reduced numbers of goblet cells, but maintenance of cell polarity and nuclear morphology. High-grade dysplasia was characterized by thickened mucosa with elongated, irregularly branching glands, cytological and nuclear atypia including loss of differentiation and polarity, closely aggregated nuclei, and numerous mitotic figures. The two scores for colon and two scores for cecum tissue in each animal were combined such that a score of 4 indicated no inflammation or dysplasia and a score of 16 reflected maximal inflammation and neoplasia.

Quantification of serum adipokines by enzyme linked immunoabsorbance assay

Adiponectin and leptin were quantified by enzyme linked immunoabsorbance assay in plasma samples from mice prior to infection according to the manufacturer's instructions (R and D Systems; Minneapolis, MN). Plasma (n = 5 per group) was diluted 1:10 for leptin and 1:10 000 for adiponectin in reagent diluent. Upon completion of the assay, the plate was read at 450 nm wavelength using a Synergy® HT plate reader (Bio-Tek; Winooski, VT).

Immunohistochemistry

Antibodies specific for cyclooxygenase (COX)-2, inducible nitric oxide synthase (iNOS), and F4/80 were purchased from Santa Cruz Biotechnology (Santa Cruz, CA), CD3 from AbCam (Cambridge, MA) and Ki67 from Novus Biologicals (Littleton, CO). A rat ABC detection kit (sc-2019) was purchased from Santa Cruz Biotechnology (Santa Cruz, CA) and remaining secondary antibodies from DAKO (DAKO Co., Carpinteria, CA). All other reagents were obtained from Sigma Chemical Co. (St. Louis, MO) unless otherwise indicated.

Five-micron thick sections of formalin-fixed paraffin-embedded colon tissue were mounted on coated slides,

and dietary differences in macrophage (F4/80) and T lymphocyte cell infiltration (CD3), proliferation (Ki67), and expression of COX-2 and iNOS were evaluated using peroxidase biotin-streptavidin immunohistochemistry. Epitope retrieval was carried out either by heating sections (92-95 ℃) in 10 mmol/L citrate buffer (pH 6.0) for COX-2, iNOS, CD3, and Ki67 or with proteinase K digestion (Roche biochemicals) for F4/80. Slides were subsequently washed, treated with 3% H_2O_2 and incubated in 2.5% bovine serum albumin to reduce non-specific binding of antibody. Sections were incubated overnight at 4 ℃ with the primary antibody diluted in blocking buffer. After washing, sections were treated with appropriate biotinylated immunoglobulins followed by peroxidase-conjugated streptavidin at room temperature for 45 min each. Antigen-linked peroxidase was detected with the chromagen 3-3'-diaminobenzidine (DAB; 0.5 mg/mL) diluted in 10 mmol/L PBS (pH 7.2) containing 0.015% H_2O_2.

For quantification of $Ki67^+$ cells, a researcher blinded to treatments evaluated 10-20 full-length crypts/animal. The total number of nuclei ($Ki67^+$ and Ki67$^-$) lining one side of the crypt and extending from the base of the crypt to the lumen was recorded. Proliferative index (number of $Ki67^+$ cells/total cells) was then calculated and analyzed. Colonic staining of COX-2, iNOS, CD3, and F4/80 were quantified using Nikon software and an inverted light microscope (Nikon; Kanagawa, Japan) equipped with a color camera (DS-U2, Nikon; Kanagawa, Japan). Using a 20 × objective, areas surrounding full length crypts in the proximal colon were traced and the positive stained area (total number of pixels) was quantified. Data are expressed as a percentage of positive stained area in relation to the total surface area. For each stain, at least 10 measurements/animal were taken.

Statistical analysis

Data for body weight and composition, colitis scores, and plasma adiponectin and leptin levels were analyzed with analysis of variance using Prism software (Graph Pad; San Diego, CA). Prior to analysis, normal distribution of the data was tested and when appropriate, data were transformed prior to statistical analysis. When statistical differences were detected, individual comparisons were made using Bonferroni's multiple comparison test.

RESULTS

Effect of dietary treatment on body fat composition and plasma adipokines

Dietary treatments significantly influenced AT stores in mice prior to initiation of *H. hepaticus* infection. HF-fed mice weighed significantly more and had a higher percent body fat than CON or CR mice (Table 1). Conversely, CR mice weighed less than both HF and CON mice primarily due to lower amount of AT.

Dietary treatment also affected plasma levels of metabolic hormones (Figure 1). Adiponectin was significantly lower in CR and HF mice compared to CON mice (Figure 1B, $P < 0.05$) whereas plasma concentrations of leptin were lowest in CR and highest in HF mice (Figure 1A, $P < 0.05$).

Table 1 Pre-infection body weights and body composition of SMAD3-/- mice after 20 wk on dietary treatment

Diet	Weight change (%)	Lean tissue (%)	Adipose (%)
CON	35 ± 17.8	68 ± 5.0	22 ± 4.0
CR	32 ± 11.8	73 ± 3.0[a]	14 ± 2.0[a]
HF	45 ± 18.4	59 ± 4.0[d]	32 ± 7.0[d]

[a]$P < 0.05$ *vs* control animals; [d]$P < 0.01$ *vs* control and calorie restricted animals. CON: Control; CR: Calorie restricted; HF: High fat.

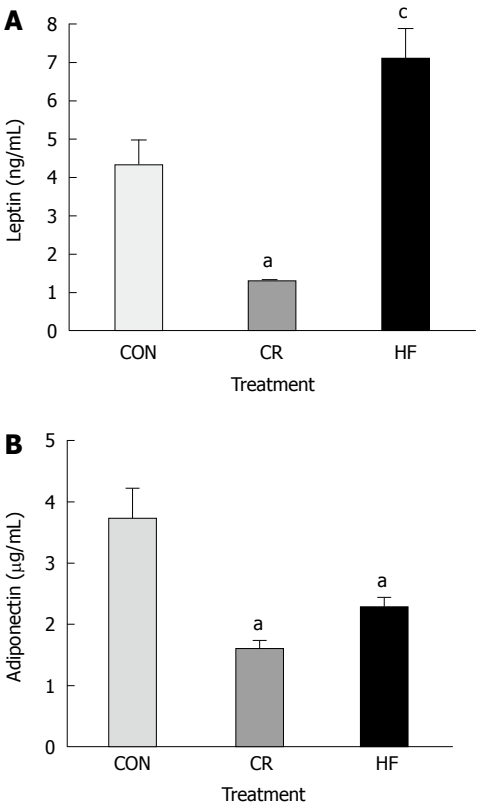

Figure 1 Plasma adipokines in SMAD3-/- mice after 20 wk on dietary treatment. A: Average plasma concentrations of leptin between diet groups prior to infection. Calorie restricted (CR) mice had significantly lower concentrations, whereas high fat (HF) mice had significantly higher concentrations of leptin compared to control (CON) mice ($P < 0.01$); B: Average plasma concentrations of adiponectin between diets prior to infection. Both CR and HF diet mice had significantly lower concentrations of adiponectin than mice on CON diet ($P < 0.05$). [a]$P < 0.05$ *vs* control; [c]$P < 0.05$ *vs* all other groups.

Effect of diet treatment on colitis and dysplasia scores 4 wk post-infection

After 20 wk on dietary treatment, mice were infected with *H. hepaticus* to determine if pre-infection adiposity would influence colitis scores 4 wk following infection. Unexpectedly, we found that CR mice had higher mortality rates beginning at 1 wk post-infection (Figure 2). Because only 40% of CR mice ($n = 2$) survived the infec-

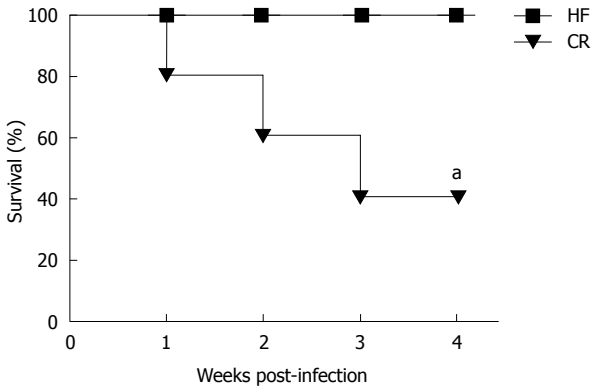

Figure 2 Survival curve of high fat, control and calorie restricted mice after infection with *Helicobacter hepaticus*. Calorie restricted (CR) mice experienced increased mortality after infection, with only 40% of CR mice surviving 4 wk post-infection. $^{a}P < 0.05$ *vs* baseline. HF: High fat.

tion period, we were unable to obtain enough tissue to appropriately evaluate colitis in this group.

HF and CON mice were sacrificed 4 wk following infection and dietary differences in colitis and dysplasia were scored in the cecum and colon. Compared to the uninfected SMAD3-/- mice, CON and HF-fed mice exhibited significant infiltration of immune cell populations into the lamina propria following infection (Figure 3A). We found no significant differences in combined scores between CON (7.9 ± 1.9) and HF (7.8 ± 2.1) mice following infection (Figure 3B). In order to examine the potential effect of time, we allowed some mice to remain infected for up to 6 wk, and compared scores at 4, 5 and 6 wk post-infection. However, there were no further significant changes between or within dietary treatments across time (Figure 3C).

Differences in pre-infection body weight on colonic proliferation and inflammatory markers

Immunohistochemistry analysis on proliferation and inflammatory markers in colon sections from CON-fed uninfected mice and CON and HF-fed mice 4 wk post-infection are presented in Figure 4. There was no significant difference in percentages of colon epithelia positively stained for Ki67, a marker of cellular proliferation, or F4/80 macrophages between CON or HF diet mice at 4 wk post-infection as compared to uninfected mice. A higher percentage of iNOS and COX-2 immunoreactivity ($P > 0.05$) and significantly higher levels of $CD3^{+}$ lymphocytes ($P < 0.05$) was observed after infection in CON and HF fed mice compared to broth-treated mice, consistent with the increased colitis scores; however, there was no difference between infected animals on either diet (Figure 4).

DISCUSSION

Local and systemic alterations in adipokines are implicated in the pathogenesis of IBD[16]. In the current study, we investigated whether diet-induced changes in adiposity prior to induction of colitis would influence inflammatory changes in the colon of SMAD3-/- mice. After 20 wk on dietary treatment, significant changes in body composition were observed, with CR mice having the least and high fat-fed mice the most body fat compared to controls. Consistent with differences in adiposity, plasma concentrations of adipokines were significantly altered. Leptin is secreted in proportion to white AT mass whereas plasma adiponectin concentrations are markedly reduced in obese individuals[45]. In the current study, leptin levels were 1.5-fold higher in HF mice and 4.5 lower in CR mice, whereas low plasma adiponectin concentrations were observed in both HF and CR mice. Significantly lower levels of adiponectin were reported in individuals with anorexia and bulimia prior to treatment, which was restored following refeeding[46], suggesting a critical fat mass may be necessary for secretion[46].

We next evaluated whether differences in adiposity and adipokine levels would influence severity of colitis. We found that restricting caloric intake to 70% that of control animals significantly impacted survival of mice following *H. hepaticus* infection, with only 40% of mice surviving the full infection period. These results were somewhat unexpected as moderate calorie restriction delays or reduces severity of autoimmune disorders[47,48], prolongs life span[49], as well as inhibiting tumorigenesis at several different sites[50,51]. Additionally, Shibolet *et al*[52] found that calorie restricted mice were protected from chemically-induced colitis, which was associated with a decrease in pro-inflammatory cytokine release and an increase in NK1.1 + T lymphocytes. However, in experimental models of infection, CR increases susceptibility to bacterial[53] and parasitic[54] infections, as well as viral infections[55-57], consistent with our findings.

Leptin is recognized to play a pivotal role in both innate and adaptive immune responses by stimulating T cell proliferation[58], chemotaxis of neutrophils[59], NK cell maturity and activation[60], differentiation of dendritic cells[61], eicosanoid synthesis and cytokine release by monocytes and macrophages[62-64], as well as in preventing thymocyte apoptosis[65]. The increased mortality observed in this study was not investigated and is the aim for future projects. However, in a parallel study, we found baseline NK cell populations are reduced in the SMAD3-/- compared to SMAD3+/- mice (Fenton, JI, unpublished observations). Therefore, it is possible that reduced immune cell populations combined with lower circulating leptin in CR mice contributed to immune suppression and reduced capability to mount a response to *H. hepaticus*. In support of this, Clinthorne *et al*[56] recently reported that short term refeeding restored leptin in CR mice, improved survival, and attenuated the decline in NK cell function following influenza infection. Low circulating leptin in tuberculosis patients was also associated with increased disease severity[66], suggesting a causal relationship between adiposity, leptin, and immune response.

The development of IBD results from a complex interaction between genetic, immune and environmental

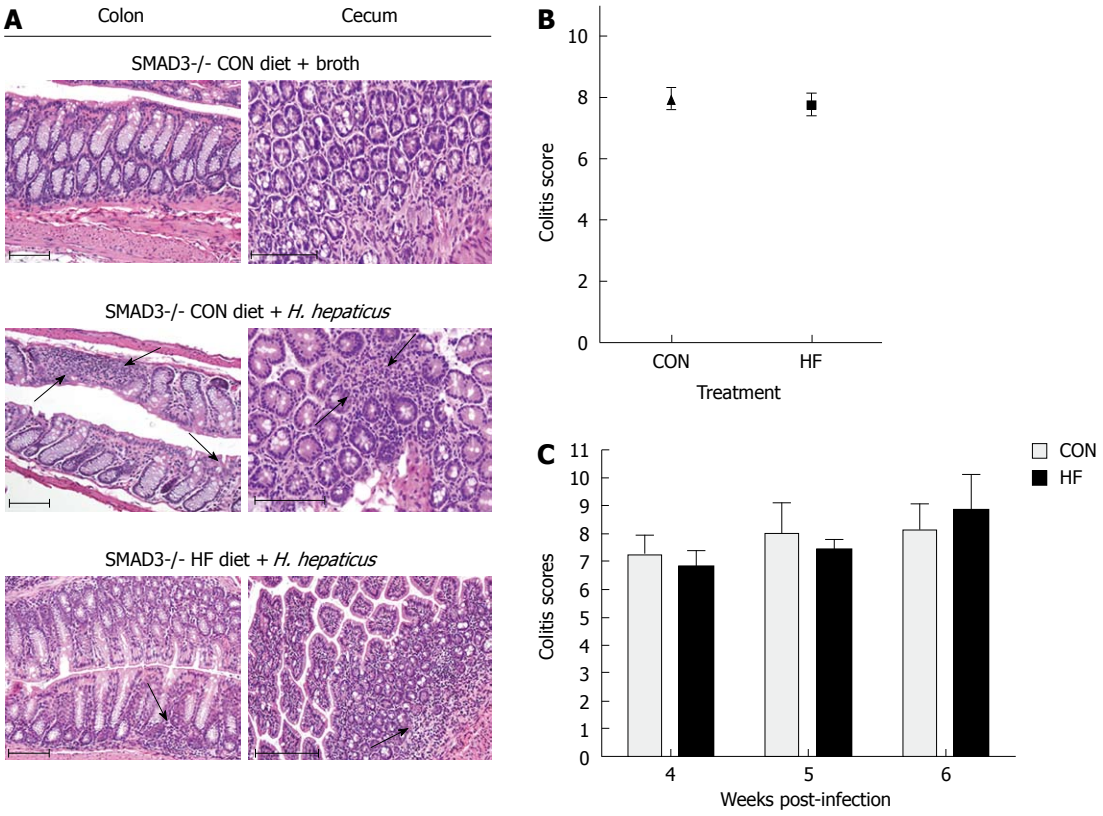

Figure 3 Effect of dietary treatment on colitis severity in SMAD3-/- mice. A: HE stained sections from the colon and cecum of SMAD3-/- control (CON)-fed mice treated with broth and SMAD3-/- CON- or high fat (HF)-fed mice 4 wk post-infection. Four weeks following infection, the number of inflammatory cells in the lamina propria is increased in the colon and cecum of both CON and HF diet animals, consistent with mild inflammation (arrows denote). Scale bars represent 100 μm; B: Average combined colitis and dysplasia scores between diet groups at 4 wk post-infection. There was no significant difference in theses scores between the CON and HF diet treatment groups; C: Average combined colitis and dysplasia scores between CON and HF mice at 4 wk, 5 wk and 6 wk post-infection. There was no difference between CON and HF diet groups at any point, and there was no effect of time on the scores between diets. *H. hepaticus*: *Helicobacter hepaticus*; HE: Hematoxylin and eosin.

factors. Diet is an important environmental factor in IBD pathogenesis; diets high in dairy products, refined sugar and fast food are associated with an increased risk of developing IBD[67,68]. However, there is little conclusive epidemiological evidence for a causal relationship between dietary intake and onset of IBD[68]. Importantly, after the onset of IBD, malnutrition (resulting from decreased food intake, malabsorption and increases in both nutrient loss and energy requirements) is common[69]. These changes in intake and energy expenditure may result from circulating inflammatory mediators associated with the pathophysiology of IBD, such as TNF-α, IL-1 and IL-6. These cytokines can increase catabolism and lead to anorexia[68,70]. Malnutrition is also associated with adverse outcomes in IBD progression, exacerbating immunodeficiency, perpetuating malabsorption and increasing risk of infections, particularly *via* bacterial translocation. This differs somewhat from what is modeled in this study. The caloric restriction diet met 100% of all nutrient needs and was only deficient by 30% of energy. The model caloric restriction of experimental-colitis is consistent with increased mortality in IBD related to energy deficit but not malnutrition[70-73]. Given the importance of leptin and immune function, our data do imply that reduced AT and leptin production (directly related to fat cell size and number) may further impair innate immune response to a pathogen. Similar mortality effects were observed in caloric restriction and influenza infection in mice discussed above.

Although low body fat stores and reduced circulating levels of leptin may impair immune responses to infectious stimuli, elevated leptin and peripheral leptin resistance is commonly observed in obese individuals. Previous studies suggest that obesity exacerbates colonic inflammation[40,74-77]. Increased mesenteric fat and fat creeping were also observed in inflamed intestinal regions in patients with CD[78]. Additionally, overweight and/or obese individuals with CD have more complications from and more frequent disease relapses than normal weight individuals[41]. In the current study, we did not observe any overall changes in colitis severity between control and HF mice, despite differences in body fat and serum adipokines. To determine whether general inflammatory markers were altered, we stained for COX-2 and iNOS, which are induced by pro-inflammatory cytokines in a variety of pathological conditions including UC in humans[79,80]. Further, we examined colons for T lymphocyte and macrophage infiltration to determine whether higher body fat

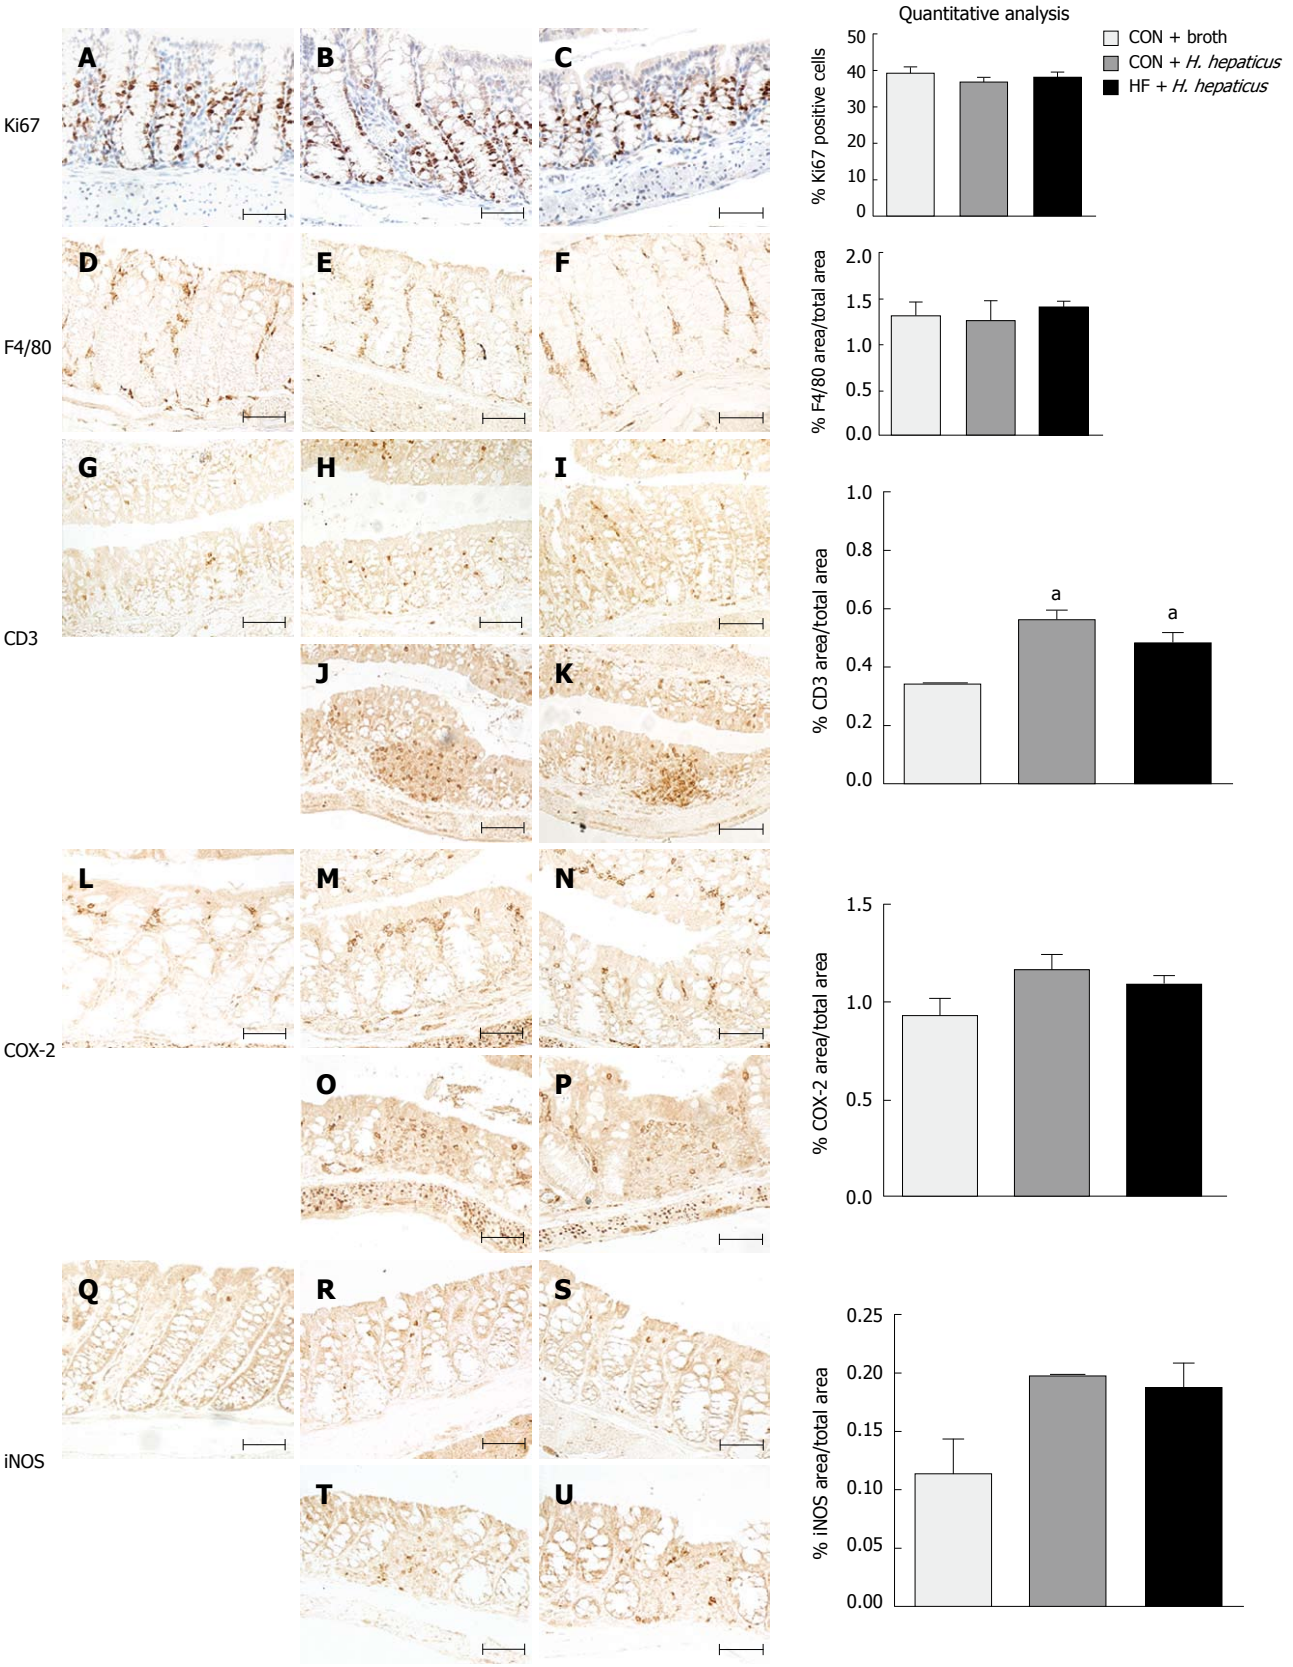

Figure 4 Effect of diet on proliferation and inflammatory markers following infection with *Helicobacter hepaticus* in SMAD3-/- mice. Immunohistochemical staining for Ki-67 (A-C), F4/80 (D-F), CD3 (G-K), COX-2 (L-P) and iNOS (Q-U) in proximal colon sections of SMAD3-/- mice fed control (CON) diet and treated with broth (A, D, G, L, Q), CON-fed mice treated with *Helicobacter hepaticus* (*H. hepaticus*) (B, E, H, J, M, O, R, T), or fed a high fat (HF) diet and treated with *H. hepaticus* (C, F, I, K, N, P, S, U) 4 wk post-infection. Normal appearing proximal colon segments (A-I, L-N, Q-S) and inflamed colon segments with lymphoid infiltrate (J, K, O, P, T, U). Scale bars represent 100 μm. There were no significant differences in proliferation indices or in macrophage infiltration. CON and HF diet mice had slightly increased staining for $CD3^+$ T lymphocytes, cyclooxygenase (COX)-2, and inducible nitric oxide synthase (iNOS) post-infection compared to broth-treated controls, but averages were not statistically significant between diets ($P > 0.05$). $^aP < 0.05$ *vs* CON animals.

would influence specific subsets of inflammatory cells. Both control and high fat mice treated with *H. hepaticus* had moderately elevated levels of $CD3^+$ T lymphocytes, as well as COX-2 and iNOS immunoreactivity in epithelia-associated myofibroblasts and macrophages, compared to broth-treated mice. However no further changes were observed between dietary treatments. We also did not observe any differences in the proliferative index in the proximal colon segments between treatments, demonstrating that higher body fat does not influence disease severity in our model.

Results from the current study suggest that moderately increased adiposity induced by high fat feeding does not influence colitis severity in SMAD3-/- mice despite changes in plasma adipokines. Although we were able to induce a body fat percentage of 32% in the SMAD3-/- mice, this percentage body fat may be insufficient to induce chronic inflammation associated with obesity observed in other mouse strains that approach 50%-60% AT. More importantly, we found that calorie restricted mice had a higher mortality in response to infection with *H. hepaticus*. Future studies examining the association between percent body fat, leptin, and immune responses to infectious stimuli leading to IBD are warranted.

COMMENTS

Background

Recent studies indicate that the constant low-grade inflammation associated with obesity or excess adipose tissue (AT), including elevated serum levels of C-reactive protein, interleukin-6 and tumor necrosis factor-α, may contribute to the severity of inflammatory bowel diseases (IBD). Additionally, overweight and/or obese individuals with Crohn's disease were found to have more complications and more frequent disease relapses than normal weight individuals, providing a potential link between excessive AT and pathogenesis of IBD.

Research frontiers

There is currently insufficient evidence to support a causal relationship between obesity and IBD; however, the conditions share similar inflammatory characteristics. In this study, the authors demonstrate that moderately increased adiposity with associated changes in adipokines does not influence colitis severity in SMAD3-/- mice.

Innovations and breakthroughs

Previous studies suggest that obesity exacerbates colonic inflammation. Malnutrition is associated with adverse outcomes in IBD progression, exacerbating immunodeficiency, perpetuating malabsorption and increasing risk of infections. We report that moderate obesity did not influence the severity of colon inflammation in experimentally-induced colitis. Importantly, caloric restriction negatively influences survival following pathogen challenge, potentially due to an impaired immune response.

Applications

Further studies should examine the role of energy balance, both positive and negative, on the pathogenesis of IBD. Understanding how caloric restriction increases mortality in this preclinical model of experimentally-induced colitis may lead to therapeutic strategies for bacterially-driven IBD in humans.

Terminology

In the current study,the authors evaluated the influence of adiposity on colitis severity in SMAD3-/- mice. SMAD3 is a transcription factor for transforming growth factor (TGF)-β. TGF-β is a protein that controls proliferation and cellular differentiation, both in normal cells and in the early stages of carcinogenesis. SMAD3-/- mice have defective TGF-β signaling and develop mild colitis within 4 wk following infection with *Helicobacter spp*. Dysfunctions in TGF-β signaling are commonly observed in human IBD and during colon cancer development.

Peer review

It is a relevant paper dealing with a demanding issue too much neglected in the biologic-era treatment of IBD. The suggestion is implementing discussion with some speculation on the potential negative influence of malnutrition in IBD.

Abstract

AIM: To investigate the angiogenesis-related protein expression profile characterizing metastatic colorectal cancer (mCRC) with the aim of identifying prognostic markers.

METHODS: The expression of 44 angiogenesis-secreted factors was measured by a novel cytokine antibody array methodology. The study evaluated vascular endothelial growth factor (VEGF) and its soluble vascular endothelial growth factor receptor (sVEGFR)-1 protein levels by enzyme immunoassay (EIA) in a panel of 16 CRC cell lines. mRNA VEGF and VEGF-A isoforms were quantified by quantitative reverse-transcription polymerase chain reaction (Q-RT-PCR) and vascular endothelial growth factor receptor (VEGFR)-2 expression was analyzed by flow cytometry.

RESULTS: Metastasis-derived CRC cell lines expressed a distinctive molecular profile as compared with those isolated from a primary tumor site. Metastatic CRC cell lines were characterized by higher expression of angiopoietin-2 (Ang-2), macrophage chemoattractant proteins-3/4 (MCP-3/4), matrix metalloproteinase-1 (MMP-1), and the chemokines interferon γ inducible T cell α chemoattractant protein (I-TAC), monocyte chemoattractant protein I-309, and interleukins interleukin (IL)-2 and IL-1α, as compared to primary tumor cell lines. In contrast, primary CRC cell lines expressed higher levels of interferon γ (IFN-γ), insulin-like growth factor-1 (IGF-1), IL-6, leptin, epidermal growth factor (EGF), placental growth factor (PlGF), thrombopoietin, transforming growth factor β1 (TGF-β1) and VEGF-D, as compared with the metastatic cell lines. VEGF expression does not significantly differ according to the CRC cellular origin in normoxia. Severe hypoxia induced VEGF expression up-regulation but contrary to expectations, metastatic CRC cell lines did not respond as much as primary cell lines to the hypoxic stimulus. In CRC primary-derived cell lines, we observed a two-fold increase in VEGF expression between normoxia and hypoxia as compared to metastatic cell lines. CRC cell lines express a similar pattern of VEGF isoforms ($VEGF_{121}$, $VEGF_{165}$ and $VEGF_{189}$) despite variability in VEGF expression, where the major transcript was $VEGF_{121}$. No relevant expression of VEGFR-2 was found in CRC cell lines, as compared to that of human umbilical vein endothelial cells and sVEGFR-1 expression did not depend on the CRC cellular origin.

CONCLUSION: A distinct angiogenesis-related expression pattern characterizes metastatic CRC cell lines. Factors other than VEGF appear as prognostic markers and intervention targets in the metastatic CRC setting.

INTRODUCTION

Colorectal cancer (CRC) is one of the leading causes of cancer-related deaths. The prognosis of CRC is dependent upon the extent of disease and approximately 60% of patients develop metastases after surgical resection. With a 5-year survival rate of less than 10% in patients with distant metastatic disease, targeting the metastatic process and sites should provide an effective treatment[1]. The progressive growth of colon cancer and subsequent metastatic process is dependent on an angiogenic network[2,3]. Thus, anti-angiogenic strategies have emerged as effective therapies in patients with colon cancer, especially in the metastatic setting of the disease[4-6]. Yet, differences in the magnitude of survival benefit point to alternative pathways in the tumor microenvironment as responsible for inconsistent outcomes[7].

Angiogenesis is a complex process dependent on the angiogenic factors secreted by the tumor and stroma cells[8]. Vascular endothelial growth factor is considered the major pro-angiogenic factor[9]. The vascular endothelial growth factor (VEGF) gene encodes for six alternatively spliced isoforms[10] with differential diffusion potential and binding to receptors[11]. The question currently consists of understanding the significance of VEGF/vascular endothelial growth factor receptor (VEGFR) signaling in cancer cells[12,13]. The VEGF isoforms and VEGF receptor expression pattern would drive the activity and functionality of the VEGF/VEGFR pathway in both tumor and endothelial cells. The multistep process of angiogenesis accompanies the multistage development of a tumor[14]. The switch into the metastatic phenotype brings a number of changes within the tumor microenvironment, including acquisition of hypoxia-tolerance mechanisms[15]. While up-regulation of VEGF expression is activated mainly under hypoxia[9], recent reports reflect on the question of whether metastatic tumors rely as much on angiogenesis and VEGF as primary tumors[15].

Other studies report that tumors in more advanced stages do not rely on a unique angiogenesis driver[2]. A network of multiple cytokines and growth factors create a crosstalk within the tumor microenvironment which ultimately drives tumor angiogenesis[2,16]. The mediators of vessel wall remodeling matrix metalloproteinases, macrophage chemoattractant proteins and angiopoietin, involved in invasion and metastasis processes, exert pro-angiogenic signals[8,17]. Chemokines such as interleukin (IL)-1α and IL-8 play an important role in colon cancer progression and angiogenesis[18], and IL-8 up-regulates MMPs[19]. VEGF expression actually determines the activity of Ang-1/Ang-2 and the expression of MCPs[20,21].

Great efforts have been made to characterize biomarkers in CRC[22]. However, the question of biomarkers of CRC metastasis remains currently unresolved. On this basis, the aim of this study was to characterize the protein factors behind the angiogenic potential of CRC cell lines of metastatic origin.

Table 1 Colorectal cancer cell lines origin

Cell line	Type/origin
SW620	Colon adenocarcinoma. Derived from: metastasis to lymph node
T84	Colon carcinoma. Derived from metastasis to lung
LoVo	Derived from metastatic site: left supraclavicular region
SW480	Colon adenocarcinoma
WiDr	Colon adenocarcinoma
RKO	Colon carcinoma
HT29	Colon adenocarcinoma
HCT15	Colon adenocarcinoma
HCT116	Colon carcinoma
SW1116	Colon adenocarcinoma
SW1417	Colon adenocarcinoma
LS174T	Colon adenocarcinoma
LS513	Colon carcinoma
Caco2	Colon adenocarcinoma
DLD-1	Colon adenocarcinoma
LS411N	Colon adenocarcinoma
Colo320	Colon adenocarcinoma

MATERIALS AND METHODS

Cell cultures and conditioned media

We used 16 CRC cell lines: HT29, WiDr, HCT116, RKO, SW480, Colo320, Caco2, SW1116, LS174T, SW1417, DLD-1, LS513, HCT15, SW620, LoVo and T84 (all from American Type Culture Collection, Manassas, VA) (Table 1). The cell lines were maintained in the recommended growth media supplemented with 10% fetal bovine serum (GIBCO) and 1% penicillin/streptomycin (GIBCO). For harvesting conditioned media, CRC lines cells were grown approximately to 70% confluence in serum free media. The conditioned media were collected after 24 h of incubation, centrifuged and kept frozen.

VEGF and sVEGFR1 protein detection by quantitative immunoassay

VEGF-A in supernatant was determined using the Human VEGF Quantikine® EIA kit (R and D Systems) and soluble vascular endothelial growth factor receptor (sVEGFR)-1 was quantified by EIA (Human sVEGF

Total VEGF and isoforms mRNA determination by quantitative reverse-transcription polymerase chain reaction

Total RNA was isolated using the RNeasy kit (Qiagen, Valencia, CA). Single strand DNA was synthesized from 1 μg total RNA using the cDNA Archive kit (Applied Biosystems). Quantitative reverse-transcription polymerase chain reaction (Q-RT-PCR) for total VEGF was performed using primers and probes purchased from Applied Biosystems (Hs00900054_m1). RNA18s (Hs99999901_s1) was used as an endogenous control and data obtained was represented as 2-ΔCt.

VEGF isoforms were determined by Q-RT-PCR using primers designed specifically for $VEGF_{121}$, $VEGF_{165}$, and $VEGF_{189}$, and glyceraldehyde-3-phosphate dehydrogenase (GAPDH) was used as an endogenous control (Table 2). The relative quantification of samples was performed using a standard curve by dilution of a specific plasmid for each isoform (ranging from 10 pg to 1 fg). Human VEGF cDNA for each isoform and GAPDH were cloned from total RNA isolated from lung cancer resection as follows. PCR products were run through a 1% agar gel and bands of the size expected for $VEGF_{121}$, $VEGF_{165}$ and $VEGF_{189}$ were isolated and purified. Each VEGF isoform was cloned into the pCRII vector (Invitrogen) and sequenced (ABI PRISM Big Dye Terminator Cycle Sequencing reaction kit; ABI Protocol, Gene Amp 9600, Applied Biosystems) to verify its identity.

Time course hypoxia-normoxia

The cell lines were maintained in the recommended growth media supplemented with 10% fetal bovine serum (GIBCO) and 1% penicillin/streptomycin (GIBCO). After washing with phosphate buffered saline (PBS), serum-free medium was added and the cells exposed to normoxic or hypoxic conditions for 6 h, 12 h, 24 h, 36 h, 48 h and 72 h. Hypoxic conditions were achieved by culturing cells in a modulator incubation chamber (Sanyo MCO-18 M) gassed with 1% O_2, 50 mL/L CO_2, and 94% N_2. VEGF protein secretion was measured in the supernatant by enzyme immune-assay (EIA) and VEGF mRNA levels by Q-RT-PCR. Cell proliferation was evaluated by the Trypan Blue exclusion method.

VEGFR-2 expression in colorectal cancer cell lines by flow cytometry

The expression of VEGFR-2 (KDR) in CRC cell lines was determined by flow cytometry (FacScan, Becton-Dickinson). After trypsinization, cells were incubated in medium for 12 h on a rocker platform to enable regeneration of the receptors. Cells were Fc-blocked by treatment with 100 μL of AB human serum for 15 min at room temperature prior to staining with 10 μL of PE-conjugated anti-VEGFR-2 antibody (Becton Dickinson Biosystems) for 30 min at 4 ℃. Following the incubation, unbounded anti-VEGFR-2 antibody was removed by washing the cells twice in 4 mL PBS buffer. The human umbilical vein endothelial cells (HUVEC) cell line was used as a positive control.

Secreted angiogenic profile by cytokine antibody-array

The secretion of angiogenic factors by CRC cell lines was evaluated in duplicate using a protein array method (RayBio® Human Angiogenesis Antibody Array, RayBiotech C Series 1000, RayBiotech, Inc Norgross, GA). This assay is capable of simultaneously detecting 44 different angiogenic factors (spotted in sub-arrays I and II) with high specificity. The sensitivity of the antibodies present in the arrays ranged from 1-2000 pg/mL. Conditioned media was obtained after the incubation of 2×10^5 cells in serum-free medium for 20 h at 37 ℃ and 5% CO_2. Each array was incubated with 1.2 mL of medium at 4 ℃ overnight, and bound antigens were detected according to the manufacturer's instructions. To determine the relative concentrations of angiogenic factors in the media, the densities of individual spots were measured using Imagene 4.1 software (Biodiscovery Inc., Marina Del Rey, United States) for image capture and analysis.

Statistical analysis

Statistical analysis was carried out with SPSS 13.0 soft-

ware (SPSS Inc.). Associations between VEGF expression and VEGF isoforms pattern were determined with the Spearman correlation. Differences between groups were determined by the Mann-Whitney *U* test. The level of two-tailed statistical significance was 0.05.

CRC cell line angiogenesis cytokine antibody-arrays raw data were normalized to the global median [BRB Array Tools 3.6.0 (NCI)] of signals detected as per manufacturer's instructions. GENESIS software (Institute for biomedical engineering, Graz University of Technology, Graz, Austria) was used for the analyses of clustering of samples and genes and K-means and hierarchical unsupervised clustering analyses were performed to determine cytokine profiles.

RESULTS

Distinct angiogenesis-related expression pattern in primary and metastatic colorectal cancer cell lines

To identify the angiogenesis-related "secretome" of CRC cell lines in normoxia, we analyzed 44 angiogenesis-related cytokines and growth factors by an antibody-array in primary (Caco2, SW1417, DLD1, HT29 and SW480) and metastatic (SW620 and T84) CRC cell lines. K-means analysis classified CRC cell line angiogenesis-related secreted factors according to their level of secretion (Figure 1A). Cluster I showed a homogeneous high expression of the pro-angiogenic IL-8, MMP-1, MCP-1, growth related oncogene (GRO)-α, regulated upon activation,

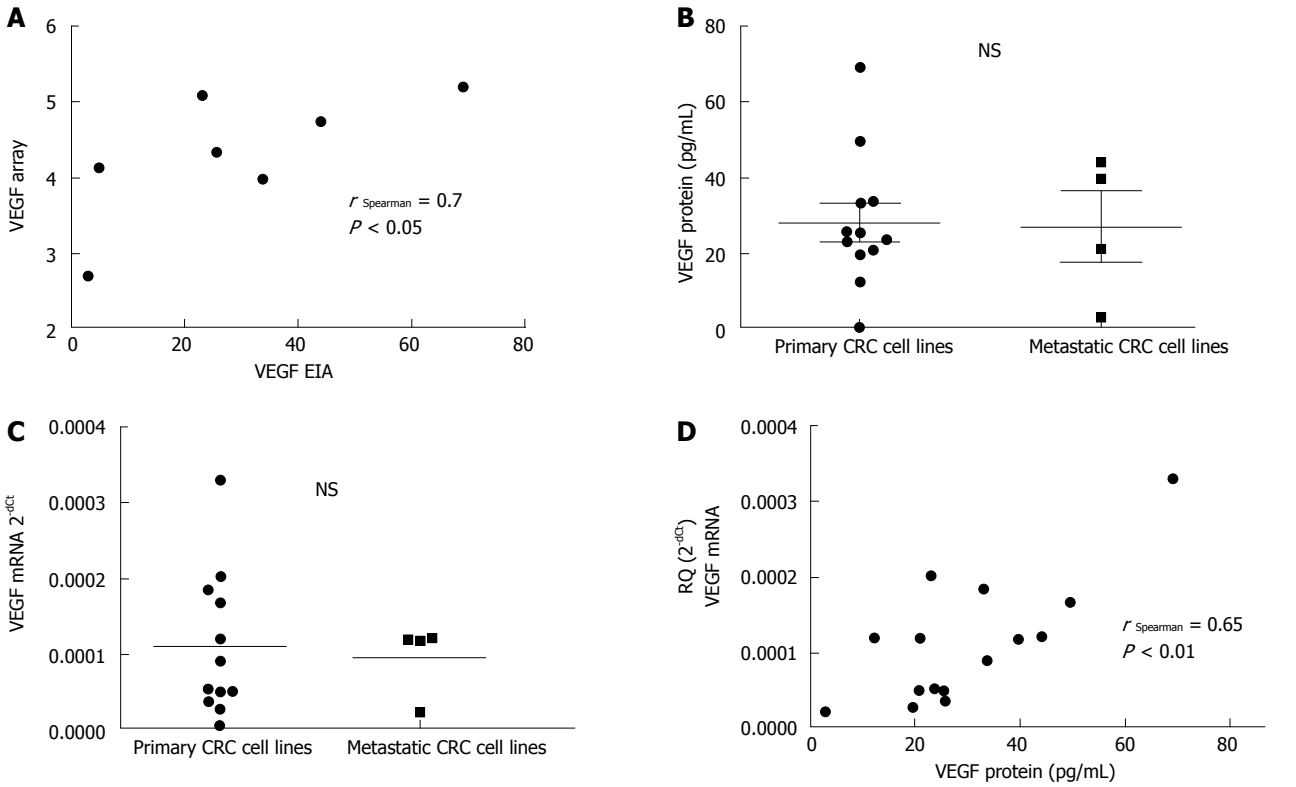

Figure 2 Vascular endothelial growth factor expression in colorectal cancer cell lines. A: A statistically significant positive correlation is found between vascular endothelial growth factor (VEGF) protein as determined by antibody-array and by enzyme immunoassay (EIA), validating the array method; B and C: Colorectal cancer (CRC) cell lines exhibit variability in VEGF protein (B) and mRNA (C) expression according to their primary or metastatic origin (not statistically significant); D: A statistically significant positive correlation is found between VEGF protein by EIA and VEGF mRNA, suggesting the major role of transcriptional mechanisms in the regulation of VEGF expression. NS: Not significant.

normal T-cell expressed, and secreted protein (RANTES), urokinase-type plasminogen activator-receptor (uPAR) and VEGF; and the anti-angiogenic tissue inhibitor of metalloproteinases tissue inhibitor of metalloproteinases (TIMP)-1 and TIMP-2 (Figure 1A, cluster Ⅰ). Cluster Ⅱ integrated angiogenic factors not secreted by CRC cell lines in normoxia, including VEGF family proteins placental growth factor (PlGF) and sVEGFR-2 and inflammatory cytokines with pro-angiogenic properties granulocyte colony-stimulating factor (G-CSF), granulocyte macrophage colony-stimulating factor (GM-CSF), IFN-γ, tumor necrosis factor-α (TNF-α) (Figure 1A, cluster Ⅱ). Primary tumor- and metastasis-derived CRC cell lines were characterized by a distinct angiogenesis-related molecular pattern in normoxia (Figure 1A, cluster Ⅲ and Ⅳ). Figure 1B shows the unsupervised hierarchical clustering of the antibody-array proteins significantly differing in expression according to their cellular origin. One-way ANOVA ($P < 0.05$) grouped primary and metastatic cell lines according to their differential molecular expression pattern. Metastasis-derived cell lines were characterized by higher expression of Ang-2, MCP-3, MCP-4, MMP-1 and the chemokines I-TAC, I-309, IL-2 and IL-1α ($P < 0.05$), and a trend was found for MMP-9, as compared to primary tumor cell lines (Figure 1B). On the other hand, CRC cell lines isolated from a primary tumor site were clustered together according to the higher expression of IFN-γ, IGF-1, IL-6, leptin, EGF, PlGF, thrombopoietin, TGF-β1 and VEGF-D ($P < 0.05$), as compared with the metastatic ones (Figure 1B). Interestingly, VEGF-A (VEGF) was not found among the proteins differentially expressed according to the cellular source of isolation. Figure 1C illustrates processed antibody-arrays and the images captured of Caco2 (primary CRC cell line) and T84 (metastatic CRC cell line).

VEGF expression in primary and metastatic colorectal cancer cell lines

The antibody array data showed no significant changes in VEGF secretion between primary and metastasis-derived CRC cell lines (Figure 1B). To validate the antibody array results, we analyzed VEGF levels by EIA. The results were confirmed by a statistically significant positive correlation between VEGF protein as determined by the antibody-array and by EIA ($r_{Spearman} = 0.7$, $P < 0.05$) (Figure 2A).

In a second step, VEGF secretion by EIA and VEGF mRNA expression was analyzed in a larger panel of 16 CRC cell lines. As shown in Figure 2B and C, we did not detect any significant difference in VEGF expression according to the primary or metastatic CRC cell lines (mean of 28.9 pg/mL and 22.7 pg/mL VEGF protein; 0.011 and 0.009 (relative quantification) VEGF mRNA, respectively). Further, a strong correlation ($r = 0.65$, $P <$

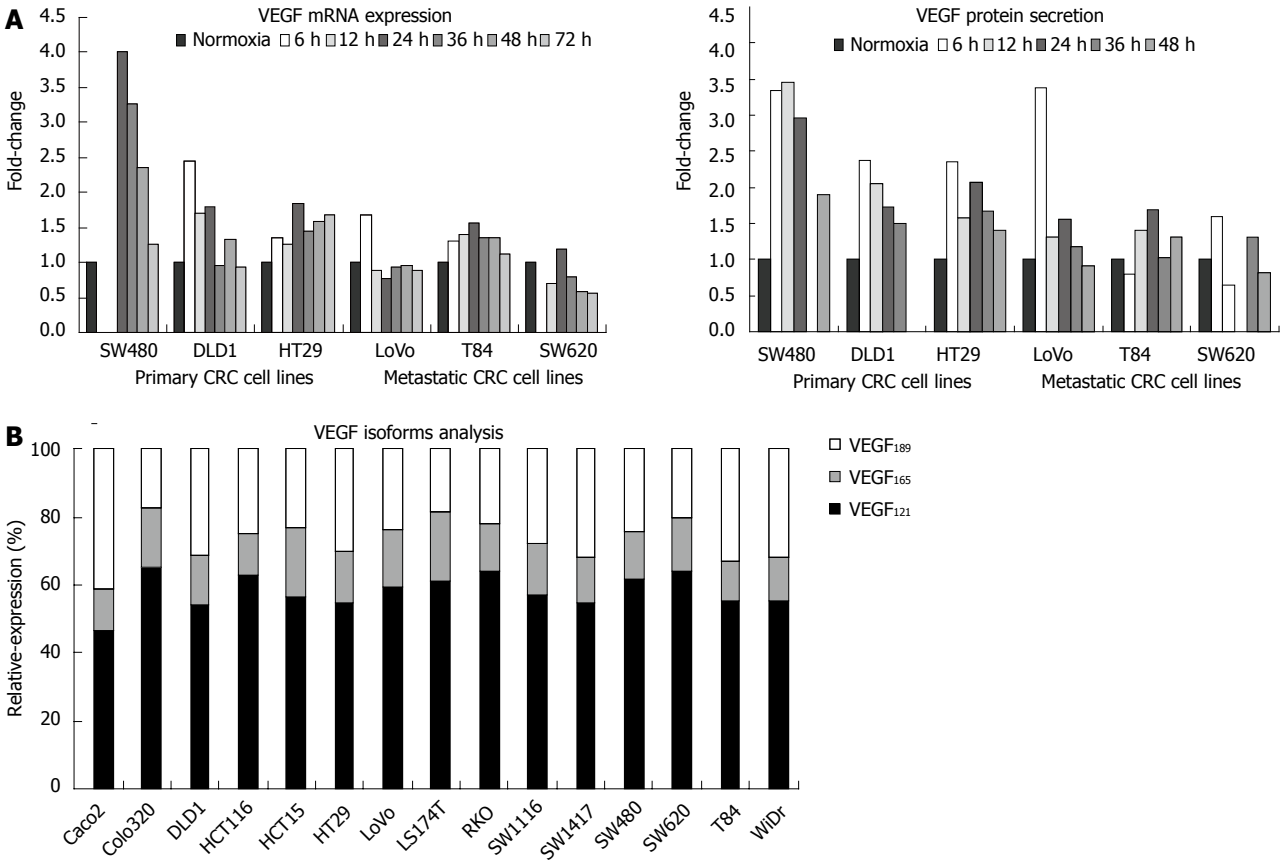

Figure 3 Vascular endothelial growth factor expression regulation. A: Modulation of vascular endothelial growth factor (VEGF) expression (mRNA and protein) in response to severe hypoxia in primary and metastatic colorectal cancer (CRC) cell lines; B: Expression of VEGF isoforms 121, 189 and 165 by CRC cells in normoxia.

$VEGF_{165}$ mRNA	$r = 0.67$ $P = 0.007$	$r = 0.93$ $P = 0.000$	
$VEGF_{189}$ mRNA	$r = 0.69$ $P = 0.005$	$r = 0.95$ $P = 0.000$	$r = 0.92$ $P = 0.000$

VEGF: Vascular endothelial growth factor.

0.01) was detected between VEGF protein (by EIA) and VEGF mRNA expression (Figure 2D) in CRC cell lines, indicative of the major role of transcriptional mechanisms in the regulation of VEGF expression[23]. A similar correlation was observed in hypoxia between VEGF protein (by EIA) and VEGF mRNA expression (Figure 3A). Severe hypoxia induced different levels of VEGF expression up-regulation depending on the CRC cellular origin. Surprisingly, the fold change normoxia-hypoxia in VEGF expression of metastatic CRC cell lines was ≤ 1.5 in the majority of time points tested, as compared with the > 1.5-4.0 fold change in primary cell lines for both protein and mRNA VEGF (Figure 3A).

VEGF isoforms have differential angiogenic and tumorigenic activities and their expression pattern may also define the CRC cell angiogenic capacity[24]. Primary and metastatic CRC cell lines had a similar expression pattern of the three major isoforms $VEGF_{121}$, $VEGF_{169}$ and $VEGF_{185}$, despite variability in VEGF expression (Figure 3B), implying a similar mechanism of regulation. $VEGF_{121}$ was the predominant isoform expressed by CRC cell lines (58.23% ± 5.05% of total VEGF mRNA), as compared to$VEGF_{165}$ and $VEGF_{189}$ (15.13% ± 2.71% and 26.6% ± 6.5% of VEGF transcripts, respectively). In line with a previous study on tumor tissue[25], the expression of the three isoforms was significantly associated with total VEGF protein; $r = 0.55$, $P < 0.05$ for $VEGF_{121}$ and furthermore, $VEGF_{165}$ and $VEGF_{189}$ showed higher correlation ($r = 0.67$ and $r = 0.69$, $P < 0.01$, respectively) (Table 3).

VEGFR expression in colorectal cancer cell lines

While the role of the VEGF/VEGFR pathway in endothelial cells is well characterized, its functionality and expression by tumor cells is still controversial[13]. Soluble VEGFR-1 was quantified in CRC cell line supernatants at a lower range than VEGF (mean 8.3 and 27.8 pg/mL respectively) and no differences were found according to the cellular origin (7.57 ± 2.12 and 10.67 ± 3.1, in primary and metastatic CRC cell lines, respectively) (Figure 4A). In agreement with other studies[26], a trend was observed for

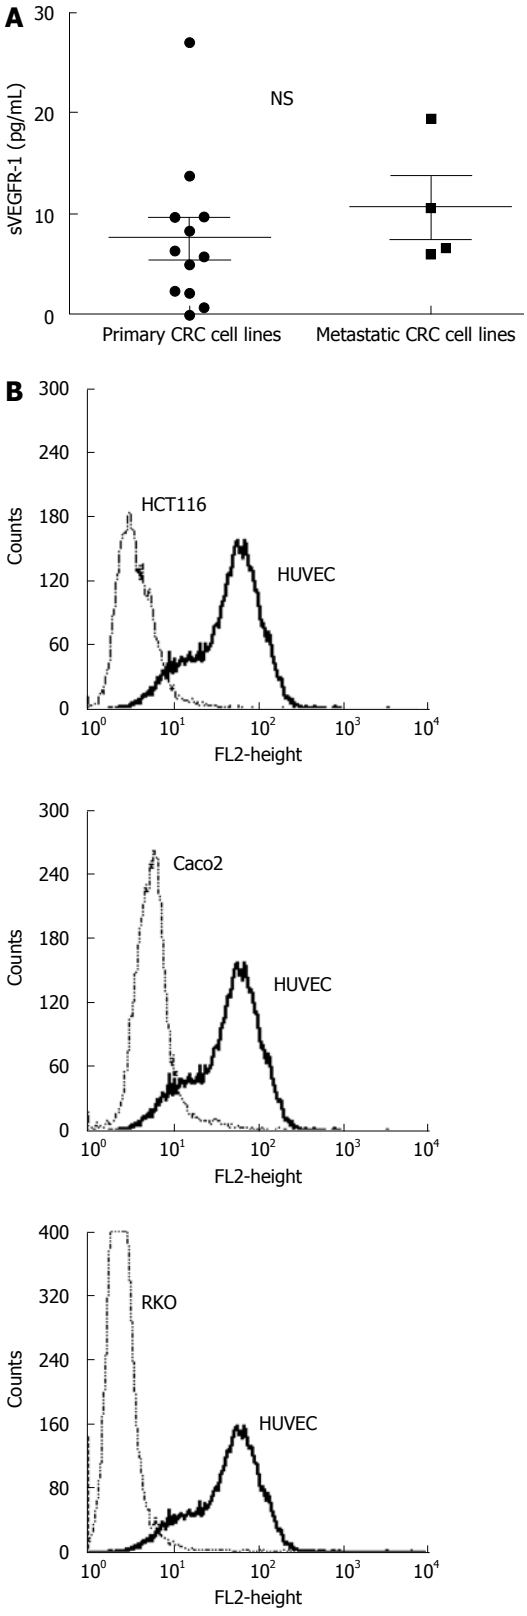

Figure 4 Vascular endothelial growth factor receptors expression in colorectal cancer cell lines. A: Soluble vascular endothelial growth factor receptor (sVEGFR)-1 expression measured by EIA is not significantly different between primary and metastatic colorectal cancer (CRC) cell lines; B: Flow cytometry of the surface expression of vascular endothelial growth factor receptor (VEGFR)-2 in human umbilical vein endothelial cells (HUVEC) and the primary CRC cell lines HCT116, Caco2 and RKO under normoxic conditions reveals a general lack of VEGFR-2 expression on the surface of CRC cells as compared to HUVEC. NS: Not significant.

an inverse correlation between sVEGFR-1 and VEGF expression (data not shown), indicative of the angiogenesis inhibiting role of sVEGFR-1[13].

In our CRC cell lines panel, the antibody array data showed a lack of expression of sVEGFR-2 (Figure 1A). Given the hypothesis that earlier tumor stages are more dependent on the VEGF/VEGFR signaling pathway[15], we analyzed surface VEGFR-2 expression in CRC cells of primary origin. Flow cytometry revealed a general lack of surface VEGFR-2 expression in CRC cells of medium to high VEGF expression, as compared to HUVEC cell line (Figure 4B). These findings add to the stock of controversial results to date[27,28].

DISCUSSION

Identifying the proteins responsible for the different behavior of more advanced CRC tumors seems warranted in order to more effectively use current treatment options. Furthermore, there is a need to characterize definite biomarkers of CRC metastasis to serve as prognostic indicators and novel interventional targets. As derived from our findings in vitro, the tumor microenvironment of CRC metastases would be different to that of primary tumors, because of the effect of the CRC cells secreted factors. Metastatic CRC cell lines are characterized by a greater expression of cytokines majorly involved in metastasis, migration and invasion, while being proven pro-angiogenic effectors. MMP-1 plays an important role in CRC tumor invasion and metastasis[29] and MMP-9 has proved to be of prognostic value in stage Ⅱ colon cancer patients, where tumors with higher protein expression had a higher recurrence rate[30]. The monocyte attractant chemokine I-309 has been shown to stimulate chemotaxis and invasion of endothelial cells and the roles of IL-1α in colon cancer angiogenesis and of IL-2 in inflammation and apoptosis, seem also consistent with the metastatic phenotype[18,31,32].

Hypoxia is widely recognized as the major transcription effector for VEGF expression[9]. However, the greater (two-fold increase) induction of VEGF expression in hypoxia observed in primary CRC as compared to metastatic cell lines is an interesting finding which agrees with recent hypotheses. Tolerance to hypoxia is frequently acquired by tumor cells progressing towards more advanced phenotypes[15]. Our finding suggests the metastatic CRC molecular phenotype provides some intrinsic resistance to the hypoxic induction of VEGF expression. Some authors have shown that hypoxia would select more malignant metastatic cells, less sensitive to anti-angiogenic treatment[33], to yield poorer patients outcomes[34,35]. The community still agrees that angiogenesis is a hallmark of cancer in metastatic stages[36]. However, given the broad angiogenic network in the tumor microenvironment, research should move in the direction of investigating the mechanisms by which metastatic tumors depend on VEGF, since they seem to be different to those exploited by primary tumors[15]. Furthermore, with the objective of individualized care in mCRC, the distinct metastatic "sec-

retome" proteins emerge as alternative targets to consider in the management of advanced disease.

Further to the VEGF expression profile, the pattern of VEGF isoforms represents the next step to identifying intrinsic differences to guide treatment choice. However, the similar expression of VEGF isoforms across cell lines does not offer clarification. Further to this finding, it would be of interest to explore how VEGF transcription factors modulate the ratio of VEGF isoforms as disease progresses, given the changes on VEGF dependence. Interestingly, a novel class of VEGF isoforms, VEGFxxxb, generated through alternative splicing of exon 8, has been recently described[37]. Studies suggest anti-angiogenic or weak angiogenic properties for these isoforms[38,39]. Not exempt from controversy, this discovery will help in further defining the role of VEGF/VEGFR signaling in CRC, yet still the testing techniques need refinement in specificity between the two classes.

Emerging data suggest VEGF to be a growth factor also for tumor cells and VEGF/VEGFR signaling to regulate their expression. However, this hypothesis remains unproven until consolidated results on VEGF receptor expression on tumor cells become available[12,28]. Extensive work has been done on the activity of VEGF/VEGFR-1 signaling in CRC cells showing that it mediates cell motility and invasiveness but not cell proliferation[13]. While this would involve VEGF/VEGFR-1 in CRC progression and metastatic processes, sVEGFR-1 secretion was not found of significant relevance in metastasis-derived CRC cells. In contrast, not so much is known about the activity of VEGF/VEGFR-2 in cancer cells. Reports suggest an involvement in the sensitivity of CRC cells to inhibition of VEGF-related survival pathways[40]. However, controversial results on the VEGFR-2 expression on tumor cells to date[27,28], to which our results add, do not help to resolve this question. Definite confirmation of the expression and functionality of this pathway is necessary in order to shed more light on the mechanism of action of anti-VEGF therapies[40].

Consistent with the key role of VEGF in the "angiogenic switch" and the hypoxia-resistance mechanisms in metastatic stages, CRC cell dependence on VEGF in more advanced settings seems attenuated in favor of other cytokines in the progression of metastasis. Further investigation of these findings and testing the significance of the distinct "secretome" of CRC metastases at the clinic side seems warranted given the implications for patient outcomes.

COMMENTS

Background

Identifying the proteins responsible for the different behavior of more advanced colorectal cancer is necessary in order to more effectively use current treatment options. The progressive growth of colon cancer depends on the blood vessels (angiogenesis) network within the tumor. Therapies targeting angiogenesis have emerged in the field; however, variances in the magnitude benefit lead to great amount of research to explain inter-individual differences. It is thought that different proteins or biomarkers in the tumor microenvironment are responsible for these facts.

Research frontiers

The lack in understanding of biomarkers of colorectal cancer metastasis led the authors to set up this work. Using a novel cytokine antibody array technique, this work identifies the differences in angiogenesis-related protein expression of colorectal cancer cell lines of primary and metastatic origin. This is the first step prior to translation into a clinic setting, where these differences are to be corroborated in patients with colorectal cancer.

Innovations and breakthroughs

The distinct profile of metastatic cell lines comprises eight proteins with different cellular properties, including favoring the growth of those tumor blood vessels. Interestingly, the classical angiogenesis marker vascular endothelial growth factor is not in such a profile, indicating that tumors in more advanced phases tend to rely on different mechanisms for their growth.

Applications

The findings of this work show that a number of markers might be of value when determining the course of disease in colorectal cancer. Furthermore, these proteins arise as novel intervention targets in the metastatic colorectal cancer setting.

Peer review

The researchers intent was to investigate the angiogenesis-related protein expression profile characterizing metastatic colorectal cancer with the aim of identifying prognostic markers. The subject of biomarkers of colorectal cancer (CRC) metastasis is not well understood up to this time. Because of that, efforts of authors to characterize the protein factors behind the angiogenic potential of CRC cell lines of metastatic origin is of great importance. This work is a next step forward to identify the proteins responsible for the different behavior of metastatic colorectal cancers and for developing new treatment options.

Abstract

AIM: To observe the synergistic effects of hyperthermia in oxaliplatin-induced cytotoxicity in human colon adenocarcinoma Lovo cells.

METHODS: The human colon adenocarcinoma cell line Lovo was obtained from Sun Yat-Sen University. Cells were sealed with parafilm and placed in a circulating water bath, and was maintained within 0.01 ℃ of the desired temperature (37 ℃, 39 ℃, 41 ℃, 43 ℃ and 45 ℃). Thermal therapy was given alone to the negative control group while oxaliplatin was administered to the treatment group at doses of 12.5 μg/mL and 50 μg/mL. Identification of morphological changes, 3-(4,5-dimethyl-thiazol-2-yl)-2,5-diphenyltetrazolium bromide assay, flow cytometry and Western blotting were used to investigate the effect of thermochemotherapy on human colon adenocarcinoma Lovo cells, including changes in the signal pathway related to apoptosis.

RESULTS: A temperature-dependent inhibition of cell growth was observed after oxaliplatin exposure, while a synergistic interaction was detected preferentially with sequential combination. Thermochemotherapy changed the morphology of Lovo cells, increased the inhibition rate of the Lovo cells ($P < 0.05$) and enhanced cellular population in the G_0/G_1 phase (16.7% ± 4.8 % in phase S plus 3.7% ± 2.4 % in phase G_2/M, $P < 0.05$). Thermochemotherapy increased apoptosis through upregulating *p53*, *Bax* and downregulating *Bcl-2*. Protein levels were elevated in p53, Bax/Bcl-2 in thermochemotherapy group as compared with the control group ($P < 0.05$).

CONCLUSION: Thermochemotherapy may play an important role in apoptosis *via* the activation of *p53*, *Bax* and the repression of *Bcl-2* in Lovo cells.

Key words: Colorectal cancer; Oxaliplatin; Thermochemotherapy; Mitochondrial apoptotic pathway

INTRODUCTION

Colorectal cancer (CRC) is one of the most common types of cancer worldwide[1,2]. Over the past decades, the incidence of CRC has been increasing in China, with an increased mortality due to early metastases[3]. Despite surgical resection, more than 40% of the CRC patients die of the metastases ultimately[4-6]. The poor prognosis is associated with difficulties in early diagnosis at a curable stage. Therefore, the urgent need to develop new therapeutic strategies in order to significantly improve the prognosis of the metastatic CRC patients is not overstated.

Oxaliplatin, a new third-generation platinum coordination complex of the 1,2-diaminocyclohexane family, has shown promising activity for CRC[7-9]. Its spectrum of antitumor activities in tumor models differs from that of cisplatin and carboplatin. Oxaliplatin is active in a broad range of cancer cell lines and does not produce cross-resistance of cisplatin and carboplatin Its side effects are also distinct from other platinum drugs-it induces no renal or hepatic toxicity but causes both a reversible acute, cold-related dysesthesia and a dose-limiting cumulative peripheral sensory neuropathy that usually rapidly regresses after treatment withdrawal[10].

It is well known that hyperthermia is a strong factor that increases tumor sensitivity to chemotherapy[11,12]. Cells in the DNA synthetic phase of the cell cycle are relatively resistant to chemotherapy, but are especially sensitive to hyperthermia. Thus, a combined treatment may, in some circumstances, be an advantage[13]. Previous data have shown that the cytotoxicity and anti-tumor effect of cisplatin are greatly enhanced at elevated temperatures[14]. It is also reported that the effect of oxaliplatin on colon cells is thermally enhanced at 42 ℃ when compared with 37 ℃[15].

A key mechanism associated with cancer cell growth is the control of apoptosis. Apoptosis is defined as programmed cell death, which occurs in response to disruption of normal homeostatic mechanisms. It is a critical parameter in tumor surveillance of abnormal cells[16]. Induction of apoptosis of cancer cells is considered a potentially new treatment for colon cancer[17].

However, whether the antitumor effect of oxaliplatin in colon cancer has a linear relationship with temperature is not known. Therefore, we explored the effect of thermal treatment in colon cancer cells and investigated the optimal temperature for the inhibitory effect of oxaliplatin in colon cancer cell lines.

MATERIALS AND METHODS

Major reagents

Newborn calf serum and Dulbecco's modified Eagle's medium (DMEM, low glucose) were purchased from GIBCO Corporation, penicillin/streptomycin was from Gibco-BRL (Germany), while 0.25% trypsin digest and trizol reagent were purchased from Invitrogen Corporation. 3-(4,5-dimethyl-thiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) and dimethyl sulfoxide (DMSO) were obtained from Sigma Corporation. Primary antibodies (applied for 1 h at room temperature or overnight at 4 ℃) were: anti-Bcl-2, anti-Bax and anti-p53 monoclonal antibody all purchased from Santa Cruz Biotechnology (Heidelberg, Germany), goat anti-rabbit IgG (secondary) and prestained protein molecular weight marker were purchased from Cell Signaling Technology (United States).

Cell culture

The human colon adenocarcinoma cell line Lovo was obtained from the Cell Bank of Sun Yat-Sen University. All cell culture operations were carried out in a sterile class II biological safety cabinet (Thermo Fisher, United States). The Lovo cell lines were cultured in DMEM containing 10% fetal bovine serum (GIBCO Corporation, Carlsbad, CA, United States), 50 U/mL of penicillin and 50 mg/mL of streptomycin (Invitrogen, Carlsbad, California, United States). The cells were grown in 25-mL and 75-mL flasks (Corning, New York, United States) in a humidified incubator at 37 ℃ with 5% CO_2 atmosphere (Thermo Fisher, United States). Cells were stained with Trypan blue (Sigma-Aldrich, St Louis, Missouri, United States) and then counted on a hemacytometer.

Hyperthermia and oxaliplatin treatment

Cells cultured in 60-mm dishes were sealed with parafilm and placed in a circulating water bath (Yiheng Corporation, Shanghai, China), and was maintained within 0.01 ℃ of the desired temperatures (37 ℃, 39 ℃, 41 ℃, 43 ℃, 45 ℃).Thermal therapy was given alone to the control group while oxaliplatin was administered to the treatment group at doses of 12.5 μg/mL and 50 μg/mL. The duration of thermal therapy and chemotherapy was 1 h, and the cells were cultured in a humidified incubator at 37 ℃ with 5% CO_2 atmosphere for 24 h.

Cellular morphological evaluation

The cells were observed under inverted phase contrast microscope (Olympus, Japan) after completion of thermal therapy or thermochemotherapy.

MTT assay

Measurement of cell growth inhibition by MTT assay was described previously[18]. Lovo cells were seeded in 96-well plates (5×10^3 cells/well) and were treated with 12.5 μg/mL or 50 μg/mL oxaliplatin at 37 ℃, 39 ℃, 41 ℃, 43 ℃ or

45 ℃. Negative control wells contained only CRC cells but not oxaliplatin. The experiment was repeated 3 times. Untreated and treated cells were cultured at 37 ℃ with 5% CO_2 for 24 h. MTT was added to 50 μL of cell suspension for 4 h. After supernatant was removed, DMSO (150 μL) was added to each well and mixed at a low speed for 10 min to fully dissolve the blue crystals. Absorbance was measured at 570 nm (A_{570}) and the percentage of growth inhibition of Lovo cells was calculated at each time point and for each concentration of oxaliplatin according to the following formula: % cell survival = (Lovo oxaliplatin group - Lovo blank)/(Lovo negative - Lovo blank) × 100% and % cell growth inhibition = 1 - % cell survival.

The fraction for each concentration of oxaliplatin was calculated. Model parameters included the concentration to inhibit 50% of cell growth (IC_{50}). At least three independent experiments were carried out to test the relationship between temperature of drug exposure and the concentration of oxaliplatin.

Flow cytometric analysis

Cells were plated at 1 × 10^6 cells/well in 6-well plates, incubated for 24 h, and then treated with different concentrations of oxaliplatin for 1 h. Trypsinized cells were washed with PBS and fixed in 70% ethanol. After fixation, the cells were incubated for 30 min with 200 mg/mL of RNase A and stained with 25 μg/mL propidium iodide (PI). The stained cells were analyzed using a flow cytometry cell sorter (Becton Dickinson, NJ, United States). Samples were analyzed using a FACScan flow cytometer (Becton Dickinson) according to the manufacturer's protocol. Experiments were performed in triplicate.

Apoptosis was measured according to the manufacturer's instructions, using an annexin V-FITC kit (BD Biosciences, San Jose, CA, United States). The cells were collected after drug delivery, washed twice with PBS and then centrifuged. The cell pellet was resuspended in ice-cold binding buffer. The annexin V-FITC and PI solutions were added to the cell suspension and mixed gently. The samples were then incubated for 15 min in the dark before flow cytometric analysis[19]. The analysis of the apoptotic cells was performed by flow cytometry (FACScan, Becton Dickinson, NJ, United States).

Western blotting analysis

Lovo cells (cultured in 6-well plate at 1.5 × 10^5 cells/well) were treated with 12.5 μg/mL or 50 μg/mL oxaliplatin at 37 ℃, 39 ℃, 41 ℃, 43 ℃ or 45 ℃ and total proteins were extracted. Protein samples were separated by SDS-PAGE and electrophoretically transferred onto a polyvinylidene difluoride membrane (Millipore, United States). The membrane was blocked overnight at 4 ℃ in TBS-Tween 20 (TBST) buffer containing 5% skimmed milk powder. The membrane was washed with TBST (3 × 8 min). Membranes were then incubated overnight at 4 ℃ in primary antibody (125 μL/cm^3; diluted 1:1000) with gentle shaking. The membranes were washed with TBST (3 × 8 min) and incubated for 1 h at room temperature in horse radish peroxidase (HRP)-conjugated secondary antibody (125 μL/cm^3; diluted 1:2500). The membranes were washed with TBST (3 × 8 min) and protein signals were detected by chemiluminescence kit (Cell signaling Technology, United States). Primary antibodies (applied for 1 h at room temperature, or overnight at 4 ℃) were: anti-Bcl-2, anti-Bax and anti-p53 monoclonal antibody all purchased from Santa Cruz Biotechnology (Heidelberg, Germany).

Statistical analysis

Normally distributed continuous variables were compared by one-way analysis of variance (ANOVA). Statistical analyses were performed using SPSS 13.0 statistical software (SPSS Inc, Chicago, IL). When a significant difference between groups was apparent, multiple comparisons of means were performed using the Holm-Bonferroni procedure with type-I error adjustment. Data were presented as means ± SD. All statistical assessments were two-sided and evaluated at the 0.05 level of significant difference.

RESULTS

Cellular morphology

Lovo cells were treated with oxaliplatin (12.5 μg/mL or 50 μg/mL) at different temperatures for 1 h and then cultured under normal conditions for 24 h. There were disparities after treatment between the control group and the thermochemotherapy group (Figure 1). Thermotherapy alone caused the inhibition of cell growth by inducing cell apoptosis and cell cycle arrest. However, thermochemotherapy caused a greater decrease of Lovo cells as compared with the control group, especially in the 50 μg/mL group. The effect of thermochemotherapy on tumor growth was observed as early as 24 h after treatment.

Thermotherapy enhances oxaliplatin-induced inhibition of cytotoxicity

First, we used the MTT assay to detect the effect of temperature on Lovo cell proliferation. With increasing temperature, the inhibition rate of cell growth became higher and higher. The cytotoxicity of Lovo cells exposed to 50 μg/mL oxaliplatin for 1 h was higher than those exposed to 12.5 μg/mL oxaliplatin at the same temperature ($P < 0.05$). And 43 ℃ was the optimal temperature to inhibit cell proliferation when the cells were exposed to 50 μg/mL oxaliplatin ($P < 0.05$, Figure 2).

Thermotherapy enhances oxaliplatin-induced cell cycle arrest and apoptosis

To elucidate the mechanism of action of thermotherapy and oxaliplatin, we used flow cytometry to determine cell cycle distribution and apoptosis in Lovo cells exposed to different temperatures.

A significant increase in the number of G_0/G_1 phase cells and a decrease in the number of S and G_2/M phase

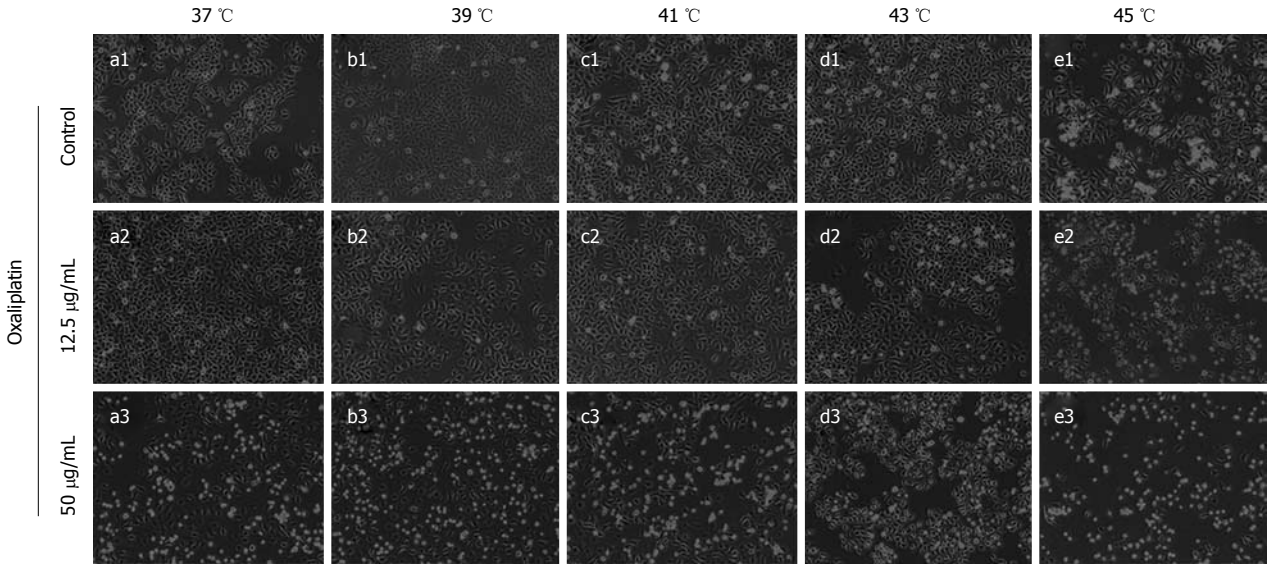

Figure 1 Effect of thermochemotherapy on human colon carcinoma Lovo cells. Cells were treated with oxaliplatin (12.5 μg/mL and 50 μg/mL) at different temperatures (37 ℃, 39 ℃, 41 ℃, 43 ℃ or 45 ℃) for 1 h and then cultured under normal conditions for 24 h. The cells were observed under inverted phase contrast microscope (Olympus, Japan) after completion of thermal therapy or thermochemotherapy.

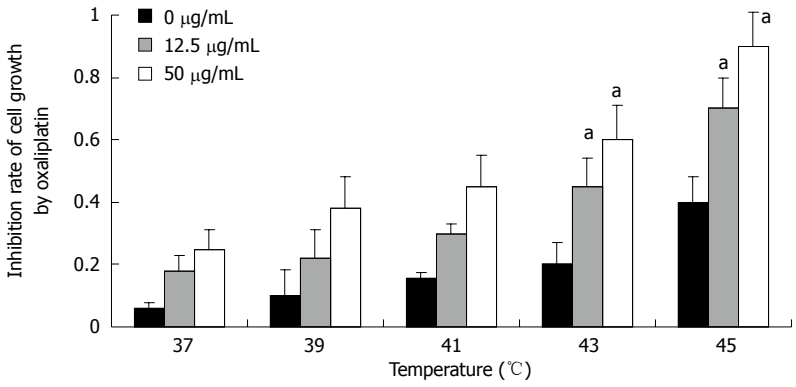

Figure 2 Effect of temperature on the proliferation of Lovo cells by MTT assay. Lovo cells were treated with oxaliplatin (12.5 μg/mL and 50 μg/mL) at 37 ℃, 39 ℃, 41 ℃, 43 ℃ or 45 ℃. The control group only used thermal therapy but not oxaliplatin. Statistically significant differences were observed between the two groups. Lovo cell viability was determined by MTT assay. The white bars are the results of the oxaliplatin treatment for 1 h at 37 ℃, 39 ℃, 41 ℃, 43 ℃, and 45 ℃ followed by 24 h recovery. The results of three independent experiments are reported as mean ± SD. $^{a}P < 0.05$ *vs* 43 ℃ or 45 ℃ *vs* 37 ℃.

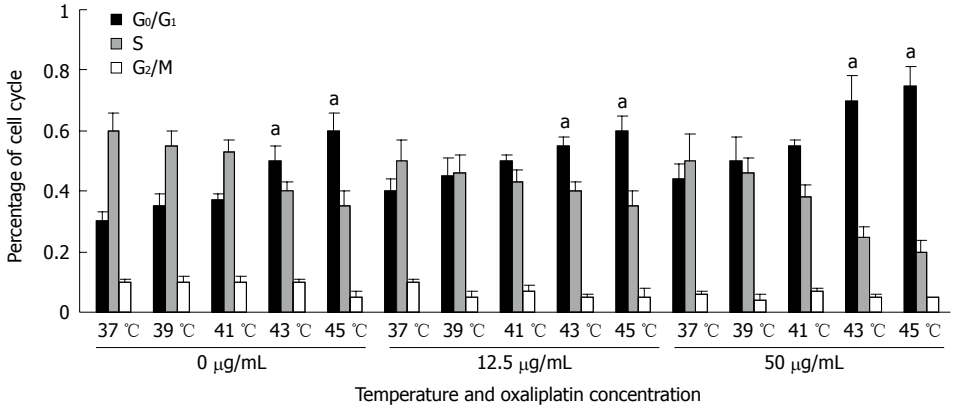

Figure 3 Effect of temperature on cell cycle and apoptosis detected by flow cytometry. Lovo cells were treated with oxaliplatin (12.5 μg/mL and 50 μg/mL) at 37 ℃, 39 ℃, 41 ℃, 43 ℃ or 45 ℃ for 1 h. The different bars represent the percentage of Lovo cells at different phases of the cell cycle at different temperature points. $^{a}P < 0.05$ *vs* 43 ℃ or 45 ℃ *vs* 37 ℃.

cells after 1 h of oxaliplatin treatment were observed. There was a linear relationship between the cell cycle

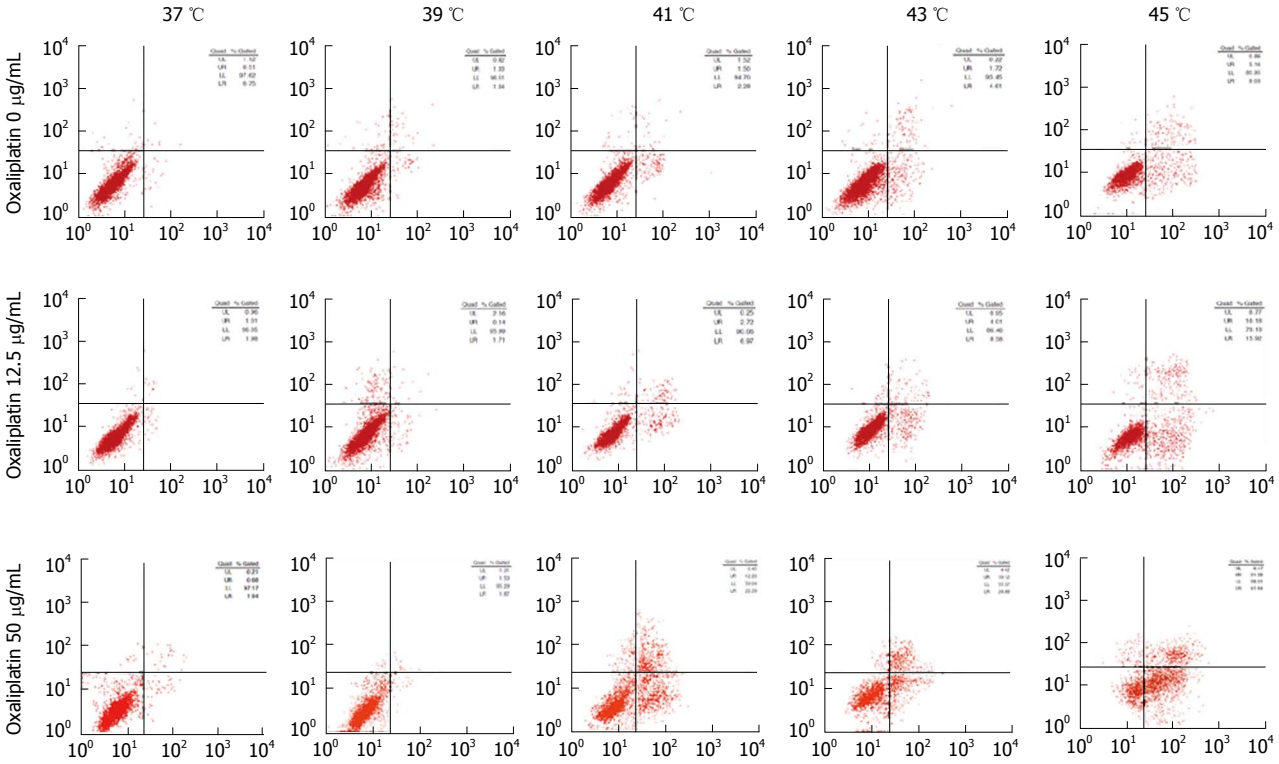

Figure 4 Measurement of Lovo cell apoptosis using apoptosis detection kit. Data are presented as dot plots in which the vertical axis represents propidium iodide (PI)-positive cells and the horizontal axis annexin V-positive cells. The upper left quadrant region contains necrotic (PI-positive) cells, the upper right region contains the late stage of apoptotic and necrotic (PI- and annexin V-positive) cells, the lower left region contains viable non-apoptotic (PI- and annexin-V-negative) cells, and the lower right region contains early apoptotic (PI-unstained and annexin-V-positive) cells.

and the temperature ($P < 0.05$). The proliferation and proportions of cells in different phases of the cell cycle were analyzed at 24 h by the incorporation of PI. DNA histogram analysis revealed that thermal therapy induced a temperature-dependent increase in the number of cells within the G_0/G_1 phase. This increase was accompanied by a decrease in the percentage of proliferating cells (16.7% ± 4.8% in phase S and 3.7% ± 2.4% in phase G_2/M) ($P < 0.05$, Figure 3). Accumulation of 12.5 μg/mL oxaliplatin-treated cells at any phase was less remarkable than that of the 50 μg/mL-treated cells ($P < 0.05$).

We also used PI staining to show that thermotherapy induced apoptosis of Lovo cells in a temperature-dependent manner (Figure 4).

Hyperthermia enhances oxaliplatin induced-regulation of p53 and Bax/Bcl-2

It is well known that reduction of intra-cellular apoptotic molecules, such as p53 and Bax/Bcl-2, sensitizes Lovo cells to thermotherapy. We therefore investigated whether changes in the amounts of apoptotic proteins were associated with the promotion of hyperthermia and oxaliplatin.

p53 stimulated the mitochondrial apoptotic pathway, thus enabling direct protein interaction or inhibition of the Bcl-2 protein family. p53 can also induce the pro-apoptotic Bcl-2 proteins by transcripting or inhibiting the transcription of anti-apoptotic Bcl-2 proteins. We examined the effect of thermal therapy on the expression of the Bcl-2 protein group.

The results showed a thermal-dependent increase in Bax expression over temperature and a concomitant decrease in the expression of Bcl-2. The maximal levels of Bax reached a peak at 43 ℃. As for Bcl-2, there was a marked decrease when compared 43 ℃ and 45 ℃ with 37 ℃. These levels later increased somewhat but always remained lower than that in the control group ($P < 0.05$). Both Bax activation and Bcl-2 inhibition were required for the release of mitochondrial apoptotic factors and the activation of the intrinsic apoptotic route.

Finally, we detected the possible signal pathway involved in the effects of oxaliplatin on Lovo cells. There was an increase in the expression of p53 and Bax protein in cells treated with oxaliplatin for 1 h. Compared with the cells of the control group, a gradual decrease in Bcl-2 levels was found at an increasing temperature, with the most significant reduction at 43 ℃ (Figure 5).

DISCUSSION

Thermotherapy combined with immediate intraperitoneal delivery of adjuvant anti-cancer drugs is a novel cancer treatment strategy to improve prognosis and prolong the overall survival of the patients with advanced CRC. The aim of this study was to assess the role of hyperthermia in oxaliplatin-induced cytotoxicity, to find an appropriate temperature using *in vitro* studies in maximizing anti-tumor activities and discuss the possible mechanism of thermochemotherapy. Preclinical studies have suggested

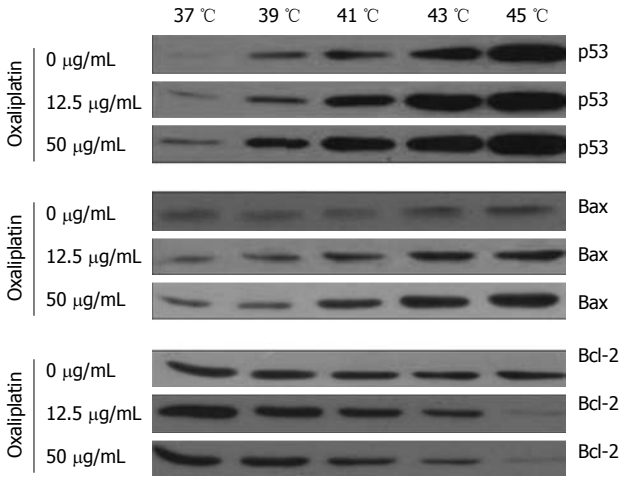

Figure 5 Effect of thermal therapy on p53, Bax and Bcl-2 detected by Western blotting. Lovo cells were treated with 12.5 μg/mL or 50 μg/mL oxaliplatin for 1 h at 37 ℃, 39 ℃, 41 ℃, 43 ℃ or 45 ℃. Cells were harvested, and total proteins were extracted and immunoblotted for p53, Bax and Bcl-2. The values represent means ± SD of at least three separate experiments. Beta-actin was used as loading control (data not shown).

that oxaliplatin may offer therapeutic advantages in a variety of malignancies with either intrinsic or acquired cisplatin resistance[20]. The primary mechanism of oxaliplatin has been shown to be mediated by the formation of intrastrand DNA cross-links[21]. Rietbroek *et al*[22] reported that thermotherapy at 43 ℃ enhanced the formation of DNA cross-links and concluded that a large portion of enhanced cytotoxicity may be attributed to the increased cross-links. Other factors such as an increased drug uptake at the elevated temperature are also suggested[23]. Evidence that oxaliplatin exerts a specific anti-tumor effect strongly suggests that oxaliplatin may be a promising new compound for the treatment of gastrointestinal tumors[24-26].

The *in vitro* exposure of human Lovo cells at clinical concentration of oxaliplatin with thermotherapy exerted a strong anti-proliferative effect and induced apoptosis of Lovo cells in this study. Our results highlight the potential clinical value of thermochemotherapy in the treatment of colon cancer. The exposure to 43 ℃ or above augmented the cytotoxicity of the oxaliplatin-treated Lovo cells in the thermochemotherapy group in a temperature-dependent fashion. This effect was observed by the MTT assay which demonstrated a linear increase in cytotoxicity with thermotherapy. After exposure to 43 ℃, the activity of oxaliplatin markedly and rapidly increased, indicating its potential inhibition ability in Lovo cells. Consistently, previous studies have demonstrated that oxaliplatin treatment with different concentrations (7.5-39.7 μg/mL) for 5-150 min can enhance cell death in various cell lines[27,28].

The exact mechanisms of thermochemotherapy remain unclear. Exposure to high temperatures can alter the fluidity of cell membranes, inhibit protein synthesis, and destroy DNA synthesis enzymes. Regulation of the cell cycle and apoptosis is a major strategy to inhibit the progression of a number of cancers. A critical role of p53, a sequence-specific DNA-binding protein, has been demonstrated to execute apoptosis. Either thermotherapy or oxaliplatin can cause cell cycle arrest at the G_0/G_1 phase and can induce apoptosis of human colon cancer cells.

Some studies have reported that p53 changes cell-cycle arrest and apoptosis induction by regulating the expression of different proteins such as p21, Bax and Bcl-2[29,30]. The *Bcl-2* gene product functions as an anti-apoptotic signal, suppressing apoptosis induced by chemotherapeutic drugs. The exact mechanism of Bcl-2 in preventing apoptosis is still not clear. Others have described *p53* expression in response to genotoxicity. It has been proposed that *p53* may be involved in the cellular response to DNA damage, producing arrest in the G_0/G_1 phase of the cell cycle to allow efficient repair of DNA before entry into S phase[31,32]. For these reasons, we inferred that the effects of thermotherapy in Lovo cells were mediated partly by the expression of *p53*.

Our results showed that thermotherapy could induce apoptosis and cell cycle arrest in Lovo cell lines in a temperature-dependent manner. Thermochemotherapy significantly induced cell cycle of G_0/G_1 phase arrest by upregulating *p53* and *Bax* expression and downregulating Bcl-2 in Lovo cells. We also detected the expression of Bcl-2 and Bax in Lovo cells to understand the impact of thermotherapy on the mitochondrial pathway of apoptosis. Down-regulation of Bcl-2 and up-regulation of p53 and Bax synthesis showed that apoptosis induced by thermochemotherapy may be mediated by the mitochondrial pathway[33,34]. Our findings were consistent with other studies[35,36] that thermotherapy caused G_0/G_1 cell cycle arrest and promoted apoptosis of Lovo cells by upregulating p53, Bax expression and downregulating Bcl-2[37,38].

In conclusion, our findings indicate that oxaliplatin is a promising agent for the treatment of human Lovo cells. Thermotherapy exerted synergistic interaction with oxaliplatin especially at 43 ℃ or above, inhibiting the survival of Lovo cells *in vitro*. Apparently, the observed synergism between thermotherapy and oxaliplatin results in mutual completion and enhancement of anticancer activity that may be extrapolated to animal models of colon cancer and to clinical use. The results of the present study suggest that thermochemotherapy might be a useful future strategy for treating colon cancers.

We thank Dr. Shi-Hui Xing for his careful revision of this manuscript and the assistance in the figure and data analyses.

COMMENTS

Background

Oxaliplatin is reported to be active in a broad range of cancer cell lines and hyperthermia is a strong factor that increases tumor sensitivity to chemotherapy. However, whether the antitumor effect of oxaliplatin in colon cancers has a linear relationship with temperature and the optimal temperature for the inhibitory

effect of oxaliplatin in colon cancer cell lines remains elusive.

Research frontiers

Thermochemotherapy may play an important role in the inhibition of the Lovo cells and the optimal temperature is 43 ℃. In addition, down-regulation of Bcl-2 and up-regulation of p53 and Bax may be essential in inducing apoptosis in human colon cancer cell lines.

Innovations and breakthroughs

Thermal therapy and oxaliplatin can inhibit colon cancer cells through inducing apoptosis and regulating the cell cycle. Suppression of Bcl-2 and up-regulation of p53 and Bax might contribute to the regulation of human Lovo cell lines.

Applications

This study may help clarify the mechanism of thermochemotherapy for colon cancer and choose the appropriate therapeutic strategy in clinical practice.

Terminology

Thermochemotherapy is the combination of thermal therapy and chemotherapy.

Peer review

This is a study using a single cell line. The experiments are straightforward and the data are short and succinct.

Abstract

AIM: To evaluate the hepatoprotective roles of (Z)-5-(4-methoxybenzylidene)thiazolidine-2,4-dione (SKLB010) against carbon tetrachloride (CCl_4)-induced acute and chronic liver injury and its underlying mechanisms of action.

METHODS: In the first experiment, rats were weighed and randomly divided into 5 groups (five rats in each group) to assess the protective effect of SKLB010 on acute liver injury. For induction of acute injury, rats were administered a single intraperitoneal injection of 2 mL/kg of 50% (v/v) CCl_4 dissolved in olive oil (1:1). Group 1 was untreated and served as the control group; group 2 received CCl_4 for induction of liver injury and served as the model group. In groups 3, 4 and 5, rats receiving CCl_4 were also treated with SKLB010 at doses of 25, 50 and 100 mg/kg, respectively. Blood samples were collected at 6, 12 and 24 h after CCl_4 intoxication to determine the serum activity of alanine amino transferase. Tumour necrosis factor-α (TNF-α), interleukin-1β (IL-1β) were determined using enzyme-linked immunosorbent assay. At 24 h after CCl_4 injection,liver fibrogenesis was evaluated by hematoxylin-eosin (HE) staining and immunohistochemical analyses. Cytokine transcript levels of TNF-α, IL-1β and inducible nitric oxide synthase in the liver tissues of rats were measured using a reverse transcriptase reverse transcription-polymerase chain reaction technique. In the second experiment, rats were randomly divided into 2 groups (15 rats in each group), and liver injury in the CCl_4-administered groups was induced by a single intraperitoneal injection of 2 mL/kg of 50% (v/v) CCl_4 dissolved in olive oil (1:1). The SKLB010-treated groups received oral 100 mg/kg SKLB010 before CCl_4 administration. Five rats in each group were sacrificed at 2 h, 6 h, 12 h after CCl_4 intoxication and small fortions of livers were rapidly frozen for extraction of total RNA, hepatic proteins and glutathione (GSH) assays. In the hepatic fibrosis model group, rats were randomly divided into 2 groups (5 rats each group). Rats were injected intraperitoneally with a mixture of CCl_4 (1 mL/kg body weight) and olive oil [1:1 (v/v)] twice a week for 4 wk. In the SKLB010-treated groups, SKLB010 (100 mg/kg) was given once daily by oral gavage for 4 wk after CCl_4 administration. The rats were sacrificed one week after the last injection and the livers from each group were harvested and fixed in 10% formalin for HE and immunohistochemical staining.

RESULTS: In this rat acute liver injury model, oral administration of SKLB010 blocked liver tissue injury by down-regulating the serum levels of alanine ami-

notransferase, suppressing inflammatory infiltration to liver tissue, and improving the histological architecture of liver. SKLB010 inhibited the activation of NF-κB by suppressing the degradation of IκB, and prevented the secretion of pro-inflammatory mediators such as tumor necrosis factor-α, interleukin-1β, and the reactive free radical, nitric oxide, at the transcriptional and translational levels. In this chronic liver fibrosis model, treatment with 100 mg/kg per day SKLB010 attenuated the degree of hepatic fibrosis and area of collagen, and blocked the accumulation of smooth-muscle actin-expressed cells.

CONCLUSION: These results suggest that SKLB010 is a potent therapeutic agent for the treatment of CCl_4-induced hepatic injury.

INTRODUCTION

Hepatic damage, i.e., acute liver injury and chronic liver fibrogenesis, has become a severe health problem worldwide. Despite considerable and continuous efforts, effective treatment strategies against this disease resulting in fewer side effects are still lacking.

Carbon tetrachloride (CCl_4), is an acknowledged hepatotoxin and can cause acute or chronic liver injury characterized by centrilobular necrosis, inflammatory cell infiltration, centrilobular fatty changes, and apoptosis[1]. CCl_4-induced hepatic inflammatory response was found to be mediated by the action of cytokines, especially tumor necrosis factor-α (TNF-α), interleukin-1β (IL-1β), and the free radical, nitric oxide (NO)[2]. CCl_4 also induced the peroxidation of lipids or lipid membranes, and up-regulated the serum level of alanine aminotransferase (ALT). Sustained hepatic inflammation provoked by long-term exposure to CCl_4 is believed to induce hepatic fibrosis through ongoing hepatocytic necrosis and the production of fibrogenic cytokines acting on fibroblasts [e.g., activated hepatic stellate cells (HSC)][3].

On the other hand, oxidative stress is capable of

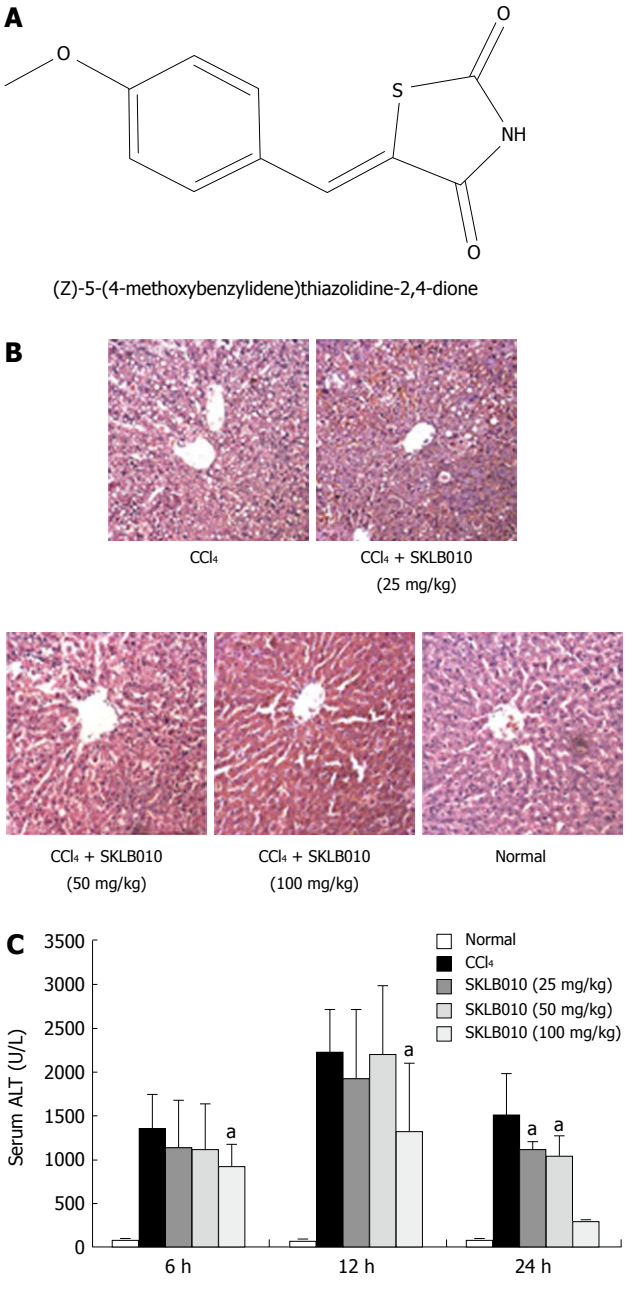

Figure 1 Effect of (Z)-5-(4-methoxybenzylidene)thiazolidine-2,4-dione on carbon tetrachloride-induced hepatitis. A: The structure of (Z)-5-(4-methoxybenzylidene)thiazolidine-2,4-dione (SKLB010); B: Representative liver histology of the rats in each group at 24 h after carbon tetrachloride (CCl_4) injection, liver sections were stained with hematoxylin-eosin (original magnification 200 ×); C: Time course of hepatocyte necrosis after CCl_4 challenge, alanine aminotransferase (ALT) was measured in serum collected at time points as indicated. Values are presented as mean ± SD of the mean. (n = 5, $^aP < 0.05$ *vs* the level in the model group).

stimulating nuclear factor-κB activation (NF-κB)[4]. NF-κB is an inducible transcription factor whose activity is primarily regulated by phosphorylation and degradation of IκB[5]. CCl_4-induced oxidative stress can stimulate the phosphorylated effect of IκB, and degradation of IκB leads to the translocation of NF-κB to the nucleus[5]. This process further regulates the expression of inducible inflammatory cytokines (such as TNF-α, NO, and IL-1β)[6]. The up-regulation of TNF-α and IL-1β con-

versely activates the expression of NF-κB. Therefore, the up-regulation of these inflammatory mediators induces a vicious cycle, which eventually alters the structure of hepatocytes and impairs their biological functions[7]. Consequently, prolonged activation of NF-κB results in the perpetuation of inflammatory responses. Hence, it is regarded as the potential target for the treatment of anti-inflammatory disease including hepatic damage[8].

In our previous study, we found that several analogues of thiazolidinediones (TZDs) showed high inhibitory effects on the chemotaxis of RAW264.7 cells. We observed that (Z)-5-(4-methoxybenzylidene)thiazolidine-2,4-dione (SKLB010) exhibited the strongest inhibitory activity against chemotaxis in MCP-1-stimulated macrophage-like RAW 264.7 cells with an IC_{50} value of 0.72 μmol/mL, and evaluated its protective effects on Con A-induced acute hepatitis[9]. In the present study, we further investigate the therapeutic effect of SKLB010 on CCl_4-induced acute hepatitis and chronic liver fibrosis, and explore its underlying mechanisms.

MATERIALS AND METHODS

Reagents and animals

SKLB010 (Figure 1A) was synthesized with purity of more than 99.5% in our lab, and dissolved in saline containing 5% (v/v) Tween-80 (Sigma-Aldrich, St. Louis, MO, USA). The structure and purity were identified by high performance liquid chromatography, a Q-TOF Premier Mass Spectrometer (Waters, Milford, MA, United States) and nuclear magnetic resonance (Bruker Avance 400 NMR system).

Female Sprague-Dawley rats from Western China Experimental Animal Center were maintained under controlled conditions and had free access to standard chow and water. All rats received human care according to the National Institutes of Health Guidelines of China until their weight was 200 g to 220 g after which they were used in the experiments.

Animal treatment

In the first experiment, rats were weighed and randomly divided into 5 groups (five rats in each group) to assess the protective effect of SKLB010 on acute liver injury. For induction of acute injury, rats were administered a single intraperitoneal injection of 2 mL/kg of 50% (v/v) CCl_4 dissolved in olive oil (1:1)[10]. Group 1 was untreated and served as the control group; group 2 received CCl_4 for induction of liver injury and served as the model group. In groups 3, 4 and 5, rats received CCl_4 to induce liver injury and were also treated with SKLB010 at doses of 25, 50 and 100 mg/kg, respectively.

In groups 2 to 5, blood samples were collected at 6, 12 and 24 h after CCl_4 intoxication to determine the serum activity of ALT using an Olympus AU2700 multifunctional biochemistry analyzer (Olympus, Tokyo, Japan).

At 24 h after CCl_4 injection, rats were killed and the livers were removed. A small portion of the liver was used for hematoxylin-eosin (HE) staining studies following fixation with 10% formalin and subsequent embedment in paraffin.

In the second experiment, rats were randomly divided into 2 groups (15 rats in each group), and liver injury in the CCl_4-administered groups was induced by a single intraperitoneal injection of 2 mL/kg of 50% (v/v) CCl_4 dissolved in olive oil (1:1). The SKLB010-treated groups received oral 100 mg/kg SKLB010 before CCl_4 administration. Five rats in each group were sacrificed at 2 h, 6 h, 12 h after CCl_4 intoxication and the livers were cut into pieces and rapidly frozen with liquid nitrogen for extraction of total RNA, hepatic proteins and glutathione (GSH) assays.

In the hepatic fibrosis model group, rats were randomly divided into 2 groups (5 rats each group). Rats were injected intraperitoneally with a mixture of CCl_4 (1 mL/kg body weight) and olive oil [1:1 (v/v)] twice a week for 4 wk[11]. In the SKLB010-treated groups, SKLB010 (100 mg/kg) was given once daily by oral gavage for 4 wk after CCl_4 administration. The rats were sacrificed one week after the last injection and the livers from each group were harvested and fixed in 10% formalin for HE and immunohistochemical staining.

Histochemistry and immunohistochemistry

In the study of acute liver injury, liver sections of 3 μm thickness were stained with HE using a standard procedure and analyzed by light microscopy to determine histological changes in tissue structure assessed using an optical microscope.

During the study of chronic liver fibrogenesis, liver tissues fixed in 10% formalin were embedded in paraffin, cut into 4-μm sections, and stained with HE to evaluate liver injury under an optical microscope. Sections were stained with Masson's Trichrome Staining to detect collagen deposition. An immunohistochemistry method was used as previously described. Briefly, liver sections were treated with 3% H_2O_2/PBS and incubated overnight at 4℃ with an anti-CD11b antibody (Cell Signaling, United States) used as the primary antibody for detecting macrophages in liver tissue and a rabbit-anti-mouse-α smooth-muscle actin (SMA) antibody (Thermo, Immunohistochemistry Specific, United States) used as the primary antibody for analyzing the activity of HSCs. The proportion of tissue stained with picrosirius red was assessed by morphometric analysis with MetaView software (Universal Imaging, Downingtown, PA, United States). Collagen staining was quantitated in random sections (under × 400 magnification, 10 fields each from sample).

GSH determinations in liver

Levels of hepatic GSH (γ-glutamyl-cysteinylglycine, GSH) were determined using the enzyme immune assay kit GSH (Jiancheng Bioengineering, Nanjing, China), following the protocol provided by the manufacturer.

Detection of serum mediators and mRNA levels

Detection of serum TNF-α, IL-1β was performed using enzyme-linked immunosorbent assay (ELISA) kits

(RandD Systems, Minneapolis, MN, United States), according to the manufacturer's instructions. Detection of serum NO was performed using the NO assay kit (nitrate reductase progress; Jiancheng Bioengineering, Nanjing, China), which reduces nitrate to nitrite as an index of NO, and was assayed colorimetrically at 450 nm.

Cytokine transcript levels of TNF-α, IL-1β and inducible nitric oxide synthase (iNOS) in the liver tissues of rats were measured using a reverse transcriptase reverse transcription-polymerase chain reaction (RT-PCR) technique. Total RNA was isolated using Trizol reagents (Invitrogen, Carlsbad, CA, United States). The RNA was reverse transcribed and PCR-amplified by the prime script one-step RT-PCR kit (TaKaRa, Japan). The results were expressed as a ratio of the number of copies of the goal gene to the number of copies the housekeeping gene, glyceraldehyde-3-phosphate dehydrogenase, from the same RNA samples. The sequences of primers for the cytokine genes are as follows: TNF-α, sense 5'-CGGGGGCCACCACGCTCTTC-3' and antisense 5'-GGCAAATCGGCTGACGGTGTG-3'; IL-1β, sense 5'-TCAAGGCATAACAGGCTCATC-3' and antisense 5'-CCACGGGCAAGACATAGGTAG-3'; iNOS, sense 5'-CCCTTCCGAAGTTTCTGGCAGCAG-3', and anti-sense 5'-GGGCTCCTCCAAGGTGTTGCCC-3'.

GADPH, sense 5'-GTGCTGAGTATGTCGTGGAGTCT-3' and anti-sense 5'-GTGGAAGAATGGGAGTTGCTGT-3'.

Electrophoretic mobility shift assay

Nuclear extracts were prepared according to the method of Hentze[12]. The oligonucleotide probes used for this experiment were sense, 5'-AGTTGAGGGGACTTTCCCAGGC-3'; antisense, 5'-GCCTGGGAAAGTCCCCTCAACT-3'; and NF-κB mutant, sense 5'-AGTTGAGGCGACTTTCCCAGGC-3', anti-sense, 5'-GCCTGGGAAAGTCGCCTCAACT-3'.

Western blotting

Forty micrograms of protein from each sample, where the concentration was measured by the Bradford assay, was separated on 10% SDS-polyacrylamide gel and electrotransferred to nitrocellulose membranes (Schlecher-Schuell, Dassel, Germany). Membranes were blocked for 1 h at room temperature with 5% nonfat dry milk in TBST buffer. The reactions were then incubated at 4℃ overnight with a 1:1000 dilution of anti-IκB or anti-β-actin antibody (Abcam, United States) in blocking buffer. After the membranes were washed three times, they were further incubated with a 1:4000 dilution of suitable secondary antibody (Cell Signaling Technology, United States) for 1 h at room temperature. The signals were normalized to the protein levels of the housekeeping gene β-actin.

Statistical analysis

SPSS 16.0 was used to determine the significance of differences between normal and experimental groups. All results were expressed as mean ± SD. Differences between groups were evaluated using an independent-samples *T* test. The results were considered significantly different at $P < 0.05$.

Table 1 SKLB010 increases the levels of hepatic glutathione in the carbon tetrachloride rat model (mean ± SD)

	Normal	6 h		12 h	
		CCl_4	CCl_4 + SKLB010	CCl_4	CCl_4 + SKLB010
GSH	5.24 ± 0.15	2.99 ± 0.01	3.26 ± 0.06[b]	4.07 ± 0.16	4.70 ± 0.21[d]

$n = 5$. [b]$P < 0.01$ *vs* 6 h after carbon tetrachloride (CCl_4) injection; [d]$P < 0.01$ *vs* 12 h after CCl_4 injection.

RESULTS

SKLB010 exerts therapeutic effects in acute hepatic injury induced by CCl_4

As shown in Figure 1B, SKLB010 effectively prevented the development of CCl_4-induced liver injury as demonstrated by the reduction in serum ALT release. The ALT level was elevated after administration of CCl_4 and peaked at 12 h. In contrast, oral administration of SKLB010 dose- and time-dependently down-regulated the level of ALT, and SKLB010 showed the most potent reduction at the dose of 100 mg/kg.

Histological changes in liver tissue shown by HE staining also confirmed the hepatoprotective effect of SKLB010 against CCl_4-induced liver injury. The histopathological changes in liver tissue in CCl_4-intoxicated rats at 24 h after CCl_4 injection are shown in Figure 1C. Compared to the normal group, the group exposed to CCl_4 exhibited extensive inflammatory cells infiltration, centrilobular fatty changes, apoptosis and widespread hepatocellular necrosis. Following treatment with SKLB010, inflammatory infiltration and the necrotic region in liver sections were reduced in a dose-dependent manner.

SKLB010 increases anti-oxidative activity

GSH is an indicator of oxidative stress at the hydrophilic level in the liver[13]. Hence, the content of GSH was measured at 6 h and 12 h after CCl_4 injection. As shown in Table 1, the liver content of GSH in the normal group was 5.24 mg/g protein. However, SKLB010-treated hepatic GSH was enhanced from 2.99 mg/g to 3.26 mg/g protein at 6 h, and from 4.07 mg/g to 4.7 mg/g protein at 12 h compared with the CCl_4-induced group, respectively. We conclude that administration of SKLB010 blocked the decrement in GSH induced by CCl_4.

SKLB010 reduces pro-inflammatory mediator levels and mRNA expression in vivo

To investigate the ability of SKLB010 to modulate the production of inflammatory cytokines, the serum levels

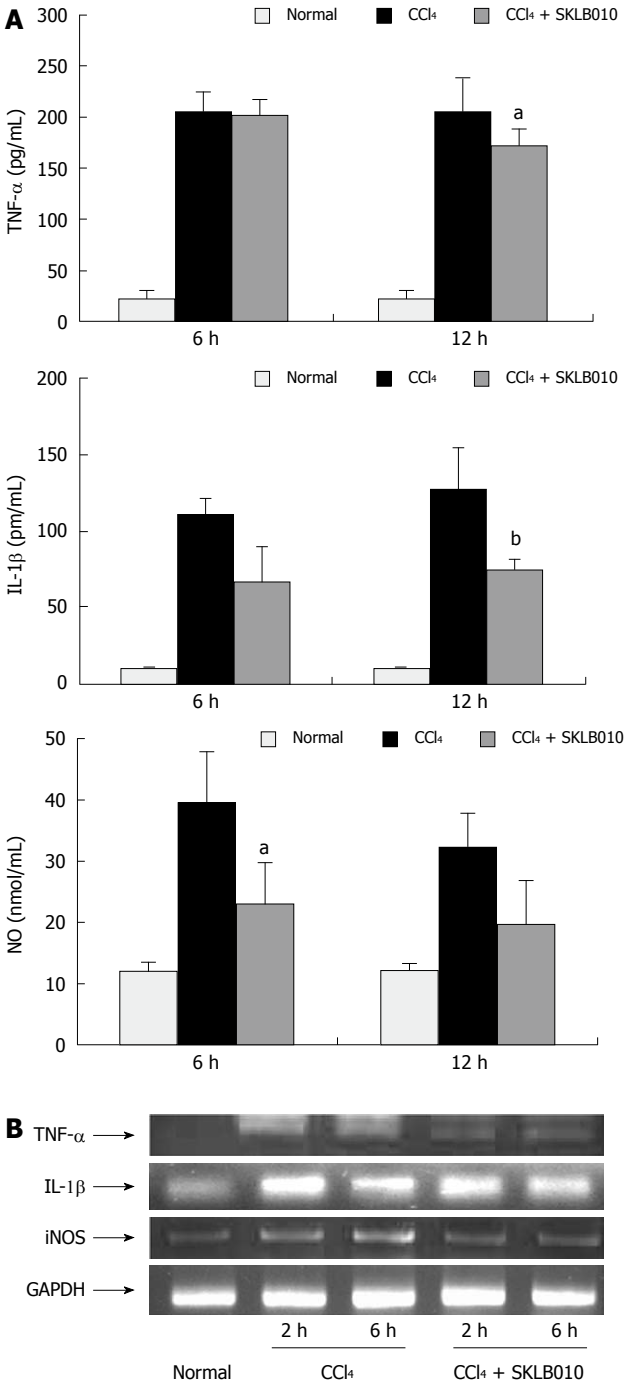

Figure 2 SKLB010 reduces the production of inflammatory mediators *in vivo*. A: Blood was collected at different time points (5 rats per time point). Tumor necrosis factor-α (TNF-α), and interleukin-1β (IL-1β) were assayed in serum using an enzyme linked immunosorbent assay (mean ± SD). Nitric oxide (NO) was assayed in serum using a NO assay kit $^{a}P < 0.05$, $^{b}P < 0.01$ *vs* the level of carbon tetrachloride (CCl_4) administration at each time point; B: Total RNA was prepared at different time points for the reverse transcription-polymerase chain reaction (RT-PCR) analysis of TNF-α, IL-1β and iNOS gene expression. IL-1β-specific sequences (387 bp), TNF-α-specific sequences (351 bp) and inducible nitric oxide synthase (iNOS)-specific sequences (474 bp) were detected by agarose gel electrophoresis, as described in Methods. PCR of glyceraldehyde-3-phosphate dehydrogenase (GAPDH) was performed to verify that the contents of the samples were similar.

of TNF-α, IL-1β, and NO production and their corresponding liver mRNA expression were determined in rats

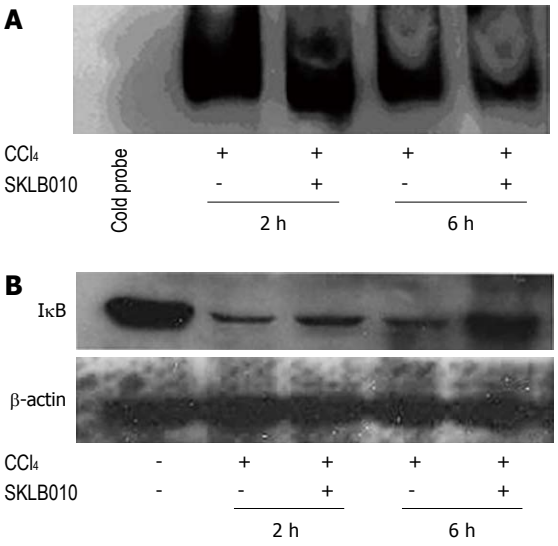

Figure 3 SKLB010 prevented the nuclear translocation of nuclear factor-κB by inhibiting degradation of IκB. A: The inhibition of nuclear factor-κB (NF-κB)-DNA binding. Carbon tetrachloride (CCl_4)-mediated activation of NF-κB resulted in an increase in DNA-binding activity of NF-κB within 2 h, followed by inactivation of NF-κB at 6 h after stimulation which was demonstrated by a lower DNA-binding activity; B: SKLB010 inhibited the CCl_4-induced degradation of IκB. Total tissue proteins were analyzed by Western blotting at different time points for IκB-α using specific IκB antibodies. β-actin was used as an internal control.

with CCl_4-induced hepatitis.

As shown in Figure 2A, treatment with SKLB010 reduced the serum levels of TNF-α and IL-1β at 12 h and NO production at 6 h compared with the CCl_4-injected groups. In order to investigate whether the reduction in serum levels of inflammatory mediators was due to the changes in mRNA expression, we examined liver mRNA expression of TNF-α, IL-1β, and iNOS both at 2 h and 6 h after CCl_4 injection. It can be seen from Figure 2B, that the administration of SKLB010 reduced the mRNA expression of TNF-α, IL-1β, and iNOS in contrast to the CCl_4-induced groups.

SKLB010 inhibits activation of NF-κB

Electrophoresis mobility shift assays (EMSA) were performed in order to examine whether SKLB010 suppressed the activation of NF-κB after CCl_4 injection. Correspondingly, a NF-κB-DNA binding assay was also carried out using nuclear extracts from acutely damaged liver stimulated by CCl_4 in the presence or absence of SKLB010. Indeed, CCl_4-mediated activation of NF-κB resulted in an increase in DNA-binding activity within 2 h, followed by inactivation of NF-κB at 6 h after stimulation which was demonstrated by a lower DNA-binding activity, suggesting that administration of SKLB010 reduced the DNA binding activity of NF-κB (Figure 3A).

As reported, degradation of IκB was required to activate NF-κB[5]. We investigated the effect of SKLB010 on the cytoplasmic level of IκB by Western blot analysis both at 2 h and 6 h after CCl_4 injection. As shown in Figure 3B, treatment with SKLB010 inhibited the degradation of IκB

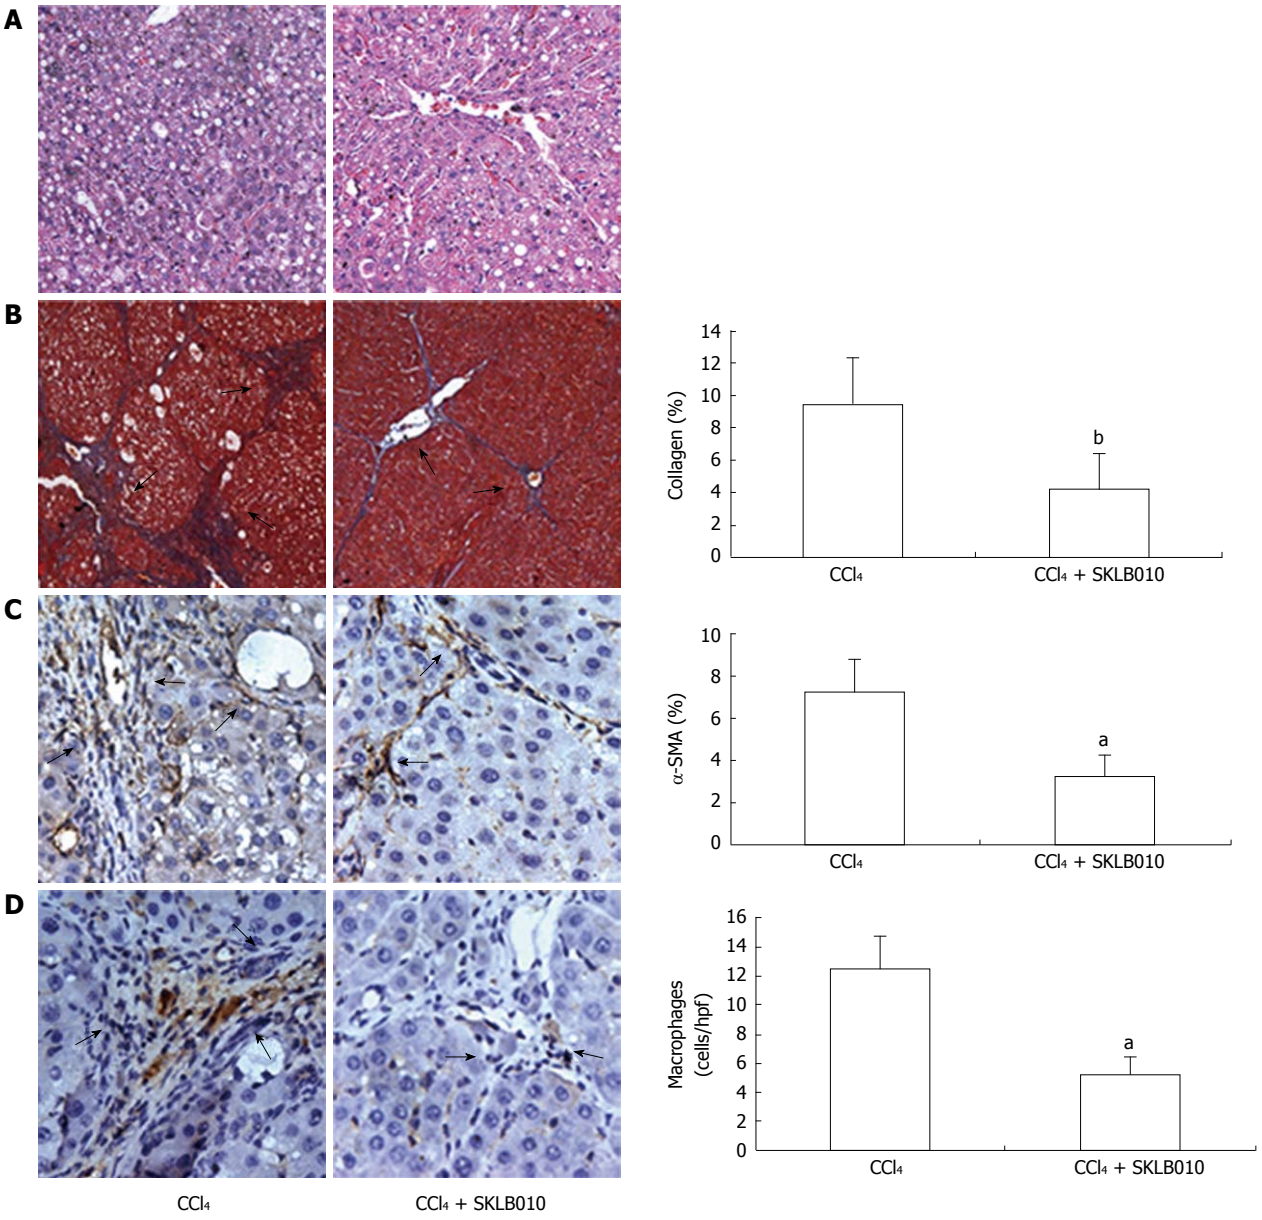

Figure 4 SKLB010 improves liver function and causes a marked reduction in liver fibrosis. Arrows points to positive direction. $^{a}P < 0.05$, $^{b}P < 0.01$. A: Hematoxylin-eosin (original magnification 200 ×); B: Masson (original magnification 100 ×) and digital image analysis quantification of collagen; C: α-smooth-muscle actin (SMA) original magnification 400 ×) and digital image analysis quantification of α-SMA; D: CD-11b (original magnification 400 ×) and digital image analysis quantification of macrophages. CCl_4: Carbon tetrachloride.

induced by the administration of CCl_4.

SKLB010 improves histology of the liver and causes a marked reduction in liver fibrosis

The hepatoprotective effects of SKLB010 on liver injury and fibrosis were initially evaluated by histological analyses. The results from HE staining showed that oral administration of SKLB010 daily for 4 wk significantly reduced the level of steatosis and necrosis, and suppressed hepatic fibrogenesis (Figure 4). Masson staining revealed that rats treated with SKLB010 showed histological improvement with a marked reduction in fibrosis and decreased expression of collagen I and IV. As a unique marker for activated HSC, α-SMA-positive cells around the fibrotic septa were significantly increased by CCl_4. In contrast, the number of α-SMA-positive cells was reduced in the livers of SKLB010-treated rats compared with those from cirrhotic rats. These findings indicate that SKLB010 efficiently reduced the presence of activated HSC in liver fibrogenesis. Furthermore, immunohistochemical analysis of CD11b revealed fewer macrophages in the fibrotic septa between nodules after treatment with SKLB010.

DISCUSSION

In the present study, oral administration of SKLB010 improved CCl_4-induced liver injury *via* the inhibition of NF-κB followed by suppression of the degradation of IκB. Treatment with SKLB010 also showed therapeutic effects

on liver fibrogenesis. In the acute liver injury study, oral treatment with SKLB010 decreased ALT enzyme levels. Histopathological findings revealed reduced levels of inflammatory cell infiltration, centrilobular fatty changes, apoptosis, and necrosis in SKLB010-treated rats. Results on the hepatoprotective effects of SKLB010 on CCl_4-induced chronic liver fibrogenesis showed that SKLB010 possessed potent ability to alleviate the development of fibrogenesis by reducing the level of steatosis and necrosis, expression of collagen I and Ⅳ, activated HSC, and macrophage infiltration of liver tissue.

SKLB010 is a novel analogue of TZDs. Recent evidence has shown that TZDs participate in the regulation of inflammation, especially in modulating the production of inflammatory mediators (such as TNF-α, IL-1β, inducible iNOS), by decreasing the activation of NF-κB while increasing the expression of IκB[1,14].

We suggest that the most likely underlying mechanism by which SKLB010 regulates the expression of proinflammatory cytokines production is through the inactivation of NF-κB.

GSH and the antioxidative enzyme system play important roles in protecting liver cells against oxidative stress[15]. CCl_4-induced liver injury was associated with decreased hepatic GSH. In our experiments, treatment with SKLB010 increased the levels of GSH which were greater than those observed for the CCl_4 control. Following exposure to CCl_4, oxidative stress was attenuated by treatment with SKLB010. Thus, we supposed that SKLB010 possessed the properties to enhance GSH and decrease reactive metabolite formation in CCl_4-induced liver injury.

These inflammatory mediators (e.g., TNF-α, IL-1β, and NO), play key roles in the induction and perpetuation of inflammation in macrophages. Our recent study using an ELISA and RT-PCR assay revealed that these mediators were inhibited by SKLB010 treatment both at the serum and mRNA level. Furthermore, the decrease in TNF-α expression occurred before the decrease in IL-1β. This is because the macrophage membrane contains the TNF-α receptor, hence the decrease in TNF-α may stimulate the expression of IL-1β. The fact that TNF-α levels initially increased rapidly and later decreased compared with the SKLB010-treated group was in accordance with the lower inactivation of NF-κB at 6 h which was able to control TNF-α production.

The expressions of these inflammatory mediators have been shown to be dependant on NF-κB activation[16,17]. Therefore, the possibility that the extract inhibited the activity of NF-κB needs to be examined further.

NF-κB, a transcription factor that regulates the expression of proinflammatory cytokines and proteins, is activated in response to several extracellular stimuli, and oxidative stress. NF-κB is sensitive to the oxidation of a particular cysteine at position 62 in p50, which is essential for DNA binding[18]. Evidence suggests that unregulated NF-κB-related gene expression in Kupffer cells contributes to CCl_4-induced liver injury[19]. To support this hypothesis, the development of a pharmacological strategy to suppress the activation of NF-κB is required.

The entry of NF-κB from the cytosol to the nucleus is regulated by IκB, and its induction and binding to NF-κB which prevents its translocation into the nucleus was estimated[20].

Since phosphorylated IκB is degraded by a multisubunit protease complex, i.e., proteasome[21], we hypothesized that SKLB010 prevented the nuclear translocation of NF-κB by inhibiting degradation of IκB through inhibition of some of the proteases in the proteasome.

The EMSA assay revealed that the subsequent NF-κB-DNA binding was inhibited in the nucleus by pretreatment with SKLB010 compared to the CCl_4-control group. CCl_4-mediated activation of NF-κB resulted in a peak of DNA-binding activity at 2 h, followed by inactivation of NF-κB at 6 h which was confirmed by lower DNA-binding activity. These results were in accordance with previous reports on the NF-κB pathway. NF-κB translocates to the nucleus and activates a series of gene transcriptions including the IκB gene which can transform NF-κB from the activated state to the inactivated state. In addition, in the study on IκB, a lower level of degradation of IκB demonstrated that SKLB010 prevented CCl_4-induced degradation of IκB. These results proved that SKLB010 inhibited the CCl_4-induced activation of NF-κB by suppressing the degradation of IκB.

In summary, based on the above results, SKLB010 had significant potent inhibitory effects on CCl_4-induced acute liver injury by reducing the activity of serum ALT, and improving the histology of liver tissue. Furthermore, the development of CCl_4-induced chronic fibrogenesis was alleviated by treatment with SKLB010, which was demonstrated by histological staining. Importantly, the underlying mechanisms of action were proved, in that SKLB010 possessed properties to enhance GSH and anti-oxidative activity, and attenuated inflammatory mediators such as TNF-α, IL-1β, and NO through inactivation of NF-κB. These observations may have potential therapeutic value in the treatment of hepatitis.

COMMENTS

Background

Hepatic damage, including acute liver injury and chronic liver fibrogenesis, constitute a major problem to human health worldwide. Despite extensive efforts, effective treatment strategies resulting in fewer side effects are still lacking.

Research frontiers

Our previous study demonstrated that (Z)-5-(4-methoxybenzylidene)thiazolidine-2,4-dione (SKLB010), a derivative of thiazolidinediones (TZDs) exhibits protective effects on Con A-induced acute hepatitis and adjuvant-induced arthritis without side effects.

Innovations and breakthroughs

SKLB010 inhibited the carbon tetrachloride (CCl_4)-induced activation of nuclear factor-κB (NF-κB) by suppressing degradation of IκB. A dose- and time-dependent relationship was found. The protection effects of SKLB010 on liver injury and fibrogenesis were initially evaluated using histological analyses.

Applications

These observations may contribute to the therapeutic value of novel small molecule drugs in the treatment of hepatitis.

Terminology

NF-κB is a transcription factor that regulates the expression of proinflammatory cytokines and proteins.

Peer review

In this manuscript, the author examined the role of SKLBO10, a derivative of TZDs, in protecting the liver against CCl_4 induced acute and chronic liver injury in rats. They found that orally administration of SKLBO10 at relatively high dose (100 mg per kg body mass per 24 h) protect the liver from acute injury (reduce serum alanine aminotransferase activity and inflammatory infiltration as well as improve histological architecture of the liver). Moreover, they have shown that SKLB010 inhibit: (1) degradation of $I_\kappa B$; (2) secretion of proinflammatory mediators; and (3) NO synthesis.

Abstract

AIM: To investigate prognostic factors of survival following curative, non-palliative surgical removal of lung metastases secondary to colorectal cancer (CRC).

METHODS: Between 1999 and 2009, a radical metastasectomy with curative intent was performed on lung metastases in 21 patients with CRC (15 male and 6 female; mean age: 57.4 ± 11.8 years; age range: 29-74 years) who had already undergone primary tumour resection.

RESULTS: The mean number of lung metastases ranged from one to five. The mean overall survival was 71 ± 35 mo (median: 25 mo). After adjusting for potential confounders, multivariable Cox regression analyses predicted only the number of lung metastases (1 *vs* ⩾ 2; hazard ratio: 7.60, 95% confidence interval: 1.18-17.2, P = 0.03) as an independent predictor of poor survival following lung resection for metastatic CRC.

CONCLUSION: Resection of lung metastases is a safe and effective treatment in selected CRC patients with single lung metastases.

Key words: Lung metastases; Colorectal cancer; Metastasectomy; Prognostic factors; Survival

INTRODUCTION

The lung is one of the most frequently affected metastatic sites in patients with colorectal cancer (CRC)[1]. Indeed, lung metastases may be detected sequentially or simultaneously in approximately 10% of patients with this malignancy[2,3]. Since Blalock first described pulmonary resection for metastases of colorectal carcinoma[4], several studies have demonstrated the efficacy of lung metastasectomy in CRC patients[5-14]. As the safety of the operation has improved over time, more patients may be able to undergo this surgery. In a recent single-center retrospective study, Maeda *et al*[15] reported an analysis

of patients with pulmonary metastases from colorectal carcinoma who underwent surgical resection. The overall 5-year survival rate was 74%. Importantly, the number of pulmonary metastases and prethoracotomy carcinoembryonic antigen (CEA) levels were significant independent predictors of survival after the first pulmonary metastasectomy[15]. Earlier studies reported wide ranges of survival percentages from 27% to 40.5% and tried to identify independent factors associated with clinical outcomes[5-14]. This knowledge is clinically helpful for defining a subset of patients who are most likely to benefit from surgical resection.

Here, we report our experience in lung metastasectomy in patients with primary CRC who were referred to a Turkish tertiary hospital during the past 10 years. A number of prognostic factors were analyzed to identify their impact on survival.

MATERIALS AND METHODS

This study was designed as a single-center retrospective investigation at the Department of Oncology, Uludag University Medical School, Bursa, Turkey. Retrospective analysis of the patient data was approved by the local ethics committee.

Patients

Between 1999 and 2009, a radical metastasectomy with curative purposes was performed in 21 patients with CRC (15 males and 6 females). These patients had already undergone primary tumor resection. The pulmonary lesions were also evaluated with conventional chest computed tomography. In addition, all patients underwent bronchoscopy, pulmonary function tests, and endoscopic evaluations before the operation. Indications for pulmonary resection of metastatic CRC were as follows: (1) completely resectable lung lesions diagnosed by preoperative imaging; (2) ability of the patient to tolerate the required surgical procedure and to carry out a normal life with the remaining respiratory function; and (3) surgically controllable extrapulmonary disease, including the primary lesion. All thoracotomy specimens were processed according to standard procedures and histologically confirmed to contain cancer consistent with CRC origin. All resected lung metastasis specimens had pathological tumor-free margins.

Clinical data and follow-up

The medical charts of all patients were reviewed and examined for sex, age, tumor differentiation, history of previous liver metastasis, prethoracotomy CEA levels, disease-free interval between the colorectal resection and the first pulmonary resection, number of metastases, location of metastases, type of resection, history of hilar or mediastinal node resection, size of lung metastases, and administration of postoperative chemotherapy after pulmonary resection. Clinical data and follow-up information were obtained from the medical records and were further complemented using telephone contacts with patients, family members, and physicians.

Statistical analysis

The primary endpoint was the time from lung resection to the time of death. Univariate and multivariable Cox proportional hazards models were used to identify predictors of survival. The appropriateness of the proportional hazards assumption was verified using graphical methods and tested as described by Grambsch and Therneau[16]. The assumption of linearity for the Cox models was examined by visual inspection, and no violation was found. All tests were two-sided, and $P < 0.05$ was considered statistically significant. All calculations were performed using SPSS version 17.0 (SPSS Inc., Chicago, IL, United States).

RESULTS

Characteristics of CRC patients

The mean age was 57.4 ± 11.8 years, with a range of 29 years to 74 years. All patients had adenocarcinoma. Regarding localization at the time of primary tumor diagnosis, 11 of 21 patients had rectal cancer, and the other 10 had colon cancer. Tumor differentiation grades were as follows: G1, one patient; G2, 18 patients; and G3, two patients. Seven patients had a history of previous liver metastases. There were no operative or hospital deaths. The median preoperative CEA level was 3.6 ng/mL (range: 1.2-77.0 ng/mL).

Characteristics of pulmonary metastatic lesions

The mean disease-free interval (interval between initial treatment and onset of pulmonary metastasis) was 28 ± 21 mo (range: 3-75 mo). A solitary metastatic lesion was found in 11 patients. Multiple metastases were found in the other 10 patients, that is, two metastatic lesions in five patients, three metastatic lesions in one patient, four metastatic lesions in two patients, and five metastatic lesions in two patients. In patients with a solitary metastasis, left lung metastasis was found in four patients, and right lung metastasis in seven. In patients with multiple metastases, left lung metastases were found in two patients, right lung metastases were found in five, and metastases were found in both lungs in three patients. Wedge resection was performed in eight patients (five with a solitary lesion, one with two lesions, one with four lesions, and one with five lesions); segmentectomy in eight patients (three with a solitary lesion, two with two lesions, one with three lesions, one with four lesions, and one with five lesions); lobectomy in four patients (two with a solitary lesion and two with two lesions); and pneumectomy in one patient with a solitary lesion. Four patients underwent either hilar or mediastinal lymph node dissection. The pulmonary metastatic tumor size was obtained for all patients and ranged from 5 mm to 41 mm (mean size: 18 ± 10 mm). Nineteen patients received postoperative chemotherapy after pulmonary resection.

Table 1 Univariate analysis of prognostic factors

Risk factors	*P* value[1]
Sex (male *vs* female)	0.52
Age (yr)	0.39
Tumor differentiation (G1 and 2 *vs* G3)	0.71
History of previous liver metastasis (yes *vs* no)	0.04
Preoperative CEA levels (below *vs* above median)	0.04
Disease-free interval (mo)	0.42
Number of metastases (1 *vs* ≥ 2)	0.01
Location of metastasis (left *vs* others)	0.82
Type of resection (wedge *vs* others)	0.74
Hilar or mediastinal node resection (yes *vs* no)	0.51
Lung metastatic tumour size (mm)	0.43
Postoperative chemotherapy (yes *vs* no)	0.89

[1]Calculated with univariate Cox regression. CEA: Carcinoembryonic antigen.

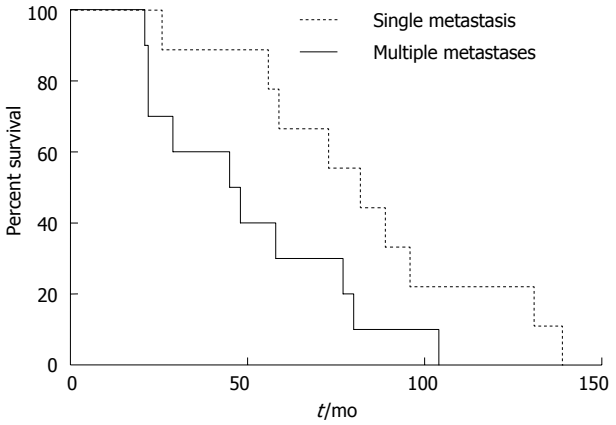

Figure 1 Kaplan-Meier plot for patients with single and multiple lung metastases from colorectal cancer.

Survival data

Survival was calculated from the time of lung resection for metastasis, and the primary end point was death. The mean overall survival was 71 ± 35 mo (median: 25 mo), ranging from 21 mo to 139 mo. The actuarial overall survival following lung metastasectomy for CRC was 71.4% at 3 years and 47.6% at 5 years.

Prognostic factors

Several prognostic factors were analyzed to identify their impact on survival. The factors that were associated with poor survival outcome following univariate analysis were the number of lung metastases ($P = 0.01$), history of previous liver metastasis ($P = 0.04$), and preoperative CEA levels ($P = 0.04$) (Table 1). No other factors had an influence on survival (Table 1). After adjusting for potential confounders, multivariable Cox regression analyses showed that only the number of lung metastases (1 *vs* ≥ 2; hazard ratio: 7.60, 95% confidence interval: 1.18-17.2, $P = 0.03$) was an independent predictor of poor survival following lung resection for CRC (Figure 1).

DISCUSSION

The results from this study indicate that the presence of a single pulmonary metastasis is the main indication for a metastasectomy in Turkish patients with CRC. The lung is a key site of metastases from CRC, and several previous studies have attempted to identify significant prognostic factors for pulmonary metastasectomy. Previously identified prognostic factors include the number of pulmonary metastases, hilar and/or mediastinal lymph node metastasis, prethoracotomy CEA levels, time of appearance of metastasis, liver metastasis before thoracotomy, mode of operation, and location of pulmonary metastases[5-14]. In our study, there were no prognostic factors except for the number of pulmonary metastases. The overall 5-year survival rate in our series was largely in agreement with previous reports[5-14], and we suggest that surgery should remain the mainstay for treating patients with single pulmonary metastases from CRC. In agreement with our current findings, Pfannschmidt *et al*[9] have reported solitary metastases as a significant prognostic factor; the post-resection outcome of patients with two or more lesions was significantly worse than that of patients with a single metastasis. Prethoracotomy CEA levels may serve as a biochemical marker for post-resection outcome[14]. CEA participates in intracellular recognition and metastasis by functioning as an attachment factor[14]. CEA levels may therefore reflect the highly malignant nature of cancer cells that undergo systemic dissemination. In our current study, an abnormal CEA level was identified as a prognostic factor in univariate but not multivariate analysis. The observation that CEA levels did not serve as a significant independent prognostic factor suggests that concentrations of this molecule simply reflect the number of lung metastases observed in our patients. A history of previous liver metastases had prognostic significance in univariate but not multivariate analysis. Our results are in agreement with numerous previous reports[17,18]. In this regard, it has been suggested that selected patients with simultaneous presentation with technically resectable liver and lung metastases may benefit from an aggressive surgical approach[19]. We cannot, however, exclude the possibility that these favorable results may be found only in selected patients.

The limitations of this study are the small patient population and the retrospective nature of the study, although the data were collected prospectively. The other drawback is that the patients included in the study may be a selected group and may not represent the general population of patients with lung metastases from CRC. These limitations notwithstanding, our results suggest a favorable outcome in Turkish CRC patients with solitary lung metastases.

In summary, the results from this study indicate that lung resection for metastatic CRC appears to be valuable in selected patients showing isolated lesions, with acceptable long-term survival. This study demonstrated that the presence of multiple lung metastases is associated with poor survival. Surgery should not be considered as the first modality of treatment for patients with multiple

lung metastases, because it is associated with a relatively poor outcome. The presence of previous liver metastases should not be considered a contraindication for lung metastasectomy. Large multicenter studies are, however, required to confirm these results.

COMMENTS

Background

The lung is one of the most frequently affected metastatic sites in patients with colorectal cancer (CRC). Several studies have demonstrated the efficacy of lung metastasectomy in CRC patients.

Research frontiers

Earlier studies have reported outcomes that varied widely and have tried to identify independent factors associated with clinical outcomes. This knowledge is clinically helpful for defining the subset of patients who are most likely to benefit from surgical resection.

Innovations and breakthroughs

Here, we report our experience concerning lung metastasectomy in patients with primary CRC referred during the past 10 years. A number of prognostic factors were analyzed to identify their impact on survival.

Applications

The results from this study indicate that lung resection for metastatic CRC appears to be valuable in selected patients with single lesions, providing acceptable long-term survival. The presence of multiple lung metastases is associated with poor survival.

Peer review

The paper is a nice addition to a growing body of literature illustrating the potential benefits of lung metastasectomy for CRC patients. This was a small series of 21 patients, yet multivariate analysis correctly identified the number of lung metastases (1 *vs* $\geqslant$ 2) as a significant predictor of survival. The message is therefore clear, and the small number of patients is not a problem. The paper is concise and well written, the results are clearly presented, and the survival data (71% and 47% at 3 years and 5 years, respectively) are in accordance with previously published series. These results also suggest that we deal with a selected population of CRC patients (mostly young individuals with resectable metastatic disease), but this is not a surprise.

Abstract

AIM: To assess the diagnostic success and outcome among patients with obscure gastrointestinal bleeding who underwent total enteroscopy with double-balloon endoscopy.

METHODS: Total enteroscopy was attempted in 156 patients between August 2003 and June 2008 at Hiroshima University Hospital and achieved in 75 (48.1%). It is assessed whether sources of bleeding were identified, treatment methods, complications, and 1-year outcomes (including re-bleeding) after treatment, and we compared re-bleeding rates among patients.

RESULTS: The source of small bowel bleeding was identified in 36 (48.0%) of the 75 total enteroscopy patients; the source was outside the small bowel in 11 patients (14.7%) and not identified in 28 patients (37.3%). Sixty-one of the 75 patients were followed up for more than 1 year (27.2 ± 13.3 mo). Four (6.6%) of these patients showed signs of re-bleeding during the first year, but bleeding did not recur after treatment. Although statistical significance was not reached, a marked difference was found in the re-bleeding rate between patients in whom total enteroscopy findings were positive (8.6%, 3/35) and negative (3.8%, 1/26) (3/35 *vs* 1/26, $P = 0.63$).

CONCLUSION: A good outcome can be expected for patients who undergo total enteroscopy and receive proper treatment for the source of bleeding in the small bowel.

INTRODUCTION

Approximately 1%-5% of cases of gastrointestinal (GI) bleeding cannot be diagnosed by upper-GI and lower-GI endoscopic examination[1,2]. In such cases, the small bowel is the suspected source of obscure GI bleeding (OGIB)[3]. Until recently, push enteroscopy[4,5] and intraoperative enteroscopy[6,7] have been the standard modalities for diagnosing OGIB. However, push enteroscopy does not reach deep into the small bowel because of the short length of the scope, and intraoperative enteroscopy

is an invasive procedure that requires general anesthesia. Double-balloon endoscopy (DBE) was developed by Yamamoto *et al*[8-10] in 2001, and it has been clinically available since 2003. DBE allows examination of the entire small bowel (total enteroscopy) through a combined oral and anal approach, providing also for diagnosis and therapeutic interventions in cases of small bowel lesions. There are many reports regarding diagnoses, therapeutic interventions, and outcomes in patients with OGIB who have undergone DBE[11-22]. However, there are no reports regarding the diagnosis of small bowel lesions in patients with OGIB based on total enteroscopy. We undertook a retrospective study to assess diagnoses and long-term outcomes in patients who have undergone total enteroscopy for OGIB.

MATERIALS AND METHODS

Patients

The study involved 156 patients in whom DBE was performed for OGIB at Hiroshima University Hospital during the period August 2003 through June 2008. Total enteroscopy was achieved in 75 (48.1%). All patients had already undergone standard upper-GI and lower-GI endoscopy at our hospital or elsewhere. OGIB was defined by the following American Gastroenterological Association criteria[3]: overt (*vs* occult) GI bleeding and recurrent fecal occult bleeding with iron-deficiency anemia that was not identifiable by upper-GI and lower-GI endoscopy, for example, hematemesis, hematochezia, or melena.

Methods

We evaluated whether sources of bleeding in the small bowel were diagnosed by DBE, whether treatment was performed during DBE, and whether complications ensued. Preliminary diagnosis was made on the basis of endoscopic findings and clinical history. Final diagnosis was made on the basis of histologic examination of biopsy specimens and/or surgically resected specimens. If a detected lesion did not explain a patient's complaints, (for example, a single small lymphangioma), the lesion was not identified as the source of the OGIB.

We also evaluated clinical outcomes. Clinical outcome was described as either continued bleeding or complete resolution of the bleeding, regardless of whether treatment was performed. Re-bleeding was defined as hematochezia, melena, or the need for blood transfusion during follow-up. In the patients who underwent total enteroscopy, clinical variables were assessed over a 1-year follow-up period. These included general condition, bleeding episodes, hemoglobin level, treatment, and blood transfusion. For patients in whom re-bleeding occurred, the source of re-bleeding, final diagnosis, treatment method, and clinical outcome after the second treatment were evaluated.

DBE procedure

The DBE system (Fujifilm, Kanagawa, Japan) consisted of a videoendoscope with a working length of 200 cm, a flexible overtube with a total length of 145 cm, and a pressure-controlled pump system. The EN-450P5 endoscope with the TS-12140 overtube, or the EN-450T5 endoscope with the TS-13140 overtube, was used; both systems have a balloon attached to the tip of the endoscope and another attached to the tip of the overtube. The balloons can be inflated and deflated with a single touch by using a specially designed pump, while the balloon pressure is accurately monitored.

Total enteroscopy was first performed by anal approach, and tattoo injection was performed at the most proximal site reached by the endoscope. DBE was then carried out by oral approach to examine the remaining area. DBE by oral approach was performed within 2 d after DBE by anal approach. For both approaches, intestinal looping was checked fluoroscopically. DBE by anal approach was performed after bowel preparation with an oral electrolyte lavage as for regular lower-GI endoscopy. DBE by oral approach was performed after overnight fasting. Patients were sedated with midazolam and pethidine or pentazocine, if necessary. Blood pressure, heart rate, and oxygen saturation were monitored during the DBE procedures.

Total enteroscopy was considered successful when the enteroscope reached the tattoo mark made during the prior approach.

Follow-up

Cases were excluded from the study if the source of bleeding was determined to be outside the small bowel. All patients underwent follow-up examinations at our hospital or an affiliated hospital, and data were obtained from the patients' medical records or by correspondence with the affiliated hospital.

Statistical analysis

Continuous data are shown as mean ± SD and range. Differences in re-bleeding rates were analyzed by Fisher's exact probability test or χ^2 test. $P < 0.05$ was considered statistically significant. JMP software, version 5.01J (SAS Institute Inc., Cary, NC, United States), was used for all statistical analyses.

RESULTS

DBE-based diagnosis and treatment of OGIB

Clinical characteristics of the 75 patients who underwent total enteroscopy are summarized in Table 1. The source of bleeding was identified in the small bowel in 36 of these patients (48.0%) and outside the small bowel in 11 of these patients (14.7%). The source of bleeding was not traced to the digestive tract in 28 patients (37.3%). The sources of bleeding identified in the small bowel were as follows: tumor (n = 7), vascular lesion (n = 5), ulcerative lesion (n = 23), and Meckel's diverticulum (n = 1) (Table 2). Specific treatments were performed in 27 patients (75.0%) in whom the source of bleeding was identified in the small bowel by total enteroscopy. Specific treatments were as follows: medical treatment (n = 9); en-

Complications of DBE

Two patients experienced complications from the diagnostic DBE. One suffered aspiration pneumonia and the other suffered acute pancreatitis. These 2 patients received medical treatment and recovered within a few days. One patient experienced a complication after therapeutic DBE: bleeding occurred after polypectomy for lipoma in the jejunum, and endoscopic hemostasis with clip placement and blood transfusion was required.

Clinical outcomes and re-bleeding rates

Data were obtained for 61 of the patients with OGIB who were followed up for more than 1 year after total enteroscopy. Excluded were the 11 patients in whom the source of bleeding was outside the small bowel and 1 patient who was lost to follow-up. The outcome and clinical course of these cases are shown in Table 3 and Figure 1, respectively. Four patients (6.6%) (4 women; mean age, 67.8 ± 7.0 years) showed signs of re-bleeding, such as hematochezia, melena, or a need for blood transfusion during this follow-up period (Table 4). The average observation period until the re-bleeding episode after total enteroscopy was 7.0 ± 4.2 mo. In 3 of the 4 patients, the re-bleeding derived from the same lesion identified upon initial total enteroscopy: 2 enteric tuberculosis lesions and 1 angioectasia. Medical treatment without endoscopic hemostasis and clinical observation was continued for the 2 patients with enteric tuberculosis. The patient in whom angioectasia was found underwent endoscopic hemostasis after epinephrine injection and argon plasma coagulation during DBE. In 1 patient in whom re-bleeding occurred, the source of the bleeding had not been identified during initial total enteroscopy. This patient was discharged from our hospital after the initial DBE examination, but severe hematochezia developed 1 mo later. Blood transfusion was performed, and DBE performed immediately thereafter revealed an arteriovenous malformation as the bleeding source. Endoscopic hemostasis with argon plasma coagulation and clip placement was performed. However, the hemorrhage did not stop, so angiography and surgical intervention were undertaken. Bleeding did

not recur after the second treatment in any of the 4 patients, and they remain healthy. The re-bleeding rate for patients with positive total enteroscopy findings was 8.6% (3/35), and that for patients with negative total enteroscopy findings was 3.8% (1/26). The difference between these 2 groups was not significant ($P = 0.63$). One patient died from leiomyosarcoma with multiple metastatic liver tumors 26 mo after the initial DBE examination.

DISCUSSION

There have been several reports concerning diagnoses and outcomes in patients with OGIB in which the small bowel was the source of bleeding[23-29]; however, the entire small bowel was not examined by DBE in these patients. Ours is the first report on the prognosis of OGIB originating from a small bowel lesion that was identified through total enteroscopy performed by means of DBE. Overall, the source of bleeding, whether within or outside the small bowel, was identified in 62.7% of cases in which total enteroscopy was performed by DBE. The source of bleeding was found to be outside the small bowel in 14.7% of patients. Arakawa *et al*[29] reported lesions outside the small bowel in 9.3% of patients. It has been reported that identification of lesions responsible for OGIB by means of DBE is successful in only 50%-76% of cases[24,30-32]; however, the reports include cases of small lesions that were unlikely to be the source

of bleeding and cases in which the interior of the entire small bowel could not be observed. Therefore, the reports do not describe the true diagnostic performance of total enteroscopy by means of DBE in patients with OGIB.

Re-bleeding occurred in 8.6% of our patients in whom the source of bleeding was identified by initial total enteroscopy and proper treatment was performed. This rate is lower than the rates reported by Hadithi *et al*[23] (14.3%), by Hsu *et al*[25] and Madisch *et al*[28] (20.0%), and by Kameda *et al*[26] (19.0%). These reports do not clarify whether the sources of bleeding were identified by initial DBE or whether total enteroscopy was achieved. Re-bleeding from a small bowel lesion occurred in 3.8% (n = 1) of our patients in whom the source of bleeding was not identified by initial total enteroscopy. This rate is lower than rates reported previously (8.7%-80.0%)[23-25,28]. Possible reasons are as follows: patients in whom the entire small bowel was not observed were included in our study; lesions outside the small bowel were included; and only lesions that were believed to be the clear source of bleeding were included.

Our data show that identifying a lesion in the small bowel and administering proper treatment results in a decrease in the re-bleeding rate, as well as a good clinical outcome. According to Arakawa *et al*[29], vascular lesions account for approximately 80% of cases of re-bleeding. Vascular lesions were the cause in 2 of our 4 patients with re-bleeding. In 1 of our patients, there was a problematic arteriovenous malformation that was not discovered during initial total enteroscopy. It is possible that the hemorrhage had stopped spontaneously by the time DBE was performed. In general, however, there is little possibility of re-bleeding from the small bowel because, if no lesions are identified in the small bowel by total enteroscopy, only exceptional minute vascular lesions would cause re-bleeding.

Among our patients, the average follow-up period was 27.2 mo after total enteroscopy, but the average period until re-bleeding was 7.0 mo, and all re-bleedings occurred within 1 year. In the Fujimori *et al*[24] and Kameda *et al*[26] series, 75.0% and 83.3% of patients, respectively, experienced re-bleeding within 1 year. Thus, we believe it is necessary to monitor patients for at least 1 year after the source of bleeding has been identified and treatment has been performed. Moreover, performing total enteroscopy in patients with OGIB is helpful in administering proper treatment for the source of bleeding and for diagnosing previously unidentified GI lesions.

One of the issues of DBE is insertability. The reported rate at which total enteroscopy is achieved by means of DBE falls between 40% and 86%[12,33-36]; however, from multicenter studies in Western countries, a much lower rate of 15%-16% was reported[37-39]. Insertion of the endoscope into a deeply situated small bowel is difficult, particularly in postoperative cases and cases of adhesion. The usefulness of capsule endoscopy (CE)[40] has been reported for such cases. Total enteroscopy has been achieved by CE in 74%-83% of cases[36,41-44]. Moreover, CE is a safe modality for diagnosing OGIB[41-44]. Although CE is suitable as an initial screening for OGIB, one disadvantage of CE is that submucosal tumors are overlooked[45-48], and CE does not provide for histopathologic biopsy or endoscopic treatment when a lesion is detected. Also, there are no reports concerning diagnostic agreement between DBE and CE in patients who have undergone total enteroscopy for OGIB. Thus, DBE is an essential modality for both diagnosing and treating small bowel lesions. Efforts are needed to improve instruments to increase insertability.

We assessed the prognosis of OGIB in patients for whom a small bowel lesion was identified as the source of bleeding by total enteroscopy. Total enteroscopy was performed by DBE, and when no source of bleeding was identified or proper treatment was administered for an identified source of bleeding, the outcome was satisfactory. However, considering the possibility of re-bleeding, a follow-up period of 1 year seems necessary for patients who have undergone treatment.

Our data lead us to conclude that total enteroscopy by DBE is advantageous over general DBE for patients with OGIB. A good outcome can be expected for such patients when the entire small bowel is examined by DBE and proper treatment is given for the source of bleeding in the small bowel.

COMMENTS

Background

There are many reports regarding diagnoses, therapeutic interventions, and outcomes in patients with obscure gastrointestinal bleeding (OGIB) who have undergone double-balloon endoscopy (DBE). However, there are no reports regarding the diagnosis of small bowel lesions in patients with OGIB based on total enteroscopy.

Research frontiers

The authors undertook a retrospective study to assess diagnoses and long-term outcomes in patients who had undergone total enteroscopy for OGIB.

Innovations and breakthroughs

The study found that total enteroscopy by DBE is advantageous over general DBE for patients with OGIB.

Peer review

The authors have presented a well written documentation of total enteroscopy for obscure gastrointestinal bleeding.

Abstract

AIM: To investigate the correlation between the nutritional risk index (NRI) and postoperative wound complications.

METHODS: From January 2008 through June 2008, 669 patients who underwent curative gastrectomy for gastric cancer were included in a retrospective study. Medical records of consecutive patients were collected and analyzed to determine postoperative wound complication rates. The NRI was assessed on the fifth postoperative day and other possible risk factors for the incidence of wound complications were analyzed to identify the factors affecting postoperative wound complications. Patients with other postoperative complications were excluded from the study.

RESULTS: On the 5th postoperative day, the NRI showed a malnutrition rate of 84.6% among postoperative patients. However, postoperative wound complications occurred in only 66/669 (9.86%) patients. Of the patients with wound complications, 62/66 (94%) belonged to the malnourished group (NRI < 97.5), and 4/66 (6%) patients to the non-malnourished group (NRI $\geqslant$ 97.5). The only factor correlated with wound complications was the NRI on the 5th postoperative day (odds ratio of NRI $\geqslant$ 97.5 *vs* NRI < 97.5: 0.653; 95% confidence interval: 0.326-0.974; P = 0.014) according to univariate analysis as well as multivariate analysis.

CONCLUSION: This study suggests that malnutrition immediately after surgery may play a significant role in the development of wound complications.

Key words: Nutritional risk index; Wound complication; Gastric cancer

Nutritional risk index as a predictor of postoperative wound complications after gastrectomy. *World J Gastroenterol* 2012; 18(7): 673-678 Available from: URL: http://www.wjgnet.com/1007-9327/full/v18/i7/673.htm DOI: http://dx.doi.org/10.3748/wjg.v18.i7.673

INTRODUCTION

Gastric cancer is the second most common cancer in the world, the most common cancer in South Korea, and the third common cause of cancer death in South Korea[1,2]. A successful outcome after surgery is highly dependent on the incidence and severity of postoperative complications, and malnutrition has been reported to be an important risk factor for perioperative morbidity and mortality[3]. Bozzetti *et al*[4] found that low serum albumin was one of the factors correlated with postoperative complications. Weight loss has also been shown to identify patients at risk of postoperative complications[5].

Wound infection has been one of the most common postoperative complications associated with surgical treatment of patients[6,7]. Its occurrence may significantly contribute to increased postoperative morbidity and longer duration of hospitalization. Typically reported risk factors for wound breakdown were duration of surgery, obesity, diabetes, patient age, coincident infection, and poor nutrition[8,9].

In a previous study, it was demonstrated that low serum albumin on the 5th day after surgery was well correlated with postoperative short-term complications[10]. It was also shown that a total of 13.45% patients developed postoperative complications, of which 55% were related to wound complications. Based on these previous data, it was assumed that malnourished patients might have a high rate of postoperative wound complications, as well as other postoperative complications. It is vital to detect and treat malnutrition in patients undergoing major surgery, because malnutrition results in poor clinical outcomes if unrecognized and not treated properly.

Thus, a proper assessment of the nutritional status in these patients should be performed. Numerous researchers have sought a reliable, valid scoring system that can identify patients with poor nutritional status[11]. Many nutrition risk scores to predict nutrition-related complications in gastrointestinal surgery are available, including the nutrition risk index (NRI), the nutrition risk score, and the bioelectrical impedance analysis[3]. None of these is generally accepted as the gold standard. Among them, the NRI, which is based on the serum albumin concentration and weight loss, has been shown to identify patients at risk for postoperative complications[3]. NRI is based on a mathematical equation, can easily be scored after one laboratory test, does not require subjective judgment, and can be safely applied in the clinical setting, with no significant effect on the predictive value[11]. On the other hand, other nutritional assessment techniques are based on clinical and subjective assessments, so can be variable between observers.

For this reason, the NRI was chosen as the index reflecting the nutritional state of the postoperative patient in this study. We aimed to evaluate the correlation of the NRI with wound complications in gastric cancer patients undergoing curative gastrectomy, and to determine strategies to support postoperative patients' nutritional status in order to reduce postoperative complications, including wound complications.

Table 1 Types and definitions of wound complications

Types	Definitions
Seroma	Serous fluid collection in the absence of infection
Hematoma	Subcutaneous blood in the absence of infection
Wound infection	Displayed two or more of the following characteristics: drainage of purulent material, erythema, tenderness, induration or fever
Wound dehiscence	(1) Hematoma, seroma, or infection that required that the incision be opened, evacuated, and/or irrigated and debrided; (2) Status that required packing and healing by secondary intention

From Chelmow *et al*[9] 2004.

MATERIALS AND METHODS

Patients

From January 2008 through June 2008, 669 patients who underwent curative gastrectomy for gastric adenocarcinoma at Samsung Medical Center were enrolled in a retrospective study, with data collected prospectively. Medical records of consecutive patients were analyzed to determine the postoperative wound complication rates and to examine the effect of other possible risk factors of wound complications. Gender, age, disease progression, types of operation, comorbid disease and nutritional status were reviewed and analyzed as the possible risk variables. Postoperative wound complications which developed during the hospital stay, and the types of wound complications were classified according to Table 1. The patients with other postoperative complications were excluded because these might affect the occurrence of postoperative wound complications and could act as confounding factors.

Nutritional assessment

The nutritional assessment of the patients was performed using the NRI on the 5th postoperative day. The NRI was calculated using the formula: NRI = (1.489 × serum albumin, g/L) + (41.7 × current weight/usual weight)[3]. The usual weight was defined as the stable weight 6 mo or more before illness[11], but in this study, the weight measured at admission was used as the usual weight. The present weight was also determined on the 5th postoperative day using a calibrated balance. It has been suggested that a NRI > 100 indicated that the patient is not malnourished, while 97.5-100 indicated mild malnourishment, 83.5-97.5 indicated moderate malnourishment, and < 83.5 indicated severe malnourishment[11,12]. However, in this study, the cutoff points suggested by Buzby *et al*[13] were used to define malnutrition for the NRI. Therefore, patients with a score $\geqslant$ 97.5 were classified as well nourished, between 83.5 and 97.5 as moderately malnourished, and below 83.5 as severely malnourished. For analysis, the patients were stratified into two groups: a well-nourished group with a NRI score $\geqslant$ 97.5 and a moderately or severely malnourished group with a NRI score below 97.5. The

Table 2 Characteristics of patients according to the nutritional risk index on the 5th postoperative day

Characteristic		NRI			*P* value

NRI: Nutrition risk index; EGC: Early gastric cancer; AGC: Advanced gastric cancer; B-Ⅰ: Subtotal gastrectomy with Billroth-Ⅰ reconstruction; B-Ⅱ: Subtotal gastrectomy with Billroth-Ⅱ reconstruction; TG: Total gastrectomy. [1]Fisher's exact test; [2]Mann-Whitney *U* test.

NRI characteristics of patients, as well as the postoperative wound complication rate (%), were compared between the two groups and evaluated for their association with wound complications. To clarify the factors affecting postoperative wound complication, logistic regression analysis were performed.

Statistical analysis

The characteristics of patients, operation types, medical comorbid disease, length of postoperative hospital stay, and wound complications were compared based on the NRI classification using Fisher's exact test (Chi-squared) and the Mann-Whitney *U* test. In addition, these variables were compared between the groups with wound complications and those without wound complications using the same statistical methods and a repeated analysis of variance test, where appropriate. A difference was considered significant at $P < 0.05$. All statistical analyses were performed using the statistical software package PASW 17.

RESULTS

A total of 669 patients who had undergone curative gastrectomy for gastric cancer were enrolled in the study. The mean age was 56.8 ± 11.4 years. The ratio of males to females was 1.8:1 (432/237). The majority of the patients, 379 (56.7%) had early gastric cancers, while 290 (43.7%) had advanced gastric cancers. Early gastric cancer is defined as tumor invasion limited to the mucosa and submucoa, irrespective of the presence of a lymph node metastasis, and advanced gastric cancer is defined as tumor invasion above the muscularis propria[14].

Most patients [*n* = 444 (66.4%)] underwent subtotal gastrectomy with Billroth-Ⅰ reconstruction, 66 (9.8%) underwent subtotal gastrectomy with Billroth-Ⅱ reconstruction, and 159 (23.8%) patients underwent total gastrectomy. Co-morbid diseases were present in 354 (52.9%) patients, with the most common being hypertension (23.7%), followed by diabetes mellitus (12.9%), hepatitis (6.7%), pulmonary tuberculosis (4.3%), and cardiovascular diseases (2.3%).

The clinical demographic characteristics are described in Table 2. Patients were stratified on the basis of the NRI on the 5th postoperative day (NRI < 97.5, malnourished or NRI ⩾ 97.5, not malnourished). Malnutrition rates on the 5th postoperative day were 84.6% (566/669), with 3% (21/669) of the patients showing severe malnutrition (NRI < 83.5), 81.5% (545/669) showing moderate malnutrition (83.5 ⩽ NRI < 97.5).

As shown in Table 2, there were statistically significant differences in gender, age, disease progression, types of operation, and postoperative wound complication rates between NRI classes. However, there were no statistically significant differences in comorbid diseases or length of postoperative hospital stay between NRI classes. Postoperative wound complications occurred in 66 (9.86%) of the 669 patients. Among these patients, 62 (94%) belonged to the malnourished group (NRI < 97.5), and 4 (6%) patients to the non-malnourished group (NRI ⩾ 97.5).

Table 3 shows the patient characteristics, or risk factors, that correlate with wound complications. The only risk factor that correlated with wound complications was the NRI on the 5th postoperative day. By contrast, there were no differences in the rates of wound complications with respect to gender, age, disease progression, type of operation, or comorbid diseases. As expected, in patients who developed wound complications, length of postoperative hospital stay was prolonged.

Table 3 Relationship between patient characteristics and occurrence of wound complications

Characteristic		Wound complication			*P* value
		(-) (*n* = 603)	(+) (*n* = 66)	All (*n* = 669)

As shown in Table 4, the most common wound complication was seroma. It was encountered in 36 (54.5%) patients, all of whom were malnourished. Seventeen (25.8%) of the patients developed wound dehiscence, which required gauze packing and healing by secondary intention. Thirteen (70%) of these patients belonged to the malnourished group. Nine patients (13.6%) had wound infection, which required draining of purulent material in all cases and treatment with antibiotics in some cases. Three (13.6%) of the patients had hematoma that required evacuation. These patients were all malnourished.

When wound complications were correlated with the six possible risk factors by logistic regression analysis, the only factor that significantly increased the rate of wound complication was the 5th postoperative NRI of the malnourished group (Table 5).

DISCUSSION

It has been well known that malnutrition is a significant risk factor for postoperative complications in major abdominal surgery[15]. The reported prevalence of malnutrition in gastrointestinal surgery patients ranges from 30% to 50%[3,16]. Kuzu *et al*[11] reported that the level of malnourishment was directly correlated with both the severity and the frequency of postoperative complications. Beattie also suggested that perioperative nutritional support in malnourished patients decreased postoperative complications such as wound infections and sepsis[16].

It was reported that serum albumin on the 5th day after surgery was correlated with postoperative short-term complications[10]. It was also shown that 13.45% of the patients developed postoperative complications and that 24% of these patients had hypoalbuminemia on the 5th postoperative day. Furthermore, 55% of the postoperative complications were wound complications. Gorman *et al*[17] suggested that malnutrition was an important risk factor for postoperative infections and wound com-

plications in patients undergoing major surgery.

An accurate and reliable method for identifying patients who are malnourished or at risk for malnutrition may be beneficial in preventing postoperative infections and wound complications[11]. Many simple nutritional assessment or screening tools have been developed in recent years and have been validated[18]. Among them, the NRI, based on serum albumin concentration and weight loss, has been shown to identify patients at risk of postoperative complications. Its value, however, is limited by non-nutritional factors that affect albumin synthesis and the fact that the score does not represent specific, disease-related nutritional risk, such as in cancer. Nonetheless, it is simple, reliable, and does not require subjective judgment[11].

In the present study, it was found that the NRI on the 5th postoperative day identified 566 (84.6%) malnourished patients and that 10.9% of these malnourished patients developed wound complications. The NRI on the 5th postoperative day was the only risk factor for wound complications which was a new finding in gastric surgery.

However, patients with severe malnutrition [serum albumin < 3.0 g/dL or weight loss > 10% or body mass index (BMI) < 18.5 kg/m^2] did not show a significantly higher incidence of postoperative complications[4]. Additionally, weight loss and hypoalbuminemia were not associated with an increased risk of mortality and morbidity in patients who underwent surgery for gastric cancer[15]. Some recent evidence suggested that overweight and obesity rather than malnutrition were significant risk factors for postoperative complications in major abdominal surgery[19]. With respect to wound complications, Shin *et al*[20] reported that overweight (BMI > 25.0 kg/m^2) patients that underwent gastrectomy had a higher wound complication rate than normal body weight (BMI ≤ 25.0 kg/m^2) patients. Furthermore, Jaibati reported that overweight at the time of surgery, as measured by increased BMI, was a significant risk factor for an increased wound complication rate following abdominoplasty[21]. In addition, Vastine *et al*[22] reported that for abdominoplasties, 80% of obese patients had complications compared with the borderline and non-obese patients, and Hester *et al*[23] showed that in abdominoplasty procedures, obesity was a significant factor in predicting major morbidity.

Bearing in mind that other factors in addition to nutritional status may be involved in the development of postoperative complications, analyses were conducted in this study to identify possible risk factors, but no other factors were correlated with wound complications. In particular, and in contrast to common expectations that diabetes mellitus may be related to wound complications, there was no association between comorbidities, including diabetes mellitus, and wound complications, which contradicted the reports related to other surgical procedures. For example, Hensel *et al*[24] found that in abdominoplasty, complications were significantly increased in patients with diabetes and/or hypertension, and Jabaiti[21] found a negative correlation between diabetes mellitus and wound complications. It was also suggested that malnutrition was not always the cause of postoperative complications, but that both malnutrition and complications were the result of the underlying disease or other factors, because malnutrition and underlying disease were inextricably interwoven.

In conclusion, it was clearly shown that malnutrition had a high correlative relationship with postoperative wound complications, and NRI on the 5th postoperative day was a very good predictor of wound complications in gastric resection.

COMMENTS

Background

It was supposed that malnutrition might be related with postoperative wound complication. Nutritional risk index (NRI) was used as an evaluation tool of nutritional status in this study because it was easy and convenient to be applied.

Research frontiers

Surgical metabolism and clinical nutrition are important areas in the research field related with this article.

Innovations and breakthroughs

NRI on the 5th postoperative day was a good predictor of postoperative wound complications.

Applications

Preoperative or postoperative nutritional support, especially with attention to serum level of albumin may reduce wound complications.

Terminology

NRI is calculated with serum albumin level and body weight to evaluate nutritional status of patients.

Peer review

Authors showed that NRI on the 5th postoperative day was useful to predict postoperative wound complications.

Abstract

AIM: To examine how high-mobility group box 1 (HMGB1) regulates hepatocyte apoptosis and, furthermore, to determine whether glycyrrhizin (GL), a known HMGB1 inhibitor, prevents HMGB1-induced hepatocyte apoptosis.

METHODS: A human hepatocellular carcinoma cell line stably transfected with a bile acid transporter (Huh-BAT cells), were used in this study. Apoptosis was quantified using 4',6-diamidino-2-phenylindole dihydrochloride staining and the APO Percentage apoptosis assay, and its signaling cascades were explored by immunoblot analysis. Kinase signaling was evaluated by immunoblotting and by using selective inhibitors. It is also tried to identify hepatocyte apoptosis affected by the HMGB1 inhibitor, GL.

RESULTS: HMGB1 increased cellular apoptosis in Huh-BAT cells. HMGB1 led to increased cytochrome c release from mitochondria into the cytosol, and induced the cleavage of procaspase 3. However, it did not affect the activation of caspase 8. HMGB1-induced caspase 3 activation was significantly attenuated by the p38 inhibitor SB203580. GL significantly attenuated HMGB1-induced hepatocyte apoptosis. GL also prevented HMGB1-induced cytochrome c release and p38 activation in Huh-BAT cells.

CONCLUSION: The present study demonstrated that HMGB1 promoted hepatocyte apoptosis through a p38-dependent mitochondrial pathway. In addition, GL had an anti-apoptotic effect on HMGB1-treated hepatocytes.

INTRODUCTION

High-mobility group box 1 (HMGB1) is an evolutionarily conserved protein present in the nucleus of almost all eukaryotic cells, where it is involved in DNA replication, repair and transcription[1-3]. This molecule is known to be released by cells undergoing necrosis as well as being

secreted by activated macrophages. While early studies of HMGB1 demonstrated its role as a late mediator of sepsis[4], HMGB1 has been more recently implicated as a putative danger signal involved in the pathogenesis of a variety of non-infectious inflammatory conditions including autoimmunity, cancer, trauma, and hemorrhagic shock, and ischemia-reperfusion injury (IRI)[5-11]. So far, HMGB1 has been studied in a number of organs including liver, lung, breast and prostate[7-9,11].

In the liver, the importance of HMGB1 signaling has been largely identified in cases of IRI, during which tissue levels of HMGB1 were elevated following reperfusion and neutralizing antibodies against HMGB1 ameliorated the damage resulting from IRI in a toll-like receptor (TLR)4-dependent manner[11]. The pathogenetic role of HMGB1 in liver disease was also clarified by studying the inflammatory response to viral infection[12]. Following hepatocyte death by hepatitis B virus-specific cytotoxic T lymphocytes in a mouse model of hepatitis, HMGB1 directs the intrahepatic recruitment of neutrophils and all other non-antigen specific inflammatory cells (natural killer cells, T cells, B cells, monocytes, macrophages and dendritic cells).

Apoptosis, a stereotyped morphologic form of cell death, is an event that contributes to liver injury in a wide range of acute and chronic liver diseases[13]. However, it is not clear whether HMGB1 contributes to apoptotic cell death in the liver. Furthermore, the regulatory mechanism of HMGB1 in hepatocyte apoptosis remains largely undefined.

Glycyrrhizin (GL) is a major active constituent of licorice root that is commonly used in Asia to treat patients with chronic hepatitis[14-16]. This compound has been associated with numerous pharmacologic effects, including anti-inflammatory, anti-viral, anti-tumor, and hepatoprotective activities[17]. Recently, GL was recognized by Sitia *et al*[18] as an HMGB1 inhibitor, which binds directly to both HMG boxes in HMGB1.

Thus, the aim of this study was to provide *in vitro* evidence and a potential theoretical basis for HMGB1 regulation of hepatocyte apoptosis in order to further elucidate the molecular mechanism of HMGB1 involvement in various pathologic conditions that can affect the liver. Furthermore, we attempted to determine whether GL attenuates HMGB1-induced hepatocyte apoptosis and, if so, to identify the signaling cascades responsible for this modulation.

MATERIALS AND METHODS

Cell line and culture

Several human hepatoma cell lines were chosen for this study: Huh-7 cells stably transfected with a bile acid transporter[19] derived from a well-differentiated hepatocellular carcinoma (HCC)[20] (Huh-BAT), HepG2 and SNU-475 cells derived from a poorly differentiated HCC[21]. All cells were cultured in Dulbecco's Modified Eagle medium supplemented with 10% fetal bovine serum, 100 000 U/L penicillin and 100 mg/L streptomycin. In all experiments, cells were serum-starved for 12 h in order to avoid the effects of serum-induced signaling.

Materials and reagents

HMGB1 (human, recombinant expressed in *E. coli*) was synthesized by Sigma-Aldrich, Inc. (St. Louis, MO, United States) at a purity of > 90%. The MAPK inhibitors [SB203580 for p38 mitogen activated protein kinase (MAPK), U0126 for p42/44 MAPK or extracellular signal-regulated kinase, and SP600125 for c-Jun N-terminal kinase (JNK) and GL] were also obtained from Sigma-Aldrich, Inc.

Preparation of mitochondrial and cytosolic extracts

Cells were washed twice with phosphate-buffered saline, and mitochondrial and cytosolic extracts were isolated using a mitochondria/cytosol fractionation kit (BioVision, Inc., Mountain View, CA, United States) according to the manufacturer's instruction.

Immunoblot analysis

Huh-BAT cells were lysed for 20 min on ice with lysis buffer (50 mol/L Tris-HCl, pH 7.4; 1% Nonidet P-40; 0.25% sodium deoxycholate; 150 mol/L NaCl; 1 mol/L EDTA; 1 mol/L PMSF; 1 μg/mL aprotinin, leupeptin, pepstatin; 1 mol/L Na_3VO_4; and 1 mol/L NaF) and centrifuged at 14 000 × *g* for 10 min at 4 ℃. Proteins in the lysates were resolved by 10% or 12% sodium dodecylsulfate-polyacrylamide gel electrophoresis, transferred to PVDF membranes, and probed using the following primary antibodies: mouse anti-caspase 8 (1:500 dilution) from Cell Signaling Technology (Danvers, MA, United States); rabbit anti-caspase 3 (1:1000 dilution) from Cell Signaling Technology; rabbit anti-ACTIVE® p42/p44 (1:2000 dilution), anti-ACTIVE® p38 (1:1000 dilution), and anti-ACTIVE® JNK (1:1000 dilution) specific for the phosphorylated forms of p42/p44 MAPK, p38 MAPK, and JNK, respectively, from Cell Signaling Technology; mouse anti-cytochrome c (1:500 dilution) from BD Pharmingen (San Jose, CA, United States), and goat anti-actin (1:1000 dilution) from Santa Cruz Biotechnology Inc. (Santa Cruz, CA, United States). Twenty μg of protein was used for each well in Western blotting. Primary antibody binding was detected with appropriate peroxidase-conjugated secondary antibodies (Biosource International, Camarillo, CA). Bound antibodies were visualized using a chemiluminescent substrate (ECL; Amersham, Arlington Heights, IL, United States) and the blots were exposed to Kodak X-OMAT film.

The signals in the Western blotting were quantified by densitometric scanning and normalized by using the intensity of corresponding protein band relative to the actin band.

Quantification of apoptosis

Quantitative detection of apoptotic cells was performed using two different methods: the nuclear binding dye DAPI and fluorescence microscopy, and the APO Per-

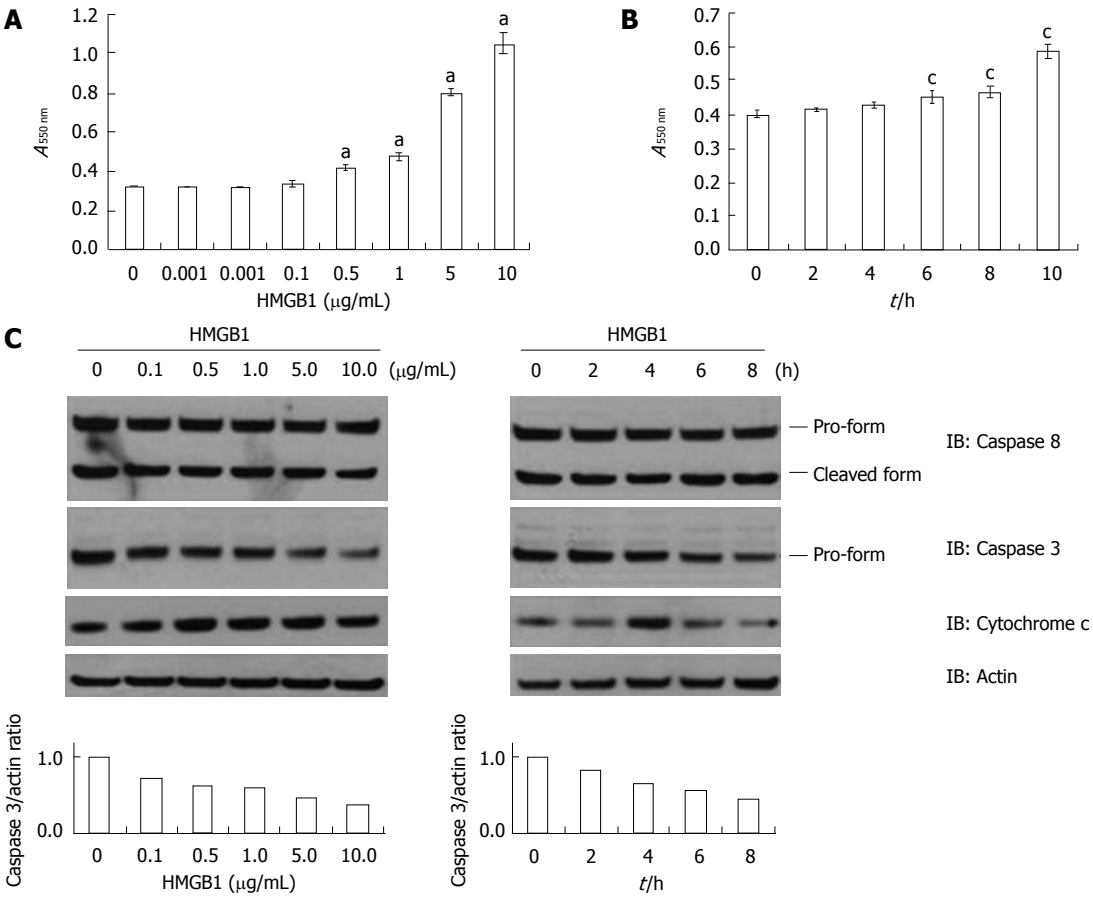

Figure 1 High-mobility group box 1 enhances hepatocyte apoptosis *via* a mitochondrial pathway. A: Huh-BAT cells were treated with high-mobility group box 1 (HMGB1) (0, 0.001, 0.01, 0.1, 0.5, 1, 5 and 10 μg/mL) for 6 h. Apoptosis was quantified using an APO Percentage apoptosis assay kit. Data are expressed as the mean ± SD of three individual experiments. $^{a}P < 0.05$, *vs* HMGB1 0 μg/mL; B: Huh-BAT cells were treated with 10 μg/mL of HMGB1 for the indicated time periods. $^{c}P < 0.05$, *vs* 0 h; C: Huh-BAT cells were treated with HMGB1 (0 μg/mL, 0.1 μg/mL, 0.5 μg/mL, 1, 5 μg/mL and 10 μg/mL) for 6 h (left column), or with 10 μg/mL of HMGB1 for the indicated time periods (right column). Cells were lysed at the indicated time points, and immunoblot analysis was performed using anti-caspase 8 and anti-caspase 3 antibodies. Mitochondrial and cytosolic extracts were also isolated, and equivalent amounts of cytosolic protein were immunoblotted with an anti-cytochrome c antibody. Immunoblot analysis using an anti-actin antibody was performed as a control for protein loading.

centage apoptosis assay kit (Biocolor Ltd., Belfast, Northern Ireland). For the APO Percentage apoptosis assay, the cells were seeded at 10^4 cells per well in a 96-well plate and processed according to the manufacturer's instructions.

Statistical analysis

All data were from at least three independent experiments using cells from a minimum of three separate isolations, and are expressed as the mean ± SD. Differences between the groups were compared using a two-tailed Student's *t* tests or the Mann-Whitney *U* test as appropriate. *P* values of < 0.05 were considered to be statistically significant.

RESULTS

HMGB1 significantly increased cellular apoptosis in Huh-BAT cells in a dose- and time-dependent manner (Figure 1A and B). We repeated the same experiments in the other two hepatoma cell lines (HepG2 and SNU-475 cells) and observed the same effects (data not shown). We next identified the pro-apoptotic signaling pathways induced by HMGB1 treatment. HMGB1 increased cytochrome c release from mitochondria into cytosol and induced the cleavage of procaspase 3. However, it did not affect the activation of caspase 8, an initiator caspase downstream of death receptor activation (Figure 1C).

Since the MAPK family signaling cascades regulate apoptotic pathways, we next evaluated whether HMGB1 modulates MAPK activation. HMGB1 induced the activation of MAPKs such as p42/44, p38 MAPK, and JNK in Huh-BAT cells (Figure 2A). In order to explore the role of individual MAPKs in apoptotic signaling, the cells were then treated with HMGB1 either in the presence or absence of various inhibitors: U0126 for p42/44, SB203580 for p38, and SP600125 for JNK. When the cells were treated with the p38 inhibitor, HMGB1-induced caspase 3 activation was significantly attenuated whereas treatment with inhibitors of p42/44 or JNK did not affect caspase 3 cleavage (Figure 2B).

Pretreatment with GL significantly attenuated HMGB1-induced hepatocyte apoptosis in a dose-dependent manner (Figure 3A). GL also attenuated cytochrome c release from the mitochondria into cytosol (Figure 3B). Finally, pretreatment with GL decreased HMGB1-induced p38

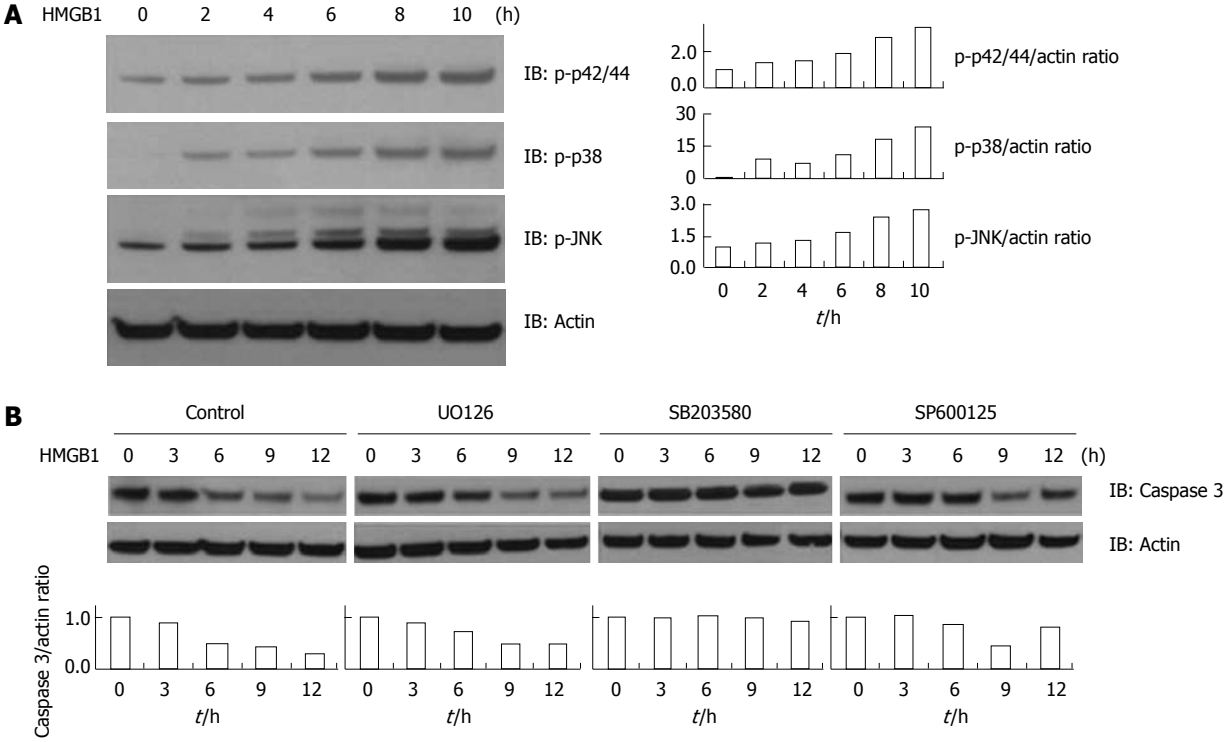

Figure 2 High-mobility group box 1-induced hepatocyte apoptosis is p38-dependent. A: Huh-BAT cells were treated with 10 μg/mL of high-mobility group box 1 (HMGB1) for the indicated time periods. Cells were lysed at the indicated time points, and immunoblot analysis was performed on cell lysates using antibodies specific for the phosphorylated forms of p42/p44, p38, or c-Jun N-terminal kinase (JNK); B: Huh-BAT cells were pretreated with mitogen activated protein kinase inhibitors U0126 (30 μmol/L), SB203580 (10 μmol/L), or SP600125 (20 μmol/L), or media (control) for 12 h. Cells were then treated with 10 μg/mL of HMGB1. Cells were lysed at the indicated time points, and immunoblot analysis was performed on cell lysates using anti-caspase 3 and anti-actin antibodies.

activation in Huh-BAT cells (Figure 3C). Taken together, all of the findings from our study indicate that HMGB1 induces hepatocyte apoptosis through a p38-dependent mitochondrial pathway which was inhibited by GL.

DISCUSSION

In virtually all human liver diseases, hepatocytes undergo cell death by apoptosis[13]. Thus, therapeutic modulation of apoptosis has the potential to alter the course of human liver disease. Apoptosis may occur *via* two fundamental pathways: (1) the death receptor or extrinsic pathway; and (2) the mitochondrial or intrinsic pathway. Caspases, representing the family of cysteine proteases, play a critical role in both pathways. Both pathways can either directly or indirectly converge to activate the "effector caspase", namely caspase-3, which induces DNA fragmentation and other morphological changes characteristic of apoptotic cell death[22]. In the present study, HMGB1 activated caspase 3 without affecting caspase 8, an initiator caspase downstream of death receptor activation. These findings suggest that the mitochondrial pathway is responsible for HMGB1-induced hepatocyte apoptosis, which was further supported by the findings that HMGB1 increased cytochrome c release from mitochondria into the cytosol.

MAPKs, which include p42/44, p38, and JNK, are involved in pro-apoptotic signal transduction as well as cell growth and differentiation[23]. It has been previously shown that the p38 MAPK cascade promotes either cell death or cell survival[23,24] depending on the cell type and the kinase isoforms activated by various stress stimuli[25]. There is abundant evidence that p38 participates in cellular apoptosis[26,27] with one mechanism being the modulation of Bcl-2 protein family members to maintain an apoptotic checkpoint for mitochondrial dysfunction and cytochrome c release[28,29]. Likewise, in the present study HMGB1-induced hepatocyte apoptosis occurred through a mitochondrial pathway which was p38-dependent.

GL, a triterpene glycoside extracted from licorice root (*Glycyrrhiza glabra*), consists of one molecule of 18b-glycyrrhetinic acid and two molecules of glucuronic acid having the structure 18-b-glycyrrhetinic acid-3-O-b-D-glucuronopyranosyl-(1/2)-b-D-glucuronide. It is known that this molecule has a variety of hepato-protective properties in terms of anti-inflammatory, antiviral, and anti-tumor effects[17]. In an animal model of acute liver injury induced by carbon tetrachloride, GL reduced the serum tumor necrosis factor-alpha (TNF-α) level and alleviates acute liver injury[30]. Moreover, GL has anti-inflammatory effects on lipopolysaccharide (LPS)-induced acute liver injury through inhibition of TNF-α release[31]. Recently, Ikeda *et al*[32] reported that GL reduced the number of TUNEL-positive cells in cases of acute hepatitis induced by LPS/D-galactosamine (GalN)-treatment. However, in a mouse model treated with LPS/D-GalN, anti-apoptotic effects of GL were found to be caspase-independent, and probably achieved

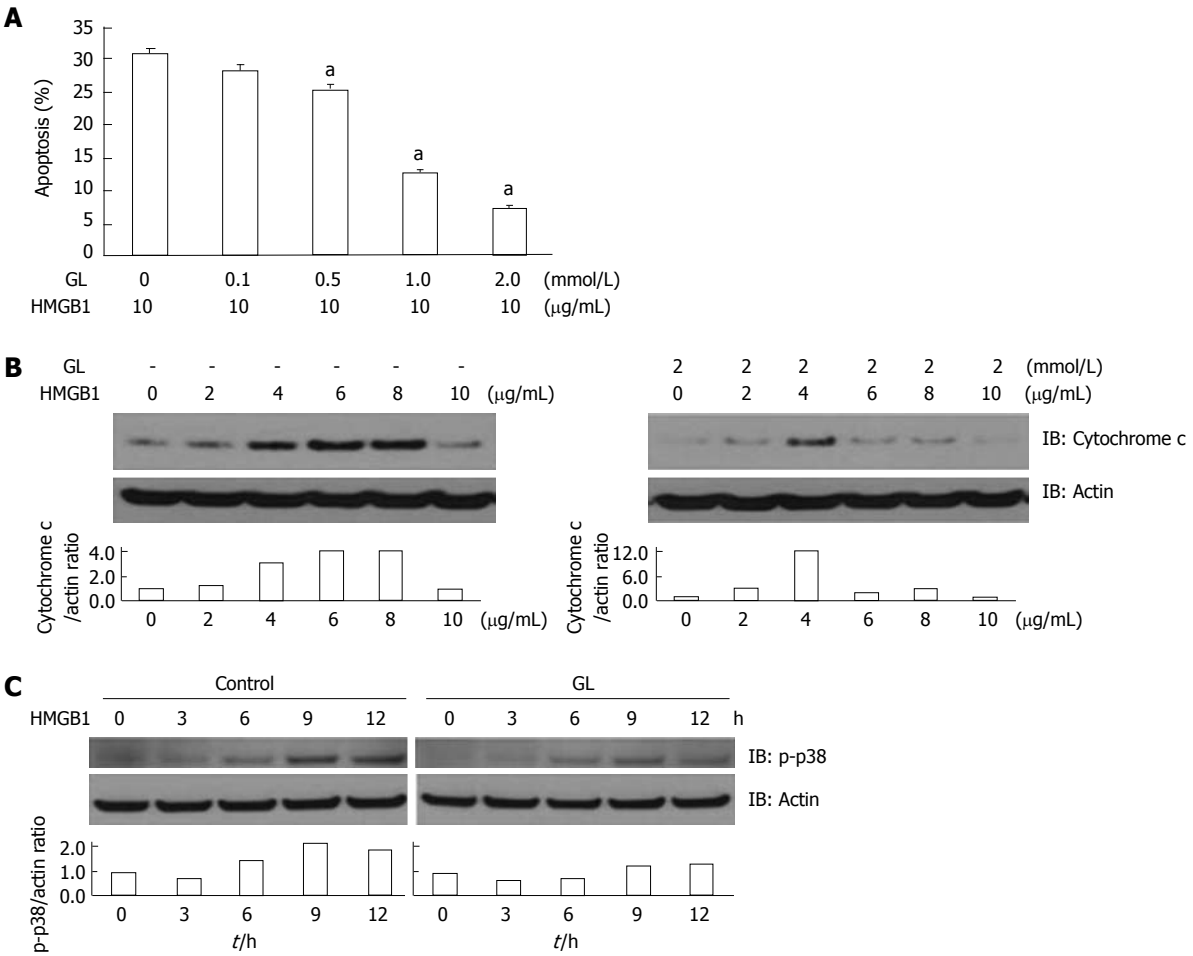

Figure 3 Glycyrrhizin attenuates high-mobility group box 1-induced hepatocyte apoptosis. A: Huh-BAT cells were pretreated with glycyrrhizin (GL) (0, 0.1, 0.5, 1.0 and 2.0 mmol/L) for 12 h. Cells were then treated with 10 μg/mL of high-mobility group box 1 (HMGB1) for 6 h. Apoptosis was quantified by 4',6-diamidino-2-phenylindole staining and fluorescence microscopy. Data are expressed as the mean ± SD of three individual experiments. $^{a}P < 0.05$, *vs* GL 0 mmo/L; B: Huh-BAT cells were pretreated with GL (2.0 mmol/L) for 12 h prior to adding HMGB1 (0-10 μg/mL). Mitochondrial and cytosolic extracts were isolated after 6 h of HMGB1 treatment, and equivalent amounts of cytosolic protein were immunoblotted with an anti-cytochrome c antibody. Immunoblot analysis using an anti-actin antibody was performed as a control for protein loading; C: Huh-BAT cells were pretreated with GL (2.0 mmol/L) for 12 h prior to being incubated with HMGB1. Cells were then lysed at the indicated time points, and immunoblot analysis was performed using antibodies specific for the phosphorylated forms of p38 and actin.

through the prevention of an interleukin-18-mediated inflammatory response. In the present study, we demonstrated that GL attenuated HMGB1-induced hepatocyte apoptosis by blocking the p38-dependent mitochondrial pathway. Therefore, it is likely that the hepato-protective effects of GL are attributed to various mechanisms.

In summary, the present study demonstrated that HMGB1 participated in hepatocyte apoptosis through a p38-dependent mitochondrial pathway. In addition, GL had an anti-apoptotic effect on hepatocytes treated with HMGB1. Therefore, HMGB1 inhibitors, including GL, might be therapeutically efficacious in treating HMGB1-mediated liver injury such as viral hepatitis, hepatic ischemia-reperfusion injury and sepsis-related liver injury.

COMMENTS

Background

High mobility group box 1 (HMGB1) is an evolutionarily conserved protein present in the nucleus of almost all eukaryotic cells, where it is involved in DNA replication, repair and transcription. Glycyrrhizin (GL) is a major active constituent of licorice root that is commonly used in Asia to treat patients with chronic hepatitis. This compound has been associated with numerous pharmacologic effects, including anti-inflammatory, anti-viral, anti-tumor, and hepatoprotective activities. Recently, GL was recognized as an HMGB1 inhibitor, which binds directly to both HMG boxes in HMGB1.

Research frontiers

The authors provide *in vitro* evidence and a potential theoretical basis for HMGB1 regulation of hepatocyte apoptosis in order to further elucidate the molecular mechanism of HMGB1 involvement in various pathologic conditions that can affect the liver. Furthermore, they attempted to determine whether GL attenuates HMGB1-induced hepatocyte apoptosis and, if so, to identify the signaling cascades responsible for this modulation.

Innovations and breakthroughs

Present study demonstrated that HMGB1 participated in hepatocyte apoptosis through a p38-dependent mitochondrial pathway. In addition, GL had an anti-apoptotic effect on hepatocytes treated with HMGB1.

Applications

HMGB1 inhibitors, including GL, might be therapeutically efficacious in treating HMGB1-mediated liver injury such as viral hepatitis, hepatic ischemia-reperfusion injury and sepsis-related liver injury.

Peer review

This is an interesting study where the authors show that HMGB1 induces hepatocyte apoptosis which is mediated by p38. In addition, glycyrrhizin was shown to inhibit HMGB1-induced apoptosis as well as activation of p38 in the

cultured hepatocyte cell line. The study is well conducted and the manuscript is well written.

Abstract

AIM: To assess the significance of chromosome translocation t(11;18)(q21;q21), B-cell lymphoma 10 (BCL-10) protein and *Helicobacter pylori* (*H. pylori*) infection in gastric mucosa-associated lymphoid tissue (MALT) lymphoma in Colombia.

METHODS: Fifty cases of gastric MALT lymphoma and their respective post-treatment follow-up biopsies were examined to assess the presence of the translocation t(11;18)(q21;q21) as identified by fluorescence *in situ* hybridization; to detect protein expression patterns of BCL10 using immunohistochemistry; and for evaluation of tumor histology to determine the correlation of these factors and resistance to *H. pylori* eradication.

RESULTS: Infection with *H. pylori* was confirmed in all cases of gastric MALT lymphoma in association with chronic gastritis. Bacterial eradication led to tumor regression in 66% of cases. The translocation t(11;18)(q21;q21) was not present in any of these cases, nor was there evidence of tumor transformation to diffuse large B-cell lymphoma. Thirty-four percent of the patients showed resistance to tumor regression, and within this group, 7 cases, representing 14% of all those analyzed, were considered to be t(11;18)(q21;q21)-positive gastric MALT lymphomas. Protein expression of BCL10 in the nucleus was associated with the presence of translocation and treatment resistance. Cases that were considered unresponsive to therapy were histologically characterized by the presence of homogeneous tumor cells and a lack of plasmacytic differentiation. Responder cases exhibited higher cellular heterogeneity and a greater frequency of plasma cells.

CONCLUSION: Both t(11;18)(q21;q21)-positive MALT lymphoma cases and those with nuclear BCL10 expression are considered resistant to *H. pylori* eradication. It is suggested that chronic antigenic stimulation is not a dominant event in resistant cases.

Key words: Mucosa-associated lymphoid tissue lymphoma; *Helicobacter pylori*; Treatment; t(11;18)(q21;q21); B-cell lymphoma 10

INTRODUCTION

Gastric B-cell lymphoma (BCL) of mucosa-associated lymphoid tissue (MALT) is an indolent B-cell non-Hodgkin lymphoma that arises from the mucosal lymphoid tissue and is normally acquired as a reaction to *Helicobacter pylori* (*H. pylori*) infection[1-3]. This disease is considered one of the best models reflecting how genetic events lead to oncogenesis, determine tumor biology, dictate clinical behavior and represent viable therapeutic targets.

Gastric MALT lymphoma pathogenesis is a multistep process initiated by infection with *H. pylori*, which induces genetic abnormalities and subsequent malignant transformation. Gene alterations include trisomy of chromosomes 3, 7, 12 or 18 and the disease-specific chromosome translocations t(1;14)(p22;q32), t(14;18)(q32;q21), t(11;18)(q21;q21) and t(3;14)(p13;q32) resulting in *IGH-BCL10*, *IGH-MALT1*, *API2-MALT1* and *IGH-FOXP1* rearrangements respectively. Notably, these events are associated with the activation of nuclear factor-κB (NF-κB)[4,5].

Various studies of gastric MALT lymphoma have shown that t(11;18)(q21;q21) is present in approximately 30% of cases. The clinical importance of the translocation is well-characterized: positive cases are usually unresponsive to *H. pylori* eradication, which is the generally accepted first-choice therapy[6,7]. The translocation is often present in advanced cases of the disease but rarely undergoes high-grade transformation to diffuse large B-cell lymphoma (DLBCL)[8-10].

However, complete tumor regression is known to occur in 20% of patients with t(11;18)(q21;q21)-positive disease. Therefore, all patients who have *H. pylori*-positive gastric MALT lymphoma should undergo eradication therapy, regardless of their t(11;18)(q21;q21) status[11]. On the other hand, new evidence has shown that translocations can be found at approximately equivalent frequencies in both gastric MALT lymphomas and gastric DLBCLs[12].

Although most patients with gastric MALT lymphoma experience an indolent clinical course[13], there is considerable individual variability in the extent of the disease response to treatment, relapse and event-free survival. Consequently, optimal management is changing, and there is a need for an improved understanding of the genetic abnormalities underlying gastric MALT lymphoma and for new genetic biomarkers that are able to guide prognosis and management.

The incidence of chromosomal translocations in gastric MALT lymphoma has been described mainly from patients in Western countries[14-17]. The prevalence of t(11;18)(q21;q21)-positive MALT lymphoma has been reported to be within a range of 15%-24% in Europe[14,15,18] but is considered relatively rare in the United States (5%)[17].

The incidence of MALT lymphoma and its genetic background has not been established and validated in Latin America; likewise, the ideal prognosis and management of the Colombian patient population is unclear given the complex genetic background of the disease.

In Colombia, the identification of MALT lymphoma resistant to *H. pylori* eradication therapy is not typically considered in initial diagnoses and patient classification is possible only after repeated follow-up assessments involving endoscopy and histology. This situation warrants validation and a search for biomarkers of treatment response to direct the treatment regimen.

In the present study, we attempted to evaluate the t(11;18)(q21;q21) status and BCL10 staining patterns in patients with gastric MALT lymphomas and the relationship among these factors with the response to the eradication of *H. pylori* in a sample of patients from Colombia.

MATERIALS AND METHODS

Cases and diagnostic criteria

Fifty cases of gastric MALT lymphomas were retrieved from the archives of the Department of Pathology, Fundación Santa Fe de Bogotá. All of these cases had hematoxylin and eosin-stained sections and immunohistochemistry (IHC)-marked slides available for reevaluation. Cases selected must have had previous histopathological diagnoses, available archival material and complete information about diagnosis and disease monitoring.

Diagnosis of MALT lymphoma was made on the basis of morphological and immunophenotypic examination according to the criteria described by Isaacson *et al*[19] and subsequently included in the Revised European American Lymphoma/World Health Organization (WHO) classification. Other factors evaluated included the accompanying epithelium (assessment of gastritis, atrophy and metaplasia) and a characterization of the tumoral infiltrate (large cells, centrocyte-like/small lymphocytes, monocytoid cells, plasma cell differentiation, residual follicles, colonization follicles and Dutcher's bodies). Detection of *H. pylori* was performed by histology and/or histochemistry using a Genta stain on all follow-up biopsies.

Assessment of the response to H. pylori eradication treatment

All 50 cases analyzed were treated with triple antibiotic therapy as the first-choice measure. This consisted of a proton pump inhibitor (such as omeprazole, lansoprazole or pantoprazole) plus two antibiotics (amoxicillin and clarithromycin) administered according to the manufacturer's recommended dose for 14 d. To confirm *H. pylori* eradication, a first endoscopic mucosal biopsy was conducted 2-3 mo after the cessation of antibiotic treatment, followed by endoscopy every 6 mo for at least 2 years at the discretion of the treating physician.

Surveillance of patients was performed by serial gastric biopsies to allow the histological evaluation of the tumor's response to treatment. Histological responses were graded using the Wotherspoon histological score. This system assigns a score and diagnosis based on histological characteristics of the tissue: a score of zero represents a normal diagnosis with scattered plasma cells in the lamina propria; score of one represents chronic active gastritis with small clusters of lymphocytes in the lamina propria, a lack of lymphoid follicles and lymphoepithelial lesions; a score of two represents chronic active gastritis with florid lymphoid follicle formation, prominent lymphoid follicles with surrounding mantle zone and plasma cells, and the absence of lymphoepithelial lesions; a score of three represents a likely reactive suspicious lymphoid infiltrate with lymphoid follicles surrounded by small lymphocytes that infiltrate diffusely into the lamina propria and occasionally into the epithelium; a score of four represents a suspicious lymphoid infiltrate, likely lymphoma, and lymphoid follicles surrounded by marginal zone cells that infiltrate diffusely into the lamina propria and the epithelium in small groups; a score of five represents MALT lymphoma with the presence of dense diffuse infiltrates of marginal zone cells into the lamina propria with prominent lymphoepithelial lesions[20].

Lymphoma remission was investigated by regular endoscopic examinations, including multiple biopsies, conducted at 6-mo intervals. Histological responses were graded using the Wotherspoon histological score, considering scores 0-2 to be a complete lymphoma regression (CR), score 3 to be a partial remission and scores 4-5 to be no response (no change). A persistence score of 5, mainly characterized by the presence of lymphoepithelial lesions after antibiotic treatment, was the criterion for tumor resistance to therapy[20].

Fluorescence in situ hybridization

The authors performed manual microdissection of tumor tissue from each of the biopsies with initial diagnoses of gastric MALT lymphoma and subsequently organized the tissues for inclusion in a new block, generating tissue microarrays to perform fluorescent in-situ hybridization (FISH) and IHC for BCL10 expression. The FISH for t(11;18)(q21;q21) was performed using standardized protocols appropriate for paraffin-embedded tissue and the commercial Dual Color probe LSI API2-MALT1 (Vysis, Downers Grove, IL, United States).

The cut-off point for translocation-positive status was determined through the analysis of 6 control samples of hyperplastic tonsils fixed in neutral formalin and embedded in paraffin, and was defined as the arithmetic mean count of 100 nuclei plus three standard deviations obtained for each sample. Assessments were performed using an Olympus BX51 fluorescence microscope with a 100-watt bulb for each 100 cells examined.

Immunohistochemistry

Immunohistochemical analysis using standardized procedures for CD20, CD3, CD43, BCL2, cytokeratin and kappa and lambda light chain immunoglobulin antibodies was performed to confirm the MALT lymphoma diagnosis and in follow-up biopsies when necessary. Expression of BCL10 was also determined using the immunoperoxidase technique in paraffin-embedded sections with a monoclonal mouse anti-human BCL10 antibody (DakoCytomation, Glosturp, Denmark). Briefly, 4-μm-thick paraffin sections were placed on silanized slides, dewaxed in xylene and hydrated through graded solutions of alcohol. Slides were then immersed in 0.01 mol/L citrate buffer (pH 6.0) and epitope retrieval was performed using a pressure cooker. The sections were then incubated with the diluted (1:40) primary antibodies and staining was performed using the EnVision system (DakoCytomation) according to the manufacturer's recommendations. Hyperplastic tonsils that were positive for cytoplasmic expression of the protein were used in each experiment as a control. Samples were considered positive for nuclear expression of BCL10 when detected in more than 5% of the nuclei of tumor cells.

Table 1 Definition of groups with respect to the presence of the *API2-MALT1* rearrangement and response to treatment (n = 50)

Gastric malt lymphoma	Treatment response	*API2-MALT1* positive	*API2-MALT1* negative
A group	Responders	0	33
B group	Non-responders	7	
C group	Non-responders		10

MALT: Mucosa-associated lymphoid tissue.

RESULTS

Characteristics of gastric MALT lymphoma in terms of response to the eradication of H. pylori, t(11;18)(q21;q21) status and BCL10 expression

H. pylori infection was confirmed in all cases of gastric MALT lymphoma in association with chronic gastritis. Ninety percent of cases showed the presence of *H. pylori* in the histological analysis of early gastric biopsies; in the remaining 10%, the presence of bacteria was documented in subsequent biopsies before the initiation of the treatment and infection was scored as mild in most cases.

The patients were classified as responders or non-responders to treatment (Table 1). All patients classified as responders showed lymphoma regression, and the median time for follow-up after remission was 29 mo (range: 6-39 mo). There were 33 (66%) patients considered as responders to treatment and 17 (34%) patients considered non-responders who did not reach remission after *H. pylori* eradication. The median time to CR after the completion of antibiotic therapy was 3.2 mo (range: 1-18 mo). The bacteria were successfully eradicated in all patients treated with the standard triple therapy applied, including all non-responders.

Non-responder cases were defined as tissues with

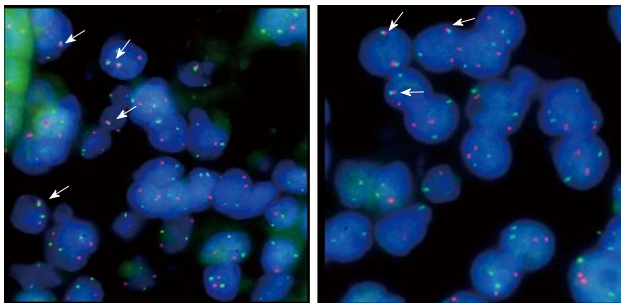

Figure 1 Fluorescence *in situ* hybridization to detect the translocation (11;18)(q21;121) using the probe LSI API2-MALT1 Dual Color (Vysis, Downers Grove, IL, United States). Arrows show translocation-positive mucosa-associated lymphoid tissue lymphomas.

histological persistence of gastric MALT lymphoma infiltrate despite successful *H. pylori* eradication as determined by histological and immunohistochemical examination. Within this group, seven cases, representing 14% of all cases analyzed, were considered positive for translocation. Cases were considered positive when more than 6% of tumor cells demonstrated the presence of fusion protein for a minimum count of 100 cells, which was the parameter set as the cut-off point for translocation-positive status for the technique. There was a statistically significant association between treatment response and the presence of the t(11;18)(q21;q21) translocation (Yales $\chi^2 = 12.57$, $P < 0.05$) because there were 7 patients within the group of non-responders who displayed the chromosomal arrangement of interest. Figure 1 shows the fluorescence patterns in positive and negative cases in the translocation study. When the response to treatment and the BCL10 staining pattern were analyzed, it was observed that all non-responders had nuclear expression of the BCL10 protein in a moderately nuclear pattern, as is shown in Figure 2. In addition, these cases showed evidence of translocation t(11;18)(q21;q21). However, in the responder group, BCL10 expression was confined to the cytoplasm. This finding confirms results reported elsewhere. Based on these results, the authors divided the cases into three groups (Table 1). Group A: patients who responded to the eradication and were negative for the studied translocation (66%); group B: patients who did not respond to eradication and were negative for t(11;18)(q21;q21) (20%); and group C: cases that did not respond to eradication of *H. pylori* and were positive for t(11;18)(q21;q21) (14%).

Table 2 Histological and immunohistochemical characteristics of 50 cases of gastric mucosa-associated lymphoid tissue lymphoma *n* (%)

[a]$P < 0.05$ is significant. NA: Not applicable.

The results of the comparisons between groups A and B (responders *vs* non-responders with fusion), show statistically significant differences in plasma cell differentiation variables with a higher percentage in group A. These groups also differed in the nuclear expression of BCL10 protein, which was observed more frequently in group B. The other variables showed no significant associations. Comparisons between groups A and C (responders *vs* non-responders without fusion) showed statistically significant differences in the presence of centrocytes/small lymphocytes, which appeared at a higher rate in group C, and nuclear expression of BCL10, which also occurred at a higher percentage in group C. Other variables did not show any significant associations. Comparisons between groups B and C did not show any significant associations with the variables assessed (Table 2). Characteristic examples of the morphology described above are presented in Figure 3.

DISCUSSION

Known predictive factors for assessing the outcome of MALT lymphoma include the evaluation of trans-

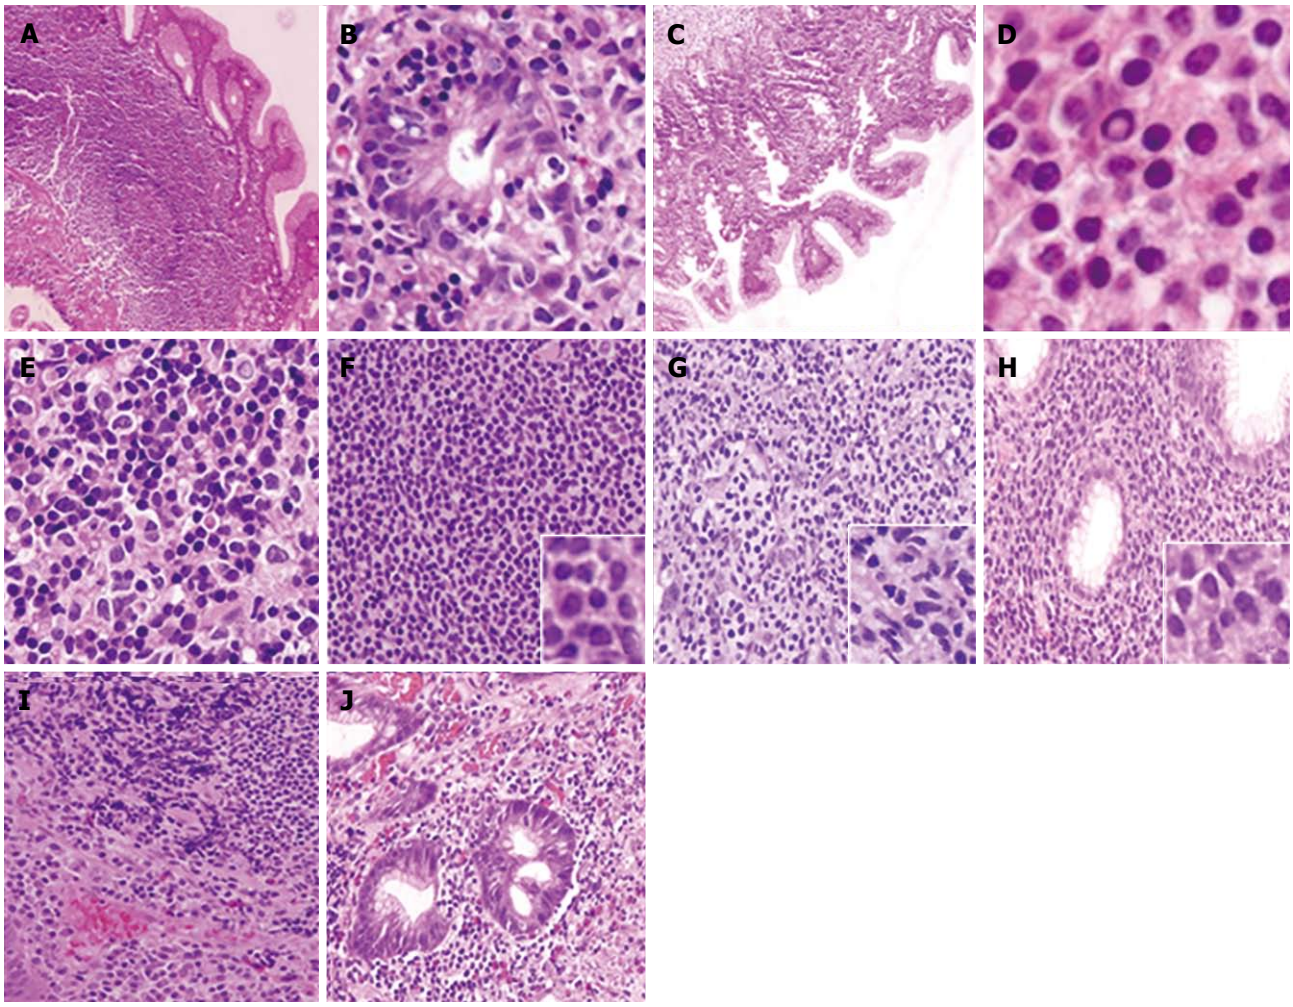

Figure 3 Stain showing tumor morphology (hematoxylin and eosin). A: Gastric mucosa-associated lymphoid tissue (MALT) lymphoma overview; B: Lymphoepithelial lesion; C: Accompanying intestinal metaplasia in the epithelial tissue surrounding the lymphoma; D: Dutcher's bodies; E: MALT lymphoma with clusters of large cells; F: Tumor cells of the centrocyte-like/small lymphocyte type; G: Monocytoid tumor cell type; H: Plasma cell differentiation; I: Mixed phenotype composed of centrocytes and plasma cell type; J: Presence of eosinophils. Original magnifications of panels A-J and inset in panel F-H are × 400 and × 1000, respectively.

formation to a high-grade B-cell lymphoma, clinical stage of the disease and molecular markers of response to treatment. It is now known that the translocation t(11;18)(q21;q21) occurs frequently in gastric MALT lymphomas in advanced stages of the disease showing resistance to treatment. However, new evidence has recently demonstrated that tumor regression might also be achieved in patients with t(11;18)(q21;q21) after *H. pylori* eradication[11]. In addition, it has been recognized that the presence of t(11;18)(q21;q21) in gastric MALT lymphomas does not exclude progression to DLBCL[4,12]. Further research is necessary to understand the molecular mechanisms involved in these latter situations.

Complete clinical staging for this study could not be obtained for all patients because cases studied were referred for pathological evaluation from different institutions. Also, this work was focused on the histological characteristics, response to bacterial eradication treatment and presence of molecular markers such as t(11;18)(q21;q21) and BCL10 protein expression. Outside of these factors, there are other variables that may also help predict the course of disease.

These results have demonstrated that BCL10 nuclear expression and the determination of the t(11;18)(q21;q21) translocation involved in neoplastic signaling processes mediated by NF-κB are two useful markers for predicting the independent status of *H. pylori* in gastric MALT lymphomas; its presence, therefore, allows for the identification of patients who will not respond to bacterial eradication therapy as a means of promoting tumor regression. The resistance of the tumor to therapy observed in translocation-positive cases is explained by the fact that the fusion protein generates a bypass of the NF-κB signaling pathway thereby allowing constitutive activation of the transcription factor, self-generating growth and independent antigenic stimulation. On the other hand, the association of BCL10 with tumor resistance can be explained by the presence of nuclear export signals of the gene *MALT1* that allows the export of BCL10 from the nucleus to the cytoplasm. Nakagawa *et al*[21] argued that IAP2 usually mediates BCL10 degradation through its ubiquitin ligase activity and inhibits antigen-receptor-

mediated signaling. This normal function is absent in the fusion protein, resulting in the stability of BCL10 in lymphomas with t(11;18)(q21;q21) and the activation of the NF-κB signal transduction pathway. Consequently, the translocation generates a gain-of-function activity in MALT1 and a loss of API2 function.

Thirty-four percent of patients treated with antibiotic therapy in the sample group showed resistance to tumor regression; within this group, there were cases in which the fusion signal was detected by FISH, a finding that may explain the mechanism of autonomous growth and independence of antigenic stimulation as previously discussed. This study therefore confirms that patients with extranodal marginal zone lymphoma carrying t(11;18)(q21;q21) do not respond to treatment for *H. pylori* as a therapeutic measure and should be treated by other methods, such as radiotherapy and chemotherapy. These results also endorse the recommendation that every patient with a diagnosis of gastric MALT lymphoma should be evaluated for the presence of the aforementioned translocation by molecular methods.

Treatment resistance in cases that do not have the t(11;18)(q21;q21) translocation could possibly be due to the carrying of other molecular aberrations, such as t(1;14)(p22;q32). However, such cases would have shown evidence of a strong nuclear BCL10 staining pattern and/or genetic evidence of the translocation.

Patients in whom the aforementioned translocations are not detected frequently have trisomy of chromosomes 3, 7, 12 or 18; these cases are still considered dependent on antigenic stimulation. Additionally, it is known that the trisomy of these chromosomes is seen in cases where transformation to high-grade tumors is present after the inactivation of the *P53* gene[21]. t(11;18)(q21;q21) and different aneuploidies, such as trisomy of chromosome 3, 7, 12 or 18, are usually considered mutually exclusive events, suggesting that at least two different routes lead to the development of the lymphoma. In patients with aneuploidy events, the oncogenesis mechanism is unclear; it is proposed that cell growth may be induced as a result of high copy numbers of genes involved in proliferation. Several genes located on chromosome 3 have been suggested as possibly responsible for these changes, including *BCL6* and *FOXP1*[21].

The authors found that cases classified as non-responders to therapy and positive for translocation are histologically characterized by the presence of more homogeneous tumor cells. In most cases, these cells were predominantly centrocyte-like/small lymphocytes, and this cell homogeneity could possibly result from a process of clonal selection. Additionally, in cases not responsive to therapy, fewer tumor cells appeared to differentiate into plasma cells, suggesting a decrease in the immune response by memory cells of the marginal zone. This is unlike the prominent cellular heterogeneity seen in responder patients, although this result has not been extensively studied and would require larger sample sizes to avoid possible statistical bias.

We applied Wotherspoon's criteria for histological evaluation of response to treatment given the current widespread use of this system adopted by the WHO in 2001 for the histological differential diagnosis of gastric MALT lymphoma and extensive use by pathologists worldwide for the evaluation of therapeutic response. However, there are other useful systems proposed for the evaluation of therapeutic response to treatment, such as the Groupe d'Etude des Lymphomes de l'Adult (GELA) system that can be used for the same objective[22]. There are no comparative studies that convincingly prove the superiority of any system, even though the GELA system has the advantage of assessment of stromal changes in the lamina propria[23]. The GELA system may become a useful tool if its reproducibility can be confirmed by further testing in a large series[24]. Therefore, the utilization of the WHO/Wotherspoon score accompanied by the assessment of stromal changes for the post-treatment evaluation in MALT lymphoma is an interesting topic for future studies.

ACKNOWLEDGMENTS

The authors thank Dr. Margarita Baldión for choosing tumor material, Dr. Adriana Plata for her assistance in the FISH procedure and Yubeli Abello for her technical collaboration.

COMMENTS

Background

Gastric mucosa-associated lymphoid tissue (MALT) lymphoma is caused by infection with *Helicobacter pylori* (*H. pylori*), which induces genetic abnormalities and malignant transformations. *H. pylori* eradication therapy leads to complete lymphoma regression in some patients in the early stages of the disease.

Research frontiers

There is considerable individual variability in the extent of the disease, response to treatment, relapse and event-free survival. Consequently, optimal management should be established and there is a need for improved understanding of the genetic abnormalities underlying gastric MALT lymphoma.

Innovations and breakthroughs

This is the first study in Colombia concerning the assessment and significance of the gastric MALT lymphoma-associated t(11;18)(q21;q21) chromosomal translocation and its relationship with *H. pylori* infection in a country with a high incidence of cancer associated with virulent *H. pylori* strains, a significant cause of mortality and a major public health problem.

Applications

This study confirms, in a previously unexplored population, the importance of molecular markers in the selection of different treatment regimens for individual patients to increase the probability of survival.

Terminology

Gastric MALT lymphoma is a low-grade malignant lymphoma of the stomach originating from B cells and is associated with chronic infection by *H. pylori*, a gram-negative bacterium strongly linked to the development of inflammation and stomach cancer. The disease carries chromosomal aberrations such as t(11;18)(q21;q21), useful for the evaluation of therapeutic response.

Peer review

It was shown that the presence of t(11;18)(q21;q21) and nuclear expression of BCL10 are associated with the treatment resistance. These findings have been documented in patients of other ethnic origins and are thus confirmatory; the results are of relevance to disease management in patients.

Abstract

AIM: To evaluate the clinical impact of multidetector computed tomography (MDCT) before double-balloon endoscopy (DBE) for patients with obscure gastrointestinal bleeding (OGIB).

METHODS: A retrospective analysis of prospectively collected cases with DBE and MDCT for overt OGIB was conducted from April 2004 to April 2010 at Changhua Christian Hospital. We evaluated the clinical impact of MDCT on the subsequent DBE examinations and the diagnostic yields of both MDCT and DBE respectively.

RESULTS: From April 2004 to April 2010, a total of 75 patients underwent DBE for overt OGIB. Thirty one cases received MDCT followed by DBE for OGIB. The overall diagnostic yields of DBE and MDCT was 93.5% and 45.2%. The MDCT had a high diagnostic yield of tumor *vs* non-tumor etiology of OGIB (85.7% *vs* 33.3%, P = 0.014). Additionally, the choice of initial route of DBE was correct in those with a positive MDCT *vs* negative MDCT (100% *vs* 52.9%, P = 0.003).

CONCLUSION: This study suggests MDCT as a triage tool may identify patients who will benefit from DBE and aid the endoscopist in choosing the most efficient route.

Key words: Multidetector computed tomography; Capsule endoscopy; Double-balloon endoscopy; Obscure gastrointestinal bleeding

Clinical impact of multidetector computed tomography before double-balloon enteroscopy for obscure gastrointestinal bleeding. *World J Gastroenterol* 2012; 18(7): 692-697 Available from: URL: http://www.wjgnet.com/1007-9327/full/v18/i7/692.htm DOI: http://dx.doi.org/10.3748/wjg.v18.i7.692

INTRODUCTION

Obscure gastrointestinal bleeding (OGIB) is defined by the American Gastroenterological Association (AGA)[1] as bleeding of unknown cause after upper or lower endoscopy. OGIB constitutes approximately 5% of patients evaluated for gastrointestinal hemorrhage[2]. OGIB can be further classified into two clinical forms: (1) obscure-occult bleeding; and (2) obscure-overt type bleeding (those with hematochezia or melena). The management of overt OGIB is clinically challenging for the gastroenterologist. With the introduction of high yield diagnostic tools such

as capsule endoscopy (CE) and double-balloon endoscopy (DBE) since the year 2000, the AGA recommended the use of CE followed by DBE as the first line diagnostic tool in 2007[2]. CE has exhibited some limitations, such as capsule retention, incomplete examination, inability to provide therapy, and high cost[3]. Compared with CE, DBE offered a therapeutic ability which is more useful in the setting of overt OGIB and is cost-effective compared with CE[4]. Multidetector computed tomography (MDCT) is a non-invasive tool and some recent reports have used it to investigate OGIB[3,5-7]. The clinical impact of MDCT prior to DBE for OGIB has not been evaluated. Thus, we performed this study to evaluate, retrospectively, the role of MDCT and DBE in patients with OGIB.

MATERIALS AND METHODS

Patients

A retrospective review of the medical records of Changhua Christian hospital from April 2004 to April 2010 identified 75 patients who underwent DBE for OGIB. A retrospective analysis of this prospectively collected database of DBE identified 31 patients who received MDCT within one month prior to DBE for obscure overt gastrointestinal (GI) bleeding and were included for this analysis. OGIB was defined as gastrointestinal bleeding after a non-diagnostic upper and lower endoscopy. All patients provided written consent to undergo MDCT and endoscopy, including endoscopic treatments, such as hemoclip and argon plasma coagulation. All patients were informed that endoscopic examination and treatment are involved in the current standard therapeutic approach used in the evaluation of OGIB. The primary end point of the study was to evaluate the clinical impact of MDCT on the subsequent DBE examinations. The secondary end point of the study was the diagnostic yield for MDCT and DBE for the diagnosis of OGIB.

MDCT procedure

All the patients received MDCT with non-enhanced and triphasic helical computed tomography (CT) scanning[8]. No oral contrast material was given before the examination. First, patients were imaged with a MDCT scanner (LightSpeed Ultra 16, GE Medical Systems, Milwaukee, WI) in a craniocaudal direction beginning at the dome of the liver. A nonionic contrast medium (Optiray 350, Tyco Healthcare, Mansfield, MA) was then administered at a total dose of 100 to 120 mL with an injection rate of 3 mL/s through an antecubital vein. For triphasic acquisitions, scanning was started with a 10 s scan delay for the hepatic arterial phase after the attenuation value of the aorta reached 120 HU. Fifteen seconds after the end point of the hepatic arterial phase, the scans for the portal venous phase were acquired. Delayed-phase images were acquired 80 s after the end of the acquisition of the portal venous phase. Whole scanning was completed in 4 to 8 s with the patients holding their breath.

The MDCT was reviewed by one radiologist (Dr. Liu) with 10 years of experience with abdominal imaging. The finding of the presence of small intestinal neoplasm (Figure 1), active contrast extravasation (Figure 2) or hyperdense fluid accumulation was considered to be diagnostic of GI bleeding[9].

DBE procedure

The double-balloon method was developed as described by Yamamoto *et al*[10]. Briefly, the double-balloon endoscope (EN-450P5 or EN-450T5, Fujinon Co., Japan) had two balloons, one attached to the distal end of the scope and the other attached to a transparent overtube (length 140 cm). Through a technique of inflating and deflating the balloons, the 7 m long small intestine can be shrunk to less than 2 m. Therefore, the entire small intestine could be theoretically examined. Fluoroscopy was required to guide the insertion or withdrawal of the endoscope. An oral route or anal route was chosen depending on clinical suspicion of the lesion. The endoscopic examination was stopped when (1) a lesion was found; (2) the endoscope was unable to be inserted or (3) due to patient intolerance. All the patients were admitted and received conscious sedation with intravenous midazolam and meperidine. During the procedure, the patients were monitored with an oximeter, EKG, and blood pressure monitor. Oxygen *via* nasal cannula was provided, as necessary.

Statistical analysis

All data were analyzed with SPSS 16.0. All quantitative data were expressed as mean ± SD. The χ^2 test was used to compare two categorical data with $P < 0.05$ being considered statistically significant.

RESULTS

Clinical features

From 2004 to 2010, a total of 75 patients underwent DBE for OGIB and, of these, 31 patients were included in this analysis. These patients had a mean age of 68.6 years. Their mean hemoglobin levels were of 7.95 g/dL. Fourteen patients exhibited shock (defined as systolic blood pressure < 90 mmHg or drop of systolic pressure > 40 mmHg) during the presentation. The median time between the MDCT and DBE procedures was 2 d (range from 0 d to 12 d). The source attributed to OGIB was found in 93.5% of these 31 patients. Two patients had no diagnosis made after both DBE and CT examination and had no further bleeding during the follow-up period (Table 1).

Diagnostic yield of DBE and MDCT

The overall diagnostic yield of DBE was 93.5% and CT was 45.2%. The diagnostic yield of CT depends on the etiology: 100% (2/2) of bleeding angiodysplasia, 85.7% (6/7) of those had bleeding from tumors, 41.7% (5/12) of those from diverticulosis, 14.3% (1/7) of those from ulcers and 0% of those from lymphangiectasia (0/1). One patient had early colon cancer diagnosed by DBE, though missed by CT. The MDCT diagnostic yields were

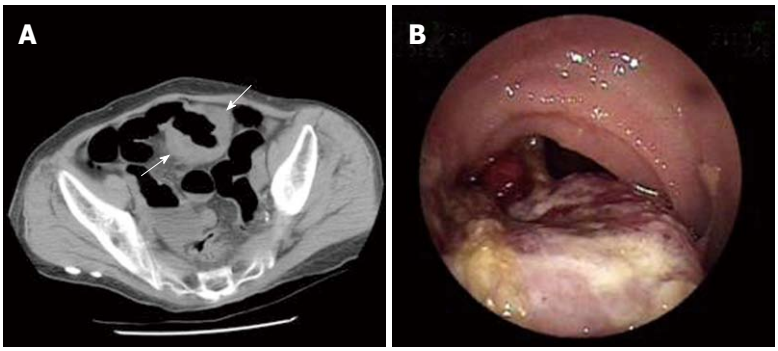

Figure 1 Multidetector computed tomography finding of small bowel neoplasm. A: Abdominal multidetector computed tomography performed after colonoscopy. Abundant bowel gas was observed as a contrast to distend the small intestinal lumen. A focal bowel thickening was discovered (arrows); B: Anal route double-balloon endoscopy disclosed ileal lymphoma accounting for the bowel wall thickening.

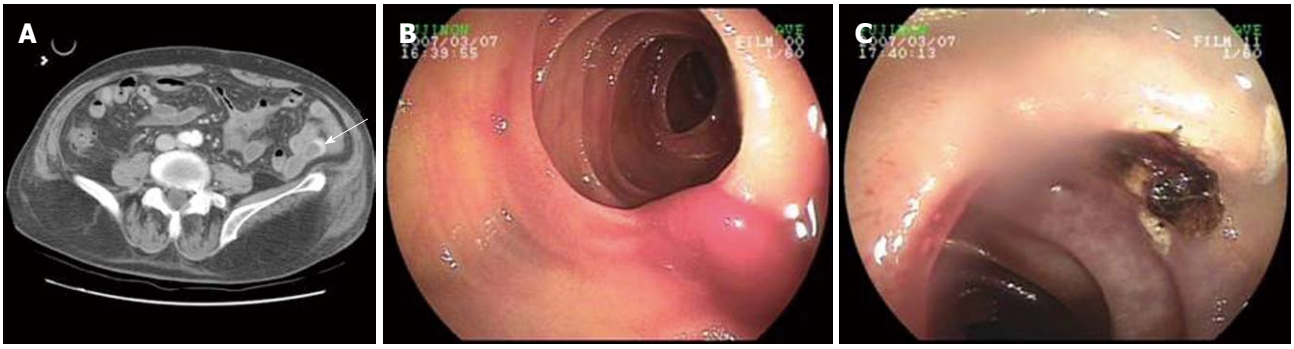

Figure 2 Multidetector computed tomography finding of small bowel bleeding. A: Multidetector computed tomography disclosed active contrast extravasations in the jejunum (arrow); B: Oral route double-balloon endoscopy disclosed active bleeding angiodysplasia; C: Endoscopic view after control of bleeding.

Table 1 Clinical features of patients (mean ± SD) *n* (%)

Item	Value
Sex (M/F)	13/18
Age (yr)	68.6 ± 11.3
Underlying diseases	
Hypertension	23 (74.2)
DM	4 (12.9)
Chronic renal failure	5 (16.1)
Cirrhosis	2 (6.5)
Abdominal operation	1 (3.2)
NSAID/aspirin use	9 (29.0)
Hemoglobin level (g/dL)	7.95 ± 1.62
Hospital stay (d)	12.8 ± 10.8
Shock at presentation	14 (45.2)
Median time between DBE and MDCT (d)	2 (0-12)
Final diagnosis	
Ulcers	7
Tumors	7
Angiodysplasia	2
Diverticulosis	10
Lymphangiectasia	1
Undiagnosed	2

DM: Design management; NSAID: Nonsteroidal antiinflammatory drugs; DBE: Double-balloon endoscopy; MDCT: Multidetector computed tomography.

Undiagnosed	0	0	2
Diagnostic yield	29 (93.5)	14 (45.2)	31

DBE: Double-balloon endoscopy; MDCT: Multidetector computed tomography.

not different according to the hospital stay, shock status, hemoglobin levels and timeframe between presentations to MDCT. The diagnostic yield of MDCT is high compared to the bleeders from tumor *vs* non-tumor (ulcerative or angiogenic cause) origin (85.7% *vs* 33.3%, $P = 0.014$) (Table 2).

Clinical impact of MDCT on subsequent DBE

The choice of initial route of DBE examination (for example, oral route or anal route) depended on the clinical suspicion of the lesion by the endoscopist. If previous imaging studies suggested the location of bleeding, the nearest route was chosen; if the patient had a history of hematemesis or tarry stool passage, the oral route was chosen; if the patient had bloody stool passage, the anal route was chosen. Our patients received DBE

Table 3 Impact of multidetector computed tomography on choice of enteroscopy insertion route

CT: Computed tomography.

via oral route only ($n = 18$), anal route only ($n = 4$), and both routes ($n = 9$). Among the 14 cases with a positive CT, the initial route of DBE was correct in all 14 cases. Among those 17 patients with a negative CT, the initial route of DBE was correct in 9 cases. A positive CT led to a correct choice of the route of DBE compared with a negative CT (100% *vs* 52.9%, $P = 0.003$) (Table 3).

DISCUSSION

The current suggested investigation into OGIB includes CE and DBE by the AGA in 2007[2]. Both methods have a variable diagnostic yield from 36% to 80%[2]. CE is non-invasive but has some limitations, such as capsule retention and incomplete examination[3]. Compared with CE, DBE is more invasive but offers therapeutic ability[4]. Unlike routine endoscopy, performing DBE is technically demanding and usually requires a two-physician team[11]. An initial approach with CE followed by DBE is ideal for patients with OGIB, but is not cost-effective[12]. Both procedures are expensive and not reimbursed by insurance in Taiwan. By contrast, MDCT is a non-invasive tool and had been used to evaluate OGIB[3,5-7]. In our previous reports[9,13,14], we determined that MDCT is particularly useful to localize the bleeding for subsequent endoscopy in the setting of active GI bleeding. MDCT is reimbursed by our insurance and is more readily available; therefore, approaching OGIB patients with initial MDCT followed by DBE was suggested as an alternative to the current AGA recommendation[2] in our institution since the introduction of DBE[15]. There are few studies that compare CE and MDCT in the management of OGIB[6,16]. In Zhang's report[16], the combination of MDCT with CE was not superior to CE alone in the diagnosis of OGIB. However, data regarding the role of MDCT before DBE in the setting of OGIB is lacking. Only one study from Chen *et al*[17] involving 70 patients suggested the usefulness of MDCT combined with DBE in the assessment of small bowel diseases. Thus, we performed this study to evaluate the role of MDCT prior to DBE in our institution during a 6-year-period.

In our study, we found DBE had higher diagnostic yield compared with MDCT (93.5% *vs* 45.2%) for OGIB. Both the diagnostic yield of DBE[2] and MDCT[3,5-7] are comparable to previous literature. Most of our patients exhibited severe GI bleeding (45.2% of shock at presentation), accounting for our high diagnostic yield. In this study, we discovered that MDCT is useful in two ways. Firstly, MDCT has a high diagnostic yield of small intestinal neoplasm compared with other non-tumor origins (ulcerative or angiogenic cause). Among seven patients with a tumor origin accounting for their OGIB, six patients were finally diagnosed to have small bowel tumors and all were diagnosed by MDCT prior to DBE procedure. The failure to diagnose one case of early colon cancer in the study can be explained by the fact that our MDCT protocol did not involve bowel preparation or optimal for colonic examination. The reported diagnostic rate of MDCT for small bowel neoplasm ranges from 67.4%[16] to 100%[5]. This is particularly useful in the management of patients with OGIB. In two recent large DBE series[18,19], patients with diagnosed neoplasm mostly benefited from the DBE due to the ability for long-term control of bleeding either endoscopically or surgically. By contrast, while a diagnosis of ulcer or vascular lesion was identified, only 40%[18,19] of the patients remained free of recurrent bleeding. Thus, the high diagnostic yield of MDCT for small bowel neoplasm allowed the clinician to identify patients that would most benefit from subsequent DBE procedures.

Secondly, in patients with positive MDCT, the choice of initial route of DBE examination was more likely to be correct compared to a negative MDCT (100% *vs* 52.9%, $P = 0.003$). As DBE usually requires examination *via* either the oral or anal route, the choice of correct insertion route of DBE is critical for allowing rapid approaches to the bleeding[20]. No recommended standard for selection of the insertion route of DBE currently exists. Although clinical presentation such as hematesis and stool color are useful for the endoscopist to choose the route of insertion, the initial route of DBE is not reliable, especially in the setting of massive bleeding[20]. Few studies[20,21] have utilized the finding of CE to guide the insertion route of subsequent DBE. In our study, we demonstrated that a positive MDCT is useful for guiding the insertion route of subsequent DBE.

Several methods of MDCT are described in the literature, including MDCT with oral saline as a contrast[16,22] or multi-phase CT-enterography[3,5,7]. The reported diagnostic yield for OGIB ranges from 30%[16] to 83%[22] with different MDCT protocols. No comparative study comparing the diagnostic yield of different CT protocols exists. In our institution, the triphasic MDCT protocol without oral contrast[8] utilized in our institution demonstrates a similar diagnostic yield as compared with previous reports. Although the use of fluid contrast can distend the intestinal lumen effectively and increase the diagnostic ability, especially for mucosal lesions[3,16,22], this may delay the subsequent DBE examination. In our institution, an emergent MDCT can be arranged as quickly as 2 h after a non-diagnostic endoscopy. If previous endoscopic studies suggested bleeding in the small bowel, the endoscopist would withdraw the endoscope without air suction, which leaves air in the bowel as a contrast (Figure 1). This approach is simple and similar to the recently described virtual enteroscopy[23]. *Via* this approach, once MDCT is positive, a DBE can be arranged early without the need to wait for

gastric emptying due to the use of an oral fluid contrast.

This study has some limitations. The first is in the retrospective nature of the study. Although CE or DBE are recommended for the diagnosis of OGIB[24], both of these procedures are expensive and neither is covered by health insurance providers in our region. In addition, MDCT is more readily available compared with CE and DBE and less invasive than conventional angiography. Thus, MDCT is used as the diagnostic and triage tool of choice for OGIB at our institution[9]. Therefore, our findings of the high diagnostic yields of both DBE and MDCT may be an overestimation because some patients with small intestinal tumors or those who have self-limited bleeding may not undergo subsequent DBE and were not included in this analysis. Secondly, the use of MDCT still has some disadvantages[4]. The procedure results in substantial radiation exposure and carries the risk of contrast nephrotoxicity that may limit its use in elderly patients, who constitute the main population of OGIB patients.

Our study demonstrates that MDCT provides a reasonable diagnostic yield for OGIB in comparison with previous reports[3,7,16,22]. The use of MDCT as a triage tool prior to DBE may aid the endoscopist in identifying patients who will benefit from the examination, and may aid the endoscopist in choosing the most efficient route of DBE examination. However, our study is limited to a retrospective nature and only a small number of patients were enrolled in this study. Further prospective studies with more patients are required to confirm our observation.

COMMENTS

Background

Capsule endoscopy followed by double-balloon endoscopy is the current standard approach for obscure gastrointestinal bleeding. Multidetector computed tomography (MDCT) has been used recently to investigate obscure gastrointestinal bleeding, but its role in current standard approach to obscure gastrointestinal bleeding (OGIB) has not been evaluated.

Research frontiers

This study analyzed the clinical impact of MDCT in a subset of patients with OGIB in a single medical center.

Innovations and breakthroughs

This study is novel in that the researchers analyzed the clinical utility of MDCT before double-balloon enteroscopy (DBE) for the indication of OGIB.

Applications

MDCT provides a reasonable diagnostic yield in this study. The use of MDCT as a triage tool prior to DBE may aid the endoscopist in identifying patients who will benefit from the examination and may aid the endoscopist in choosing the most efficient route of DBE examination.

Peer review

The authors demonstrated that MDCT may provide a reasonable diagnostic yield in a select group of patients with OGIB by a retrospective study.

Abstract

AIM: To investigate the efficacy and safety of imatinib dose escalation in Chinese patients with advanced gastrointestinal stromal tumor (GIST).

METHODS: Advanced GIST patients previously failing 400 mg imatinib treatment were enrolled in this study. Patients received imatinib with dose escalation to 600 mg/d, and further dose escalation to 800 mg/d if imatinib 600 mg/d failed. Progression-free survival, overall survival, clinical efficacy, c-kit/PDGFRA genotype and safety were evaluated.

RESULTS: 52 patients were enrolled in this study. For the 47 evaluable patients receiving imatinib (600 mg/d), the disease control rate was 40.4%, and the median progression-free survival for all patients was 17 wk (95% CI: 3.9-30.1). The median overall survival after dose escalation was 81 wk (95% CI: 36.2-125.8). Adverse events, mainly edema, fatigue, granulocytopenia and skin rash were tolerable. However, further dose escalation (800 mg/d) in 14 cases was ineffective, with disease progression and severe adverse events. Among 30 cases examined for gene mutations, patients with exon 9 mutations experienced a better progression-free survival of 47 wk.

CONCLUSION: Imatinib dose escalation to 600 mg/d is more appropriate for Chinese patients and may achieve further survival benefit.

Key words: Gene mutation; Gastrointestinal stromal tumor; Imatinib; Increased dose

INTRODUCTION

Gastrointestinal stromal tumors (GISTs) are tumors that may occur throughout the gastrointestinal tract and in the omentum and mesentery, and account for about 2% of gastrointestinal tract tumors[1]. Various types of *KIT* gene mutations are present in the majority of GISTs[2]. Imatinib mesylate, a molecular tyrosine kinase inhibitor targeting *KIT*, platelet-derived growth factor receptor (PDGFR) and/or *bcr-abl* has remarkable clinical efficacy in the treatment of advanced GIST. Imatinib mesylate 400 mg/d is recommended in the first-line treatment of advanced GIST[3,4]. However, about 5% of patients show

primary resistance to imatinib and about 50% of patients develop secondary resistance within a median treatment duration of 2 years[4,5].

The results of two studies proved that after the failure of first-line treatment with imatinib 400 mg/d an escalated dose (800 mg/d) can still achieve tumor control and confer further survival benefits in some patients[6,7]. However, these studies were conducted in Western countries, thus whether Chinese patients with advanced GIST could benefit from an escalated dose of imatinib is unclear. It is also unknown whether increased dose increments are tolerated in these patients, due to differences in body weight and race between Chinese patients and Western patients.

KIT gene mutations can predict the objective efficacy of imatinib in the first-line treatment of advanced GIST[8], however, the relevance of these mutations to the objective response of imatinib dose escalation has not yet been reported. In this study, Chinese patients with advanced GIST, previously treated with 400 mg/d imatinib and who received dose escalation therapy, were examined to evaluate the median progression-free survival (PFS) and overall survival (OS) after imatinib dose escalation, objective efficacy, relationships between gene mutation types and efficacy, and the safety of imatinib dose escalation.

MATERIALS AND METHODS

Study design

This was a single arm, open-label, prospective study designed to evaluate the objective response and safety of imatinib dose escalation in Chinese GIST patients with resistance to imatinib 400 mg/d. The primary end point was PFS and the secondary end points were OS, disease control rate (DCR) defined as a combination of complete response (CR) + partial response (PR) + stable disease (SD), relationships between the gene mutation types and objective responses, and safety of imatinib dose escalation.

Adult patients (age $\geq$ 18 years) with a histologically confirmed recurrent or metastatic GIST which was CD117 positive, and who failed prior imatinib 400 mg/d treatment were eligible for the trial. The pathological and CD117 diagnosis was made immunohistochemically. All patients were Eastern Cooperative Oncology Group (ECOG) performance status 2 or lower and provided informed consent. Patients were assigned to receive imatinib 600 mg/d orally, taken once daily with food, in the form of 100 mg capsules. If the disease progressed after imatinib 600 mg therapy, the dose of imatinib was further increased to 800 mg/d until the next instance of tumor progression or tolerance failure. CT or MRI examination was conducted every 8 wk and the objective response was based on the Response Evaluation Criteria In Solid Tumors (RECIST) guidelines. The PFS was defined as the time from the first dose of imatinib 600 mg/d to the occurrence of progression, death from any cause, or withdrawal from the trial. OS was defined as the time from the first dose of imatinib 600 mg/d to the occurrence of death from any cause. Adverse events were graded according to the National Cancer Institute Common Toxicity Criteria version 2.0.

Detection of KIT and PDGFR gene mutations

Formalin-fixed, paraffin-embedded tumor tissue samples, taken prior to imatinib treatment, were collected for *KIT* and *PDGFR* gene mutation analyses. Genomic DNA was extracted from the tumor sample using the e.Z.N.A. FFPE DNA Kit (OMEGA Bio-Tek Inc., Norcross, GA, United States). Initially, polymerase chain reaction (PCR) amplification and mutational analyses of *KIT* exon 11 were performed. Patient samples negative for *KIT* exon 11 mutations were subsequently amplified with primers specific for *KIT* exons 9, 13, and 17. When *KIT* mutations were not identified, additional mutational analyses were conducted for exons 12 and 18 of the *PDGFR* gene.

Statistical analysis

All statistical analyses were based on the SPSS 15.0 platform (SPSS Inc., Chicago, IL, United States). PFS and OS curves were constructed according to the Kaplan-Meier method and the log-rank test was used to compare differences between PFS curves. Frequency and percentage descriptions were used for categorical variables and the chi-square test was conducted to compare the incidence of different events. If the theoretical frequency was lower than 1, Fisher's exact test was conducted. Continuous variables were expressed as mean ± SD and mean differences between two groups were compared using Student's *t*-test.

RESULTS

Patient characteristics following disease progression on imatinib 400 mg/d treatment

Between April 2004 and March 2009, 168 patients with advanced GIST received imatinib 400 mg/d. Of these patients, 52 were eligible for imatinib dose escalation therapy. Most of the patients had secondary resistance (96%) and two had primary resistance. The duration of imatinib 400 mg/d treatment ranged from 3.0 to 56.0 mo, with a median PFS of 20.0 mo (95% CI: 15.3-24.7). Before the initiation of imatinib dose escalation, three patients with progression in liver metastasis and one patient with new-onset pelvic metastasis received complete tumor resection, while one patient with liver metastasis received local radiofrequency ablation therapy and four patients received primary palliative surgical resection. The 52 eligible patients received imatinib dose escalation therapy of 600 mg/d orally. The clinical features of these patients are shown in Table 1.

Toxicities and dose reductions

Dose escalation therapy of imatinib 600 mg/d was well tolerated. All 52 patients had Grade 1 or 2 adverse events and only 7 patients had Grade 3 adverse events. Adverse events consisted of edema, fatigue, granulocytopenia and skin rash. Adverse events more severe than those found

in the previous 400 mg/d treatment were experienced by 73.1% of patients, particularly edema and fatigue. Imatinib dose was reduced to 500 mg/d in one patient due to fatigue and abdominal pain. In other patients, 600 mg/d was well tolerated and discontinuation of imatinib was not required due to adverse events.

The dose of imatinib was further escalated to 800 mg/d in 14 patients due to disease progression during 600 mg/d treatment. All 14 patients had Grade 1 or 2 adverse events and showed worsening adverse events; predominantly edema, fatigue, abdominal pain, nausea, and loss of appetite. Among these patients, 6 had Grade 3 adverse events, and imatinib was discontinued in three and dose reduction to 600 mg/d in two. Hematologic and non-hematologic toxicities are summarized in Table 2.

Response rate

Of 52 patients, four were excluded due to complete tumor resection and one patient received local radiofrequency ablation therapy prior to dose escalation therapy. The remaining 47 patients all had measurable disease according to RECIST criteria and tumor assessment was performed at least once. Among these patients, three (6.4%) achieved PR, 16 (34.0%) had SD, and 28 (59.6%) showed disease progression (PD) after imatinib dose escalation to 600 mg/d. The overall DCR was 40.4%.

Fourteen patients with disease progression on 600 mg/d imatinib received further dose escalation to 800 mg/d, of which three patients discontinued therapy due to adverse reactions. Eleven patients with measurable disease all showed PD.

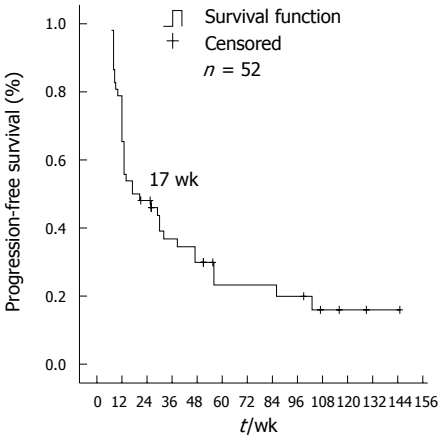

Figure 1 Progression-free survival for all patients. Forty-eight patients (92.3%) had disease progression after imatinib 600 mg/d treatment, and the median PFS of all the 52 patients was 17 wk (95% CI: 3.9-30.1). PFS: Progression-free survival; CI: Confidence interval.

PFS and OS

As of February 2011, 48 patients (92.3%) had progression after imatinib 600 mg/d treatment. The median PFS for all 52 patients was 17 wk (95% CI: 3.9-30.1) (Figure 1). Patients with PR or SD had a significantly longer PFS than patients who progressed on 600 mg/d dose escalation therapy. The median PFS for patients with PR or SD was 51 wk (95% CI: 26.8-75.2) and was 12 wk for patients with PD (95% CI: 10.6-13.4) ($P < 0.001$) (Figure 2).

As of February 2011, 13 patients were alive, 38 patients had died due to tumor progression and 1 patient had died due to other reasons. The median OS following dose escalation in all patients, starting from the first prescription of 600 mg/d imatinib, was 81 wk (95% CI: 36.2-125.8) (Figure 3). The 1-year survival rate for all patients was 63.5%.

Of the four patients who received complete resection of tumor metastasis before dose escalation, two experi-

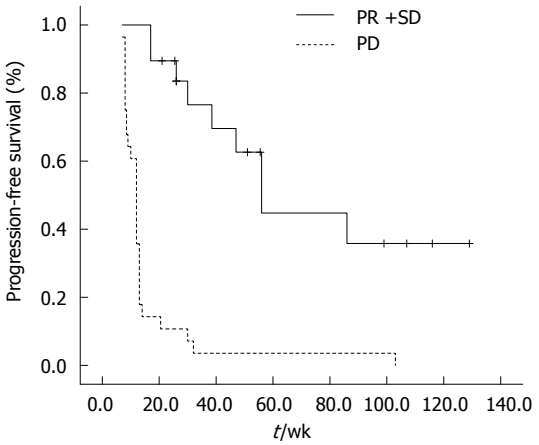

Figure 2 The median progression-free survival for partial response or stable disease patients was 51 wk (95% CI: 26.8-75.2) and that of patients with progressive disease was 12 wk (95% CI: 10.6-13.4) (*P* < 0.001). PR: Partial response; SD: Stable disease; CI: Confidence interval.

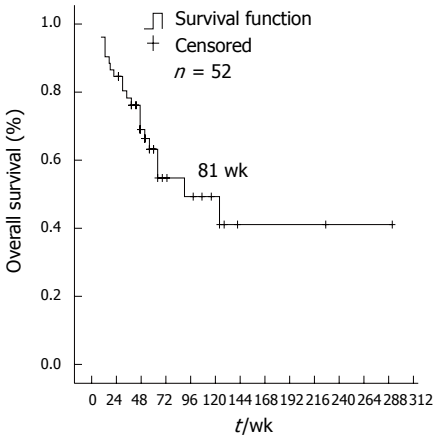

Figure 3 Median overall survival of all patients starting from the first prescription of 600 mg/d imatinib. Median OS was 81 wk (95% CI: 36.2-125.8). OS: Overall survival; CI: Confidence interval.

enced tumor recurrence and died of tumor progression. PFS in these two cases was 48 wk and 29 wk, respectively, and OS was 90 wk and 51 wk, respectively. The other two patients, and one patient receiving microwave treatment of local liver metastasis, had no recurrence; PFS was 135 wk, 151 wk, and 145 wk, respectively.

Gene mutation analyses

A total of 30 patients underwent gene mutation analysis before first-line imatinib 400 mg/d treatment, of which 19 (63.3%) had a mutation in *KIT* exon 11, 6 (20.0%) in *KIT* exon 9, and two (6.7%) in *KIT* exon 13. The remaining five (10.0%) patients showed wild-type GIST. No *PDGFR* gene mutations were found.

Among the 19 patients with *KIT* exon 11 mutations, 17 were evaluable. One patient achieved a PR and 7 patients remained stable. The remaining 9 patients progressively worsened. The overall DCR was 47.1%. Among the 4 evaluable *KIT* exon 9 patients, 1 achieved PR and 3 displayed SD. In the 3 evaluable wild-type GIST patients, 1 stabilized and the remaining 2 had PD. In patients with *KIT* exon 13 mutations, one was stable and the other had PD.

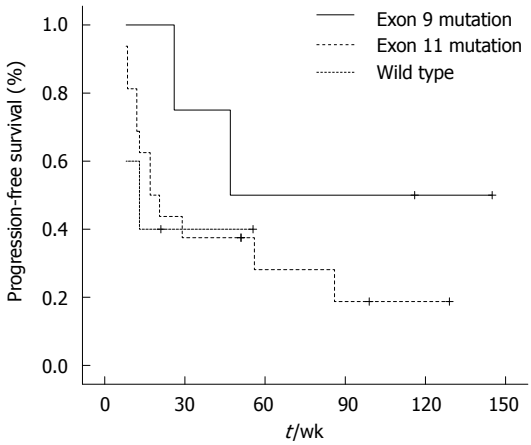

Figure 4 Progression-free survival of patients by gene mutation. PFS of the patients with exon 9 mutation, exon 11 mutation, and wild type were 47 wk, 21 wk, and 8 wk, respectively, but the difference was not significant (*P* = 0.083). PFS: Progression-free survival.

The median PFS of patients with *KIT* exon 11 mutations, *KIT* exon 9 mutations, and *KIT*/PDGFR wild-type patients was 21 wk (95% CI: 3.4-37.6), 47 wk (95% CI: 11.6-82.4), and 8 wk, respectively, as shown in Figure 4.

Although the difference in PFS between the three categories was not significant (*P* = 0.083), patients with *KIT* exon 9 mutations tended to have longer PFS than those with exon 11 mutations and wild-type patients.

Follow-up after imatinib treatment

Up to February 2011, of 52 patients, 4 are progression-free and continue to receive imatinib 600 mg/d treatment. All patients receiving further dose escalation to imatinib 800 mg/d have discontinued treatment. 21 patients received sunitinib treatment. 39 patients died due to tumor progression with the exception of 1 patient.

DISCUSSION

The efficacy of imatinib mesylate in advanced gastrointestinal stromal tumors was confirmed and patients with advanced disease can achieve prolonged OS. Imatinib 400 mg/d is recommended as the first-line treatment for advanced GIST patients. However, a proportion of GIST patients experience secondary resistance to imatinib after tumor remission, and tumor progression occurs. Results of the phase Ⅲ trials, EORTC62005 and US0033, confirmed that after resistance to 400 mg/d imatinib, dose escalation therapy to 800 mg/d can offer further disease control in 30%-40% of patients[6,7]. The results of the analyses in these two studies showed that patients obtained a PFS benefit of 11.3 and 21.4 wk after cross-over to 800 mg/d imatinib, which represents a further survival benefit for a number of GIST patients[9].

The conclusions in the present study are consistent with those of the above-mentioned studies: imatinib 600 mg/d dose escalation treatment improved PFS and OS of patients after progression on imatinib 400 mg/d. The

PFS of patients achieving PR and SD was superior to that of patients with PD, suggesting that disease remission or control may bring about a benefit in PFS. In addition, late follow-up revealed that about 40% of patients received sunitinib after failure of imatinib escalation treatment. Sunitinib, a multi-target tyrosine kinase inhibitor, provided prolonged OS for imatinib-resistant patients in a phase Ⅲ trial[10]. Thus, due to an unclear mechanism, sunitinib also contributed to the median OS of 81 wk.

In this study, of the 11 patients with evaluable disease receiving imatinib 800 mg/d dose escalation therapy, none of these patients benefited from this escalation, and adverse events were severe and intolerable. The results of the EORTC62005 and US0033 studies showed that Western patients were tolerant to imatinib 800 mg/d. However, because Chinese patients tend to have a smaller body surface area than Western patients, it is unclear whether Chinese patients can tolerate imatinib 800 mg/d dose escalation therapy. In this study, the median PFS of Chinese patients receiving 600 mg/d dose escalation therapy was similar to the PFS of Western groups in the two phase Ⅲ trials, and imatinib 600 mg/d dose escalation was generally well-tolerated. In addition, since none of the patients benefited from imatinib dose escalation therapy to 800 mg/d and adverse events were severe, imatinib dose escalation to 800 mg/d is not recommended when imatinib 600 mg/d is ineffective for the treatment of Chinese patients with advanced GIST.

Some gene mutations can predict the objective efficacy of imatinib for advanced GIST[8]. In addition, results from the EORTC62005 study have shown that, during the initial treatment, imatinib 800 mg/d may significantly prolong PFS in patients with GISTs harboring exon 9 mutations, although no further improvement in PFS was seen in patients with *KIT* exon 11 mutations[9]. However, the relationship between gene mutations and the efficacy of imatinib dose escalation therapy following secondary imatinib resistance is unclear. Previous studies have shown that secondary resistance to imatinib might be related to a secondary *c-kit*/*PDGFRA* mutation, gene amplification, or imatinib-related drug resistance due to changes in drug metabolism[11-13]. A recent, small sample size study[14] in Korea reported that dose escalation of imatinib to 600 mg/d or 800 mg/d following 400 mg/d treatment failure can produce better outcomes in patients with exon 9 mutations than with other mutation types. Due to the difficulty in obtaining tissue samples following drug resistance, the analysis of secondary gene mutations was not possible. Thus, the gene mutation analyses were conducted on tissue samples taken prior to the start of imatinib treatment. Similar to the results of the Korean study, patients with exon 9 mutations had a relatively long PFS after receiving imatinib dose escalation therapy. Although the sample size, especially the number of patients with exon 9 mutations, was comparatively small, and the results of the analysis of PFS with different mutation types showed no statistical difference, patients with exon 9 mutations showed a trend towards longer PFS following imatinib dose escalation therapy. Moreover, although the results of the EORTC62005 study showed that first-line treatment with imatinib 800 mg/d may not improve the objective efficacy and PFS in *KIT* exon 11 mutation patients compared with standard treatment of imatinib 400 mg/d, a proportion of *KIT* exon 11 mutation patients can still achieve disease control with dose escalation therapy after progression on previous treatment with imatinib 400 mg/d. As for *KIT* exon 11 mutation patients, dose escalation therapy is still one of the available treatment strategies following failure of imatinib standard treatment.

The NCCN guidelines recommend that GISTs with exon 9 mutations should receive high-dose imatinib treatment. Whether these patients can receive standard imatinib treatment followed by high-dose imatinib treatment following disease progression is still not known. Since the number of patients with exon 9 mutations in the present study was very small, no conclusion can be made. It is hoped that the EORTC62005 and S0033 studies will provide further insight.

A variety of molecular targeted compounds are available or under development to overcome imatinib resistance. These include the new generation tyrosine kinase inhibitor, nilotinib, the multiple kinase inhibitor sorafenib, and the molecular target of rapamycin inhibitor, everolimus, all of which have been shown to be effective in overcoming imatinib resistance in phase Ⅰ or Ⅱ studies of advanced GIST patients[15-17]. As a multi-target tyrosine kinase inhibitor, sunitinib has been approved by the United States Food and Drug Administration for the treatment of patients with advanced GIST whose disease has progressed on imatinib treatment. For patients who failed prior standard dose imatinib treatment, there has been no direct evidence to suggest whether it is preferable to use imatinib dose escalation therapy or switch to second-line treatment with sunitinib. An expanded, global, retrospective analysis of sunitinib showed that the OS of patients who received previous imatinib treatment of $\leqslant$ 400 mg/d was 93 wk, which was superior to the 70 wk observed in patients previously receiving > 400 mg/d imatinib, suggesting that patients previously receiving comparatively small doses of imatinib may obtain greater survival benefit after sunitinib treatment[18]. However, this suggestion still does not answer the above question, and further evidence is needed to select between the two secondary treatment strategies.

Dose escalation therapy to 600 mg/d after treatment failure with imatinib 400 mg/d is more appropriate for Chinese patients with advanced GIST due to good tolerability and survival benefits. Regarding the comparatively poor objective efficacy and severe adverse events, further escalation of imatinib dose to 800 mg/d following imatinib 600 mg/d failure is not recommended.

COMMENTS

Background

Imatinib 400 mg/d is recommended as the standard first-line treatment for advanced gastrointestinal stromal tumor (GIST). An escalated dose (800 mg/d) can still achieve tumor control and confer further survival benefits after failure

with imatinib 400 mg/d in some patients. However, whether Chinese patients with advanced GIST could benefit from an escalated dose of imatinib is unclear. It is also unknown whether increased dose increments are tolerated in these patients, due to differences in body weight and race between Chinese patients and Western patients. *KIT* gene mutation can predict the objective efficacy of imatinib in the first-line treatment of advanced GIST, however, its relevance to the objective response of imatinib dose escalation has not yet been reported.

Research frontiers

In this study, the authors demonstrate that imatinib dose escalation was effective in some Chinese GIST patients after failure of imatinib standard dose, and KIT genotype could predict the efficacy of imatinib dose escalation treatment.

Innovations and breakthroughs

This is the first report of imatinib dose escalation treatment for GIST in Chinese patients and the results showed imatinib escalation to 600 mg/d was more appropriate for Chinese patients than imatinib 800 mg/d. There are few reports on the relationship between KIT genotype and the efficacy of imatinib dose escalation. This study demonstrated that patients with KIT exon 9 mutations benefited more from imatinib dose escalation treatment.

Applications

The results of this study help to clarify the efficacy and safety of imatinib dose escalation treatment in Chinese GIST patients. More importantly, the appropriate treatment dose between Western patients and Chinese patients may be different. Genotype may be helpful in predicting the efficacy of imatinib dose escalation treatment.

Peer review

Generally, this is an interesting and well-done study that even though its patient size limits the conclusions of the genetic studies, it provides important clinical information for the management of these patients with higher drug doses.

Abstract

AIM: To investigate the effects of ESC-3 isolated from crocodile bile on the growth and apoptosis induction of human cholangiocarcinoma cells.

METHODS: ESC-3 was isolated from crocodile bile by Sephadex LH-20 and RP-18 reversed-phase column. 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide assay was conducted to determine the effects of ESC-3 on the proliferation of human cholangiocarcinoma cell lines (QBC939, Sk-ChA-1 and MZ-ChA-1). Giemsa staining, Hoechst 33258 and acridine orange/ethidium bromide staining showed the morphological changes of Mz-ChA-1 cells exposed to ESC-3 at different concentrations. Flow cytometry with regular propidium iodide (PI) staining was performed to analyze the cell cycle distribution of Mz-ChA-1 cells and to assess apoptosis by annexin v-fluorescein isothiocyanate (V-FITC)/PI staining. Rh123 staining was used to detect the alteration of mitochondrial membrane potential ($\Delta\Psi m$). The protein levels of Bax, Bcl-2, Cdk2, cytochrome c and caspase-3 were further confirmed by Western blotting.

RESULTS: ESC-3 significantly inhibited the growth of three human cholangiocarcinoma cell lines and arrested Mz-ChA-1 cell cycle at G0/G1 phase. Mz-ChA-1 cells showed typical apoptotic morphological changes after treated with ESC-3 (10 μg/mL) for 48 h. Cell death assay indicated that Mz-ChA-1 cells underwent apoptosis in a dose-dependent manner induced by ESC-3. In addition, ESC-3 treatment could downregulate the protein level of Bcl-2 and upregulate the Bax, leading to the increase in the ratio of Bax to Bcl-2 in Mz-ChA-1 cells. Meanwhile, cytochrome c was released from the mitochondria into the cytosol, which subsequently initiated the activation of caspase-3. All these events were associated with the collapse of the mitochondrial membrane potential.

CONCLUSION: ESC-3, the active ingredient of crocodile bile, induced apoptosis in Mz-ChA-1 cells through the mitochondria-dependent pathway and may be a potential chemotherapeutic drug for the treatment of cholangiocarcinoma.

INTRODUCTION

Cholangiocarcinoma is the second most common primary hepatic tumor and currently accounts for 3% of all gastrointestinal cancers; its incidence has recently been increasing globally[1-3]. Clinically, cholangiocarcinoma patients are treated with surgical resection, radiation and chemotherapy. Although progress has been made in the diagnosis and treatment of cholangiocarcinoma in recent years, the prognosis is still unsatisfactory due to the lack of efficient anticancer drugs[4]. Currently, more than 30 compounds of natural origin are in various phases of clinical study for the treatment of several types of cancer[5]. Hence, it is a potential strategy to discover effective compounds from natural products for cancer treatment[6].

With the progress in research on traditional Chinese medicine (TCM), more natural products have been used in medical treatment, especially in the treatment of cancers. Bile is a fluid that consists of several acids, including cholic acid (CA) and chenodeoxycholic acid (CDCA) and has potential anticancer effects; CA and CDCA are the predominant active components in snakes[7]. Previous reports showed that bile acid played a key role in regulating cholangiocyte growth and secretion[8,9]. In addition, deoxycholic acid (DCA) has been shown to rapidly induce apoptosis in HCT116 cells, a colon tumor cell line[10]. The effects of synthetic derivatives of ursodeoxycholic acid (UDCA), such as HS-1183, and CDCA, such as HS-1199 and HS-1200, on the proliferation of human prostate carcinoma PC-3 cells have been investigated[11]. Based on these previous reports, it was suggested that components of crocodile bile could inhibit cell proliferation and induce apoptosis and may be a source of potential anti-tumor agent. In this study, we isolated anti-tumor component ESC-3 from crocodile bile, demonstrated the effects of ESC-3 on Mz-ChA-1 cells and elucidated the mechanism by which ESC-3 induces apoptosis.

MATERIALS AND METHODS

Reagents

3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT), bisbenzimide (Hoechst 33258), acridine orange (AO), ethidium bromide (EB), propidium iodide (PI) and proteinase K were purchased from Sigma-Aldrich Co. (St. Louis, MO, United States). RPMI-1640 medium and fetal calf serum were purchased from Gibco (Grand Island, NY, United States). Mouse monoclonal antibodies against human p53, Bax, Bcl-2, cytochrome c, CDK2 and caspase-3 were obtained from Santa Cruz Biotechnology, Inc. (CA, United States). *Crocodylus siamensis* bile was obtained from the Sriracha Tiger Zoo Thailand Co. Ltd.

Isolation of Crocodylus siamensis bile

The gallbladder containing bile was directly deposited after dried. The whole gallbladder was homogenized and extracted with phosphate buffered saline (PBS) for 4 h at 4 ℃ in triplicate and then centrifuged at 20 000 × *g* for 30 min at 4 ℃. The supernatant was pooled and lyophilized by vacuum freeze-drying, and the powder was stored at -20 ℃ until purification. The powder was redissolved in methanol and loaded onto a Sephadex LH-20 column (Pharmacia, Sweden) with a flow rate of 2 mL/min, and 1 mL per tube was collected. The anti-cancer compound-containing fraction was then loaded onto a RP-18 reversed-phase column (25 cm × 0.3 cm). The solvent system was methanol-0.01 M NaH_2PO_4 (70:30, v/v), which was adjusted to pH 4.0 by the addition of H_3PO_4. The solvent was filtered through a 0.22 μm filter (Millipore) prior to use. The detection wavelength was 215 nm.

Cell culture and treatment

The QBC939, Sk-ChA-1 and MZ-ChA-1 cell lines were maintained in RPMI-1640 medium supplemented with 10% heat-inactivated fetal calf serum, 100 U/mL penicillin, and 100 μg/mL streptomycin at 37 ℃ in a humidified atmosphere containing 50 mL/L CO_2. Twenty-four hours after seeding, the cells were treated with culture medium containing various concentrations of ESC-3.

Cell viability assay

Cell viability was determined using the MTT assay. Briefly, cells were seeded in a 96-well plate at a density of 1 × 10^5/mL. After overnight growth, the cells were treated with various concentrations of ESC-3 for 12 h, 24 h, 36 h, 48 h or 72 h. After the ESC-3 treatment, 20 mL MTT (5 mg/mL) was added to each well, and the cells were cultured for another 4 h at 37 ℃. The medium was then removed, and 150 mL dimethyl sulfoxide (DMSO) was added to each well. The absorbance of each well was recorded at 490 nm.

Giemsa staining

Mz-ChA-1 cells from the control group and the group treated with 10 μg/mL ESC-3 for 48 h were seeded onto coverslips and grown for 24 h. After washing with PBS three times, the cells were stained with Giemsa staining solution for 10 min and observed under a light microscope (Olympus BH-2).

Hoechst 33258 and AO/EB staining

Cells treated with 10 μg/mL ESC-3 for 48 h were harvested and fixed with a mixture of glacial acetic acid and methanol (1:3, v/v) for 5 min and then washed twice with PBS. The cells were resuspended in Hoechst 33258 solution (5 μg/mL) and incubated at room temperature for 10 min. After three washes with PBS, the cells were dried thoroughly and observed under a fluorescence mi-

croscope. For AO/EB staining, the cells were harvested and washed twice with PBS. The cells were then incubated with 100 μL PBS plus 4 μL AO/EB solution (100 μg/mL AO and 100 μg/mL EB in PBS) for 3 min at room temperature in the dark and immediately observed under a fluorescence microscope.

Flow cytometry

After treatment with ESC-3 at different concentrations (0, 5, 10 and 15 μg/mL) for 72 h, the Mz-ChA-1 cells were harvested, washed twice with PBS and fixed with 70% ethanol at 4 ℃ overnight. After centrifugation, the cells were resuspended in 100 μg/mL RNase A at 37 ℃ for 30 min and subsequently stained with 50 μg/mL propidium iodide at 4 ℃ for 30 min in the dark. The cells were analyzed by flow cytometry at 488 nm, and the data were analyzed with the CellFit software.

For quantifying cell apoptosis, an annexin v-fluorescein isothiocyanate (V-FITC)/PI double staining assay was performed according to the manufacturer's instructions. Briefly, the cells were harvested and stained with annexin V-FITC and PI for 20 min at room temperature. The cells were then washed twice with PBS, and the fluorescence of the cells was measured by flow cytometry.

Analysis of mitochondrial transmembrane potential (ΔΨm)

After treatment with different concentrations of ESC-3 (0 μg/mL, 5 μg/mL, 10 μg/mL and 15 μg/mL) for 48 h, the Mz-ChA-1 cells were incubated with Rh123 (1 mg/mL in dimethyl sulfoxide) at 37 ℃ for 30 min and washed three times with PBS. The cells were harvested and analyzed by flow cytometry at an excitation wavelength of 488 nm and an emission wavelength of 530 nm.

Western blotting analysis

Western blotting analysis was performed as previously described. Briefly, cell lysates were prepared, separated on 12% sodium dodecyl sulfate polyacrylamide gels and transferred onto polyvinylidene fluoride (PVDF) membrane (Amersham Biosciences, Piscataway, NJ). Non-specific reactivity was blocked by incubating the membranes for 1 h in 5% nonfat milk at room temperature. The membranes were incubated with primary antibody overnight at 4 ℃. After three washes for 10 min with phosphate buffered saline tween-20 (PBST), the membranes were incubated at 37 ℃ for 1 h with the appropriate secondary antibody (1:5000 dilution, Sigma) and washed three times with PBST. Reactive proteins were detected with the enhanced chemiluminescence (ECL) detection system (Pierce). β-actin was used as an internal control.

Caspase-3 activation assay

To investigate caspase-3 activation after treatment with ESC-3, a caspase-3 colorimetric assay kit (Kaiji Bio Co., Nanjing, China) was used according to the manufacturer's instructions. Briefly, cells were harvested and lysed by incubation with cell lysis buffer on ice for 1 h, followed by centrifugation at 10 000 × *g* for 1 min. Enzymatic reactions were performed in a 96-well microplate, and 50 μL cell lysate was incubated with the substrate for 4 h at 37 ℃. The absorbance was measured at 405 nm. The total protein concentration was determined using the Coomassie brilliant blue method.

Statistical analysis

All results obtained from ESC-3-treated Mz-ChA-1 cells were analyzed using the SPSS software. Data were expressed as the means ± SD error of the mean (SEM) of separate experiments ($n \geqslant 3$). Differences between two treatments were considered significant at $P < 0.05$.

RESULTS

Purification of bile acid from Crocodylus siamensis gall bladder

The crude extract was subjected to separation on a Sephade × LH-20 column. As shown in Figure 1A, four peaks were obtained. The effects of each pooled peak on Mz-ChA-1 cells were tested. Peak 3 had the strongest anticancer activity (data not shown). Peak 3 was further analyzed by high performance liquid chromatography (HPLC) with methanol elution. Figure 1B shows that the elution profile had only one main peak, which was pooled and named ESC-3.

Effect of ESC-3 on proliferation of human cholangiocarcinoma cells

To evaluate the cytotoxicity of ESC-3 on the proliferation of human cholangiocarcinoma cells, QBC939, Sk-ChA-1 and MZ-ChA-1 cells were treated with 5 μg/mL, 10 μg/mL and 15 μg/mL ESC-3 for 48 h, as shown in Figure 1C, the cell survivals of the three cholangiocarcinoma cell lines were all sensitive to ESC-3 in a dose-dependent manner and MZ-ChA-1 cells are more sensitive to ESC-3 than are the other human cholangiocarcinoma cell lines.

With ESC-3 concentrations of 5 μg/mL, 7.5 μg/mL, 10 μg/mL, 12.5 μg/mL, 15 μg/mL and 17.5 μg/mL, the proliferation of Mz-ChA-1 cells was inhibited significantly. After treatment with various concentrations of ESC-3 for 72 h, the survival rates were 64.3%, 53.2%, 31.3%, 19%, 11.2% and 5.8%, respectively (Figure 1D).

Morphological changes of Mz-ChA-1 cells after exposure to ESC-3

Giemsa staining was used to visualize morphological changes under an optical inverted microscope. After exposure to 10 μg/mL ESC-3 for 48 h, the Mz-ChA-1 cells showed typical apoptotic morphology. When compared with the untreated cells, the chromatin of the ESC-3-treated cells was condensed, and the size of the cells decreased. As shown in Figure 2, after AO/EB staining, the untreated Mz-ChA-1 cells displayed green fluorescence, while the ESC-3-treated cells emitted orange and red fluorescence and were smaller in size. The results of the Hoechst 33258 staining showed that the nuclei of un-

treated Mz-ChA-1 cells emitted a low fluorescence intensity in a homogeneous manner, and the nuclear structure was intact. Our data indicated that the ESC-3-treated Mz-ChA-1 cells displayed typical morphological features of apoptosis: condensed chromatin, gradual disintegration of the nuclear membrane, and pyknotic (shrunken and dark) nuclei.

Cell cycle analysis

To confirm that ESC-3 inhibited cellular proliferation by affecting the cell cycle distribution of the cells, we performed a cell cycle analysis after treatment with various concentrations of ESC-3 (0 μg/mL, 5 μg/mL, 10 μg/mL and 15 μg/mL). Forty-eight h after ESC-3 treatment, the cell cycle distribution of Mz-ChA-1 cells was altered in a dose-dependent manner. The percentage of cells in G0/G1 phase was 41.74% in the control group and increased to 78.46% after treatment with 15 μg/mL ESC-3, while the percentage of cells in G2/M phase decreased from 14.9% to 6.17% (Figure 3A). These results suggested that ESC-3 arrested Mz-ChA-1 cells at G0/G1 phase and suppressed cellular proliferation.

ESC-3-induced apoptosis

To further verify the apoptotic effect of ESC-3 on Mz-ChA-1 cells, flow cytometric analysis was conducted using dual staining with annexin V and PI, which was used to distinguish between viable, early apoptotic, late apoptotic or necrotic cells. As shown in Figure 3B, the population of early apoptotic cells increased with treatment with increasing ESC-3 concentrations (4.4%, 39.72%, 63.38% and 67.78% for 0 μg/mL, 5 μg/mL, 10 μg/mL and 15 μg/mL ESC-3, respectively). We, therefore, demonstrated that ESC-3 induced apoptosis.

Apoptosis via mitochondria-dependent pathway

Rhodamine 123 staining was used to measure the change in the mean fluorescence intensity as a measure of the mitochondrial membrane potential (ΔΨm), which drives the uptake and accumulation of Rh123 in the mitochondria. The hypofluorescence peak observed was indicative of a collapse in the ΔΨm and depolarization of the mitochondrial membrane. As shown in Figure 4A, significant changes in the mean fluorescent intensity of the cells and a collapse of the ΔΨm were observed in the Mz-ChA-1 cells 48 h after treatment with ESC-3 in a dose-dependent manner.

To investigate how ESC-3 induced apoptosis in Mz-ChA-1 cells, we examined the expression levels of apoptosis-related proteins, including Bax, Bcl-2, CDK2 and caspase-3, which are generally activated by the caspase-dependent apoptotic signal transduction pathways[12]. As shown in Figure 4B and C, after exposure to ESC-3 for 48 h, the procaspase-3 expression level was lowered, while the activity of caspase-3 increased significantly in dose- and time-dependent manners in Mz-ChA-1 cells. Moreover, the expression of Bax was increased, while the levels of the Bcl-2 and Cdk2 proteins significantly decreased; therefore, the ratio of Bax to Bcl-2 also increased in a time-dependent manner (Figure 4B). Furthermore, we observed that the levels of cytochrome c in the cytosol of ESC-3-treated Mz-ChA-1 cells increased in a dose-dependent manner. This suggests that the mitochondrial release of cytochrome c into the cytosol may

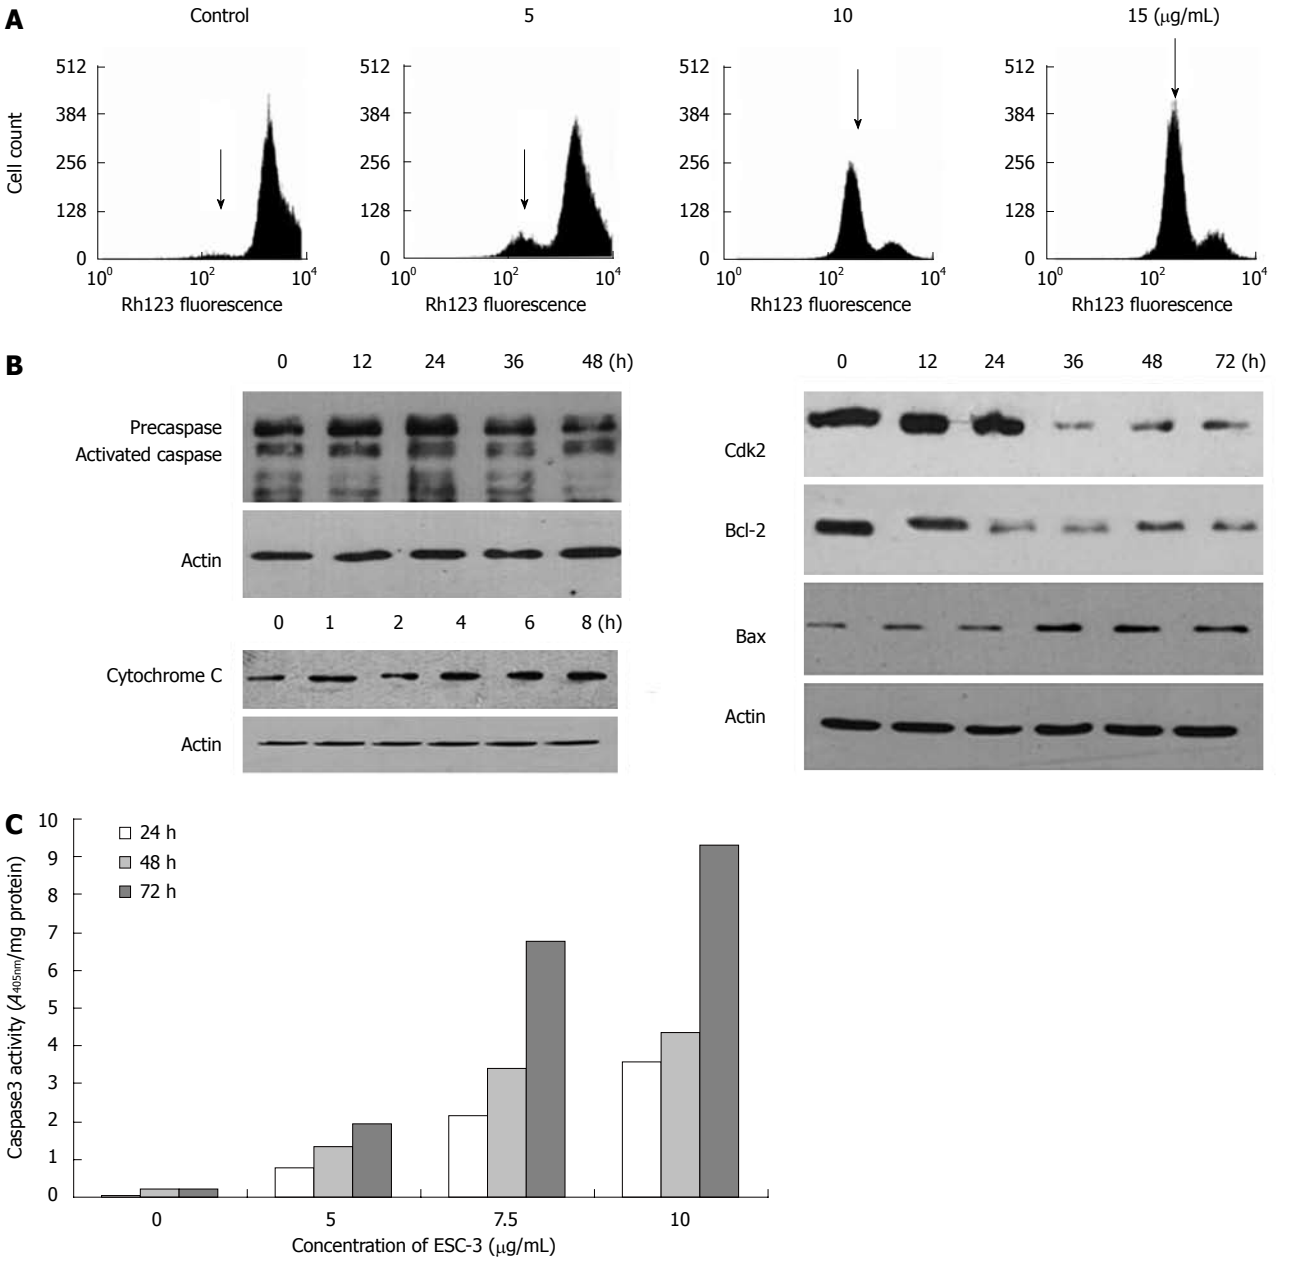

Figure 4 Apoptosis induced by ESC-3 through the mitochondria-dependent pathway. A: Effect of ESC-3 on the ΔΨm of cholangiocarcinoma cells. The increase in Rh123 hypofluorescence indicates a reduction in ΔΨm, which is shown with arrows; B: Expression of cytochrome C, caspase-3, CDK2, Bax, and Bcl-2 in Mz-ChA-1 cells treated with 10 μg/mL ESC-3 for different periods of time; C: Effect of ESC-3 on the activation of caspase-3 activity in Mz-ChA-1 cells. The cells were treated with 0 μg/mL, 5 μg/mL, 7.5 μg/mL and 12.5 μg/mL ESC-3, and caspase-3 activity was analyzed after 24 h, 48 h or 72 h.

play a role in induction of cell apoptosis by ESC-3.

DISCUSSION

Apoptosis is a process by which cells undergo programmed cell death under certain physiological or pathological conditions[13]. Apoptosis and its related signaling pathways have a profound effect on the progression of cancer[14]; therefore, the induction of apoptosis is a desirable goal for the prevention of cancer[15]. Recently, researchers have focused on screening novel anticancer drugs from organisms to identify compounds that could induce apoptosis.

In the present study, we isolated an anticancer compound, ESC-3, from the components of the *Crocodylus siamensis* bile. Our results demonstrated that ESC-3 significantly inhibited the proliferation of QBC939, Sk-ChA-1 and MZ-ChA-1 cells in a dose-dependent manner. Cell cycle arrest is one of the typical responses displayed by proliferating eukaryotic cells after exposure to DNA damaging agents, such as UV light and inhibitors[16]. To determine whether ESC-3 arrested the cell cycle in Mz-ChA-1 cells, we examined the cell cycle distribution of ESC-3-treated cells using flow cytometry. Our data indicated that ESC-3 induced a cell cycle arrest at G0/G1 phase.

Changes in cell morphology are the primary indicators of apoptosis[17-19]. There were significant morphological changes in Mz-ChA-1 cells after exposure to ESC-3,

including cell shrinkage, chromatin agglutination, marginalization, nuclear fragmentation, and apoptotic body formation. Early apoptotic cells exhibited bright annexin V-FITC fluorescence (annexin V-FITC positive only), and the proportion of apoptotic cells increased in a dose-dependent manner. It is reported that CDCA and DCA presented significant cytotoxic activities in ovarian cancer cells *via* inducing apoptosis[20], which is consistent with our results, suggesting that ESC-3 is capable of inducing apoptosis in Mz-ChA-1 cells.

The mechanisms of apoptosis mainly involve two signaling pathways: the mitochondrial pathway and the cell death receptor pathway[21]. Upregulation of Bax is often associated with the mitochondrial release of cytochrome c, which is a key element of the mitochondrial pathway[22,23]. Cytochrome c is regulated by the Bcl-2 family and has been shown to initiate the activation of caspase-3[24]. The Bcl-2 family consists of many important regulators of apoptosis, including Bcl-2, which prevents cells from entering apoptosis, and Bax and Bak, which induce cell death[25]. The increase in the ratio of Bax to Bcl-2 usually triggers cell death[22]. In the present study, we found that ESC-3 downregulated Bcl-2 expression while upregulating Bax expression, which resulted in an elevation of the ratio of Bax to Bcl-2 in Mz-ChA-1 cells. Hydrophobic bile acids have been reported to cause oxidative stress, DNA damage, and mitochondrial membrane instability in several cancer cells[26,27]. Mitochondrial dysfunction is correlated with DNA damage and oxidative stress[28]. ESC-3 also induced a loss of the mitochondrial membrane potential and the release of cytochrome c into the cytosol. Depolarization of the mitochondrial membrane was also detected. All these data suggest that DNA damage or oxidative stress may induce mitochondrial damage and dysfunction which finally triggers apoptosis in cancer cells. Thus, our data indicates that ESC-3-induced apoptosis of Mz-ChA-1 cells occurs through the mitochondrial pathway.

All of the typical signs of apoptosis result from a complex biochemical cascade of events[21]. A family of cysteine-dependent aspartate-directed proteases propagates death signaling by cleaving key cellular proteins. Caspase-3 is a well-known key executioner of apoptosis. Our results showed that ESC-3 activated caspase-3 and enhanced the levels of cleaved caspase-3 in a dose-dependent manner.

In summary, ESC-3 is a novel cytotoxic compound that blocked the proliferation of three cholangiocarcinoma cell lines and arrested the Mz-ChA-1 cell cycle at G0/G1 phase. ESC-3 induced apoptosis in Mz-ChA-1 cells in a dose-dependent manner *via* the mitochondria-dependent pathway. Understanding how ESC-3 regulates cell death would provide insight into the potential anticancer mechanisms and help screen novel active natural compounds for cancer treatment.

COMMENTS

Background

Cholangiocarcinoma is the second most common primary hepatic tumor and currently accounts for 3% of all gastrointestinal cancers; its incidence has recently been increasing globally. Progress in the diagnosis and treatment of cholangiocarcinoma has been achieved in recent years, but the prognosis is still unsatisfactory due to the lack of efficient anticancer drugs.

Research frontiers

Anti-tumor component ESC-3 isolated from crocodile bile could inhibit cell proliferation and induce apoptosis, and it may be a source of potential anti-tumor agent.

Innovations and breakthroughs

ESC-3 induced apoptosis in Mz-ChA-1 cells in a dose-dependent manner *via* the mitochondria-dependent pathway. Understanding how ESC-3 regulates cell death would provide insight into potential anticancer mechanisms and help screen novel active natural compounds for cancer therapy.

Applications

ESC-3, the active ingredient of crocodile bile may be a potential chemotherapeutic drug for the treatment of cholangiocarcinoma.

Peer review

This paper reports the effects of some extracts from crocodile's bile (ESC-3) on cholangiocarcinoma cells. In particular, these authors showed that ESC-3 inhibits cell proliferation, induces apoptosis and cell death. In addition, they provided evidences of Bax/Bcl-2 ratio increase and changes of the mitochondrial membrane potential in these cell lines. It is of interest to identify the natural products with anti-cancer activities in traditional Chinese medicine. Indeed, one component of the bear bile, i.e., the ursodeoxycholic acid, was found to have anti-cholestatic effect and it is now the only accepted therapy for many cholestatic disorders.

Abstract

AIM: To explore the expression pattern of OCT4 in human esophageal squamous cell carcinoma and its significance in diagnosis and prognosis.

METHODS: Using real-time polymerase chain reaction (PCR), Western blotting, immunocytochemistry and immunohistochemistry, the expression of OCT4 in three esophageal squamous cancer cell lines, KYSE70, KYSE140 and KYSE450, was characterized. OCT4 expression was investigated in a series of 153 esophageal squamous cell carcinoma samples using immunohistochemistry and explored its association with clinicopathological features.

RESULTS: Immunohistochemically, OCT4 positive immunostaining was observed in cancer cell nuclei. OCT4 was variably expressed in three esophageal squamous cancer cell lines. Among 153 specimens, 105 (68.7%) were negative or weakly positive for OCT4 staining; 21 (13.7%) were moderately positive and 27 (17.6%) were strongly positive. Higher expression level of OCT4 was significantly associated with higher histological grade ($P < 0.001$) and poor clinic outcome ($P < 0.001$).

CONCLUSION: The expression of OCT4 enables the tumor to have a higher degree of stemness, which in turn results in a poorer clinical outcome for patients with esophageal squamous cell carcinoma.

Key words: Esophageal squamous cell carcinoma; Immunohistochemistry; OCT4; Real-time polymerase chain reaction; Western blotting

Expression of OCT4 in human esophageal squamous cell carcinoma is significantly associated with poorer prognosis. *World J Gastroenterol* 2012; 18(7): 712-719 Available from: URL: http://www.wjgnet.com/1007-9327/full/v18/i7/712.htm DOI: http://dx.doi.org/10.3748/wjg.v18.i7.712

INTRODUCTION

OCT4, also known as OCT3, belongs to the POU (Pit-Oct-Unc) transcription factor family[1]. The POU family of transcription factors can activate the expression of their target genes through binding the octameric sequence motif with an AGTCAAAT consensus sequence[2,3]. The expression of this gene is necessary for the maintenance of pluripotentiality in embryonic stem cells (ESCs) and primordial germ cells and is down-regulated in all differentiated cells *in vitro* as well as *in vivo*[2].

Previous studies have demonstrated that many cancers express OCT4 and that its expression appears to be important for cancer cell survival. Hattab *et al*[4] reported OCT4 immunoreactivity in all of 25 primary intracranial germinomas. Jin *et al*[5] discovered that the human breast

cancer cell line, MCF7, expressed at least four POU gene products including OCT4. Sung *et al*[6] proposed that with its superior sensitivity and easy interpretation compared with other markers, OCT4 immunostaining is a powerful tool for confirming the diagnosis of retroperitoneal seminoma. In addition, OCT4 has been shown to be expressed in human tumors including pancreatic and gastric carcinomas[7,8].

Recent studies have argued that the transcription factor, OCT4, exhibited the hallmark of global regulators during mammalian embryogenesis. OCT4 works together with SOX2, another type of transcription factor, which plays important roles in the regulation of organ development and cell type specification[9,10] during embryogenesis to co-ordinate their own transcriptions[11,12], *via* the OCT4/SOX2 complex in ESCs[13]. OCT4 constitutes part of an important gene regulatory network and is essential for embryogenesis and/or the pluripotency and self-renewal of ESCs[14].

Cancer cells, especially in poorly differentiated or undifferentiated tumors, have been characterized by many phenotypic traits similar to undifferentiated embryonic cells[15-17]. These similarities suggest the expression of genes determining cell renewal and stemness.

Esophageal cancer is one of the leading causes of cancer-related death worldwide, especially in some high risk populations in China, such as in Linxian (Western Anyang, Henan Province). In the present study, we first attempted to characterize the expression status of OCT4 in three esophageal cell lines, and then explore their clinicopathological and survival correlations in a series of 153 esophageal cancers in patients from Anyang, Henan, China. It was found that OCT4 was expressed in all three esophageal squamous cancer cell lines (KYSE70, KYSE140 and KYSE450). Furthermore, the expression of OCT4 was significantly associated with higher histological grade and poorer clinical survival, indicating that this embryonic self-renewal factor may exert a positive influence on tumor cell stemness, which in turn results in a negative clinical course for the tumors.

MATERIALS AND METHODS

Patients and cell lines

In this retrospective study, 153 consecutive esophageal cancer patients who underwent potentially curative surgery without preoperative chemotherapy or radiotherapy during the period of 1990-1994 at the Anyang Tumor Hospital, Henan, China were randomly selected. Among them, 93 were men and 60 were women, ranging from 33-73 years of age with a mean age of 56.4 years. According to the International Union Against Cancer (UICC) 1997 standard, 100 were classified as stage I or II and 53 cases as stage III or IV. The patients' information and tumor parameters are listed in Table 1. All the patients were followed at the Anyang Tumor Hospital until May 2004 supported by an international collaboration project between Anyang Tumor Hospital and the Norwegian Radium Hospital[18]. Among these patients, 97 (63.4%) patients died during the follow-up period. Surgically removed specimens were routinely fixed in buffered formalin and embedded in paraffin blocks for clinical diagnosis and reclassification for this study.

The human esophageal squamous cell carcinoma cell lines, KYSE70, KYSE140 and KYSE450 (DSMZ, Germany), were cultured in RPMI 1640 medium supplemented with 10% fetal bovine serum at 37 ℃ under 5% CO_2 and saturated moisture. The sample cells were collected and counted by trypan blue exclusion using a hemocytometer.

Immunocytochemistry

Immunocytochemistry was performed on all three cell lines. Simply, the cultured cells were detached and the cell suspension was centrifuged at 2000 rpm for 10 min. The supernatant was removed before the sediment was mixed with 2-3 drops of plasma and 2 drops of thrombin for 1 min, followed by the addition of 4% buffered formalin

to the coagulated cell mass, which was then fixed for 30 min and placed in linen paper for further conventional paraffin cytoblock preparation. Sections (4 μm thick) were cut from the paraffin-embedded cytoblocks and immunostained according to the same procedure as the tissue blocks described below.

Tissue arrays

Multitissue array blocks were made with the MTA-1 manual tissue arrayer (Beecher Instruments Inc., Sun Prairie, WI, United States). Briefly, 4 μm sections from the routinely made paraffin blocks were stained with H and E and reevaluated to confirm the diagnosis and to identify two representative tumor areas and one stromal area. Then, the related paraffin blocks were oriented and marked. From these blocks, tissue cores with a diameter of 0.6 mm were punched and arrayed in triplicate on a recipient paraffin block. When the block construction was complete, the block was placed into a 40 ℃ oven overnight to tighten the cylinders by slightly melting the paraffin. Then, 5 μm sections of these tissue array blocks were cut and placed on charged Super-Frost Plus glass slides and dried in a 60 ℃ oven for 2-4 h. These sections were used for immunohistochemical analysis. For those samples whose tissue array materials were not representative or not available, the paraffin-embedded conventional sections were also used for additional immunohistochemistry analyses.

Immunohistochemistry

Immunohistochemical analysis of OCT4 was performed on 5 μm sections which were prepared from the tissue microarray blocks. The Envision Plus detection system (Dako, Carpinteria, CA, United States) was used for immunostaining. The sections were deparaffinized in xylene and microwaved in 10 mmol/L citrate buffer (pH 6.0) to unmask the epitopes. Endogenous peroxidase activity was blocked by incubation with 0.03% hydrogen peroxide in methanol for 5 min. For the detection of OCT4, the sections were incubated with the polyclonal goat anti-human OCT4 antibody (microwaving retrieval in citrate buffer in 1:40 concentration, catalog no. AF1759, R and D Systems) for 30 min at room temperature. Then, mouse anti-goat IgG (sc-2489, Santa Cruz Biotechnology Inc, Santa Cruz, CA, United States) diluted at 1:100 was added for incubation for another 30 min followed by a gentle rinse with washing buffer three times. Thereafter, the sections were incubated with a peroxidase labeled polymer conjugated to goat anti-mouse IgG (Dako, Carpinteria, CA, United States) for 30 min before staining for 5 min with 3'3-diaminobenzidine tetrahydrochloride (DAB), counterstained by hematoxylin, dehydrated and mounted in Diatex. Known OCT4 positive seminoma was used as a positive control, while the same concentration of non-immune goat IgG was applied as a negative control for OCT4.

Evaluation of staining for OCT4

Only nuclear staining was considered as OCT4 positive. Both intensity and percentage of immunostained carcinoma cells were taken into consideration according to a previously published method with modification[19]. Briefly, the extent of positivity was scored as 0 when no positive cells were observed; 1 when the percentage of positive cells was < 10%; 2 when it was 10%-50%; and 3 when it was > 50%. The intensity was scored as 0 when no positive cells were identified; 1, weak; 2, moderate; and 3, strong staining. Multiplying the extent by intensity gave the following immunohistochemical staining grades as 0, 1, 2, 3, 4, 6 and 9. For statistical analyses, grades 0, 1 and 2 were considered as not or weakly stained and scored as 0, grades 3 and 4 were considered as moderately stained and scored as 1, and grades 6 and 9 were considered as strongly stained and scored as 2.

Total RNA and protein isolation

Total RNA and protein isolation was performed using a Total RNA and Protein Isolation kit (Macherey-Nagel, Düren, Germany) according to the user manual. About 5×10^6 cultured cells were collected and lysed. Through the NucleoSpin RNA/Protein column, RNA and DNA were bound to the column and protein was contained in the flow-through. After digestion of DNA, total RNA was isolated by washing the column. Protein was isolated from the flow-through and incubated for 3 min at 98 ℃ for dissolving and denaturation and stored at -20 ℃ until used. All of the preparations and handling steps of RNA took place in a laminar flow hood, under RNase-free conditions.

cDNA synthesis

RNA quality and quantity were determined by absorbance readings at 260 nm and 280 nm with the Nano Drop (ND-1000) spectrophotometer (Wilmington, DE, United States). RNA integrity was tested by polymerase chain reaction (PCR) amplification of the *gapdh*. Reverse transcription of RNA was performed using Transcriptor First Strand cDNA Synthesis Kit (Roche, Mannheim, Germany). cDNA was synthesized from 5 μg of total RNA isolated from the cell lines according to the manufacturer's handbook.

Primer and probe design

The primer pairs and hydrolysis probes for quantitative real-time PCR of *oct4* and *gapdh* were designed by Universal ProbeLibrary Assay Design Center (Roche, Mannheim, Germany). For *oct4*, the sense primer sequence was 5'-AGCAAAACCCGGAGGAGT-3' and the antisense primer sequence was 5'-CCACATCGGCCTGTGTATATC-3', giving a product of 114pb. For *gapdh*, the sense primer sequence was 5'-AGCCACATCGCTCAGACA-3' and the antisense primer sequence was 5'-GCCCAATACGACCAAATCC-3', giving a product of 66bp. The hydrolysis probes (#35, cat No. 04687680001 for *oct4*, and #60, cat No. 04688589001, for *gapdh*) were bought from Roche Diagnostics (Mannheim, Germany). In addition to the primer pairs for real-time PCR, the specific primer pair

for *oct4* which had been verified avoiding pseudogenes amplification by Suo *et al*[20] was also applied in this study for conventional PCR analyses.

Quantitative real-time PCR and conventional PCR

Quantitative real-time PCR was performed with the LightCycler 2.0 Real-Time PCR System (Roche, Mannheim, Germany) in a total volume of 20 μL in glass-capillaries containing 2 μL of cDNA, 0.5 μmol/L of each primer, 0.1 μmol/L of hydrolysis probe and 4 μL of LightCycler TaqMan Master Mix (Roche, Mannheim, Germany). Quantification was carried out according to a published method with some modification[21]. After the expression ratio value for target gene (*oct4*) *vs* house keeping gene (*gapdh*) was obtained, the ratio of KYSE450 was set as 1, and all other ratio values were normalized by this value as relative quantities. The PCR was initiated with a 12 min denaturation at 95 ℃ and terminated with a 30 s cooling step at 40 ℃. The cycling protocol consisted of denaturation at 95 ℃ for 10 s, annealing at 54 ℃ for 10 s and extension at 72 ℃ for 10 s and was cycled 45 times. Fluorescence detection was performed at the end of each extension step. The housekeeping gene *gapdh* and DEPC-H_2O were set as the internal control and negative control, respectively.

The specific conventional PCR for *oct4* was initiated with a 5 min denaturation at 95 ℃. Amplification was carried out for 30 cycles consisting of 30 s at 95 ℃, 50 s at 55 ℃ and 50 s at 72 ℃. An additional extension step of 5 min at 72 ℃ was added at the end of the cycles. *gapdh* was used as an internal control to confirm the success of the reverse-transcription action and the identical quantity of different cDNA templates. PCR products were analyzed by electrophoresis on 1.5% agarose gel.

Western Blot analysis

20 μL of protein samples were separated on a 10% SDS-acrylamide gel (Bio-Rad) for 1 h at 150V and the proteins were transferred to a nitrocellulose membrane (Whatman, Kent, United Kingdom). After blocking in 5% fat-free milk, the membrane was treated with the dilution of the primary antibody overnight at 4 ℃ and the dilution of the secondary IgG-horseradish peroxidase (HRP) conjugated antibody for 1 h at room temperature. The antibody used for immunohistochemistry was applied for Western blotting. The antibody was diluted in phosphate buffered saline containing 5% Blotto and 0.1% Tween-20. The stained membranes were visualized by an enhanced chemiluminescence reaction using the ECL Plus (GE Healthcare, Fairfield, CT, United States). Western blotting experiments were repeated at least three times on every sample with similar results.

Statistical analysis

Bivariate association between ordinal variables was assessed using Spearman's correlation (exact version). For categorical data, Pearson's χ^2 test was used. All tests of statistical significance were two-sided. Overall survival was calculated from the date of diagnosis to the date of death or May 1st, 2004. Survival curves were plotted according to the Kaplan-Meier method, and the log-rank test was used to determine significant differences among groups. Multivariate analysis according to Cox's proportional hazards regression model adjusted for clinicopathological factors (age, gender, tumor location, tumor size, lymph node metastasis, histological grade, and T stage) was performed to assess which tumor variables were independently correlated with overall survival. Statistical analyses were performed using the SPSS 16.0 package and $P < 0.05$ was considered as statistically significant.

RESULTS

Characterization of OCT4 in esophageal cancer cell lines

Quantitative real-time PCR was employed to analyze *oct4* mRNA level in three human esophageal squamous cell carcinoma cell lines (KYSE70, KYSE140 and KYSE450). Comparatively, the ratios of *oct4 vs gapdh* in KYSE70 and KYSE140 were 2.7 and 1.73 times that in KYSE450, respectively (Figure 1A). To further examine the protein level of OCT4, Western blotting analysis was performed on these three cell lines. Figure 1B shows 38KD OCT4 bands, which are in agreement with the NP_002692 OCT4 characterization on NCBI. The band of OCT4 in KYSE450 was weak, but in KYSE140 and KYSE70, it was strong and stronger, respectively. Immunocytochemistry of the cell lines cytoblock paraffin sections gave similar results as shown by RT-PCR and Western blotting (Figure 1D).

Six *oct4* pseudogenes have been proposed to exist using a bioinformatics approach to analyze the genomic nucleotide sequences[22]. To confirm the specific transcription of *oct4*, a specific primer pair for *oct4* conventional PCR examination was designed and the specificity of this pair was verified by Suo *et al*[20]. This primer pair was also applied in the present study for additional verification of OCT4 expression. As shown in Figure 1C, the predicted PCR products (408 bp) with the specific primer pair were detected in these cell lines, highly in KYSE70 and KYSE140 and weakly in KYSE450. This verified the immunocytochemistry and Western blotting results that OCT4 was variably expressed in the human esophageal squamous cell carcinoma cell lines.

OCT4 expression in tumor samples

Immunohistochemically, OCT4 positive immunostaining was observed in cancer cell nuclei (Figure 2). Among the 153 tumors, 100 were negative for OCT4 staining, and 5 were scored as 1 or 2. These tumors were again classified as either negative or weakly positive for OCT4 immunostaining (105 in total, 68.7%). Twenty-one (13.7%) were scored as 3 or 4 and classified as moderately positive. Twenty-seven (17.6%) were scored as 6 or 9 and classified as strongly positive (Table 2).

Clinicopathological correlations

The correlations between the clinicopathological features

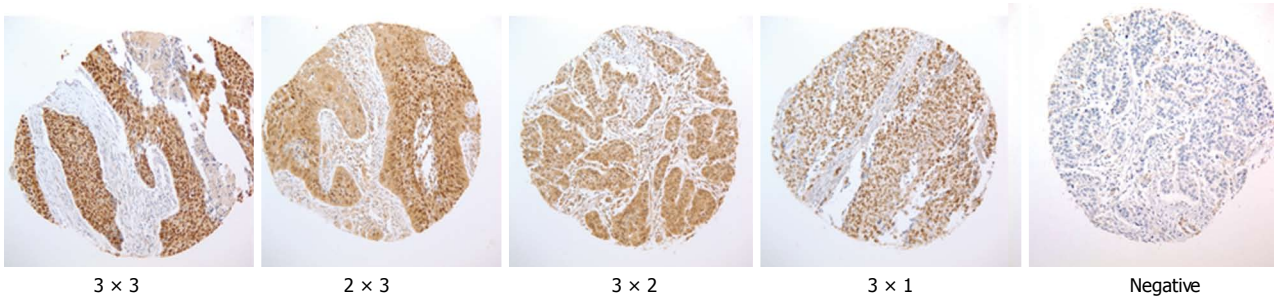

Figure 2 Evaluation of immunohistochemistry staining for OCT4 in tissue array materials of esophageal squamous cell carcinomas (multiplying the extent by intensity, × 400).

Table 2 Immunohistochemical staining results for OCT4

Score	OCT4	
	n	%
0	100	65.4
1	2	1.3
2	3	2
3	15	9.8
4	6	3.9
6	17	11.1
9	10	6.5
Total	153	100

and OCT4 expression in the primary tumors are summarized in Table 1. The expression level of OCT4 was not correlated with age, sex, tumor location, tumor size or clinical stage. However, a higher level of OCT4 expression was significantly associated with higher histological grade ($P < 0.001$), indicating its correlation with dedifferentiation of these tumors.

Relation to survival

Follow-up information was available for 153 patients for a minimum period of 10 years. The median follow-up time for the 56 patients still alive was 124 mo (range 118-155 mo) and for the remaining 97 patients who died during the follow-up period was 61 mo (range 1-139 mo). In univariate analysis, patients with low OCT4 expression

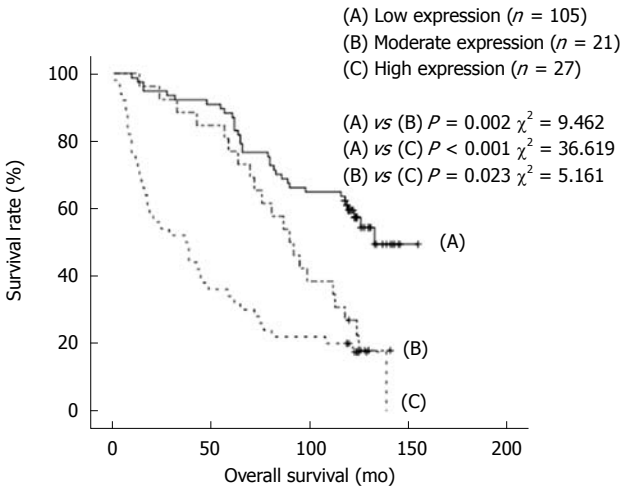

Figure 3 Kaplan-Meier survival curves for esophageal squamous cell carcinoma patients with regard to OCT4 protein expression.

level in tumors had a better overall survival than patients with tumor showing moderate or high OCT4 expression level ($P = 0.002$ and $P < 0.001$, respectively, Figure 3).

In multivariate Cox's regression analysis, we detected a 2.625-fold increased risk of tumor-related death for patients ($P < 0.001$) whose tumors showed high OCT4 expression level compared to patients with low expression level (Table 3).

DISCUSSION

The expression of OCT4 was first discovered in human esophageal squamous cancer cell lines with the antibody AF1759 from R and D System for immunocytochemistry in the authors' lab. Since controversial results concerning the expression of OCT4 in tumors exist[23], the expression status of this factor in these cell lines was investigated. The expressions were repeatedly demonstrated immunocytochemically, with different positive and negative controls. To verify these findings, real-time PCR with hydrolysis probes was carried out, and repeatedly demonstrated similar results in these cell lines. Considering the fact that *oct4* pseudogenes are also transcribed[20], the *oct4* specific PCR primer pair (poct4a, 5'-TCCCTTCGCAAGCCCTCAT-3' and poct4b, 5'-TGACGGTGCAGGGCTCCGGGGAGGCCCCATC-3') were applied in conventional PCR for these three cell lines, obtaining similar results. All these experiments were repeated at least twice. The additional Western blotting analysis also disclosed similar results as shown by immunocytochemistry and PCR. Therefore, we can conclude that OCT4 is variably expressed in these esophageal squamous cancer cell lines.

Based on the findings on cell lines, this work was extended to clinical esophageal cancer samples for which official follow-up data were obtained during the international collaboration. To date, this study is the first to report the expression patterns of the embryonic stem cell factor OCT4 in esophageal squamous carcinomas.

Esophageal cancer is one of the most aggressive neoplasms and the overall prognosis for esophageal cancer patients is poor[24]. One of the reasons for the low survival rate is the tumor's intrinsic resistance to many clinical therapies, especially chemotherapy. Chemotherapy often removes the bulk of a tumor mass without preventing tumor recurrence, suggesting the survival of a subset of cancer stem cells. Recent studies have provided experimental evidence for the concept that human tumor growth may depend on a small portion of cancer stem cells[25].

The present investigation on esophageal squamous carcinomas revealed several novel observations. Firstly, it was discovered that 17.6% of these esophageal cancer samples had strong positive expression of OCT4. Secondly, although the expression level of OCT4 did not correlate with age, sex, tumor size, location, histological type or UICC stage, it was significantly associated with higher histological grade of the tumors and poorer clinical outcome of the patients.

It has been proposed that OCT4 is a key regulator of stem cell pluripotency and differentiation, indicating that it is the primary factor determining the fate of ESCs by controlling cell self-renewal and differentiation[26]. Phenotypically, human preimplantation embryonic cells resemble cancer cells in many ways, especially in their ability to grow indefinitely. Both types of cells undergo deprogramming to a proliferating state and become immortal, self-renewable and invasive. It has been reported that OCT4 is expressed in human tumors but not in normal somatic tissues[27], in agreement with the hypothesis that embryonic genes are re-activated in tumor cells.

In this series, OCT4 expression was strongly associated with the histological grade of the tumors and survival of the patients, which supports the findings of previous reports[28-30]. Given the previously reported functions of OCT4, the results suggest that it may play a role in conferring a less differentiated phenotype or inactivating the ability to differentiate in esophageal carcinomas.

It has been demonstrated that human somatic cells can be reprogrammed into pluripotent stem cells by either a combination of OCT4, SOX2, Nanog and Lin28 factors[31] or a combination of OCT4, SOX2, Klf4 and c-Myc factors[32]. A common feature of these studies is the contribution of OCT4 and SOX2 for pluripotency,

indicating that tumor cells with OCT4 expression may behave as or close to tumor stem cells. It is also known that SP positive tumor cells, which most probably harvest tumor stem cells, are resistant to chemotherapy and radiotherapy[33,34]. Thus, the present investigation on esophageal squamous cancer samples may indicate that OCT4 conveys a stemness feature in tumor cells, so that these tumors could easily develop and relapse, resulting in poorer clinical outcome.

The current results demonstrate that the ESC marker, OCT4, could be detected in human esophageal squamous cancer cell lines and related cancer tissues. The poorly differentiated esophageal squamous cancer cell lines expressed higher levels of OCT4. The higher expression level of OCT4 in esophageal carcinomas was correlated with higher histological grade and poorer overall survival of esophageal squamous cell cancer patients. Since the function of pluripotency and self-renewal of this factor has been characterized in adult human cells[31,32], the role of OCT4 in esophageal carcinogenesis, especially in consideration of tumor cell stemness, merits further studies.

COMMENTS

Background

The embryonic stem cell factor, OCT4, is essential for pluripotency and self-renewal of embryonic stem cells. Cancer cells, especially in poorly differentiated or undifferentiated tumors, have been characterized by many phenotypic traits similar to undifferentiated embryonic cells, indicating that OCT4 may be expressed in solid tumors.

Research frontiers

Previous studies have demonstrated that many cancers express OCT4 and that its expression appears to be important for cancer cell survival, such as in germinoma, breast cancer, seminoma, pancreatic and gastric carcinomas. However, the expression pattern of OCT4 in human esophageal squamous cell carcinoma and its significance in diagnosis and prognosis remain unclear. In this study, the authors demonstrated that OCT4 positive immunostaining was observed in cancer cell nuclei, and the expression of OCT4 enabled the tumor to have a higher degree of stemness, which in turn resulted in poorer clinical outcome for the patients with esophageal squamous cell carcinomas.

Innovations and breakthroughs

To date, this study is the first to report the expression patterns of the embryonic stem cell factor, OCT4, in esophageal squamous carcinomas. The present investigation revealed several novel observations. Firstly, it was discovered that 17.6% of these esophageal cancer samples had strong positive expression for OCT4. Secondly, although the expression level of OCT4 did not correlate with age, sex, tumor size, location, histological type or International Union Against Cancer stage, it was significantly associated with higher histological grade of the tumors and poorer clinical outcome of the patients.

Applications

By knowing that the embryonic stem cell (ESC) marker, OCT4, can be detected in human esophageal squamous cancer cell lines and related cancer tissues, and the higher expression level of OCT4 in esophageal squamous carcinomas was correlated with higher histological grade and poorer overall survival of esophageal squamous cell cancer patients, this study may represent a future strategy for therapeutic intervention in the treatment of patients with esophageal squamous carcinoma.

Terminology

OCT4 belongs to the POU (Pit-Oct-Unc) transcription factor family. The expression of this gene is necessary for the maintenance of pluripotentiality in ESCs and primordial germ cells and is down-regulated in all differentiated cells *in vitro* as well as *in vivo*.

Peer review

This study considers the investigation of the expression of the embryonic stem cell factor OCT4 in three esophageal cell lines and additionally in esophageal squamous carcinoma patients. Important finding of this study was the observation that OCT4 expression was strongly associated with the histological grade of the tumors and survival of the patients. The poorly differentiated esophageal squamous cancer cell lines expressed higher level of OCT4. This study make a great contribution to studies of OCT4 as one of the transcription factors and its role in cancer cell's survival. The study support the hypothesis that the expression of OCT4 as embryonic self-renewal factor may exert a positive influence on tumor cell stemness, which in turn results in a negative clinical course for the tumors.

Abstract

Pancreatic tuberculosis (TB) is a relatively rare disease that can mimic carcinoma, lymphoma, cystic neoplasia, retroperitoneal tumors, pancreatitis or pseudocysts. Here, I report the case of a 31-year-old immigrant Burmese woman who exhibited epigastralgia, fever, weight loss and an epigastric mass. The patient was diagnosed with pancreatic TB and acquired immunodeficiency syndrome, and was treated with antituberculous drugs and percutaneous catheter drainage without a laparotomy. The clinical presentation, radiographic investigation and management of pancreatic TB are summarized in this paper to emphasize the importance of considering this rare disease in the differential diagnosis of pancreatic masses concomitant with human immunodeficiency virus infection. I also emphasize the need for both histopathological and microbiological diagnosis *via* fine-needle aspiration.

Key words: Pancreas; Tuberculosis; Abscess; Antituberculous drugs; Human immunodeficiency virus; Fine-needle aspiration

INTRODUCTION

Tuberculosis (TB) is an extremely common opportunistic infection in human immunodeficiency virus (HIV)-positive patients and is considered to be an acquired immunodeficiency syndrome (AIDS)-defining illness[1]. Because of the virulence of TB, its symptoms tend to manifest at an early stage of HIV infection. The most overt feature of TB in HIV-seropositive patients is their substantially greater likelihood of extrapulmonary involvement and dissemination[2]. Intraabdominal involvement is frequently observed in the abdominal lymph nodes (LNs), the spleen, the peritoneum, the liver, and the gastrointestinal tract[3]. However, even in HIV-infected patients, TB of the pancreas is relatively rare with an incidence of 0.46% based on ultrasonographic findings[4], and isolated primary pancreatic TB is particularly rare. Because of its rarity, the natural course of the disease is currently unknown. Several case reports have included a detailed review of this subject; however, we still lack a complete clinical picture of the disease[5-7]. Here, I report a case of pancreatic TB with AIDS that initially followed a classic pattern, but in which the patient subsequently exhibited an uncommon natural history of disease. I review the current literature regarding HIV-associated pancreatic TB. To the best of my knowledge, the present systematic review includes the largest number of published case reports on this subject, and is the first to describe the natural history of disease in a patient with pancreatic TB and AIDS.

CASE REPORT

In April 2010, a 31-year-old immigrant Burmese woman was admitted at Mae Sot General Hospital for approximately 1 wk due to epigastralgia. Two day before admission, she experienced constant severe abdominal pain and fever. She also reported weight loss of 5 kg over the preceding month. Upon admission, her temperature was 39.8 ℃, her pulse was 128 bpm, her respiratory rate was 18 breaths/min, and her blood pressure was 116/81 mmHg. Her weight and body mass index were 39 kg and 15.82 kg/m^2, respectively. She presented with oral thrush on her tongue and a pruritic papular eruption on her extremities and trunk. Her abdomen was bulging and contained a well-defined, round, smooth-surface, tender mass measuring 9 cm × 9 cm in the epigastrium. No hepatosplenomegaly or significant lymphadenopathy was observed.

A serological test for HIV was positive, and the patient's lymphocyte subset profile showed a CD4-positive cell count of 120 cells/mm^3 (range, 410-1 264/mm^3). A sputum examination for acid-fast bacilli (AFB) was negative, and a chest radiograph was normal. An ultrasound (US) of the upper abdomen revealed a lobulated, heterogeneous, hypoechoic cystic mass with septation and an irregular wall at the head of the pancreas (5.6 cm × 5.3 cm × 5.7 cm in size) (Figure 1). Multiple small LNs that ranged from 1.0 cm to 1.9 cm in diameter were observed in the paraaortic, peripancreatic, and porta hepatis regions.

US-guided fine-needle aspiration (FNA) of the mass was performed, and 50 mL of purulent, turbid fluid was harvested. The level of amylase in the cyst fluid was 33 801 U/L. An examination of a specimen using the Ziehl-Neelsen stain revealed AFB in the proteinaceous fluid and abundant acute inflammatory cells. An analysis of the cultures identified pure growth of *Mycobacterium tuberculosis* that was susceptible to isoniazid, rifampicin, ethambutol, and streptomycin. Consistent with the patient's clinical features, she was diagnosed with AIDS with a tuberculous pancreatic abscess. Note that a pancreatic pseudocyst typically contains an amylase-rich fluid, and when pus is present instead of sterile pancreatic juice, an infected pancreatic pseudocyst is referred to as a pancreatic abscess. Antituberculous drugs (ATDs) including isoniazid, rifampicin, pyrazinamide, and ethambutol were administered on the 6th d of admission. The treatment plan included quadruple ATDs for 2 mo followed by isoniazid and rifampicin for the next 7 mo. The patient was discharged after 12 d of hospitalization in an improved and stable condition, but she was still febrile at that time. Antiretroviral treatment was not planned due to a lack of monetary support.

The patient was readmitted 4 mo later due to epigastric fullness and shortness of breath. The epigastric mass was found to be enlarged. A physical examination revealed that the epigastric mass measured 15 cm × 15 cm in size. On admission, the patient had a temperature of 38.9 ℃, a pulse of 100 bpm, and a respiratory rate of 24 breaths/min; her blood pressure was 123/87 mmHg.

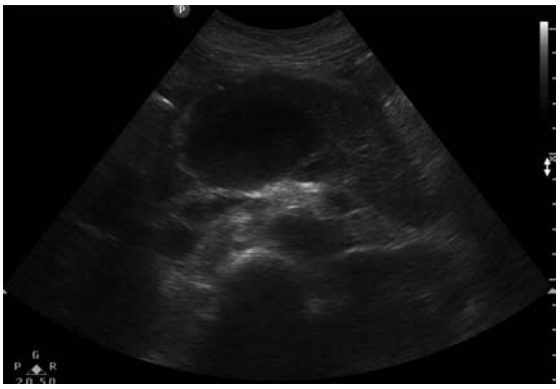

Figure 1 Ultrasound demonstrated a well-defined, lobulated cystic lesion with fluid debris at the pancreatic head. The size of the lesion is approximately 5.6 cm × 5.3 cm × 5.7 cm.

The patient's body weight was 39 kg. The patient's septic workups were unremarkable. An abdominal US revealed that the pancreatic cystic lesion had increased in size (11.8 cm × 8.7 cm × 11.6 cm) and contained a clear fluid (Figure 2A). Encasement of the celiac trunk was noted. Main portal vein compression and varices in the porta hepatis were observed (Figure 2B). A clear, serosanguinous fluid with an intracystic amylase level of 55 708 U/L was obtained from the pancreatic pseudocyst. Aerobic and mycobacterial cultures were negative. Although the patient's abdominal symptoms had improved, she still experienced an intermittent fever, cachexia, malnutrition (with a body weight of 34 kg and a serum albumin level of 21.0 g/L), and weakness within the month following admission. She continuously complied with the ATD regimen for 5 mo and 1 wk prior to discharge. Unfortunately, the patient was lost to follow-up after discharge and died 3 wk later (i.e., 6 mo after being diagnosed with pancreatic TB) in Myanmar from a suspected AIDS-related complication.

DISCUSSION

The PubMed, EMBASE databases, and Google were searched in July 2011 using the following terms in various combinations: tuberculosis, tuberculous, tubercular, mycobacterial infection and pancreas, pancreatitis, pancreatic, peripancreatic and HIV, AIDS, immunocompromised. The reference lists of the retrieved articles or of articles dealing with literature review were searched for additional studies. Only HIV-positive patients with informative clinical characteristics were reviewed.

A total of 43 cases of HIV-positive patients with pancreatic TB (including the present case) were reviewed[2,5-38]. Of these cases, 40 were primarily analyzed[2,5-23,25-38]. Table 1 illustrates the clinical characteristics of the pancreatic TB patients with AIDS. Most of the patients appeared to be affected between the age of 30 and 40 (this was the case in 53.7% of cases); the median age was 33 years with a range of 19-61 years, n = 41, and most of the patients (75.6%) were ≤ 43 years old. Five of the 40 patients (12.5%) had

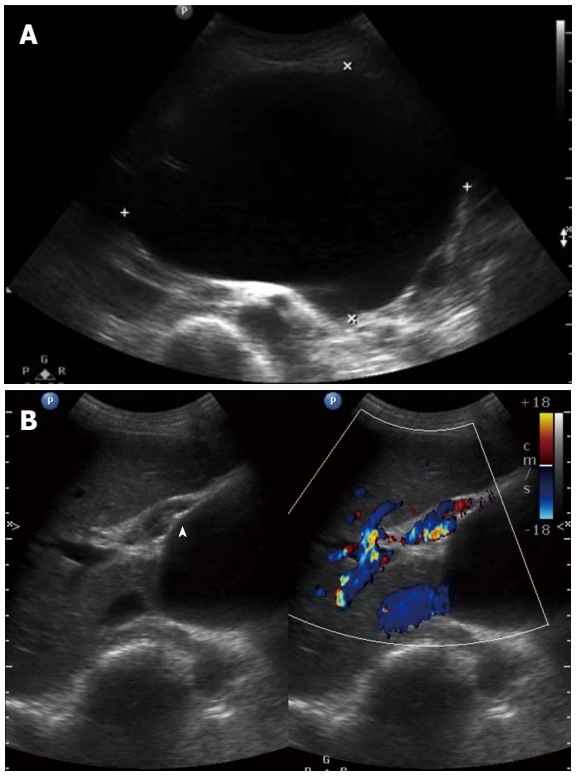

Figure 2 An abdominal ultrasound was performed 4 mo after discharge and revealed an increase in the size of the pancreatic cystic lesion (to 11.8 cm × 8.7 cm × 11.6 cm) with a clear fluid content (A). Portal vein compression (arrowhead) and varices in the porta hepatis were observed (B).

Table 1 Clinical characteristics, diagnostic studies, investigations yielding definitive diagnosis, preoperative diagnoses and definitive diagnosis of patients with pancreatic tuberculosis and acquired immunodeficiency syndrome

Clinical characteristics	*n* (%)
Gender[2,5-20,22-28,30-32,34-38]	
Male	28/39 (71.8)
Female	11/39 (28.2)
Known HIV-infected cases[2,5-23,25-38]	11/38 (28.9)
Positive tuberculin skin tests[2,5,6,9,12,13,16,29-31,33,34,38]	7/14 (50.0)
Symptoms[2,5-23,25-38]	
Abdominal pain	38/40 (95.0)
Fever	36/40 (90.0)
Weight loss	21/40 (52.5)
Anorexia	12/40 (30.0)
Night sweats	10/40 (25.0)
Nausea or vomiting	9/40 (22.5)

Preoperative diagnoses	(*n* = 15)[2,5,7-13,16-17,19,22,25] (%)
Pancreatic mass	4 (26.7)
Pancreatic cancer	3 (20.0)
Pancreatic abscess of unknown pathogen	3 (20.0)
Acute pancreatitis	2 (13.3)
Tuberculous pancreatic abscess[c]	2 (13.3)
Lymphoma or retroperitoneal tumor	1 (6.7)
Definitive diagnosis	(*n* = 40)[2,5-23,25-38] (%)
Tuberculous pancreatic abscess without duodenal fistula	26 (65.0)
Tuberculous pancreatic abscess with duodenal fistula	2 (5.0)
Acute tuberculous pancreatitis without duodenal fistula	2 (5.0)
Acute tuberculous pancreatitis with duodenal fistula	1 (2.5)
Focal acute tuberculous pancreatitis with chronic pancreatitis	1 (2.5)
Pancreatic TB	8 (20.0)

TB: Tuberculosis; AIDS: Acquired Immunodeficiency Syndrome; HIV: Human Immunodeficiency Virus; CT: Computed tomography. [a]One was performed from the left supraclavicular lymph node instead of the pancreatic mass, and one patient underwent both fine needle aspiration and laparotomy due to clinical deterioration. [b]No histopathological specimens. [c]Diagnosis was based on a computed tomography scan only in one patient.

a confirmed history of TB; in 3 cases, the patient had had a positive purified protein derivative skin test, and there were 2 cases of pulmonary TB. The median CD4 count (n = 21) was 54/mm^3 (range, 0-718/mm^3); 76.2% and 90.5% of the patients had a CD4 count ⩽ 120 or ⩽ 190/mm^3, respectively. The median duration of abdominal pain (n = 31) before presentation was 30 d (range: 3 d-1 year).

The results of the diagnostic studies conducted in cases of pancreatic TB with AIDS are summarized in Table 1. The types of abdominal imaging studies (n = 43) used included computed tomography (CT) scanning (n = 36), US (n = 27), endoscopic US (n = 1), and magnetic resonance imaging (n = 1). In at least 20 cases, both US and CT scans were performed. A CT scan usually confirmed or completed the US findings and revealed a pancreatic/peripancreatic mass with or without diffuse pancreatic enlargement; this was true in all but 2 cases.

The masses ranged from cystic or hypodense masses to complex soft tissue masses or mixed solid/cystic masses. The CT data for the remaining cases indicated only diffuse pancreatic enlargement or small nodular lesions (< 1 cm) in the pancreas[24]. The pancreatic masses were 2-8 cm in diameter. Abdominal lymphadenopathy was detected as follows: peripancreatic LN (n = 9), retroperitoneal LN (n = 7), paraaortic/aortocaval LN (n = 4), porta hepatic/hepatic hilum LN (n = 4), mesenteric LN (n = 2), periportal LN (n = 2), unspecified abdominal LN (n = 2), celiac LN (n = 1), and splenic hilum LN (n = 1). Hepatomegaly and splenomegaly were noted in 10 and 9 patients, respectively. Concomitant hepatic and splenic granulomas and concomitant splenic and kidney granulomas were each observed in one patient. Other associated conditions included ascites (n = 3), extrahepatic bile duct obstruction and dilatation (n = 2), pancreatic duct dilatation (n = 1) or compression (n = 1), and ileocecal thickening (n = 1).

The diagnoses for the pancreatic TB cases are summarized in Table 1. FNA was attempted in 29 cases, but was successful in only 25 (86.2%), 2 of which did not include a documented AFB smear or mycobacterial culture. Only one specimen was successfully obtained using endoscopic US-guided aspiration[38], whereas the other specimens were obtained percutaneously[6,10,15,18,21,25-32,34-37]. In the cases in which AFB smears and/or mycobacterial cultures of the FNA specimens were conducted, 20 of 20 (100.0%) and 18 of 19 (94.7%), respectively, were positive. In the sole culture-negative FNA sample, *Mycobacterium tuberculosis* (*M. tuberculosis*) DNA was identified *via* the polymerase chain reaction (PCR) method. ATD susceptibility was studied in 9 samples, and only one was resistant to streptomycin; the others were sensitive to the prescribed first-line ATDs. PCR was performed in 4 cases, and all 4 were positive for *M. tuberculosis* DNA. The probability of positive results from at least one mycobacterial culture or AFB smear for body fluid (excluding the pancreatic mass) was 32.5% (13/40). In these cases, mycobacterial cultures of sputum (n = 8), blood (n = 3), bronchoalveolar lavage (n = 2), urine, ascites fluid, pleural effusion, stool, or preauricular LN (n = 1 for each) were taken, as were ABF smears of urine, bone marrow, or supraclavicular LN (n = 1 for each). Active pulmonary TB was documented in 9 cases.

The preoperative diagnoses made in all 15 cases in which laparotomies were conducted are summarized in Table 1. A provisional diagnosis of acute pancreatitis with a pseudocyst was made in one autopsy case[14]. Pancreatic TB was suspected in each of the cases in which FNA was performed; an AFB smear and/or mycobacterial culture was performed in each of these cases. The definitive diagnoses of pancreatic TB are listed in Table 1.

A laparotomy and/or FNA was performed in every case except for one that was diagnosed after autopsy and another in which a presumptive diagnosis was made based on an imaging study and a positive mycobacterial sputum culture[23]. There were 13 cases in which an exploratory laparotomy for a biopsy and/or open drainage was considered due to an uncertain diagnosis (n = 11) or a deteriorating tuberculous pancreatic abscess (n = 2). A distal pancreatectomy/ splenectomy was performed in one case for an unknown reason. In a second case, a Whipple's operation was performed to treat suspected pancreatic cancer.

Thirty-four patients received ATD treatment. The most commonly used treatment was a quadruple ATD regimen that consisted of isoniazid, rifampicin, pyrazinamide, and ethambutol (n = 15). The initial response to the ATDs usually occurred rapidly, manifesting between 72 h and 2 wk later; however, fever and cachexia occasionally persisted for years. The duration of ATD treatment ranged from 3 wk to 2 years. Of the 37 documented patients, 33 (89.2%) survived and were dischargeable after their admission. The remaining 4 patients deteriorated and died during their initial hospitalization (yielding a 10.8% in-hospital mortality rate) due to upper gastrointestinal bleeding[12], severe sepsis[14], viral meningoencephalitis[30], or an unreported cause (n = 1 for each)[31]. Twenty-four patients were followed from 3 wk to 32 mo (median, 9.50 mo), and 9 died during the follow-up period from AIDS-related causes, including full-blown AIDS (n = 5)[25,26], disseminated cryptococcosis[9], non-Hodgkin's lymphoma[2], pyogenic chest infection[18], and *Pneumocystis jirovecii* pneumonia (n = 1 for each)[7]. The probability of survival after discharge was determined *via* Kaplan-Meier analysis. A 35.9% long-term survival rate emerged with a median survival period of 18 mo. No recurrence of TB was found in the pancreas or in other organs. In 15 cases, follow-up abdominal imaging data were available. In all but one of these cases (the present case), the size of the pancreatic mass decreased. Antiretroviral drugs were prescribed in only 6 cases; most of the reports did not mention any antiretroviral treatment.

Pancreatic TB is extremely rare, even in countries in which TB is highly prevalent. Pancreatic TB most often occurs as a complication of miliary TB[9]. The low frequency of pancreatic TB may be partly due to the biological resistance of the pancreas to tubercular infection. Pancreatic enzymes, including lipases and deoxyribonucleases, have antimycobacterial effects[28]. However, the incidence of pancreatic TB has recently increased. In India, Bhansali did not discover a single case of pancreatic TB in a review of 300 cases of abdominal TB in 1977[39]; however, a recent study of collective data from 1999-2004 from the same endemic area detected pancreatic TB in 8.3% of the 384 patients who were diagnosed with abdominal TB[40]. Globalization, the HIV pandemic, and the worldwide resurrection of *M. tuberculosis* are all responsible for this increasing incidence[41]. Pancreatic TB typically presents in the following patient types: in patients who reside in endemic tuberculous zones, sporadically in no-risk healthy patients, and in patients who are immuno-compromised[26]. In AIDS cases, tuberculous pancreatic abscesses are most common, accounting for 70.0% of cases. In addition,

71.1% of cases include no previous serological evidence of HIV infection, and 76.2% of patients are severely immunocompromised hosts with a CD4 cell count of $\leqslant 190/mm^3$. If the diagnosis is delayed, pancreatic TB can be fatal; the disease has a 10.8% mortality rate (which is comparable to the mortality rate of 9.1% in immunocompetent patients)[42]. However, pancreatic TB responds well to standard ATDs.

Diagnosing pancreatic TB is challenging. From 1989-1998, 13 of 21 cases were diagnosed postoperatively or postmortem, although this was true for only 2 of 19 cases in subsequent years. This trend indicates increasing surgeon awareness of cases in HIV-infected patients. Pancreatic TB can be classified radiologically as follows: the most common form is mass-forming (with or without diffuse pancreatic enlargement) and accounts for 94.4% of cases, but there is also a diffuse form and a small, nodular form[24]. The masses can be radiographically similar to pancreatic tumors, abscesses, lymphomas, or pseudocysts. US scans of the abdomen are simple, non-invasive, cost-effective, and readily available; thus, they are usually used as an initial diagnostic tool and exhibit excellent sensitivity. Furthermore, US scans can reveal focal hypoechoic lesions[12,13,18,20,21,32,34,35,38] and heterogeneously hypo-isoechoic lesions[5,12,14,18] (primarily in the head of the pancreas), diffuse enlargement of the pancreas[14,20,23] and enlarged peripancreatic[12,21,25] and other abdominal LNs[2,11,18,20,21,31]. Based on the 90.6% sensitivity of association (half of all pancreatic TB patients are HIV-positive), Nagar *et al*[40] recommended that TB of the pancreas be a differential diagnosis for pancreatic masses associated with peripancreatic lymphadenopathy. Occasionally, biliary dilatation results from the obstruction of the common bile duct[18,35], pancreatic duct dilatation[12], air bubble(s) within the mass[12], encasement of the celiac artery, or compression of the portal vein with collaterals (as in the present case). Tubercular etiology should be suspected in the case of certain ancillary findings, including characteristic lesions in other solid viscera such as the liver, kidney, or spleen; hepatomegaly[12,31]; splenomegaly[12,31]; ascites[12,20]; peritoneal nodularity; mural thickening in the ileocecal area[20]; pulmonary TB[2,11,12,14,18,19,23,28,32]; or pleural effusion[14]. Because of its high sensitivity, a CT scan should be used to rule out associated pathology and to plan for further disease management. However, radiographic signs of pancreatic TB are neither specific nor pathognomonic, and most radiographic findings can be observed in pancreatitis of any cause or pancreatic carcinoma[20].

A definitive diagnosis is usually based on a histopathological or microbiological examination of a specimen that is obtained from the pancreas or based on peripancreatic LNs exhibiting chronic granulomatous inflammation with caseous necrosis and multinucleated giant cells. In addition, an AFB smear using Ziehl-Neelsen or auramine staining can also be employed for this purpose. Nevertheless, in pancreatic TB cases with advanced HIV-associated immunosuppression and AIDS, there is a striking paucity of granuloma formation with little cellular recruitment, and the AFB findings are copious[43]. In non-HIV-infected patients, the success rate of FNA in diagnosing pancreatic TB is 50.0% for specimens that are obtained percutaneously[42]. This rate is much lower than the 85.7% rate in HIV-infected cases in the present study, which reflects the operator-dependent nature of the procedure. Therefore, it is reasonable to attempt a second percutaneous image-guided FNA by a more experienced operator or an endoscopic US-guided FNA if the first attempt fails. The extremely high identification rate (100.0%) of acid-fast smears of FNA specimens from HIV-positive individuals, compared with the 23%-38% detection rate associated with mixed specimens from HIV-negative individuals[28,44], indicates the much higher pathogen burden and lower immunological response in these immunocompromised hosts. As a result, and given the simplicity and availability of the test and the rapid results that it produces, FNA with an acid-fast smear should be a required test for pancreatic TB with immunodeficiency. A PCR assay, when used to detect mycobacterial DNA, yields highly specific same-day results. Although its sensitivity to TB in FNA specimens has not yet been determined, the PCR assay is increasingly used as an adjunct to special staining techniques and mycobacterial cultures. It may yield positive results even when specimen cultures are negative[31,32].

In cases of AIDS with suspected pancreatic TB, mycobacterial smears and cultures from the sputum, bronchoalveolar lavage, blood, urine, stool, bone marrow, superficial LNs, ascites, or pleural effusion specimens should be performed due to the augmented yield of these sites. The more aggressive the investigation, the more likely it is that a primary infection will be discovered. In a study of abdominal TB in HIV infection, all of the cases exhibited at least one extraabdominal TB site (with 3.9 sample sites/case). The incidence of positive mycobacterial cultures from various sites was as follows; extraabdominal LNs (87%), sputum (82%), blood (74%), stool (63%), ascites (67%), bone marrow (56%), and urine (35%). Disseminated TB was present in 93% of cases[3]. Therefore, the total number of case reports of primary or isolated pancreatic TB may be overestimated, and it may thus be exceedingly rare.

In most cases of pancreatic TB, medication is the preferred treatment; surgery and the drainage of fluid are not preferred. A standard multiple ATD regimen with directly observed therapy for 6-12 mo is usually effective[5]. In the present case, the fluid was clear and sterile even though the pancreatic mass was subsequently further enlarged. However, if the tuberculous pancreatic mass is enlarged or causes symptoms even after the ATDs have been employed for a reasonable period, minimally invasive procedures should be considered. These might include percutaneous catheter drainage (preferably in patients with no pancreatic duct-pseudocyst communications and pancreatic duct strictures, those with immature

or infected pseudocysts, those at high surgical risk, or those who exhibit malnourishment)[45] or endoscopic internal drainage. Although the prognosis for this disease is good in immunocompetent patients (only 1 out of 58 cases that were reported in the Chinese-language literature resulted in death[41]), the prognosis is grave in AIDS patients due to the underlying disease[25], particularly in settings where antiretroviral therapy is unavailable[46].

Pancreatic TB is extremely rare, has various clinical presentations, and tends to masquerade as a pancreatic malignancy, cystic tumor, or pseudocyst. In HIV-infected patients, a differential diagnosis of a pancreatic mass that is combined with a histopathological and microbiological diagnosis *via* FNA can often prevent unnecessary surgery.

Acknowledgments to reviewers of *World Journal of Gastroenterology*

Many reviewers have contributed their expertise and time to the peer review, a critical process to ensure the quality of *World Journal of Gastroenterology*. The editors and authors of the articles submitted to the journal are grateful to the following reviewers for evaluating the articles (including those published in this issue and those rejected for this issue) during the last editing time period.

ISSN 1007-9327 (print) ISSN 2219-2840 (online)

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1352 experts in gastroenterology and hepatology from 64 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systemically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensuses and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing
Statistical review is performed after peer review. We invite an expert in Biomedical Statistics from to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Ridit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc*. The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

Conflict-of-interest statement
In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent
Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights
When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www.clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://www.wjgnet.com/1007-9327office. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no less than 256 words) and structured abstracts (no less than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no less than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections.

AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/…"; MATERIALS AND METHODS (no less than 140 words); RESULTS (no less than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 *vs* 3.61 ± 1.67, $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: …*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of *P* values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of *P* values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that...".

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed and http://www.crossref.org/SimpleTextQuery/, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in boldfaced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in boldfaced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*

Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*

Biology: *H. pylori*, *E coli*, *etc.*

Guidelines: http://www.wjgnet.com/1007-9327/g_info_20100312232134.htm

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be re-submitted online (http://www.wjgnet.com/1007-9327office/). The author should send the copyright transfer letter, responses to the reviewers, English language Grade B certificate (for non-native speakers of English) and final manuscript checklist to wjg@wjgnet.com.

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

WJG is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1300 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.

Abstract

Non-alcoholic fatty liver disease (NAFLD) includes a variety of histological conditions (ranging from liver steatosis and steatohepatitis, to fibrosis and hepatocarcinoma) that are characterized by an increased fat content within the liver. The accumulation/deposition of fat within the liver is essential for diagnosis of NAFLD and might be associated with alterations in the hepatic and systemic inflammatory state. Although it is still unclear if each histological entity represents a different disease or rather steps of the same disease, inflammatory processes in NAFLD might influence its pathophysiology and prognosis. In particular, non-alcoholic steatohepatitis (the most inflamed condition in NAFLDs, which more frequently evolves towards chronic and serious liver diseases) is characterized by a marked activation of inflammatory cells and the up-regulation of several soluble inflammatory mediators. Among several mediators, cytokines and chemokines might play a pivotal active role in NAFLD and are considered as potential therapeutic targets. In this review, we will update evidence from both basic research and clinical studies on the potential role of cytokines and chemokines in the pathophysiology of NAFLD.

Key words: Inflammation; Non-alcoholic fatty liver disease; Cytokine; Chemokine

INTRODUCTION

In the last decade, there has been a remarkable scientific effort to improve our understanding of the pathogenesis, diagnosis, and treatment of non-alcoholic fatty liver disease (NAFLD). Clinical studies revealed dramatically high prevalence of NAFLD worldwide[1,2]. Worrying data on the prevalence of NAFLD in children and adolescents was also revealed[3]. Importantly, in American adolescents followed in the National Health and Nutri-

tion Examination Survey between 1999 and 2004, serum elevation of hepatic enzymes [i.e., alanine aminotransferase (ALT)] was observed in 6% to 11% of subjects (depending of ethnicity)[4]. Furthermore, serum ALT increase was positively associated with waist circumference and insulin resistance, suggesting that NAFLD might be considered as the hepatic manifestation of other epidemic diseases, such as metabolic syndrome and obesity[1,2]. In fact, in obese children and adolescents, NAFLD affects about 20% to 74%, indicating that this disease might start early during life, providing more time for its deleterious evolution[5-7]. However, we believe that NAFLD is limited to patients suffering from obesity, metabolic syndrome, or other fat-related diseases. Although NAFLD has been described as an increased hepatic accumulation of fat (steatosis), a recent scientific consensus defined it as a complex spectrum of diseases, ranging from asymptomatic steatosis with possible aminotransferase alterations to non-alcoholic steato-hepatitis (NASH), cirrhosis, and also hepatocellular carcinoma[8-10]. Whether these conditions are different stages of a common progressive disease or should be considered as different entities, is still an open question. Thus, additional pathophysiological studies on improved animal models are needed to clarify this issue. Indeed, NAFLD is often underestimated, under diagnosed, and not treated in the current medical practice; therefore, its pathophysiological history is at risk of remaining a mystery for several years.

At present, the most suitable area for improving our knowledge of the pathophysiology of NAFLD is represented by the chronic inflammation that underlies all NAFLD entities/stages[11]. Soluble cytokines and chemokines, regulating inflammatory cell function and survival, could be considered as very promising candidates. On the other hand, hormonal axes, adipocytokines, and growth factors have also received attention from NAFLD scientists. In the following paragraphs, we focus on cytokines and chemokines, updating evidence of their role in NAFLD pathophysiology, both in human (Table 1) and animal studies.

CYTOKINES

Cytokines are soluble molecules that are involved in intercellular communication and are produced by a wide variety of cells in the body, including most types of liver cells[12]. They comprise several subfamilies, including interferons, interleukins, tumor necrosis factors (TNF), transforming growth factors (TGF), colony-stimulating factors, and chemokines. Cytokines mediate several fundamental biological processes, including body growth, adiposity, lactation, hematopoiesis, as well as inflammation and immunity. However, they are also implicated in various pathologies, such as atherosclerosis, rheumatoid arthritis, systemic lupus erythematosus, psoriasis, as well as NAFLD[13-16].

Under physiological conditions, constitutive cytokine generation is absent or minimal in the liver. Nevertheless, pathological stimuli like lipid accumulation induces hepatic cells to produce these inflammatory molecules. Cytokines might play an active role in the development and the potential progression of NAFLD through stimulation of hepatic inflammation, cell necrosis and apoptosis, and induction of fibrosis. Nevertheless, they are also essential for liver regeneration following injury[16]. Evidence on the pathophysiological role of cytokine in NAFLD is reported and discussed below.

TNF-α

TNF-α is an inflammatory mediator secreted by several inflammatory cell types, including monocyte/macrophages, neutrophils, and T-cells, but also by many other tissues, such as the endothelium, adipose tissue, or neuronal tissue. In the liver, TNF-α is secreted directly by hepatocytes and Kupffer cells or indirectly by abdominal fat[17]. Several studies have shown that TNF-α is a key factor in the development of NAFLD and NASH in both humans and animals. Hotamisligil *et al*[18] showed for the first time a relationship between TNF-α expression and insulin resistance in NASH. The authors stated that adipose tissue represents an important source of obesity-induced inflammation, notably by the expression of TNF-α, which can induce inflammation and insulin resistance. Indeed, in several rodent models of obesity, TNF-α expression in adipose tissue was upregulated as compared to controls[18]. Accordingly with these study, obese mice lacking TNF-α showed an improved insulin sensibility[19]. Recently, mice treated with the anti-TNF-α drug thalidomide showed some improvements in the hepatic alterations mediated by a high-fat diet[20]. Moreover, the use of anti-TNF-α antibodies in an experimental model of NASH decreased inflammation, necrosis, and fibrosis in rats[21].

Although TNF-α inhibition in animal models of NAFLD presents encouraging therapeutic perspectives, in humans, the role of this cytokine remains controversial. In patients, TNF-α levels were shown to be higher in obese than in lean individuals, and were correlated with insulin resistance[22,23]. Moreover, a positive correlation was observed between the degree of liver fibrosis and circulating TNF-α levels in patients with NASH[24]. Another study showed increased TNF-α expression in the liver and adipose tissue in NASH patients with significant fibrosis in comparison with those with a slight or nonexistent fibrosis[25]. More recently, Hui *et al*[26] strengthened these results, showing increased TNF-α levels in subjects with steatohepatitis as compared to controls. The potential involvement of TNF-α in NAFLD pathophysiology was recently suggested by genetic studies on its polymorphisms[27,28]. Moreover, treatment with pentoxifylline (a molecule inhibiting TNF-α) decreased the serum levels of aminotransferases and displayed hepatic beneficial effects in patients with NASH[29].

Nevertheless, the involvement of TNF-α in insulin resistance and NAFLD is questionable. Some studies did

NAFLD: Non-alcoholic fatty liver disease; NASH: Non-alcoholic steato-hepatitis; TNF: Tumor necrosis factor; TGF: Transforming growth factor; IL: Interleukin; MCP: Monocyte chemotactic protein; RANTES: Regulated on activation normal T-cell expressed and secreted; Mig: Monokine induced by interferon-γ; IR: Insulin resistance; IGT: Impaired glucose tolerance; NIDDM: Noninsulin-dependent diabetes mellitus; ALT: Alanine aminotransferase; HCV: Hepatitis C virus.

not show any correlation between insulin resistance and TNF-α levels[30,31], whereas two clinical studies, using an antagonist and an anti-TNF-α antibody, did not show any improvements in insulin sensitivity[32,33]. Moreover, in a recent study, Lucero *et al*[34] did not observe any difference in circulating levels of TNF-α between patients with NAFLD as compared to controls without NAFLD.

TGF-β

TGF-β is a cytokine/growth factor with immunosuppressive, anti-inflammatory, and pro-fibrotic properties[35]. In the liver, TGF-β1 is the most abundant isoform, and it is secreted by immune cells, stellate cells, and epithelial cells[36]. TGF-β1 plays a pivotal role in hepatic fibrosis by mediating the activation of stellate cells and their production of extracellular matrix proteins[37-39]. Indeed, Kupffer and stellate cells produce TGF-β1, which induces the transformation of resting stellate cells to myofibroblasts[40]. In experimental models of hepatic fibrosis induced by CCl_4 or schistosomiasis, expression of TGF-β1 is upregulated[41-43]. Moreover, in patients with liver fibrosis, the expression of TGF-β1 mRNA is increased[40,44,45]. Stärkel *et al*[46] showed that the upregulation of TGF-β1 is an early molecular step in the progressive fibrotic steatohepatitis. A study by Hasegawa and co-workers showed that TGF-β1 levels were increased in patients with NASH as compared to hepatic steatosis. Thus, the measurement of serum levels of TGF-β1 might be useful to distinguish NASH patients in the spectrum of NAFLD[47]. Moreover, polymorphisms that induce high angiotensinogen and TGF-β1 are associated with advanced hepatic fibrosis in obese patients with NAFLD[48].

Interleukin-6

The role of interleukin-6 (IL-6) in liver pathology is very complex, and its participation in the development of NAFLD remains unclear. IL-6 activates several cells, such as immune cells, hepatocytes, hematopoietic stem cells, and osteoclasts[49]. Furthermore, IL-6 has a wide range of biological functions, including induction of inflammation and oncogenesis, regulation of immune response, and support of hematopoiesis[49]. IL-6 was initially considered as a hepatoprotector in liver steatosis, capable of reducing oxidative stress and preventing mitochondrial dysfunction[50,51]. Furthermore, this potential hepatoprotective effect of IL-6 was confirmed in other models of liver disease, such as ischemic preconditioning models and in liver regeneration after partial hepatectomy in mice[52-55].

Nevertheless, IL-6 is a key element in the acute phase response, mediating the synthesis of several acute phase proteins (such as C-reactive protein and serum amyloid A)[56]. Thus, we cannot exclude the possibility that IL-6 might also play an indirect deleterious role in NAFLD pathogenesis. In diet-induced obese mice, treatment with IL-6 antibodies improved sensitivity to insulin[57]. Furthermore, IL-6 is considered as a predictor marker of insulin resistance and cardiovascular diseases. In patients undergoing bariatric surgery, decreased IL-6 concentrations were associated with weight loss and insulin resistance improvement[58]. Serum IL-6 levels are higher in animal models and patients with NAFLD[59-61]. Recently, Mas and co-workers showed that diet-induced NASH was reduced in IL-6 knockout mice as compared to controls[62]. In humans with NASH, a positive correlation between IL-6 expression in hepatocytes and the severity of NAFLD was observed [63].

Thus, although IL-6 could improve hepatic regeneration and repair, it could also sensitize the liver to injury, stimulate hepatocyte apoptosis, induce insulin resistance, and participate in NASH development. Recent studies from Yamaguchi illustrated this paradoxical role of IL-6 in NAFLD. Indeed, IL-6 pathway neutralization with tocilizumab, a specific antibody against the IL-6 receptor, enhanced hepatic steatosis, but improved liver damage in mice with methionine choline deficient (MCD) diet-induced NASH[64]. Furthermore, Yamaguchi *et al*[65], in

a second study, showed that not only upregulation of IL-6, but also severe suppression of hepatic IL-6/signal transducer and activator of transcription 3 signaling may lead to the progression of NASH.

IL-10

IL-10 is considered as an anti-inflammatory cytokine that regulates the inflammation in several organs and tissues in physiological or pathological situations[66]. It inhibits T cell-, monocyte-, and macrophage-mediated functions. In the liver, IL-10 has been detected in several cells, including hepatocytes, stellate cells, and Knuppfer cells, but only few studies have been performed to investigate the role of endogenous IL-10 in the progression of NAFLD. A study using IL-10-deficient mice fed on high fat diet, suggested that endogenous IL-10 was protective for hepatic steatosis, but not for concomitant insulin resistance[67]. In another study, Cintra and co-workers observed that the inhibition of IL-10 (either using an anti-IL-10 antibody or an IL-10 antisense oligonucleotide) led to increased expression of pro-inflammatory markers (TNF-α, IL-6, IL-1β, and F4/80) and impaired insulin signal transduction and steatosis[68]. In humans, Esposito and co-workers showed an inverse correlation between IL-10 levels and metabolic syndrome in obese woman, suggesting a potential IL-10-mediated benefit in metabolic syndrome patients also affected by NAFLD[69]. However, Calcaterra *et al*[70] did not confirm this association in obese children and adolescents.

CHEMOKINES

Chemokines (chemotactic cytokines) are small heparin-binding proteins known to induce mainly leukocyte trafficking, growth, and activation in inflammatory sites[71,72]. Many cell types, including endothelial cells, smooth muscle cells, leukocytes, hepatocytes, and stellate cells, can secrete them. Approximately 50 currently identified chemokines are classified in four subfamilies (C, CC, CXC, CX_3C) according to their structural arrangement of N-terminal conserved cysteine residues. Chemokines need to bind to their coupled seven transmembrane protein G coupled receptors on target cells to induce cellular changes. Chemokines and their receptors have been implicated in multiple inflammatory diseases, such as atherosclerosis, multiple sclerosis, psoriasis, and insulin resistance[73]. Expression of several chemokines and chemokine receptors has been shown to be upregulated in the livers of obese patients with severe steatosis and NASH[74]. Inflammatory processes are crucial in the potential progression of NAFLD; therefore, chemokines might also play a pivotal role in NAFLD pathophysiology[75].

CCL2/monocyte chemotactic protein-1

CCL2 is a potent chemoattractant that is principally secreted by macrophages and, to a lesser extent, by activated endothelial cells, smooth muscle cells, and hepatic stellate cells[76-79]. It activates target cells (mainly macrophages) through binding with its receptor, CCR2[76-79]. It is widely secreted in adipose tissue and plasma of obese mice[80]. Monocyte/macrophage infiltration in adipose tissue has been observed in animal models and humans[81]. Monocyte/macrophage accumulation in the steatotic liver was reduced in mice fed on high-fat diet and who were deficient for *CCL2* or *CCR2* genes[82]. However, the role of CCL2 is actually more complex, extending far beyond the monocyte/macrophage chemoattractant effect. For instance, low density lipoprotein receptor and CCL2 double knockout mice showed alterations in glucose and lipid metabolism induced by high-fat diet[83]. When fed with a normal chow diet, these mice are characterized by lower alterations in the lipid and glucose profile. However, obesity is also reduced under normal diet, suggesting that different food intake might regulate CCL2-mediated inflammation in mice prone to develop obesity and atherosclerosis. Importantly, CCL2 deficiency in mice fed on a high-fat diet decreases insulin resistance and hepatic steatosis[84]. On the other hand, mice overexpressing CCL2 in adipose tissue presented increased insulin resistance and hepatic triglyceride levels[84].

Interestingly, CCL2 was also upregulated in the livers of animals with high-fat diet-induced NASH[85]. This pathophysiological aspect of CCL2 directly contributed to the lipid accumulation in hepatocytes *via* the activation of peroxisome proliferator-activated receptor α gene expression[86]. More recently, Obstfeld and co-workers showed that hepatic myeloid cells might play a crucial role in the promotion of obesity-induced hepatic steatosis. Indeed, they observed that obesity upregulates CCL2 expression in hepatocytes, leading to the recruitment of CCR2-positive myeloid cells and thus, promoting hepatosteatosis[87]. Pharmacological treatments inhibiting the CCL2/CCR2 pathway in several mouse models of metabolic diseases significantly improved obesity, insulin resistance, hepatic steatosis, and inflammation in the adipose tissue[88-90]. These benefits were not confirmed by other studies. For example, CCL2 deletion in an experimental model of MCD diet-induced steatosis did not improve liver fat accumulation and associated inflammation[91].

In humans, only few studies have been performed to investigate the role of CCL2 in NAFLD pathology. Haukeland *et al*[61] showed that patients with NAFLD had low-grade systemic inflammation and presented with higher serum levels of CCL2 compared to controls. Moreover, CCL2 has been confirmed to also be elevated in the steatotic livers of NAFLD patients[92]. More recently, another study showed that CCL2 expression was positively correlated with liver fat content in patients with NAFLD[93]. These studies suggest an important participation of CCL2 in the potential progression of simple steatosis to NASH. Therefore, although the role of CCL2 in metabolic diseases requires further investigation, these studies suggest a potential direct role of CCL2 in NAFLD and, in particular, in NASH.

CCL5/regulated on activation normal T-cell expressed and secreted

CCL5 is involved in several chronic immune-inflammatory diseases, such as atherosclerosis, acute myocardial infarction, myocarditis, rheumatoid arthritis, and multiple sclerosis[94,95]. It is secreted by various cells, such as endothelial cells, smooth muscle cells, macrophages, or hepatic stellate cells. This chemokine is mainly involved in migration of T cells, monocytes, neutrophils, and dendritic cells through binding to its cognate transmembrane receptors, CCR1, 3 and 5. The receptor CCR5 has been identified on isolated hepatic stellate cells, suggesting that these hepatic cells are both the target and source of CCL5[96,97]. The association of CCL5 with NAFLD was shown recently in humans and mice. Indeed, two studies showed that obesity increased hepatic expression of CCL5 in a murine model of NASH and in obese patients[98,99]. Hepatocytes are the major source of serum and hepatic CCL5 in NAFLD[100]. CCL5 release in the liver is mediated by hepatocellular lipid accumulation, suggesting that hepatic steatosis *per se* has pathophysiological relevance[100]. CCL5 is also involved in the progression of hepatic fibrosis in mice *via* CCR1 and CCR5 triggering[97]. More recently, Berres and co-workers defined CCL5 as a critical mediator of experimental liver fibrosis. Indeed, antagonism of CCL5 on receptor CCR5 improved experimental liver fibrosis in mice, indicating that CCL5 is a promising therapeutic target to reduce NAFLD[101].

CXCL8/IL-8

CXCL8/IL-8 is a CXC chemokine produced by several cell types, including inflammatory and endothelial cells[102]. The major role of this chemokine is to orchestrate neutrophil recruitment within inflamed tissues. There is little data documenting its potential role in NAFLD. Serum levels of CXCL8 were significantly higher in subjects with NASH as compared to hepatosteatosis or healthy control group[103,104]. More recently, Jarrar and co-workers showed that serum levels of CXCL8 were higher in NAFLD patients as compared to obese and non-obese patients[105]. In addition, CXCL8 serum levels were independently associated with NASH[105]. Conversely, the study from Abiru and co-workers did not confirm this association or any significant differences in serum CXCL8[106].

Other CXC chemokines

Chemokines CXCL9/monokine induced by interferon-γ, and CXCL10/interferon inducible protein-10, which bind the common receptor CXCR3, are generally not detectable in most non-lymphoid tissues under physiological conditions. However, in some inflammatory conditions, interferon gamma might increase their release. CXCR3 is found at high levels on activated T cells, memory T cells, and natural killer cells[107]. CXCL9 and CXCL10 mainly induce the migration of these cell types. In the liver, endothelial cells highly express CXCL9 leading to the transmigration of the CXCR3-expressing lymphocytes[108]. Recently, high levels of CXCL9 were found in the livers of patients with NASH[109]. In this study, Wasmuth and co-workers identified the CXCL9-CXCR3 axis as a potential anti-fibrotic pathway in the liver in both humans and animals.

CONCLUSION

The take-home message of the present update on the inflammatory pathophysiology of NAFLD do not recommend any optimistic insights for the near future. Much research remains to be done to clarify the pathophysiology of NAFLD and to identify selective targets for treatment. The involvement of cytokines and chemokines and their receptors in the pathogenesis of NAFLD is only partially understood. Although the first studies attempting therapeutic strategies targeting the chemokine system have been recently published, we believe that scientific interest in NAFLD should be increased. In particular, effort is required to improve the consideration of NAFLD as a dangerous condition that should not be underestimated or by-passed. Another crucial aspect is represented by the identification of common cytokines and chemokines between NAFLD and metabolic or cardiovascular diseases. The most promising mediators (such as TNF-α, CCL2 and CCL5) also require more selective inhibitory drugs to safely improve NAFLD, limiting the potential risk of deleterious immune-suppression.

Abstract

In the past 15 years, we have seen few therapeutic advances for patients with pancreatic cancer, which is the fourth leading cause of cancer-related death in the United States. Currently, only about 6% of patients with advanced disease respond to standard gemcitabine therapy, and median survival is only about 6 mo. Moreover, phase Ⅲ trials have shown that adding various cytotoxic and targeted chemotherapeutic agents to gemcitabine has failed to improve overall survival, except in cases in which gemcitabine combined with erlotinib show minimal survival benefit. Several meta-analyses have shown that the combination of gemcitabine with either a platinum analog or capecitabine may lead to clinically relevant survival prolongation, especially for patients with good performance status. Meanwhile, many studies have focused on the pharmacokinetic modulation of gemcitabine by fixed-dose administration, and metabolic or transport enzymes related to the response and toxicity of gemcitabine. Strikingly, a phase Ⅲ trial in 2010 showed that, in comparison to gemcitabine alone, the FOLFIRINOX regimen in patients with advanced disease and good performance status, produced better median overall survival, median progression-free survival, and objective response rates. This regimen also resulted in greater, albeit manageable toxicity.

INTRODUCTION

In 2010, there were an estimated 43 140 new cases and 36 800 deaths from pancreatic cancer in the United States[1]. This represents the 10th most common new cause of cancer and the fourth most common cause of cancer-related death in 2010, highlighting the disproportionate mortality associated with this disease. Additionally, unlike most of the more frequent causes of cancer mortality (lung, colon, prostate, and breast), whose death rates are declining, the death rate for pancreatic cancer has remained relatively stable, which also indicates the limited progress in this field.

Data from the 2000-2007 Surveillance, Epidemiology and End Results registry indicate that at diagnosis, the majority of pancreatic cancer is advanced (50.5% metastatic, 8% localized, 25.9% regional spread, and 15.5% unstaged)[2]. Only 15%-20% of patients are eligible for

surgery at diagnosis[3]. Standard surgical procedures include pancreaticoduodenectomy (stomach-or pylorus-preserving) for tumors of the pancreatic head, and distal pancreatectomy with splenectomy for tumors arising in the body or tail of the pancreas[4]. Although radical resection alone, or in combination with other therapy, is the only way to eradicate the disease, only 10%-20% of patients who have radical resection survive beyond 5 years, underscoring the need for better preoperative staging and more effective systemic therapy.

This article reviews a variety of clinical trials for locally advanced or metastatic pancreatic cancer, including those using cytotoxic drugs and targeted agents, to evaluate if gemcitabine (Gem) should still remain the standard chemotherapy for advanced or metastatic pancreatic cancer after 15 years of developments in this field. We also briefly discuss the pharmacokinetic modulation by fixed-dose administration and metabolic or transport enzymes, related to the response and toxicity of Gem.

PALLIATIVE CHEMOTHERAPY IN PANCREATIC THERAPY

5-Fluorouracil

5-Fluorouracil (5-FU) was considered the only chemotherapeutic option for about 20 years until the development of Gem. A systematic review and meta-analysis of nine trials from the American Society of Clinical Oncology (ASCO) 2003, which compared 5-FU-based combination to best support care, showed positive results in overall survival (OS) (6.38 mo *vs* 3.87 mo, $P < 0.0001$)[5].

Gem

Single agent Gem: Gem became the standard regimen for advanced pancreatic cancer after a randomized trial in 1997 that presented significant improvements in median OS compared to 5-FU (5.6 mo *vs* 4.4 mo, $P = 0.002$). One hundred and twenty-six untreated pancreatic cancer patients randomly received either 5-FU (600 mg/m^2 once weekly) or Gem (1000 mg/m^2 weekly × 7 with 1 wk off, followed by weekly × 3 wk every 4 wk). The clinical benefit response (CBR) also significantly improved in Gem-treated patients (23.8% *vs* 4.8%, $P = 0.0022$)[6].

Fixed-dose Gem: There has been some evidence suggesting that maintaining a constant dose rate of Gem with a fixed dose rate regimen (FDR) may improve outcomes[7-9]. An initial trial was done by Tempero and colleagues to test this hypothesis. Patients were administered either 2200 mg/m^2 Gem over 30 min (standard arm) or 1500 mg/m^2 Gem over 150 min (FDR arm) on days 1, 8 and 15 of every 4-wk cycle. Patients treated with FDR had a trend towards improved survival (8 mo *vs* 5 mo, $P = 0.013$) but more severe adverse events, namely hematological toxicity[10]. However, a subsequent phase Ⅲ Eastern Cooperative Oncology Group (ECOG) trial failed to demonstrate a statistically significant improvement in OS of Gem FDR regimen over the standard administration (6.2 mo *vs* 4.9 mo)[11].

Biomarkers of Gem: Gem is a specific analog of the pyrimidine nucleotide deoxycytidine, and a prodrug that requires cellular uptake and intracellular phosphorylation[12]. Gem intracellular uptake is mainly mediated by the human equilibrative nucleoside transporter (hENT1) and to a lesser extent, by human concentrative nucleoside transporters (hCNTs), hCNT1 and hCNT3. Gem is phosphorylated to its monophosphate form by deoxycytidine kinase (dCK), and this step is essential for further phosphorylation to its active triphosphate form. The active diphosphate metabolite of Gem is also active and inhibits DNA synthesis indirectly by inhibiting ribonucleotide reductase (RRM1). Gem is inactivated by deoxycytidine deaminase (CDA) and deoxycytidylate deaminase into 2',2'-difluorodeoxyuridine[13]. Many studies have demonstrated the relationship between Gem metabolic or transport enzymes and clinical outcome.

In clinical studies of pancreatic cancer, the high expression of hENT1 in tumors has been associated with improved survival in patients treated with Gem[14-16]. In the RTOG 9704 trial, 538 patients were randomly assigned to groups that were given either Gem or 5-FU after surgical resection. Immunohistochemistry analysis showed that hENT1 expression was associated with OS and disease-free survival (DFS) in the group given Gem ($P = 0.004$ and $P = 0.003$, respectively), whereas hENT1 expression was not associated with survival in the group given 5-FU.

The relationship between the expression of dCK, RRM1, and efficacy of Gem is inconsistent[17-24]. A study reported in ASCO 2011 evaluated the association of hENT1, dCK and RRM1 with efficacy of Gem in 434 patients with resected pancreatic cancer. In multivariate models, Gem was associated with better OS in hENT1 high tumors [$n = 163$; hazard ratio (HR): 0.44, 95% CI: 0.28-0.69, $P < 0.001$] and in dCK high tumors ($n = 302$; HR: 0.57, 95% CI: 0.41-0.78, $P = 0.001$). In contrast, in dCK low tumors ($n = 114$, $P = 0.73$) and in hENT1 low tumors ($n = 249$, $P = 0.66$), patients derived no benefit from Gem[25]. Fujita *et al*[17] also showed high dCK expression groups had a significantly longer DFS in the Gem-treated group ($P = 0.0067$).

Several reports have demonstrated that the genotype of degradation enzymes such as CDA, is related to Gem-mediated severe adverse reactions[26-30]. Major contributing factors for Gem clearance are genetic polymorphisms of CDA. The CDA 208AA homozygote allele and its related haplotype, is associated with severe drug toxicity in Japanese cancer patients after Gem-based chemotherapy. However, Tanaka *et al*[30] from MD Anderson Cancer Center have shown that the CDA A-76C genotypes were significantly associated with grade 3/4 neutropenia ($P = 0.020$).

S-1

S-1 is an oral fluorinated pyrimidine, which contains tegafur, gimeracil, and oteracil in a molar ratio of 1:0.4:1[31-32].

Tegafur, a prodrug of 5-FU, is gradually converted to 5-FU by hepatic microsomal enzymes. Gimeracil inhibits the degradation of 5-FU by inhibiting dihydropyrimidine dehydrogenase; oteracil is a competitive inhibitor of orotate phosphoribosyltransferase that inhibits phosphorylation of 5-FU in the gastrointestinal tract to reduce the gastrointestinal toxicity associated with 5-FU.

Two phase Ⅱ trials of S-1 in untreated patients with metastatic pancreatic cancer have shown that this appears to be an active and well-tolerated drug[33,34]. A randomized, open-label, three-arm, phase Ⅲ study (GEST) was reported in ASCO 2011, in which 834 chemotherapy-naive unresectable advanced pancreatic cancer patients with an ECOG performance status (PS) of 0-1 were randomly assigned to receive Gem (1000 mg/m^2, days 1-8 and 15, q4w), S-1 (80/100/120 mg/d based on BSA, days 1-28, q6w), or GS (Gem 1000 mg/m^2, days 1 and 8 plus S-1 60/80/100 mg/d based on BSA, days 1-14, q3w)[35]. S-1 was confirmed to be non-inferior to Gem with respect to OS (9.7 mo *vs* 8.8 mo, $P < 0.001$). Response rate (RR) was 13.3% and 21.0%, respectively. Grade 3/4 hematological toxicities were more common in the Gem arm (neutropenia 41.0% *vs* 8.8%, thrombocytopenia 11.0% *vs* 1.5%), while digestive toxicities were more common in the S-1 arm (anorexia 7.3% *vs* 11.4%, diarrhea 1.1% *vs* 5.5%). This is the first trial demonstrating that oral S-1 has similar efficacy and tolerable toxicity to Gem. Therefore, its potential as a first-line treatment for pancreatic cancer warrants further study.

Gem-based combination chemotherapy

Due to the dissatisfactory results of single-agent Gem for advanced pancreatic cancer, a variety of phase Ⅲ trials have been initiated to investigate the efficacy and toxicity of Gem-based combination therapy (Table 1).

Gem and FU: Two phase Ⅲ trials which compared Gem plus FU with single-agent Gem in patients with advanced disease did not show any benefit in terms of survival[36,37]. In a phase Ⅲ ECOG trial, 322 patients with advanced pancreatic cancer were randomized into groups treated with Gem alone or Gem combined with 5-FU. OS was 5.4 mo for Gem and 6.7 mo for Gem plus FU ($P = 0.09$). Progression-free survival (PFS) was 2.2 mo *vs* 3.4 mo ($P = 0.022$).

Gem and capecitabine: Capecitabine is an orally administered fluorouracil pro-drug, which is activated by a three-step targeted process (carboxylesterases, cytidine deaminase, and thymidine phosphorylase). This drug mimics the continuous infusion of 5-FU, and its intratumoral activation improves the therapeutic index and reduces toxicity in normal tissue[38-40].

A phase Ⅲ trial conducted by Herrmann and colleagues randomized 319 patients into a Gem (1000 mg/m^2 on days 1 and 8) plus capecitabine (1300 mg/m^2 on days 1-14 every 21 d) (GemCap) arm, or a standard Gem arm. OS was not statistically significant different between the two arms (8.4 mo *vs* 7.2 mo, $P = 0.23$). Only subgroup analysis of patients with good PS (Karnofsky performance status 90-100) showed significant prolongation of median OS in the GemCap arm compared to the Gem arm (10.1 mo *vs* 7.4 mo, respectively, $P = 0.014$)[41]. In addition, a more recent analysis of the CBR and quality of life (QOL) did not disclose differences between the two treatment arms[42]. In the more recently reported United Kingdom Phase Ⅲ trial, a higher dose intensity of Gem (12% higher) and capecitabine (44% higher) was used in 533 patients. GemCap significantly improved objective response rate (ORR) (19.1% *vs* 12.4%; $P = 0.034$) and PFS (5.3 mo *vs* 3.8 mo, $P = 0.004$), and was associated with a trend towards improved OS (7.1 mo *vs* 6.2 mo, $P = 0.08$) compared with Gem alone[43]. A meta-analysis of these two studies revealed a survival benefit for GemCap combination (HR: 0.86; 95% CI: 0.75-0.98).

Gem and S-1: In the GEST trial, 454 patients were enrolled in the Gem arm or GS arm[35]. There was no significant difference in OS between these two treatment groups (8.8 mo *vs* 10.1 mo, $P = 0.15$), but PFS differed significantly (4.1 mo *vs* 5.7 mo, $P < 0.0001$). RR was 13.3% and 29.3% for the Gem and GS arms, respectively. The EQ-5D QOL score in the GS arm was significantly better than that in the Gem arm ($P = 0.003$). This trial suggests that GS contributes to a better QOL. Further clinical investigations are needed to ensure its efficacy.

Gem and platinum derivatives: Platinum derivatives are frequently used in combination schedules to treat pancreatic cancer[44-47]. Encouraging results have been obtained in several phase Ⅱ trials using Gem combined with cisplatin, with a RR ranging from 11.5% to 26.0%, and median OS ranging from 7.1 mo to 8.2 mo[44-46]. The following phase Ⅲ trial conducted by Colucci and colleagues did not present a benefit in survival for combination treatment (7.5 mo *vs* 6.0 mo, $P = 0.43$), despite a marked improvement in RR (26.4% *vs* 9.2%, $P = 0.02$) and time to progression (TTP) (4.6 mo *vs* 1.8 mo, $P = 0.048$)[48]. Recently, Colucci and colleagues reported another phase Ⅲ trial with the same regimen. There, the improvement in PFS and RR disappeared when the number of patients increased from 107 to 400[49]. Another randomized phase Ⅲ trial conducted by Heinemann *et al*[50] also did not demonstrate statistically significant differences in OS (7.5 mo *vs* 6.0 mo , $P = 0.15$), PFS (5.3 mo *vs* 3.1 mo , $P = 0.053$) and RR (10.2% *vs* 8.2%).

The French Multidisciplinary Clinical Research Group in Oncology (GERCOR) conducted a phase Ⅱ study of Gem and oxaliplatin (GemOx) in 64 patients with advanced or metastatic pancreatic cancer[51]. The encouraging results (PFS 5.3 mo, OS 9.2 mo) in this study prompted the initiation of a phase Ⅲ trial, conducted by both GERCOR and the Italian Group for the Study of Gastrointestinal Tract Cancer. In this phase Ⅲ study, GemOx was superior in terms of PFS (5.8 mo *vs* 3.7 mo, $P = 0.04$), RR (26.8% *vs* 17.3%, $P = 0.04$), and clinical

Table 1 Gem combined chemotherapy regimens

OS: Overall survival; PFS: Progression-free survival; RR: Response rate; Gem: Gemcitabine; NR: Not reported; NS: Not significant.

benefit (38.2% *vs* 26.9%, $P = 0.03$) in both the metastatic and locally advanced population[52]. However, median OS did not significantly improved (9.0 mo *vs* 7.1 mo, $P = 0.13$). The largest trial, the ECOG 6201 trial which was mentioned earlier, showed that the median OS was 4.9 mo for the standard Gem arm, and 5.7 mo for the GemOx arm. These differences were not statistically significant, and GemOx caused higher rates of neuropathy, nausea and vomiting[11].

Gem and pemetrexed: Pemetrexed is a multi-targeted antifolate that has synergistic activity with Gem[53]. Miller *et al*[54] reported an OS of 6.5 mo, and a median time to treatment failure (TTF) of 4 mo in a phase Ⅱ trial of pemetrexed as a single agent therapy for advanced pancreatic cancer. A phase Ⅲ trial was carried out in 565 advanced pancreatic patients who were randomly assigned to either Gem plus pemetrexed (PG) or Gem alone. No significant differences between the two treatment arms were observed in terms of OS (6.2 mo *vs* 6.3 mo, $P = 0.85$) and PFS (3.9 mo *vs* 3.3 mo, $P = 0.11$), although RR was significantly better in the PG arm (14.8% *vs* 7.1%, $P = 0.004$), although hematologic toxicity was significantly more common in this arm as well[55].

Gem and topoisomerase inhibitors: Irinotecan (CPT-11) and exatecan are the most widely used topoisomerase inhibitors[56,57]. The first phase Ⅱ trial to evaluate the combination regimen of irinotecan with Gem showed a median survival of 5.7 mo and a median TTP of 2.8 mo[58]. A subsequent phase Ⅲ study failed to improve OS (6.4 mo *vs* 6.5 mo, $P = 0.970$), TTP (2.8 mo *vs* 2.9 mo, $P = 0.795$) and tumor RR (15% *vs* 10%, $P = 0.387$). The incidence of grade 3 diarrhea was higher in the combination group, but grade 3/4 hematologic toxicity and QOL were similar[59]. Another topoisomerase inhibitor, exatecan (DX-8951f), was studied in a randomized phase Ⅲ trial and was shown to be inferior to Gem in respect to RR and improvement in QOL[60]. Furthermore, the combination of exatecan and Gem failed to show any significant survival benefit over Gem alone in a phase Ⅲ study (6.7 mo *vs* 6.2 mo, $P = 0.52$)[61]. Patients in the combination treatment arm experienced significantly more grade 3/4 toxicity, in particular neutropenia (30% *vs* 15%, $P = 0.001$), thrombocytopenia (17% *vs* 5%, $P = 0.004$), and vomiting (11% *vs* 5%, $P = 0.04$).

Meta-analysis

To overcome the statistical limitation of the individual trials, a meta-analysis was performed to investigate the treatment effects of combination regimens.

In 2007, Sultana and colleagues reported a systematic review and meta-analysis of 4060 patients, comparing Gem-based combination chemotherapy with Gem alone in patients with locally advanced and metastatic pancreatic cancer[62]. OS was significantly better for combination chemotherapy (HR: 0.91; 95% CI: 0.85-0.97), and results from subgroup analysis suggested a survival advantage for Gem combined with either a platinum agent (HR: 0.85; 95% CI: 0.74-0.96) or capecitabine (HR: 0.83; 95% CI: 0.72-0.96), although there was insufficient evidence to support combinations of Gem with either 5-FU (HR: 0.98; 95% CI: 0.86-1.11) or irinotecan (HR: 1.01; 95% CI: 0.84-1.22). Another meta-analysis conducted by Banu and colleagues, which included 5886 patients with advanced pancreatic cancer, showed a small but significant improvement in OS for patients receiving Gem-based doublets compared to Gem alone[63]. In addition, a meta-analysis conducted by Heinemann and colleagues, which included 4465 patients, also revealed a significant survival benefit for Gem combination chemotherapy, with a pooled HR of 0.91 ($P = 0.004$)[64]. The analysis of platinum-based combinations indicated a HR of 0.85 ($P = 0.010$), whereas for fluoropyrimidine-based combinations, the HR was 0.90 ($P = 0.030$). No risk reduction was observed when combining Gem with irinotecan, exatecan or pemetrexed. For the 1682 patients with adequate information on baseline PS, analysis indicated that patients with a good PS had a marked survival benefit when receiving combination chemotherapy (HR: 0.76, $P < 0.0001$). In contrast, application of combination chemotherapy to patients with an initially poor PS

Table 2 Gem in combination with targeted therapy

Phase Ⅲ trial	Combination	No. of patient	OS (mo)	*P* value	PFS	*P* value	ORR (%)	*P* value
Moore *et al*[76]	Gem ± Erlotinib	569	6.24 *vs* 5.91	0.038	3.75 *vs* 3.55	0.004	8.6 *vs* 8.0	NS
Philip *et al*[79]	Gem ± Cetuximab	745	6.3 *vs* 5.9	0.23	3.4 *vs* 3.0	0.18	12 *vs* 14	0.59
Kindler *et al*[83]	Gem ± BEV	602	5.8 *vs* 5.9	0.95	3.8 *vs* 2.9	0.07	13 *vs* 10	NS
Van Cutsem *et al*[84]	Gem + Erlotinib ± BEV	607	7.1 *vs* 6.0	0.2087	4.6 *vs* 3.6	0.0002	13.5 *vs* 8.6	0.057
Goncalves *et al*[87]	Gem ± Sorafenib	104	8.5 *vs* 9.2	0.146	3.8 *vs* 5.6	0.601	NR	NR

OS: Overall survival; PFS: Progression-free survival; ORR: Objective response rate rate; Gem: Gemcitabine; BEV: Bevacizumab; NR: Not reported; NS: Not significant.

appeared to be ineffective (HR: 1.08, $P = 0.40$). However, a meta-analysis conducted by Bria and colleagues, involving 6296 patients, did not show significant differences in the primary endpoint OS, although a significant advantage was evident with regard to both PFS and the ORR, especially in platinum combination therapy[65].

Taken together, it appears that patients taking Gem in combination with either a platinum analog or capecitabine, may have a clinically relevant survival prolongation, especially if they have good PS.

Targeted therapy

Several pathways have been targeted in an attempt to treat pancreatic cancer, but the results from most of these have been disappointing[66-68] (Table 2).

Epidermal growth factor receptor inhibitors

The overexpression of epidermal growth factor receptor inhibitors (EGFR) has been reported in pancreatic cancer, thus EGFR inhibitors has emerged as a new therapeutic approach for this disease. EGFR can be inhibited by small molecular tyrosine kinase inhibitors that block the intrinsic tyrosine kinase activity pathway and monoclonal antibodies directed against the extracellular ligand binding domain[69-75].

Gem and erlotinib: The original approval of erlotinib to be used in the treatment of pancreatic cancer was obtained in 2005 after a double-blind international Phase Ⅲ trial in which a total of 569 patients were randomly assigned to receive standard Gem plus erlotinib at 100 mg or 150 mg daily, or Gem alone plus placebo[76]. The study showed statistically significant improvements in OS (6.24 mo in the erlotinib arm and 5.91 mo in the control arm, $P = 0.038$) and PFS (3.75 mo *vs* 3.55 mo , $P = 0.004$). However, ORR were not significantly different (8.6% *vs* 8.0%), and most patients had disease stabilization. Although this study was statistically significant, major concerns still remained about using erlotinib in light of the minimal median survival duration benefit and high costs. In addition, patients receiving erlotinib had higher frequencies of rash, diarrhea, infection and stomatitis, although they were generally well-tolerated and were notably of grade 1 or 2[77]. As in studies of anti-EGFR agents in colorectal cancer, the presence of rash was associated with a higher likelihood of achieving disease control ($P = 0.05$).

Gem and cetuximab: A phase Ⅱ trial of cetuximab combined with Gem in pathologically confirmed EGFR-expressing pancreatic cancer patients showed moderate activity (TTP 3.8 mo, OS 7.1 mo)[78]. However, a phase Ⅲ study (SWOG S0205) that assigned 745 patients to Gem plus cetuximab or Gem alone did not have any survival benefits[79]. There were also no significant differences in terms of OS (6.3 mo *vs* 5.9 mo, $P = 0.23$), PFS (3.4 mo *vs* 3.0 mo, $P = 0.18$) and RR (12% *vs* 14%, $P = 0.59$).

Antiangiogenesis

Vascular endothelial growth factor receptor (VEGF) is known to stimulate cell growth, survival, and proliferation. VEGF inhibitors effectively reduce neovascularization. They inhibit new and recurrent tumor vessel growth and improve the capacity of the tumor vasculature for effective delivery of antitumor growth compounds[80,81].

Gem and bevacizumab: A phase Ⅱ study evaluated the combination of bevacizumab plus Gem in 52 advanced pancreatic patients; the median OS and PFS were 8.8 and 5.4 mo, respectively[82]. These interesting results led to a phase Ⅲ study that failed to confirm the previous findings. It showed median OS was 5.8 mo *vs* 5.9 mo ($P = 0.95$), and PFS was 3.8 mo *vs* 2.9 mo ($P = 0.07$) in the bevacizumab arm and the control arm, respectively[83]. Subgroup analysis demonstrated statistically significant differences in survival by PS. Patients with a PS of 0 survived a median of 7.9 mo compared to 4.8 mo, and 2.4 mo for PS 1 and PS 2 patients, respectively ($P = 0.001$). Another Roche sponsored trial, in which 607 patients with metastatic pancreatic cancer were randomized to Gem and erlotinib with or without bevacizumab, showed no significant prolongation of survival with the addition of bevacizumab (7.1 mo *vs* 6.0 mo, $P = 0.20$), although the PFS was statistically significantly improved (4.6 mo *vs* 3.6 mo, $P = 0.0002$)[84]. Bevacizumab was reported to be safe in this combination, despite an increase in the incidence of epistaxis, hypertension, and proteinuria.

Gem and sorafenib: With its inhibitory effects against Raf-1 kinase and VEGF-2, sorafenib is an oral anticancer agent that targets Ras-dependent signal transduction as well as angiogenic pathways[85]. A phase Ⅰ trial demonstrated that Gem in combination with sorafenib was well tolerated and had activity in advanced pancreatic cancer patients[86]. A multicenter, randomized, double-blind, pla-

cebo-controlled phase Ⅲ trial (BAYPAN study), which was reported in ASCO 2011, compared Gem combined with sorafenib to Gem combined with placebo in 104 untreated patients with locally advanced or metastatic pancreatic adenocarcinoma[87]. There was no significant differences in median PFS between the two groups (5.6 mo *vs* 3.8 mo, $P = 0.601$). Median OS were also similar (9.2 mo *vs* 8.5 mo, $P = 0.146$).

Other targeted agents: Recently there have been many phase Ⅰ or Ⅱ trials assessing the efficacy and safety of other novel targeted agents, including the hypoxia-activated prodrug (TH-302), the PARP inhibitor (ABT-888), the anti-IGF-1R antibody (MK-0646, GAN), and the fully human monoclonal antibody directed against prostate stem cell antigen. Some of these have shown promising results[88-93].

Non-Gem containing regimen

In 2005, Conroy *et al*[94] evaluated the RR and toxicity of FOLFIRINOX in 46 chemotherapy-naive advanced pancreatic adenocarcinoma patients. The FOLFIRINOX regimen comprised oxaliplatin 85 mg/m^2 and irinotecan 180 mg/m^2 plus leucovorin 400 mg/m^2 followed by bolus FU 400 mg/m^2 on day 1, then FU 2400 mg/m^2 as a 46-h continuous infusion. This report showed promising results with an RR of 26%, a TTP 8.2 mo, and an OS of 10.2 mo. Despite the fact that grade 3/4 neutropenia occurred in 52% of patients, patients had improvement in all functional scales of the EORTC QLQ-C30. Based on these data, Conroy and colleagues conducted a phase Ⅲ trial comparing FOLFIRINOX with Gem as first-line treatment for metastatic pancreatic adenocarcinoma in 342 patients with good PS (0-1)[95]. The median OS was 11.1 mo in the FOLFIRINOX group compared to 6.8 mo in the Gem group (HR: 0.57; 95% CI: 0.45-0.73; $P < 0.001$). Median PFS was 6.4 mo *vs* 3.3 mo (HR: 0.47; 95% CI: 0.37-0.59, $P < 0.001$). The ORR was 31.6% *vs* 9.4% ($P < 0.001$). At 6 mo, 31% of the patients in the FOLFIRINOX group had a definitive degradation of the QOL, *vs* 66% in the Gem group (HR: 0.47; 95% CI: 0.30-0.70; $P < 0.001$). Grade 3/4 toxicities were more common in the FOLFIRINOX, diarrhea 12.7% *vs* 1.8%, nausea 15.6% *vs* 6.3%, vomiting 14.5% *vs* 8.3%, fatigue 23.6% *vs* 17.8%, neutropenia 45.7% *vs* 21%, and febrile neutropenia 5.4% *vs* 1.2%. In the FOLFIRINOX arm, 42% of patients received support with granulocyte colony-stimulating factor. Two patients died from treatment-related causes: one from febrile neutropenia in the FOLFIRINOX group and one from cardiac decompensation in the Gem group. This trial was highly selective: only 39% of patients had a primary tumor in the head of the pancreas; whereas in clinical practice, about two-thirds of patients present with a primary tumor in the pancreas, possibly requiring biliary stents. Therefore, for patients with a good PS, normal bilirubin, and a good supportive care system, FOLFIRINOX could be a viable option.

CONCLUSION

As a first-line therapy, Gem has been the standard treatment for pancreatic cancer since 1997, despite its low RR and short OS. Trials for Gem-based combination regimens have failed to improve survival. Striking, FOLFIRINOX regimen increased median OS from 6.8 mo to 11.1 mo ($P < 0.0001$), and RR was 31.6% for patients with a good PS. Thus the question that arises is whether FOLFIRINOX should be considered standard therapy for advanced pancreatic cancer instead of Gem. Does this trial represent the start of a change for the management of advanced pancreatic cancer? The FOLFIRINOX regimen was quite toxic because nearly half of the patients suffered grade 3/4 toxicity. Considering the efficacy and toxicity, FOLFIRINOX could be a viable option in selected patients (good PS, normal bilirubin, and a good supportive care system). This trial provided more evidence that Gem does not have to be the backbone of chemotherapy in pancreatic cancer[96-98]. The GEST trial was the first to show that oral S-1 had similar efficacy and tolerable toxicity to Gem in pancreatic cancer patients with good PS. Considering the convenience of oral S-1, it may be worthwhile to initiate further studies. Based on its high RR, further studies are needed to explore the value of a FOLFIRINOX regimen in borderline or unresectable pancreatic tumors, together with radiation for a possible downstaging effect. FOLFIRINOX should also be studied in adjuvant settings where patients can potentially accept more toxic effects. In the future, better tolerated doublet regimens such as FOLFOX and FOLFIRI should be compared to Gem. It will also be necessary to screen the dominant group based on the expression and genotype of metabolic or transport enzymes of Gem.

Abstract

AIM: To verify the usefulness of FibroQ for predicting fibrosis in patients with chronic hepatitis C, compared with other noninvasive tests.

METHODS: This retrospective cohort study included 237 consecutive patients with chronic hepatitis C who had undergone percutaneous liver biopsy before treatment. FibroQ, aspartate aminotransferase (AST)/alanine aminotransferase ratio (AAR), AST to platelet ratio index, cirrhosis discriminant score, age-platelet index (API), Pohl score, FIB-4 index, and Lok's model were calculated and compared.

RESULTS: FibroQ, FIB-4, AAR, API and Lok's model results increased significantly as fibrosis advanced (analysis of variance test: $P < 0.001$). FibroQ trended to be superior in predicting significant fibrosis score in chronic hepatitis C compared with other noninvasive tests.

CONCLUSION: FibroQ is a simple and useful test for predicting significant fibrosis in patients with chronic hepatitis C.

Key words: Liver fibrosis; Noninvasive test; FibroQ; Aspartate aminotransferase; Alanine aminotransferase; FIB-4 index; Aspartate aminotransferase to platelet ratio index; Lok's model; Cirrhosis discriminant score; Pohl score

INTRODUCTION

Viral hepatitis C is one of the most common liver diseases in the world, affecting an estimated 200 million individuals[1], with a particularly high prevalence in Southern Taiwan[2]. Approximately 60%-80% of infected individu-

als develop chronic hepatitis[2], and patients with higher degrees of fibrosis may progress rapidly to cirrhosis and hepatocellular carcinoma. Approximately 20% of patients with chronic hepatitis C advance to cirrhosis, and 5% of them develop hepatocellular carcinoma[3,4].

Knowledge of the extent of liver fibrosis is important for the clinical management of chronic hepatitis C. Patients with no fibrosis or with only portal fibrosis at the time of diagnosis have more favorable outcomes and a lower chance of reaching end-stage liver disease than patients with severe fibrosis or cirrhosis[5-8]. The probability of developing cirrhosis and/or other unfavorable outcomes is closely related to fibrosis stage, therefore, liver biopsy is recommended prior to antiviral treatment. However, liver biopsy adds expense, requires an experienced clinician, and may cause complications, including mortality in 0.018% of patients[9]. In addition, sampling errors and inter- and intraobserver variations may lead to understaging of cirrhosis, particularly macronodular cirrhosis[10-13]. Hence, several noninvasive tests have been proposed to assess the severity of hepatic fibrosis as an alternative to liver biopsy. As reported by Akkaya *et al*[14], alanine aminotransferase (ALT) levels in patients with hepatitis C virus (HCV) infection correlate with periportal bridging/necrosis, and Lu *et al*[15] have reported that thrombocytopenia is a surrogate for cirrhosis. Furthermore, aspartate aminotransferase (AST)-to-platelet ratio index (APRI)[16] and AST/ALT ratio (AAR)[17], cirrhosis discriminant score (CDS)[18], age-platelet index (API)[19], Pohl score[20], FIB-4 index[21], and Lok's model[22] are well-known parameters that are based on routine laboratory data, and are therefore readily available in clinical practice (Table 1). These parameters have been reported to predict the presence of significant fibrosis and extensive fibrosis in some patients[14-23].

Recently, we proposed a novel index, FibroQ[23], which is calculated from common laboratory test results that include prothrombin time international normalized ratio (PT INR), platelet count, AST, ALT, and age, as 10 × (age × AST × PT INR)/(ALT × platelet count) to predict significant fibrosis. In a previous study, we enrolled 140 patients with hepatitis B virus (HBV) and HCV infection. To focus on HCV, 113 of these patients were included in the 237 patients in the present study. The aims of the present study were to assess the value of the FibroQ index and to determine its threshold values to differentiate significant fibrosis. We also compared the discriminatory performance of FibroQ to that of AAR, APRI, CDS, API, Pohl score, FIB-4 index, and Lok's model.

Table 1 Fibrosis tests composed of laboratory parameters

Fibrosis test	Calculation
AAR	AST/ALT
APRI	[(AST/ULN)/platelet count (10^9/L)] × 100
FibroQ	(10 × age × AST × PT INR)/(PLT × ALT)
CDS	Platelet count (10^9/L): > 340 = 0; 280-339 = 1; 220-279 = 2; 160-219 = 3; 100-159 = 4; 40-99 = 5; < 40 = 6 ALT/AST ratio: > 1.7 = 0; 1.2-1.7 = 1; 0.6-1.19 = 2; < 0.6 = 3
API	INR: < 1.1 = 0; 1.1-1.4 = 1; > 1.4 = 2 CDS is the sum of the above (possible value, 0-11) Age (yr): < 30 = 0; 30-39 = 1; 40-49 = 2; 50-59= 3; 60-69 = 4; > 70 = 5 Platelet count (10^9/L): ≥ 225 = 0; 200-224 = 1; 175-199 = 2; 150-174 = 3; 125-149 = 4; ≤ 125 = 5 API is the sum of the above (possible value, 0-10)
Pohl score	Positive: AAR ≥ 1 and platelet count < 150 × 10^9/L
FIB-4 index	[Age (yr) × AST (U/L)]/[platelet count (10^9/L) × ALT (U/L) 1/2]
Lok's model	Log odds (predicting cirrhosis) = -5.56 to 0.0089 × platelet (× 10^3/mm^3) + 1.26 × AST/ALT ratio + 5.27 × PT INR Predicted probability = exp (log odds)/[1 + exp (log odds)]

AST: Aspartate aminotransferase; ALT: Alanine aminotransferase; AAR: AST/ALT ratio; APRI: AST-to-platelet ratio index; API: Age-platelet index; CDS: Cirrhosis discriminant score; ULN: Upper limit of normal; PLT: Posterolateral thoracotomy; PT-INR: Prothrombin time international normalized ratio.

MATERIALS AND METHODS

We retrospectively studied 250 consecutive treatment-naïve patients with chronic HCV infection that was confirmed by the presence of anti-HCV antibody by enzyme immunoassay methods (Abbott Architect I 2000; Abbott, Champaign, IL, United States) as recorded in the departmental files of the Department of Gastroenterology, Chang Gung Memorial Hospital, Chiayi, between May 2005 and December 2008. All patients were Taiwanese. The research study was approved by the Clinical Research Sub-committee of the hospital. Patients with the following conditions were excluded from the study: those co-infected with human immunodeficiency virus or HBV, and those with alcohol consumption in excess of 20 g/d, hepatocellular carcinoma, liver transplantation, antiviral or immunosuppressive therapy, metabolic liver disease, insufficient liver tissue for fibrosis staging, or recent warfarin or other anticoagulant usage. Thirteen patients were excluded due to incomplete data on liver function tests or platelet count within 1 mo before the date of biopsy. The clinical data were reviewed, and the following parameters were recorded: sex, age, AST, ALT, platelet count, PT INR, hemoglobin, white blood cell count, serum creatinine, free thyroxine, thyroid-stimulating hormone, and bilirubin. Liver biopsies were performed by hepatologists and were interpreted by a single pathologist using the Metavir fibrosis score[10]. Significant liver fibrosis and extensive liver fibrosis were defined as Metavir fibrosis scores of ≥ 2 (F2, F3 and F4) and ≥ 3 (F3 and F4), respectively.

Statistical analysis was performed using SPSS software version 12.0 (SPSS Inc., Chicago, IL, United States). Patient characteristics were represented as the mean ± SD. Bivariate Spearman's rank correlation coefficient (r_s) was calculated to measure the relationship between the clinical variables and degree of fibrosis. Receiver operating characteristic (ROC) curves were constructed for each test. To evaluate the diagnostic accuracies of the simple fibrosis prediction tests, their sensitivity, specific-

Table 2 Clinical characteristics of 237 patients with chronic hepatitis C

Male/female	135/102
Age (yr)	54.3 ± 11.6 (19-76)
AST (U/L)	101.2 ± 56.0 (21-348)
ALT (U/L)	156.3 ± 92.5 (24-637)
PT INR	1.049 ± 0.080 (0.88-1.34)
PLT (× 10^3/μL)	170.9 ± 55.1 (60-373)
Hemoglobin (g/L)	14.4 ± 1.37 (9.0-18.0)
WBC count (x 10^9/L)	5.85 ± 1.73 (2.8-16.7)
Creatinine (mg/dL)	0.94 ± 0.23 (1.0-2.0)
FT4 (μg/dL)	1.12 ± 0.19 (1.0-2.0)
TSH (mU/mL)	2.06 ± 2.13 (0.1-23.0)

AST: Aspartate aminotransferase; ALT: Alanine aminotransferase; PLT: Posterolateral thoracotomy; PT-INR: Prothrombin time international normalized ratio; WBC: White blood cell; FT4: Free thyroxine; TSH: Thyroid stimulating hormone.

Table 3 Correlation of histological fibrosis severity with the variables

	Bivariate Spearman's rank correlation coefficient (95% CI)	*P* value
Age (yr)	0.232 (0.108-0.349)	< 0.001
AST (U/L)	0.188 (0.062-0.308)	0.004

FIB-4	0.429 (0.319-0.528)	< 0.001
CDS	0.185 (0.059-0.305)	0.004
API	0.360 (0.244-0.466)	< 0.001
Lok's model	0.430 (0.320-0.528)	< 0.001
Pohl score	0.144 (0.017-0.267)	0.027

We used Fisher's Z-transform to compute asymmetric confidence limits for the Spearman's rank correlation coefficients. Hb: Hemoglobin; Bil(T): Total bilirubin; AST: Aspartate aminotransferase; ALT: Alanine aminotransferase; PLT: Posterolateral thoracotomy; PT-INR: Prothrombin time international normalized ratio; WBC: White blood cell; FT4: Free thyroxine; TSH: Thyroid stimulating hormone; AAR: AST/ALT ratio; APRI: AST-to-platelet ratio index; API: Age-platelet index; CDS: Cirrhosis discriminant score.

ity, positive predictive value (PPV), negative predictive value (NPV), and the area under the ROC curve (AUC) were calculated. In tests of significance, two-sided $P < 0.05$ was considered significant.

RESULTS

Patient characteristics

The demographics of the 237 patients and standard laboratory tests around the time of liver biopsy are summarized in Table 2. The mean age of the 237 patients (135 male and 102 female) was 54.3 ± 11.6 years. The AST range was 21-348 U/L (mean value, 101.2 ± 56.0 U/L). The ALT range was 24-637 U/L (mean value, 156.3 ± 92.5 U/L). The platelet count range was 60-373 × 10^3/μL (mean value, 170.9 ± 55.1 × 10^3/μL).

Correlations between fibrosis stage and fibrosis-predicting models

Correlations between routine blood tests, fibrosis-predicting models, and histological fibrosis stage are summarized in Table 3. The highest correlation was observed for FibroQ ($r_s = 0.444$), Lok's model ($r_s = 0.430$), and FIB-4 ($r_s = 0.429$) ($P < 0.001$). Figure 1 shows the box-plots of fibrosis scores according to Metavir fibrosis stage. Weaker correlations were also found between other scores and histological fibrosis stage, especially for API ($r_s = 0.360$), AAR ($r_s = 0.341$), and APRI ($r_s = 0.322$) ($P < 0.001$).

There were 41 (17.3%) patients with Metavir stage F1 fibrosis, 85 (35.9%) with F2, 98 (41.4%) with F3, and 13 (5.5%) with F4. AAR, FibroQ, FIB-4, API, and Lok's model results increased significantly as the fibrosis advanced (Table 4, analysis of variance test: $P < 0.001$).

ROC curve analysis

ROC curves evaluating the diagnostic accuracies of FibroQ, AAR, APRI, CDS, API, Pohl score, FIB-4 index, and Lok's model were constructed and superimposed (Figure 2) to determine which score would have the most clinical utility to predict significant fibrosis (≥ F2). The AUC (95% CI) using the procedures described by Hanley and McNeil[24] was greatest for FibroQ (0.789, 0.720-0.857), then FIB-4 (0.785, 0.686-0.830), followed by Lok's model (0.768, 0.695-0.840), API (0.739, 0.660-0.818), AAR (0.709, 0.626-0.792), APRI (0.651, 0.566-0.736), CDS (0.580, 0.485-0.674), and Pohl score (0.523, 0.429-0.617) (Table 5). The AUC of FibroQ was significantly higher than those of AAR, APRI, CDS, and Pohl score ($P < 0.05$).

To predict extensive fibrosis (≥ F3), ROC curves for FibroQ, AAR, APRI, CDS, API, Pohl score, FIB-4 index, and Lok's model were also constructed and superimposed to determine which score would have the most clinical utility (Figure 3). The AUC curves (95% CI) using the procedures described by Hanley and McNeil[24] were greatest for FibroQ (0.728, 0.662-0.793), then FIB-4 (0.725, 0.659-0.791), followed by Lok's model (0.721, 0.656-0.786), API (0.696, 0.628-0.764), APRI (0.681, 0.613-0.749), AAR (0.675, 0.607-0.743), CDS (0.609, 0.537-0.680), and Pohl score (0.532, 0.458-0.606) (Table 5). The AUC of FibroQ was significantly higher than those of CDS or Pohl score ($P < 0.05$).

Sensitivity, specificity, positive predictive value, and negative predictive value

Table 6 shows the performance of FibroQ, AAR, APRI, CDS, API, Pohl score, FIB-4, and Lok's model at various cutoff levels for the prediction of significant fibrosis (F2,

AAR: AST/ALT ratio; APRI: AST-to-platelet ratio index; AST: Aspartate aminotransferase; ALT: Alanine aminotransferase; API: Age-platelet index; CDS: Cirrhosis discriminant score; AUC: Area under the receiver operating characteristic curve.

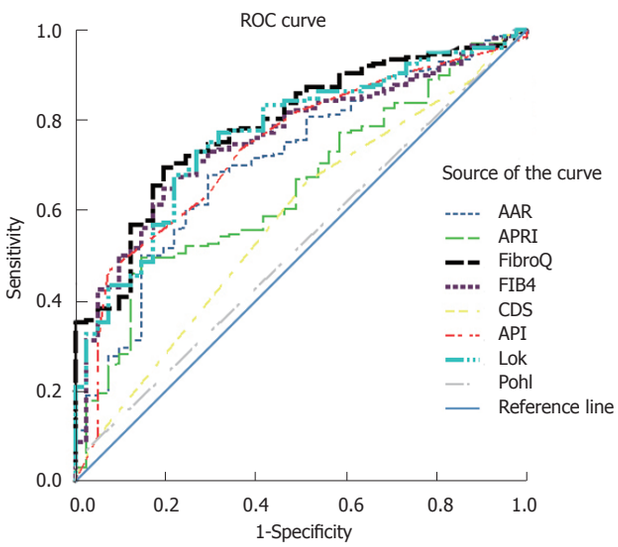

Figure 2 Receiver operating characteristic curves of simple noninvasive tests evaluated for prediction of significant fibrosis (F2, F3 and F4). AAR: AST/ALT ratio; APRI: AST-to-platelet ratio index; AST: Aspartate aminotransferase; ALT: Alanine aminotransferase; API: Age-platelet index; CDS: Cirrhosis discriminant score; ROC: Receiver operating characteristic.

F3 and F4) and extensive fibrosis (F3 and F4). To compare our results with those of previous reports, the sensitivity, specificity, PPV, and NPV of the simple fibrosis prediction tests were calculated using cutoff values exactly as originally described[16,17,21-23]. Using a cutoff value of the FibroQ score of > 1.6 to predict the presence of significant fibrosis resulted in a sensitivity of 77.6%, specificity of 65.9%, PPV of 91.6%, and NPV of 38.0% in 166 (70%) of the 237 patients. With AAR, the cutoff levels to predict the presence (AAR > 1.0) of significant fibrosis had a sensitivity of 8.16%, specificity of 100%, PPV of 100%, and NPV of 18.5%. Using APRI, the cutoff values to predict the presence (APRI > 1.5) or absence (APRI < 0.5) of significant fibrosis had a sensitivity of 56.6% and 96.9%, specificity of 58.5% and 9.7%, PPV of 86.7% and 83.7%, and NPV of 22.0% and 40.0%, respectively.

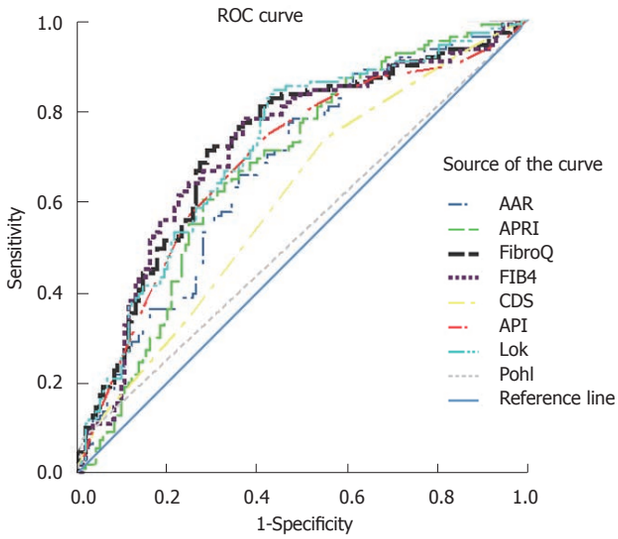

Figure 3 Receiver operating characteristic curves of simple noninvasive tests evaluated for prediction of extensive fibrosis (F3 and F4). AAR: AST/ALT ratio; APRI: AST-to-platelet ratio index; AST: Aspartate aminotransferase; ALT: Alanine aminotransferase; API: Age-platelet index; CDS: Cirrhosis discriminant score; ROC: Receiver operating characteristic.

In Lok's model, the cutoff values to predict the presence (Lok's model > 0.5) or absence (Lok's model < 0.2) of extensive fibrosis had a sensitivity of 37.8% and 88.3%, specificity of 88.1% and 37.3%, PPV of 73.7% and 55.4%, and NPV of 61.7% and 78.3%, respectively. At a cutoff of FIB-4 < 1.45, the NPV to exclude extensive fibrosis (F3 and F4) was 75.9% with a sensitivity of 87.4%. A cutoff of FIB-4 > 3.25 had a PPV of 70.1% and a specificity of 77%.

Since lower cutoffs were originally described to exclude significant fibrosis, specific attention must be paid to NPVs that ranged from 18.0% to 41.7%. For the same cutoffs, NPVs to exclude extensive fibrosis showed superior performance compared with performance on significant fibrosis cases, ranging from 54.8% to 90.0%. For example, a FibroQ < 1.4, which was observed in 25.7% of patients, excluded significant fibrosis with 36.1% certainty and excluded extensive fibrosis with 75.4% certainty. The best predictive value was observed for positive Pohl score, but this cutoff selected only 3.8% of patients.

DISCUSSION

To assess the pathological grade and stage of chronic viral hepatitis, liver biopsy is necessary. However, liver biopsy is invasive, costly, and has its own limitations[11,25]. Hence, several noninvasive tests combining biological parameters have been proposed to attempt to predict the degree of fibrosis, with the objective of replacing liver biopsy[20,26-29]. There are also some noninvasive tests, such as PⅢP (N -terminal peptide of type Ⅲ procollagen)[29], fibrometer[26], Hepascore[30], FibroTest[31], and Forn's score[27]. The current study excludes these tests due to their expense (e.g., procollagen level), because they can only be checked in the laboratory (e.g., hyaluronic acid),

Table 6 Diagnostic accuracy of simple fibrosis prediction tests for significant and extensive fibrosis

Score	Cut-off value	(%)	Significant fibrosis (F2, F3 and F4)				Extensive fibrosis (F3 and F4)

or because they are not included in the routine monitoring and investigations of patients with chronic liver disease (e.g., haptoglobin or cholesterol).

We believe that an ideal noninvasive test for assessing liver fibrosis should be reliable, reproducible, and based on readily available tests and parameters. APRI, AAR, FibroQ, FIB-4, CDS, API, Lok's model, and Pohl score fulfilled these criteria, therefore, we compared these measures for evaluation of patients with chronic hepatitis C. The aim was to validate the usefulness of these simple tests in a community hospital in an area with hyperendemic HCV infection.

In addition, bias of the biopsy examination is also acknowledged. Regev *et al*[32] have reported discordances in fibrosis stage in one third of patients when right and left liver lobes were compared. As a liver biopsy specimen from a cirrhotic liver is often fragmented, the inadequate size of biopsy samples can lead to an underestimation of fibrosis as reported by Colloredo *et al*[33] and Bedossa *et al*[11]. Therefore, some cases diagnosed as F3 may have had cirrhosis (F4). Biopsy length and fragmentation were not recorded or compared in our study; however, a recent study has found that these variables did not affect the performance of their model[34]. Furthermore, we should notice that four different staging systems were used in the original studies for liver fibrosis tests. AAR results were based on the Scheuer system; APRI and FIB-4 were based on the Ishak system; FibroQ, API, and Pohl's score were based on the Metavir system; and CDS and Lok's model were based on a modified Knodell system. The different staging systems using either a 5-stage (F0-F4) or a 7-stage (F0-F6) scale prevented us from comparing fibrosis scores more precisely.

Although the current study was retrospective, it had some advantages over previous studies. First, the patients were all from a treatment-naïve population with HCV infection as the only problem. Second, we compared all fibrosis markers that combined routine blood tests rather than markers only available in the laboratory. Third, all histological assessment was performed blindly by one pathologist, thus preventing interobserver bias in fibrosis staging. Finally, using a 5-stage fibrosis scoring system in this study resulted in a lower tendency to induce interpretation error than would be the case with a 7-stage scoring system[22].

We divided the patients in two different ways to obviate liver biopsy. The first grouping was F1 *vs* F2, F3 and F4, the second was F1 and F2 *vs* F3 and F4. The ratio-

nale for the F1 *vs* F2, F3 and F4 grouping was that there was no need for treatment in patients with mild fibrosis. Patients with severe fibrosis or cirrhosis need screening for hepatocellular carcinoma, esophageal varices, and complications of portal hypertension, therefore, we made a second patient grouping of F1 and F2 *vs* F3 and F4. Applying the cutoff values, we were able to discriminate patients according to two relevant thresholds of fibrosis based on the needs for clinical treatment decision-making.

The result of our current study showed that Pohl score and CDS had high specificity but low sensitivity, and their AUCs were not statistically different from 0.5. In addition, FibroQ, FIB-4, and Lok's model showed the best performance characteristics. The AUCs for predicting significant fibrosis were 0.789, 0.785 and 0.768, respectively. The AUCs for predicting extensive fibrosis were 0.728, 0.725 and 0.721, respectively[21-23]. To evaluate the accuracy of the fibrosis index, we also checked the percentage of patients that were correctly classified according to the stage of fibrosis. Using FibroQ results below the lower cutoff value (0.6) and above the higher cutoff value (1.6), 157 of 178 patients (88.2%) were correctly identified as having or not having significant fibrosis, which was a better performance than in the original study on the use of FibroQ[23]. Using FIB-4, 72.3% of the 155 patients with FIB-4 values outside 1.45-3.25 would be correctly classified, and liver biopsy could be avoided in 65.4% of patients, which is slightly lower than the value of 71% reported by Sterling *et al*[21]. Using Lok's model with a cutoff of 0.2 to exclude extensive fibrosis, only 11.7% of those with extensive fibrosis were misclassified. Using a cutoff of 0.5, only 11.9% of those without extensive fibrosis had a score > 0.5. These results are compatible with those reported by Cheung *et al*[22]. Using the same cutoff values, 7.8% and 14.8% of patients were misclassified in their study.

In summary, the current study demonstrated that FibroQ, FIB-4, and Lok's model were simple methods that correlated well with the stages of fibrosis in patients with chronic hepatitis C. FibroQ showed a trend to be superior to the other modalities evaluated. Further prospective studies involving larger numbers of patients are warranted to validate the usefulness of FibroQ in clinical practice.

COMMENTS

Background

Viral hepatitis C is one of the most common liver diseases in the world, affecting an estimated 200 million individuals. Knowledge of the extent of liver fibrosis is important for the clinical management of chronic hepatitis C. Liver biopsy is recommended prior to antiviral treatment. However, liver biopsy may cause complications, including mortality in 0.018% of patients. Hence, several noninvasive tests have been proposed to assess the severity of hepatic fibrosis.

Research frontiers

Aspartate aminotransferase (AST)-to-platelet ratio index (APRI) and AST/alanine aminotransferase (ALT) ratio (AAR), cirrhosis discriminant score (CDS), age-platelet index (API), Pohl score, FIB-4 index, and Lok's model are well-known parameters that are based on routine laboratory data and are therefore readily available in clinical practice.

Innovations and breakthroughs

Recently, the authors proposed a novel index, FibroQ, which was calculated from common laboratory test results that included prothrombin time international normalized ratio (PT INR), platelet, AST, ALT, and age, calculated as 10 × (age × AST × PT INR)/(ALT × platelet count) to predict significant fibrosis. FibroQ trended to be superior in predicting significant fibrosis score in chronic hepatitis C compared with other noninvasive tests.

Applications

FibroQ is a simple and useful noninvasive test for predicting significant fibrosis in patients with chronic hepatitis C.

Terminology

FibroQ, APR, AAR, CDS, API, Pohl score, FIB-4 index, and Lok's model are well-known parameters that are based on routine laboratory data and are reported to predict the presence of liver significant fibrosis and extensive fibrosis.

Peer review

The study is of particular practical medical interest. The results provide sufficient evidence that the FibroQ correlates with significant liver fibrosis in patients with hepatitis C virus.

Abstract

AIM: To investigate the effects of resistin-like molecule β (RELMβ) over-expression on the invasion, metastasis and angiogenesis of gastric cancer cells.

METHODS: Human RELMβ encoding expression vector was constructed and transfected into the RELMβ lowly-expressed gastric cancer cell lines SGC-7901 and MKN-45. Gene expression was measured by Western blotting, reverse transcription polymerase chain reaction (PCR) and real-time quantitative PCR. Cell proliferation was measured by 2-(4,5-dimethyltriazol-2-yl)-2,5-diphenyl tetrazolium bromide colorimetry, colony formation and 5-ethynyl-20-deoxyuridine incorporation assays. The *in vitro* migration, invasion and metastasis of cancer cells were measured by cell adhesion assay, scratch assay and matrigel invasion assay. The angiogenic capabilities of cancer cells were measured by tube formation of endothelial cells.

RESULTS: Transfection of RELMβ vector into SGC-7901 and MKN-45 cells resulted in over-expression of RELMβ, which did not influence the cellular proliferation. However, over-expression of RELMβ suppressed the *in vitro* adhesion, invasion and metastasis of cancer cells, accompanied by decreased expression of matrix metalloproteinase-2 (MMP-2) and MMP-9. Moreover, transfection of RELMβ attenuated the expression of vascular endothelial growth factor and *in vitro* angiogenic capabilities of cancer cells.

CONCLUSION: Over-expression of RELMβ abolishes the invasion, metastasis and angiogenesis of gastric cancer cells *in vitro*, suggesting its potentials as a novel therapeutic target for gastric cancer.

Effects of resistin-like molecule β over-expression on gastric cancer cells *in vitro*. *World J Gastroenterol* 2012; 18(8): 754-766 Available from: URL: http://www.wjgnet.com/1007-9327/full/v18/i8/754.htm DOI: http://dx.doi.org/10.3748/wjg.v18.i8.754

INTRODUCTION

Gastric cancer is one of the most common cancer types in the world[1]. In spite of the standardization of surgical techniques and multimodal therapy, the postoperative survival of patients with advanced gastric cancer still remains very low[1]. Recent evidence shows that goblet cell-derived proteins, such as intestinal trefoil factor (ITF) and mucin 2 (MUC2), participate in the pathogenesis of gastric cancer[2-6]. As a member of trefoil peptide family that is expressed exclusively in the goblet cells of small intestine and colon[7], ITF is over-expressed in several cancer tissues including gastric cancer[2,7], and promotes tumor cell invasion and angiogenesis[7-9]. Blocking ITF expression *via* an antisense strategy suppresses the *in vitro* growth and tumorigenicity of gastric cancer cells[3], suggesting that ITF may serve as a potential target in the control of gastrointestinal cancer progression. Similarly, MUC2 is expressed in the goblet cells of colon, small intestine and airways[10], and is aberrantly expressed in gastric cancer[4,5]. Measuring the MUC2 transcriptional levels is a sensitive and specific approach to detect lymph node micrometastasis in gastric cancer patients[6]. These results suggest that goblet cell-specific proteins may be involved in the progression of gastric cancer, which are potential targets for regulating the invasion, metastasis and angiogenesis of gastric cancer.

Resistin-like molecule β (RELMβ), also known as Found in Inflammatory Zone 2 (FIZZ2), belongs to a family of resistin-like cytokine molecules consisting of small and cysteine-rich secretory proteins[11]. As a novel goblet cell-specific protein that is abundantly expressed in proximal and distal colon[11,12], RELMβ is induced by intestinal microbial colonization, and plays a key role in epithelial barrier function and integrity[12,13]. In addition, RELMβ functions not only as a Th2 cytokine immune effector but also as an inhibitor of chemotaxis of parasites, through interfering with parasite nutrition by directly binding to the chemosensory components of parasites[13]. Recent evidence shows that RELMβ has the potentials to contribute to the airway remodeling in diseases such as asthma[14], and is involved in the pathogenesis of fibrotic lung diseases as a Th2-associated multifunctional mediator[15] and the development of scleroderma-associated pulmonary hypertension[16]. However, the role of RELMβ in cancer development still remains unclear.

Our previous studies have indicated that RELMβ is over-expressed in a majority of human colon cancer tissues[17], and in the metaplastic epithelium of Barrett's esophagus and associated dysplasia[18]. Moreover, RELMβ is aberrantly expressed in the goblet cells of intestinal metaplasia and cytoplasm of cancer cells in gastric cancer tissues, which is positively correlated with tumor differentiation and longer overall survival, and inversely correlated with tumor infiltration and lymph node metastasis, indicating the value of RELMβ in predicting the outcomes of gastric cancer patients[19]. In this study, to further elucidate the exact role of RELMβ in the progression of gastric cancer, we investigated the effects of RELMβ over-expression on the RELMβ lowly-expressed gastric cancer cells. We found that over-expression of RELMβ attenuated the invasion, metastasis and angiogenesis of cancer cells, suggesting the anti-tumor role of RELMβ in the progression of gastric cancer.

MATERIALS AND METHODS

Cell culture

Human gastric cancer cell lines SGC-7901 and MKN-45 were obtained from the Type Culture Collection of Chinese Academy of Sciences (Shanghai, China). Human endothelial cell line HUVEC (CRL-1730) was purchased from American Type Culture Collection (Rockville, MD, United States). The cells were grown in RPMI1640 medium (Life Technologies, Inc., Gaithersburg, MD, United States) supplemented with 10% fetal bovine serum (FBS, Life Technologies, Inc., Gaithersburg, MD, United States), penicillin (100 U/mL) and streptomycin (100 μg/mL). Cells were maintained at 37 ℃ in a humidified atmosphere of 5% CO_2.

Vector construction and transfection

Full-length RELMβ cDNA was amplified from human colon tissues, subcloned between the restrictive sites Hind Ⅲ and Bam HI of pcDNA3.1/Zeo(+) (Invitrogen, Carlsbad, CA, United States), and validated by sequencing. The primers used for the RELMβ cDNA amplification were 5'-CGCCCAAGCTTATGGGGCCGTCCTCTTGC-3' (forward) and 5'-CGCGGATCCTCAGGTCAGGTGGCAGCA-3' (reverse). The recombinant pcDNA 3.1-RELMβ or empty vector (mock) was transfected into SGC-7901 and MKN-45 cells with Lipofectamine 2000 (Life Technologies, Inc., Gaithersburg, MD, United States), according to the manufacturer's instructions. To monitor the transfection efficiency, the cancer cells were co-transfected with pEGFP-N1 (Clontech, Mountair View, CA, United States).

Western blotting

Western blotting was performed as previously described[20], with antibodies specific for RELMβ (Abcam Inc, Cambridge, MA, United States), matrix metalloproteinase-2 (MMP-2), MMP-9, v-ets erythroblastosis virus E26 oncogene homolog 1 (Ets1), vascular endothelial growth factor (VEGF) and glyceraldehyde-3-phosphate dehydrogenase (GAPDH) (Santa Cruz Biotechnology, Inc., Santa Cruz, CA, United States). ECL substrate kit (Amersham, Piscataway, NJ, United States) was used for the chemiluminscent detection of signals with autoradiography film (Amersham).

Reverse transcription polymerase chain reaction and real-time quantitative reverse transcription polymerase chain reaction

The reverse transcription reactions were conducted with Transcriptor First Strand cDNA Synthesis Kit (Roche, Indianapolis, IN, United States). The polymerase chain reac-

tion (PCR) amplification was performed with the primer sets indicated in Table 1. Real-time PCR with SYBR Green PCR Master Mix (Applied Biosystems, Foster City, CA, United States) was performed using ABI Prism 7700 Sequence Detector (Applied Biosystems). The fluorescent signals were collected during extension phase, Ct values of the sample were calculated, and the transcript levels were analyzed by $2^{-\Delta\Delta Ct}$ method.

MTT colorimetric assay

Cancer cells were cultured in 96-well plates at 5×10^3 cells per well and transfected with pcDNA3.1-RELMβ or empty vector (mock). After transfection for 24 h, 72 h and 120 h, cell viability was monitored by the 3-(4,5-dimethyltriazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT, Sigma, St. Louis, MO, United States) colorimetric assay[20]. All experiments were done with 6-8 wells per experiment and repeated at least three times.

Colony formation assay

Seventy-two hours after transfection, the cells were seeded at a density of 300/mL on 35-mm dishes. Colony formation assay was performed as previously described[20]. Positive colony formation (more than 50 cells/colony) was counted. The survival fraction of cells was expressed as the ratio of plating efficiency of treated cells to that of untreated control cells.

EdU incorporation assay

Cancer cells were cultured in 96-well plates at 5×10^3 cells per well, transfected with pcDNA3.1-RELMβ or empty vector (mock) for 72 h, then exposed to 50 μmol/L of 5-ethynyl-20-deoxyuridine (EdU, Ribobio, China) for additional 4 h at 37 ℃. The cells were fixed with 4% formaldehyde for 15 min and treated with 0.5% Triton X-100 for 20 min at room temperature. After washing with phosphate buffered saline for three times, the cells of each well were reacted with 100 μL of 1 × Apollo® reaction cocktail for 30 min. Subsequently, the DNA contents of cells in each well were stained with 100 μL of Hoechst 33342 (5 μg/mL) for 30 min and visualized under a fluorescent microscope.

Cell adhesion assay

Seventy-two hours after transfection, 2×10^4 cancer cells were inoculated into each well of 96-well plates that were precoated with 100 μL of 20 μg/mL matrigel (BD Biosciences, Franklin Lakes, NJ, United States), and incubated at 37 ℃ in serum-free complete medium (pH 7.2) for 2 h. Cell adhesion was measured as previously described[20]. And 0%, 20%, 50% and 100% of inoculated cells were directly fixed in 4% paraformaldehyde 2 h after inoculation.

Scratch migration assay

Cancer cells were cultured in 24-well plates and transfected with pcDNA3.1-RELMβ or empty vector (mock). Seventy-two hours after transfection, the cells were scraped with the fine end of 1-mL pipette tips (Time 0). Scratch migration assay was performed as previously described[20]. Remodeling was measured as diminishing distance across the induced injury and normalized to the 0 h control.

Matrigel invasion assay

The Boyden chamber technique (transwell analysis) was applied as previously described[20]. Briefly, 72 h after transfection, homogeneous single cell suspensions (1×10^5 cells/well) were added to the upper chambers and allowed to invade for 24 h at 37 ℃ in a CO_2 incubator. The migrated cells were counted according to the published criteria[21].

Tube formation assay

Fifty microliters of growth factor-reduced matrigel were polymerized on 96-well plates. HUVECs were serum starved in RPMI1640 medium for 24 h, suspended in RPMI1640 medium preconditioned with pcDNA3.1-RELM- or empty vector-transfected SGC-7901 or MKN-45 cells, added to the matrigel-coated wells at the density of 5×10^4 cells/well, and incubated at 37 ℃ for 18 h. Tube formation was visualized using a Leitz inverted microscope equipped with a Sony color digital DXC-S500 camera. Anti-angiogenic activity was detected by measuring the length of tube walls formed in the discrete endothelial cells in each well compared with the controls.

Statistical analysis

Unless otherwise stated, all data were shown as mean ± SE. Statistical significance ($P < 0.05$) was determined by *t* test or analysis of variance (ANOVA) followed by assessment of differences using SigmaStat 2.03 software (Jandel, Erkrath, Germany).

RESULTS

Transient transfection-mediated over-expression of RELMβ in gastric cancer cells

To examine the effects of RELMβ over-expression on

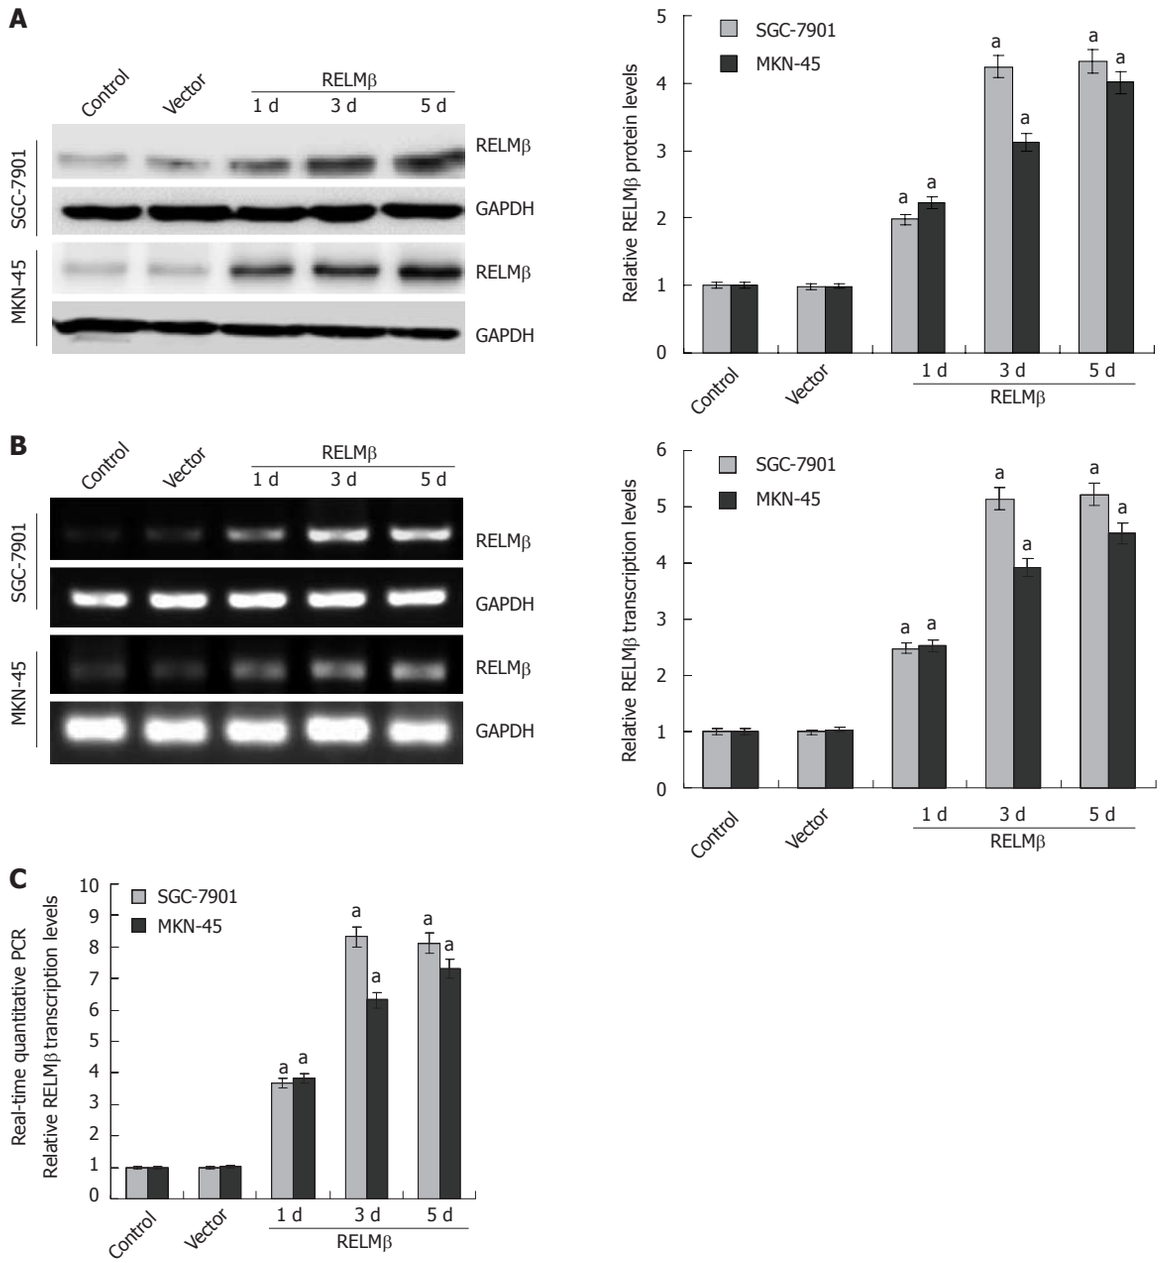

Figure 1 Transient transfection-mediated over-expression of resistin-like molecule β in gastric cancer cells. A: Western blotting indicated that low resistin-like molecule β (RELMβ) protein was detected in the parental SGC-7901 and MKN-45 cells, and transient transfection of the empty vector (mock) did not affect the expression levels of RELMβ. However, transient transfection of pcDNA3.1-RELMβ for 24 h, 72 h and 120 h resulted in increased RELMβ expression; **B: 24 h, 72 h and 120 h** after **transfection, reverse transcription polymerase chain reaction (RT-PCR) indicated the increased RELM**β transcription levels in pcDNA3.1-RELMβ transfected SGC-7901 and MKN-45 cells, but not in mock group; C: Real-time quantitative RT-PCR further demonstrated that transfection of pcDNA3.1-RELMβ for 24 h, 72 h and 120 h resulted in upregulation of RELMβ transcription levels in SGC-7901 and MKN-45 cells. The symbol (a) indicates a significant increase **compared with parental** cells ($P < 0.01$). Triplicate experiments were performed with essentially identical results.

human gastric cancer, the RELMβ cDNA was amplified from human colon tissues, subcloned into pcDNA3.1/Zeo(+) and validated by sequencing. Gastric cancer SGC-7901 and MKN-45 cells were transfected with pcDNA3.1-RELM or empty vector (mock). The transfection efficiency was monitored by co-transfection with the enhanced green fluorescent protein (EGFP) reporter vector pEGFP-N1. Seventy-two hours after transfection, EGFP expressed within the cytoplasm of cancer cells, with the transfection efficiency around 60% (data not shown). The protein and mRNA expression of RELMβ was examined by Western blotting, reverse transcription polymerase chain reaction (RT-PCR), and real-time quantitative RT-PCR. As shown in Figure 1A-C, low RELMβ protein and mRNA could be detected in the parental SGC-7901 and MKN-45 cells, and transient transfection of empty vector did not affect the expression levels of RELMβ ($P > 0.05$). However, RELMβ was significantly increased in the pcDNA3.1-RELMβ-transfected cells ($P < 0.01$). These results indicated that the eukaryotic vector

for RELMβ used in this study was efficient in up-regulating the expression of RELMβ in gastric cancer cells.

Over-expression of RELMβ did not affect the in vitro cell proliferation of gastric cancer cells

The effects of RELMβ over-expression on proliferation of SGC-7901 and MKN-45 cells were measured by MTT colorimetric assay. We found that transfection of pcDNA 3.1-RELMβ or empty vector (mock) did not affect the cell proliferation when compared with the parental cells ($P > 0.05$, Figure 2A). In addition, colony formation and EdU incorporation assays further revealed that over-expression of RELMβ did not influence the proliferation of cultured SGC-7901 and MKN-45 cells ($P > 0.05$, Figure 2B and C). These results indicated that over-expression of RELMβ did not affect the *in vitro* proliferation of gastric cancer cells.

Over-expression of RELMβ attenuated the adhesion, migration and invasion of gastric cancer cells in vitro

Since the adhesion, migration and invasion are three critical steps involved in metastasis, and RELMβ expression in gastric cancer is correlated with tumor infiltration and lymph node metastasis[19], we examined the effects of RELMβ over-expression on these characteristics in cultured gastric cancer cells. In the adhesion assay, SGC-7901 and MKN-45 cells transfected with pcDNA3.1-RELMβ exhibited markedly reduced ability in adhesion to the pre-coated matrigel, when compared with parental cells ($P < 0.01$, Figure 3A). However, the cells transfected with empty vector (mock) had similar adhesive abilities as parental cells (Figure 3A). In addition, transfection of pcDNA3.1-RELMβ into SGC-7901 and MKN-45 cells resulted in an impaired migration capacity ($P < 0.01$), when compared with the parental and mock cells as evidenced by scratch migration assay (Figure 3B). Moreover, over-expression of RELMβ abolished the invasion capabilities of SGC-7901 and MKN-45 cells, when compared with the parental and mock cells as evidenced by transwell analysis ($P < 0.01$, Figure 3C). These results suggested that over-expression of RELMβ suppressed the adhesion, invasion and metastasis of gastric cancer cells *in vitro*.

Over-expression of RELMβ decreased the expression of MMP-2 and MMP-9 in gastric cancer cells

To explore the mechanisms underlying RELMβ-mediated suppression on the adhesion, invasion and metastasis of gastric cancer cells, the protein and mRNA expression of MMP-2 and MMP-9 were examined by Western blotting, RT-PCR and real-time quantitative RT-PCR. As shown in Figure 4A, B and C, the expression of MMP-2 and MMP-9 was significantly decreased in the pcDNA3.1-RELMβ-transfected SGC-7901 and MKN-45 cells ($P < 0.01$) as compared with the parental cells. However, transient transfection of the empty vector (mock) did not affect the expression level of MMP-2 or MMP-9. These results indicated that over-expression of RELMβ attenuated the expression of MMP-2 and MMP-9 in gastric cancer cells.

Over-expression of RELMβ inhibited the in vitro angiogenesis of gastric cancer cells

We further investigated the effects of RELMβ over-expression on the *in vitro* angiogenic capabilities of SGC-7901 and MKN-45 cells. As shown in Figure 5, extensive tube formation of endothelial cells was observed in parental and mock cells. However, when the endothelial cells were treated with the medium preconditioned with pcDNA3.1-RELMβ-transfected SGC-7901 or MKN-45 cells, the tube formation was significantly suppressed ($P < 0.01$, Figure 5). These results indicated that over-expression of RELMβ remarkably decreased the angiogenesis of gastric cancer cells *in vitro*.

RELMβ attenuated the expression of VEGF, but not Ets1 in gastric cancer cells

Since Ets1 is one of the most important transcription factors to promote tumor angio-genesis[22], and based on the evidence that resistin, a member of the RELM family, influences the VEGF expression in cancer cells[23], we hypothesized that RELMβ might affect its expression in gastric cancer cells. The expression levels of Ets1 and VEGF were examined by Western blotting, RT-PCR and real-time quantitative RT-PCR. As shown in Figure 6A, B and C, the protein and mRNA levels of Ets1 and VEGF could be detected in the parental SGC-7901 and MKN-45 cells, and transient transfection of the empty vector (mock) did not affect their expression levels. However, VEGF, but not Ets1, was significantly decreased in the pcDNA3.1-RELMβ-transfected cells ($P < 0.01$). These results indicated that over-expression of RELMβ attenuated the expression of VEGF in gastric cancer cells.

DISCUSSION

Resistin-like molecules/found in inflammatory zone (RELM/FIZZ) gene family consists of four members, including resistin, RELMα, RELMβ and RELMγ, which exhibit unique distribution patterns in mammalian species[11]. Resistin, a small and cysteine-rich protein hormone secreted from adipose tissue, is named for its ability to induce insulin resistance[24]. RELMα is expressed in several tissues including white adipose tissue and lung, and participates in the regulation of inflammatory process[25,26]. RELMβ is highly conserved in all examined mammalian species, and its expression is tightly restricted to intestinal goblet cells, from where it is secreted apically into the intestinal lumen as a homodimer[11]. RELMγ is expressed in mouse spleen, bone marrow and intestine, and may play a role in promyelocytic differentiation[27,28]. Currently, although most studies have focused on the roles of RELMβ in intestinal defense against parasitic nematode infection and colonic inflammation[29], the functions of RELMβ remain to be further elucidated. Interestingly, recent evidences reveal the close relationship between resistin and prostate cancer[30], gastric cancer[31], colorectal cancer[32,33], breast cancer[34,35], and endometrial cancer[36]. It has been indicated that resistin induces cell

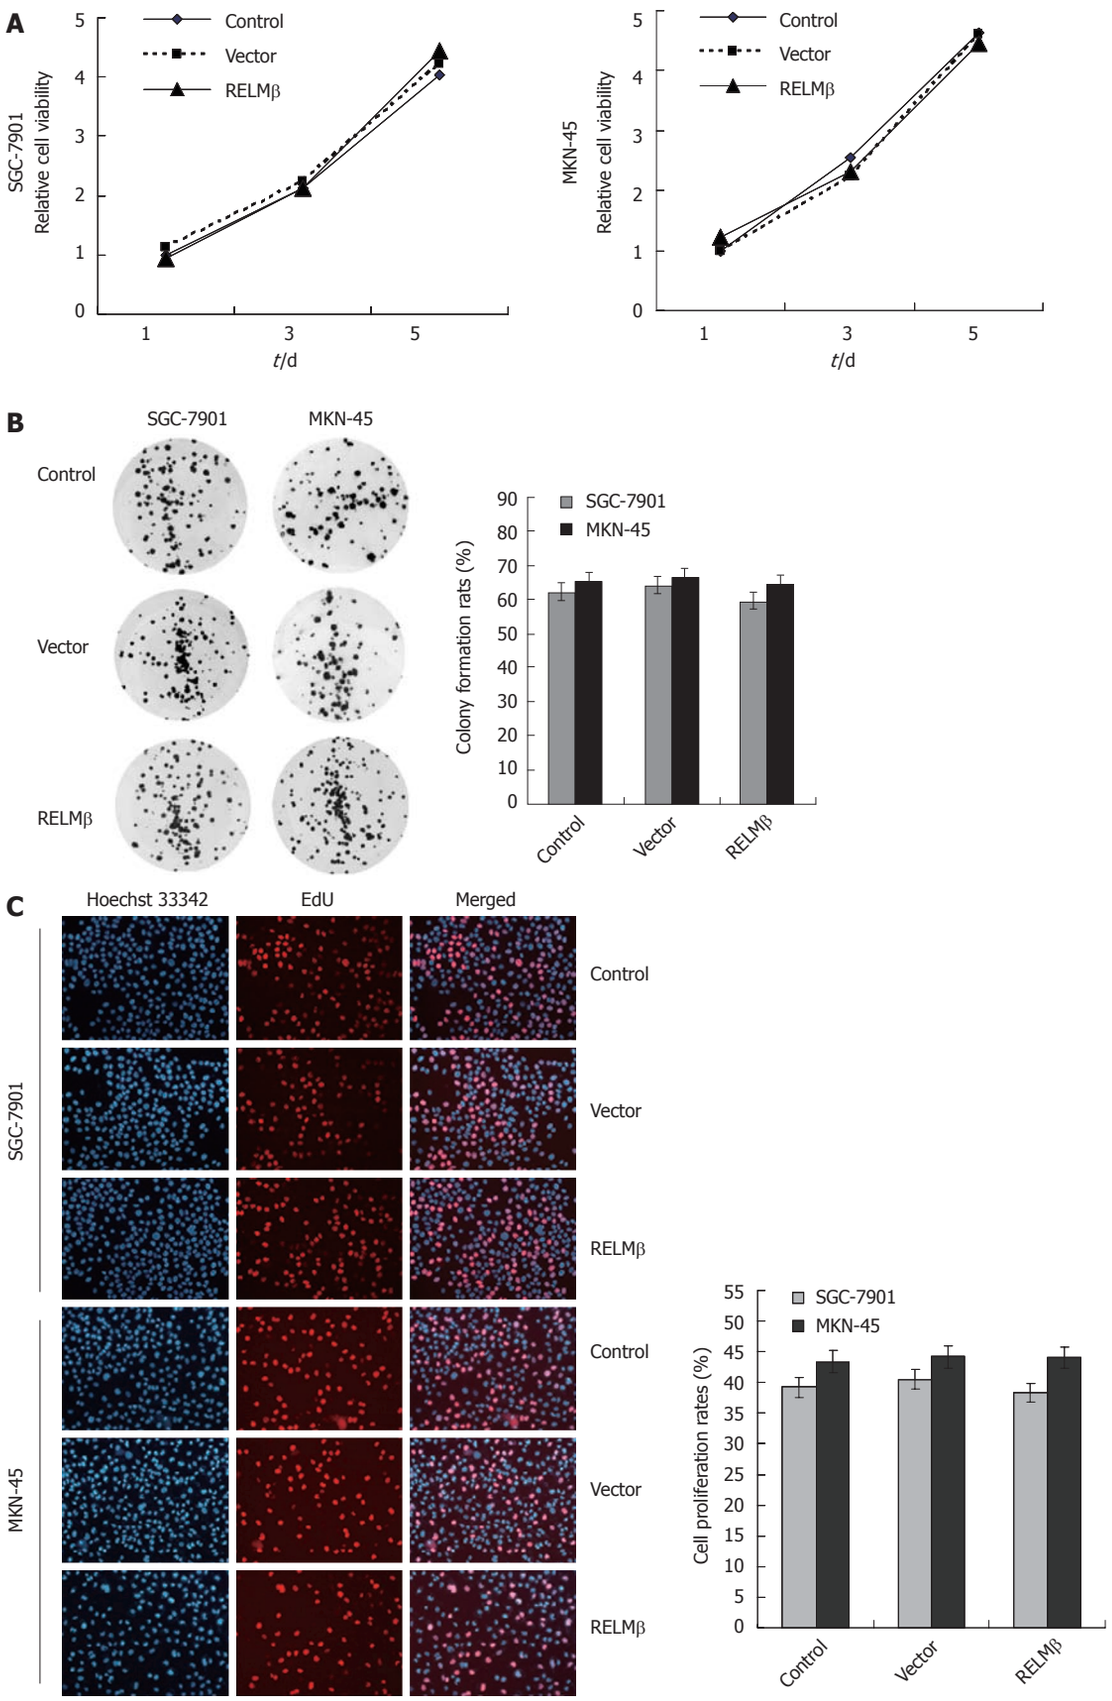

Figure 2 Upregulating resistin-like molecule β expression did not affect the *in vitro* proliferation of gastric cancer cells. A: In 3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide colorimetric assay, transfection of pcDNA3.1-resistin-like molecule β (RELMβ) or empty vector (mock) for 24 h, 72 h and 120 h, did not affect the cell proliferation, when compared with the parental SGC-7901 and MKN-45 cells ($P > 0.05$); B: Colony formation assay indicated that 72 h after transfection, over-expression of RELMβ did not affect the *in vitro* proliferation of SGC-7901 and MKN-45 cells ($P > 0.05$); C: 5-ethynyl-20-deoxyuridine incorporation assay revealed that 72 h after transfection, over-expression of RELMβ did not influence the proliferation of cultured SGC-7901 and MKN-45 cells ($P > 0.05$). Triplicate experiments were performed with essentially identical results.

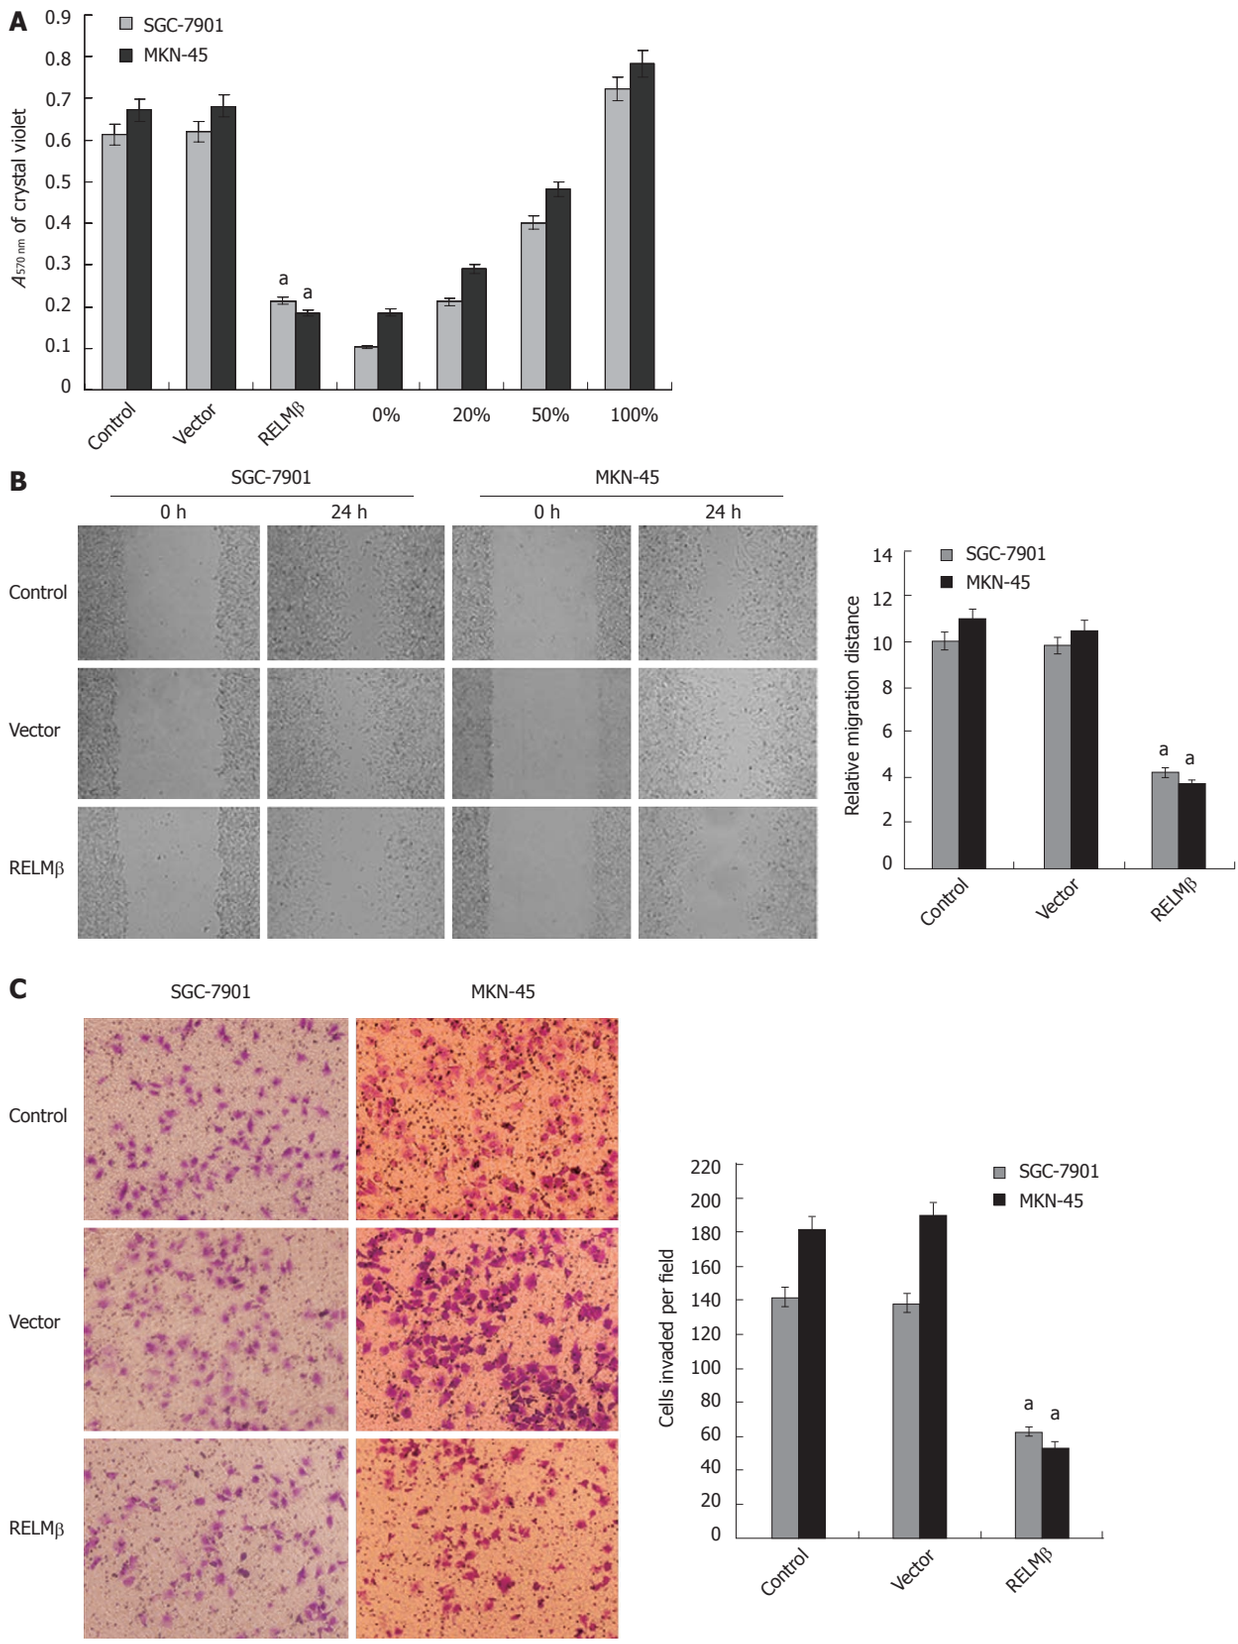

Figure 3 Over-expression of resistin-like molecule β attenuated the adhesion, migration and invasion of gastric cancer cells *in vitro*. A: In the adhesion assay, SGC-7901 and MKN-45 cells transfected with pcDNA3.1-resistin-like molecule β (RELMβ) for 72 h exhibited markedly reduced ability in adhesion to the precoated matrigel, when compared with parental cells. However, the cells transfected with empty vector (mock) had a similar adhesive ability as parental cells; B: Scratch migration assay indicated that transfection of pcDNA3.1-RELMβ into SGC-7901 and MKN-45 cells for 72 h resulted in an impaired migration capacity, when compared with the parental cells and mock group; C: Transwell analysis indicated that transfection of pcDNA3.1-RELMβ for 72 h abolished the invasive capabilities of SGC-7901 and MKN-45 cells, when compared with the parental and mock cells. The symbol (a) indicates a significant decrease compared with parental cells ($P < 0.01$). Triplicate experiments were performed with essentially identical results.

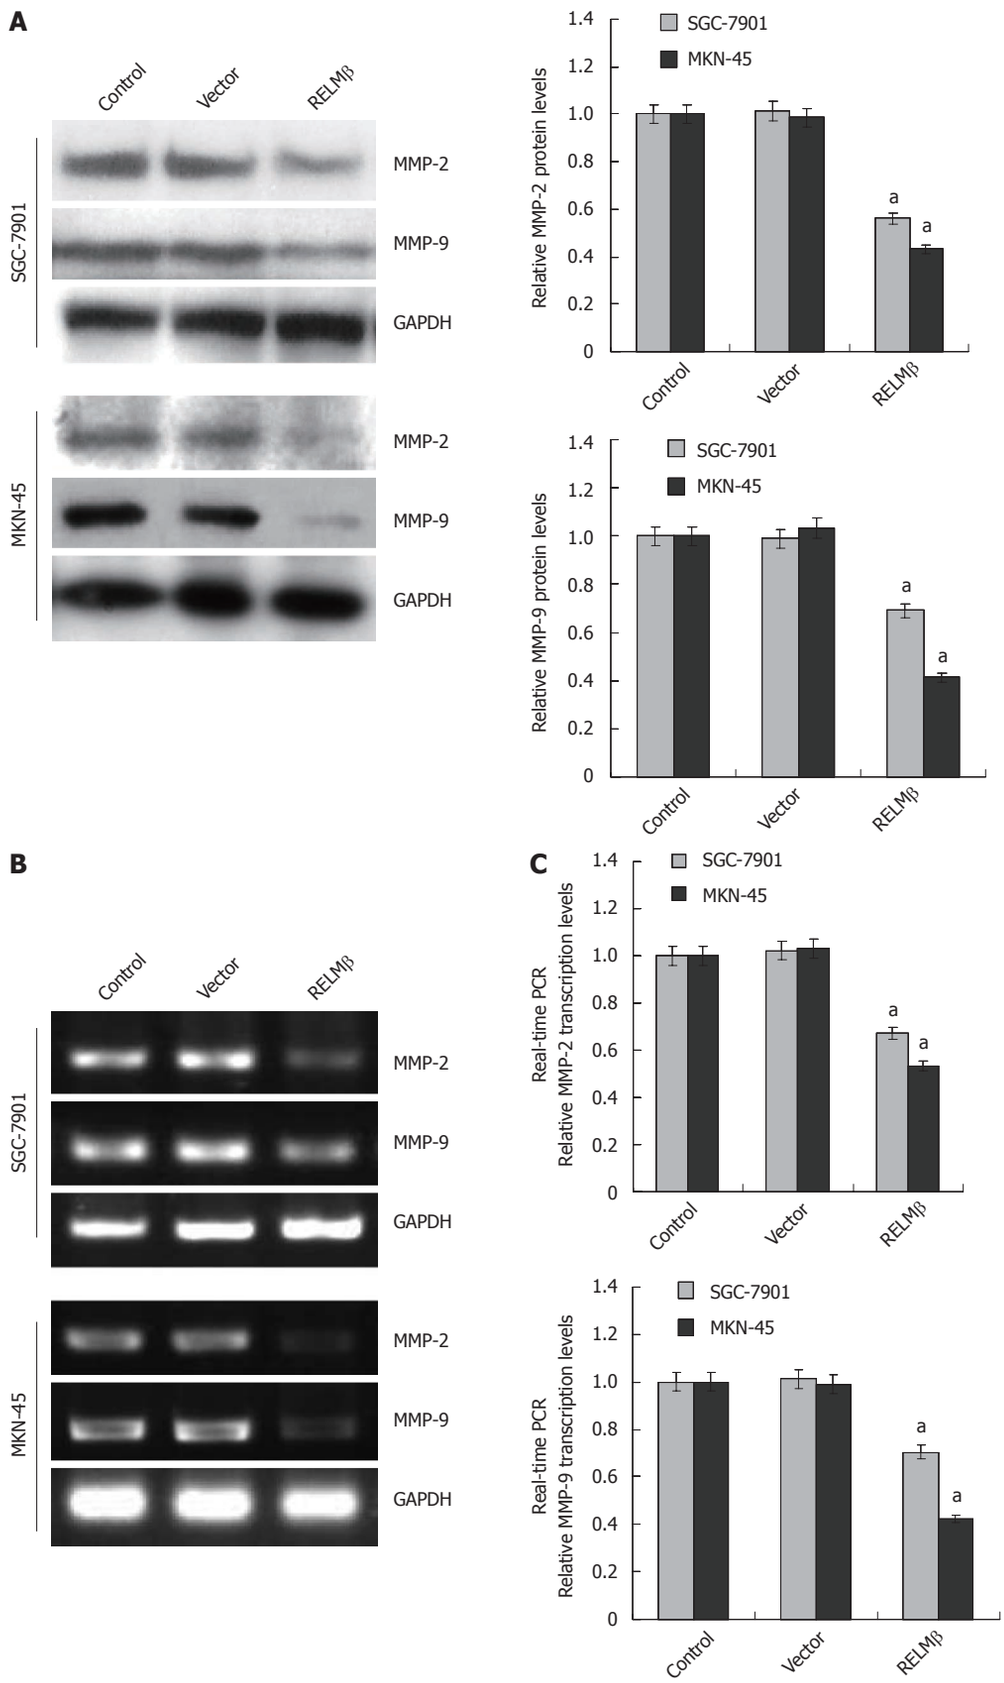

Figure 4 Over-expression of resistin-like molecule β decreased the expression of matrix metalloproteinase-2 and matrix metalloproteinase-9 in gastric cancer cells. A: Western blotting indicated that 72 h **after transfection, over-expression of resistin-like molecule** β (RELMβ) abolished the expression of matrix metalloproteinase (MMP)-2 and MMP-9 in SGC-7901 and MKN-45 cells. However, transfection of empty vector (mock) did not influence their expression; B: Reverse transcription polymerase chain reaction (RT-PCR) indicated the decreased MMP-2 and MMP-9 transcription levels in SGC-7901 and MKN-45 cells transfected with pcDNA3.1-RELMβ for 72 h, but not in mock group; C: Real-time quantitative RT-PCR further demonstrated that transfection of pcDNA3.1-RELMβ for 72 h resulted in decreased transcription levels of MMP-2 and MMP-9 in SGC-7901 and MKN-45 cells. The symbol (**a) indicates a significant decrease compared with parental cells (***P* < 0.01). Triplicate experiments were performed with essentially identical results. GAPDH: Glyceraldehyde-3-phosphate dehydrogenase.

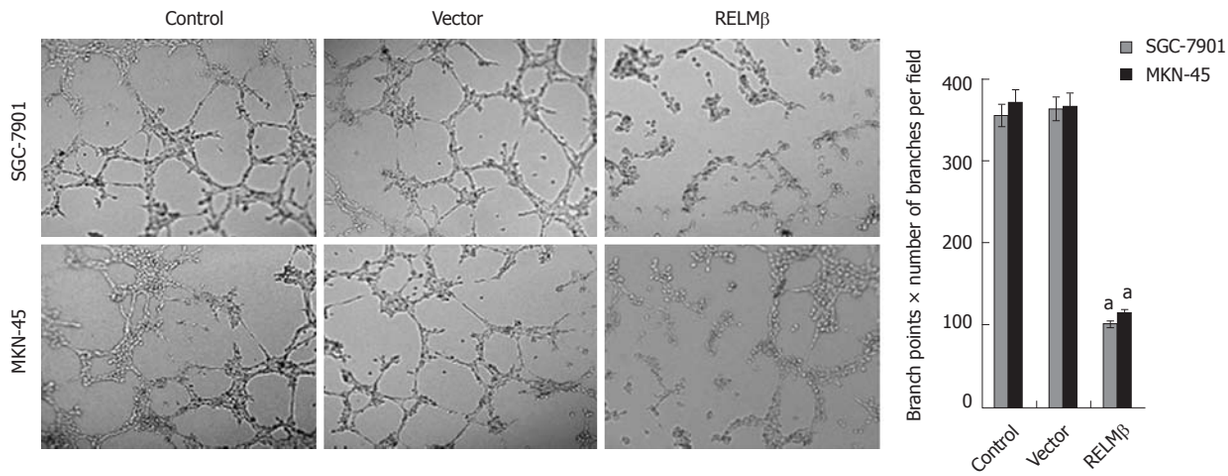

Figure 5 Over-expression of resistin-like molecule β inhibited the *in vitro* angiogenic capabilities of gastric cancer cells. Extensive tube formation of endothelial cells was observed in parental and empty vector (mock) groups. However, when the endothelial cells were treated by the medium preconditioned with pcDNA3.1-resistin-like molecule β (RELMβ)-transfected *SGC*-7901 or MKN-45 cells, the tube formation was suppressed. The symbol (**a) indicates a significant decrease compared with parental cells (***P*** < 0.01)**. Triplicate experiments were performed with essentially identical results.

proliferation of prostate cancer through phosphatidylinositol 3-kinase (PI-3K)/Akt signaling pathways[37]. In addition, transfection of RELMγ into promyelocytic HL60 cells resulted in increased proliferation rate and an altered response to retinoic acid-induced granulocytic differentiation[27]. Thus, these findings indicate the potential role of RELM/FIZZ gene family in the progression of cancer.

Our previous studies have revealed that RELMβ is virtually absent in normal gastric mucosa, whereas gastric cancer exhibits aberrant RELMβ expression[19]. Patients showing positive RELMβ expression have a significantly longer overall survival than those with negative expression, indicating the prognostic value of RELM-β in predicting the outcomes of gastric cancer[19]. Current literatures show conflicting results regarding the role of RELMβ in cell proliferation[38,39]. McVay *et al*[38] reported that RELMβ did not alter colonic epithelial proliferation or barrier function in the dextran sodium sulfate-induced model of murine colonic injury. In cultured lung adenocarcinoma A549 cells, transfection of a RELMβ encoding expression vector resulted in increased proliferation *via* the PI-3K pathway[39]. In this study, we found low expression levels of RELMβ in the poorly or moderately differentiated gastric cancer cell lines SGC-7901 and MKN-45. Unexpectedly, over-expression of RELMβ did not affect the proliferation of SGC-7901 and MKN-45 cells as evidenced by MTT colorimetry, colony formation and EdU incorporation assays. We believe that the effects of RELMβ on cell proliferation varied among different cancer types. In our previous studies, we have observed the correlation between the intensity of RELMβ and metastatic index heparanase, one of the key enzymes involved in the invasion and metastasis of gastric cancer[19]. We found that in primary gastric cancer tissues, lower RELMβ intensity was correlated with higher heparanase expression[19]. In this study, we chose the RELMβ lowly-expressed gastric cancer cell lines as models, and demonstrated that over-expression of RELMβ resulted in attenuated adhesion, migration and invasion, three important steps for cancer metastasis.

MMPs are a family of enzymes that proteolytically degrade various components of the extracellular matrix (ECM), and are closely correlated with tumor invasive and metastatic potentials[40]. MMP-2 and MMP-9 participate in the degradation of basement membrane and the remodeling of ECM[41], and appear to promote tumor initiation, invasion, and metastasis[42]. Tumor cells can synthesize and secret large amounts of MMP-2 and MMP-9 in a paracrine and/or autocrine manner to stimulate angiogenesis[41]. Previous studies show that high levels of MMP-2 and/or MMP-9 have a significant correlation with the invasion and metastasis of gastric cancer[43,44], and are associated with poor prognosis[44]. In this study, we found that over-expression of RELMβ inhibited the expression of MMP-2 and MMP-9 in gastric cancer cells, which at least in part, contributed to the RELM-mediated suppression of migration and invasion of cancer cells.

Angiogenesis, the process of new capillary formation from pre-existing vessels to provide oxygen and nutrients to tumor, plays an essential role in invasion and metastasis of malignancies[45]. Previous studies indicate that resistin increases *in vitro* angiogenesis in human coronary artery endothelial cells and umbilical vein endothelial cells[46]. As a mouse homolog of RELMβ, hypoxia-induced mitogenic factor (HIMF) is found to promote angiogenesis and participate in pulmonary vascular remodeling and fibrotic lung disease[47-49]. RELMβ is expressed in the lung tissue of patients with sclerodermaassociated pulmonary hypertension[16], and recombinant RELMβ induces the proliferation and activation of extracellular signal regulated kinase 1/2 (ERK1/2) in primary cultured human pulmonary endothelial and smooth muscle cells[16]. However, the influence of RELMβ on the angiogenic capabilities of cancer cells still remains exclusive.

In the current study, we demonstrated the anti-angiogenic properties of RELMβ in gastric cancer cells. It has

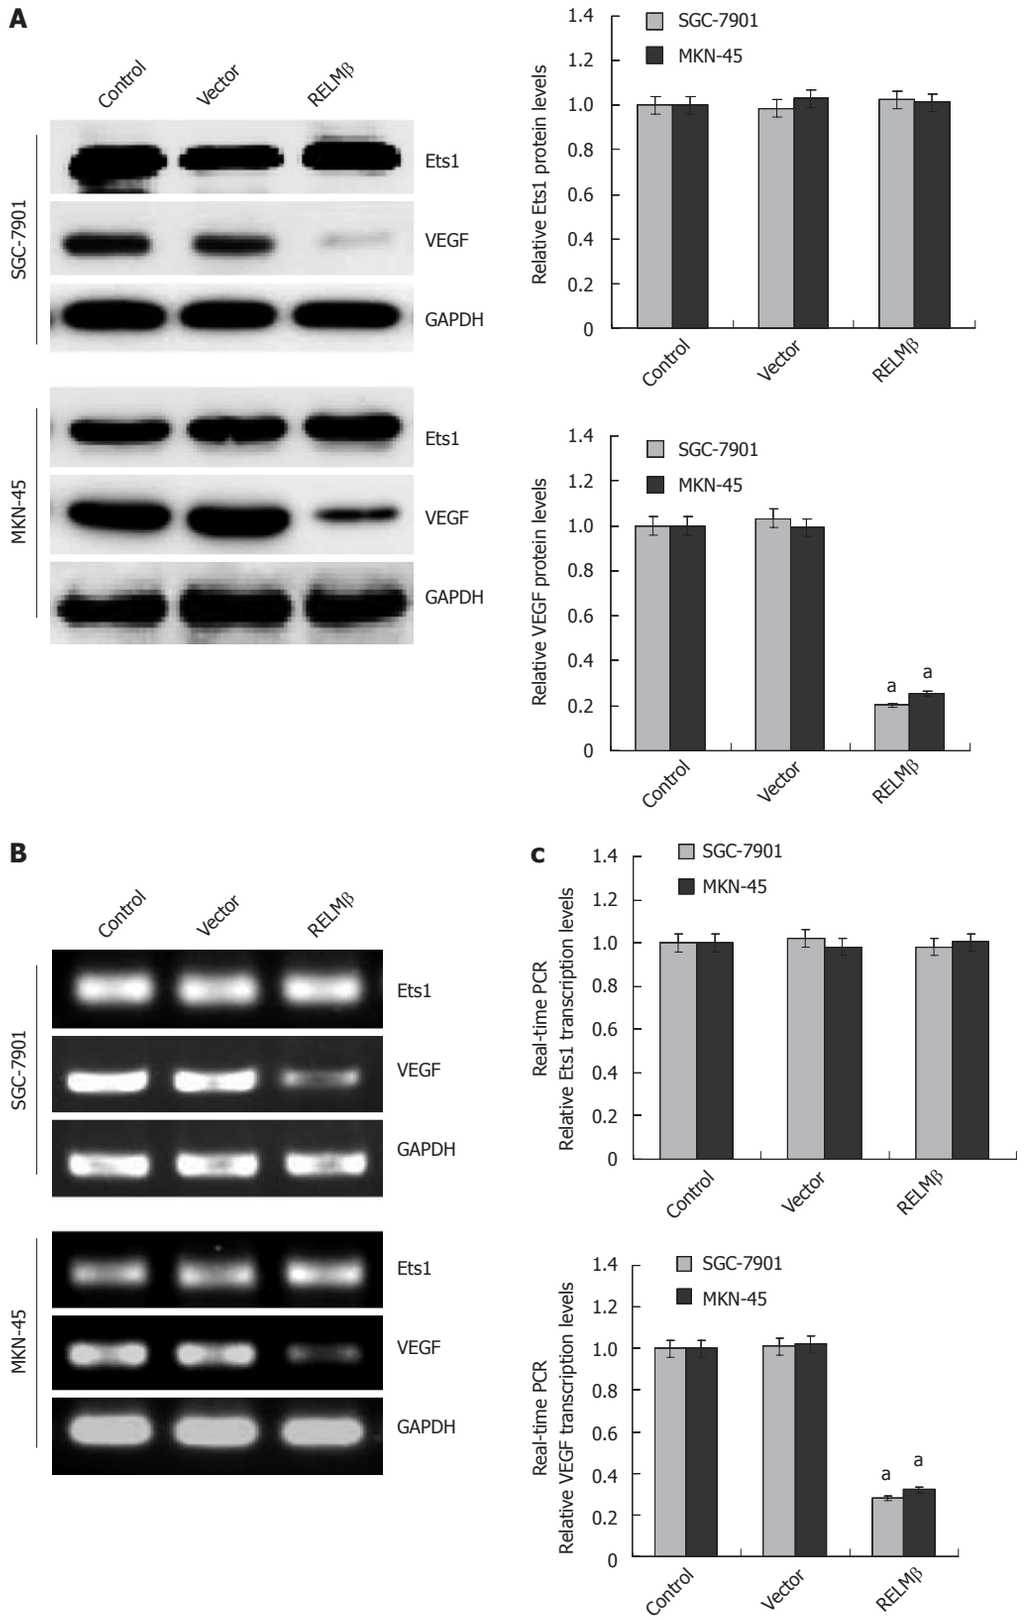

Figure 6 Over-expression of resistin-like molecule β decreased the expression of vascular endothelial growth factor, but not v-ets erythroblastosis virus E26 oncogene homolog 1, in gastric cancer cells. A: Western blotting indicated that 72 h after transfection, over-expression of resistin-like molecule β (RELMβ) abolished the expression of vascular endothelial growth factor (VEGF), but not v-ets erythroblastosis virus E26 oncogene homolog 1 (Ets1), in SGC-7901 and MKN-45 cells. Moreover, transfection of empty vector (mock) did not influence the expression of VEGF and Ets1; B: Reverse transcription polymerase chain reaction (RT-PCR) indicated the decreased VEGF transcription levels in SGC-7901 and MKN-45 cells transfected with pcDNA3.1-RELMβ for 72 h, but not in mock group. Moreover, the Est1 transcription levels were not influenced by transfection of pcDNA3.1-RELMβ or empty vector (mock); C: Real-time quantitative RT-PCR further demonstrated that transfection of pcDNA3.1-RELMβ for 72 h resulted in decreased transcription levels of VEGF, but not of Ets1, in SGC-7901 and MKN-45 cells. The symbol (a) indicates a significant decrease from parental cells ($P < 0.01$). Triplicate experiments were performed with essentially identical results. GAPDH: Glyceraldehyde-3-phosphate dehydrogenase.

been established that VEGF is secreted by most tumor cells, and plays a determinant role in regulating tumor angiogenesis through inducing cell proliferation, differentiation, and migration of vascular endothelial cells[50]. VEGF induces the formation of new vessels by targeting VEGF receptor 2 signaling pathway, and benefits primary tumor growth and metastasis[51]. Thus, targeting constitutive VEGF and/or its receptors has been an attractive approach for cancer therapy. Our results further showed that over-expression of RELMβ inhibited the expression of VEGF in gastric cancer cells. Based on our recent evidence that recombinant RELMβ protein possesses anti-angiogenic effects *via* decreasing the proliferation, migration, and tube formation of human umbilical vein endothelial HUVEC cells (data not shown), we believe that RELMβ is of potential values as a novel therapeutic target for human gastric cancer.

The mechanisms underlying RELMβ expression in gastric cancer still remains exclusive. Previous evidence indicates that a region between -418 and -588 in the human RELMβ promoter contains two potential caudal type homeobox (CDX) binding sites[52]. Moreover, CDX-2, but not CDX-1, binds to the human RELMβ promoter and thereby transactivates RELMβ expression in a goblet cell-specific fashion[52]. However, our preliminary findings indicate that CDX-2 does not transactivate the RELMβ expression in cultured gastric cancer cells (data not shown). The constitutive expression of RELMβ in gastric cancer tissues with or without intestinal metaplasia[19] suggests that other transcription factors are involved in the regulation of RELMβ expression in gastric cancer, which warrants further investigations.

In summary, for the first time, we have demonstrated that over-expression of RELMβ can efficiently inhibit the invasion, metastasis and angiogenesis of gastric cancer cells. It is likely that the RELMβ over-expression depresses the expression of MMP-2 and MMP-9, thus inhibiting the invasion and metastasis of gastric cancer. In addition, transfection of RELMβ suppresses the VEGF expression, which may result in decreased angiogenesis of gastric cancer cells. These results suggest a potential strategy for gastric cancer therapy *via* modulating or regulating the RELMβ expression. Further knocking down the RELMβ expression in RELMβ highly-expressed cell lines and *in vivo* studies are warranted to investigate the role of RELMβ in the development and progression of gastric cancer.

COMMENTS

Background

According to the previous studies of the authors, the aberrant expression of resistin-like molecule β (RELMβ), an intestinal goblet cell-specific protein, in gastric cancer tissues, is positively correlated with tumor differentiation and longer overall survival, and inversely correlated with tumor infiltration and lymph node metastasis. However, the exact roles and underlying mechanisms of RELMβ in the progression of gastric cancer still remain unknown.

Research frontiers

Although most studies of RELMβ have focused on its function in intestinal defense against parasitic nematode infection of the intestine and colonic inflammation, increasing attention has been paid to the role of RELMβ in tumor biology. The authors in their previous studies have demonstrated that RELMβ is a biomarker of intestinal metaplasia in Barrett's esophagus, and over-expressed in gastric cancer and colon cancer. However, no study has yet investigated the exact role of RELMβ in invasion, metastasis and angiogenesis of gastric cancer.

Innovations and breakthroughs

In this study, the authors demonstrate, for the first time, that over-expression of RELMβ can efficiently inhibit the invasion, metastasis and angiogenesis of gastric cancer cells. It is likely that the RELMβ over-expression depresses the expression of matrix metalloproteinase (MMP)-2 and MMP-9, thus inhibiting the invasion and metastasis of gastric cancer. In addition, transfection of RELMβ suppresses the vascular endothelial growth factor expression, which may result in decreased angiogenesis of gastric cancer cells.

Applications

RELMβ expression is a useful prognostic factor for predicting the outcomes of gastric cancer patients. The effects of RELMβ over-expression on the invasion, metastasis and angiogenesis of gastric cancer cells suggest a potential strategy for gastric cancer treatment *via* modulating or regulating the RELMβ expression. Further knocking down the RELMβ expression in RELMβ highly-expressed cell lines and *in vivo* studies are warranted to investigate the role of RELMβ in the development and progression of gastric cancer.

Terminology

RELMβ is a recently described goblet cell-specific protein that belongs to the resistin-like molecules, or found in inflammatory zone (*RELM/FIZZ*) gene family and functions as a critical immune-effector molecule in the expulsion of gastrointestinal tract nematodes.

Peer review

The authors reported a study elucidating the effects of RELMβ over-expression on the invasion, metastasis and angiogenesis of gastric cancer cell lines. It revealed that transient transfection of RELMβ into low-expressing gastric cancer cell lines resulted in attenuated adhesion, migration and invasion, three important steps for cancer metastasis. In addition, over-expression of RELMβ suppressed the angiogenic capabilities of cancer cells. The results are original and may represent a novel strategy for the treatment of gastric cancer.

Abstract

AIM: To characterize the efficacy of rifaximin in the management of hepatic encephalopathy (HE) as several randomized controlled studies have shown contradictory results on its effectiveness in comparison to other oral agents.

METHODS: We performed a systematic review and random effects meta-analysis of all eligible trials identified through electronic and manual searches. Twelve randomized controlled trials met the inclusion criteria with a total of 565 patients.

RESULTS: The clinical effectiveness of rifaximin was equivalent to disaccharides or other oral antibiotics [odds ratio (OR) 0.96; 95% CI: 0.94-4.08] but with a better safety profile (OR 0.27; 95% CI: 0.12-0.59). At the completion of treatment protocols, patients receiving rifaximin showed lower serum ammonia levels [weighted mean difference (WMD) = -10.65; 95% CI: -23.4-2.1; *P* = 0.10], better mental status (WMD = -0.24; 95% CI: -0.57-0.08; *P* = 0.15) and less asterixis (WMD -0.1; 95% CI -0.26-0.07; *P* = 0.25) without reaching statistical significance. On the other hand, other psychometric outcomes such as electroencephalographic response and grades of portosystemic encephalopathy were superior in patients treated with rifaximin in comparison to the control group (WMD = 0.21, 95% CI: -0.33-0.09, *P* = 0.0004; and WMD = -2.33, 95% CI: -2.68-1.98, *P* = 0.00001, respectively). Subgroup and sensitivity analysis did not show any significant difference in the above findings.

CONCLUSION: Rifaximin appears to be at least as effective as other conventional oral agents for the treatment of HE with a better safety profile.

Key words: Hepatic encephalopathy; Lactulose; Neomycin; Non-absorbable disaccharides; Rifaximin

INTRODUCTION

Hepatic encephalopathy (HE) is a reversible neuropsychiatric and functional syndrome occurring in 50%-70% of

patients with advanced liver disease[1]. The pathophysiology of HE is complex and it manifests with progressive deterioration of the superior neurological functions. HE occurs in the presence of insufficient hepatic clearance of toxins absorbed from the intestine resulting in neurochemical abnormalities across the blood brain barrier[2]. The clinical manifestations of HE range from altered mental status to deep coma[3]. Elevated serum ammonia level is the best described cause of HE and is detected in 60%-80% of affected patients[4,5]. Current treatment strategies[6] are aimed at reducing the serum level of ammonia. This is done by introducing agents that reduce or inhibit production of intestinal ammonia or minimize its absorption from the gastrointestinal tract as well as correcting precipitating factors such as gastrointestinal hemorrhage, electrolyte imbalances and constipation[7].

For both acute and chronic HE, the mainstay treatment has been the use of non-absorbable disaccharides[3] since they decrease the absorption of ammonia through cathartic effects and by altering the colonic pH[6]. Several oral antibiotics such as neomycin, paromomycin, metronidazole, vancomycin and rifaximin have shown some degree of effectiveness in lowering serum ammonia concentration by reducing the intestinal flora responsible for its production[8]. With the exception of rifaximin, all the other antibiotics have been associated with some side effects such as ototoxicity and nephrotoxicity (neomycin)[9,10] and neurotoxicity (metronidazole)[11,12]. Vancomycin may be a safer option, however, its use has been associated with the development of bacterial resistance[13]. On the other hand, rifaximin is a poorly-absorbed broad spectrum antibiotic with very few systemic side effects and at low risk of inducing bacterial resistance[14,15]. These properties make rifaximin an ideal antibiotic for the treatment of patients with HE as several studies have shown a significant decrease in plasma ammonia levels[16-18] with minimal impact on the normal gastrointestinal flora[13].

Several small randomized controlled trials (RCT) comparing rifaximin with oral disaccharides or with other antibiotics have found that rifaximin is effective and safe. Nevertheless, these trials were insufficiently powered. A meta-analysis of randomized controlled trials comparing disaccharides *vs* antibiotics for the treatment of HE has shown superior outcomes with the use of antibiotic therapy[19]. Sub-group analysis of five studies comparing rifaximin to disaccharides favored the use of rifaximin ($P = 0.04$)[19]. On the other hand, a more recent and larger meta-analysis including seven studies comparing rifaximin with non-absorbable disaccharides showed no significant difference between the two interventions, although rifaximin had fewer side effects[20]. In light of these limitations, we conducted a systematic review of the literature to identify, appraise and collectively analyze all RCTs comparing rifaximin with conventional oral therapies for the treatment of patients with HE.

MATERIALS AND METHODS

Data sources and study selection

Randomized controlled trials comparing oral rifaximin to non-absorbable disaccharides and other antibiotics used for the treatment of HE were searched in PubMed, Excerpta Medica Database, Scopus, Web of Science, Cochrane central register of controlled trials, and hepatobiliary group in the Cochrane library, EMBASE, CINAHL through December 4th 2010 without restriction on the publication status or language. Database specific search terms for rifaximin (rifaximin, rifamycins), disaccharides (disaccharides, lactulose, lactitol, sugar alcohols) and antibiotics (anti-bacterial-agents, antibiotics) were combined and all reference sections of eligible studies and review articles on the topic were hand-searched for additional potential studies. Two reviewers (Eltawil KM and Molinari M) independently assessed the eligibility of all potential abstracts and titles. When in disagreement or in the presence of insufficient information, the full text of the potential paper was reviewed for eligibility. Authors of all potential trials were also contacted by electronic mail for additional information if the published data were insufficiently described.

Inclusion and exclusion criteria

We included all RCTs that reported the effect of rifaximin *vs* non-adsorbable disaccharides or other antibiotics on the grade of HE according to Conn's modification of Parsons Smith classification[21], irrespective of language and publication status. Exclusion criteria were: studies conducted on pediatric patients, studies that compared the use of rifaximin *vs* placebo, non-controlled clinical trials, studies that assessed the efficacy of rifaximin in preventing HE, trials including patients with psychiatric illness, with undercurrent infections, with hypersensitivity to rifaximin and other antibiotics and/or intolerance to non-absorbable disaccharides, trials that included individuals affected by gastrointestinal bleeding and studies reporting results of the same population published more than once.

Outcomes

The primary outcomes of this study were the effectiveness and the safety of the use of rifaximin for the treatment of patients with at least one episode of HE. Secondary outcomes were reduction of serum ammonia levels and changes in psychometric parameters [mental status, asterixis, electroencephalographic characteristics and portosystemic encephalopathy (PSE) sum] measured at the end of the treatment.

Definitions

The study population was defined as patients older than 18 years of age with a diagnosis of reversible neurological decline secondary to end-stage liver disease. Effectiveness was calculated by the proportion of patients

who had resolution or clinical improvement of HE during the treatment. Partial neurological response was measured by mental status scores according to Conn's classification[21] as follows: 0, no personality or behavioral abnormality; 1, trivial lack of awareness, euphoria or anxiety, shortened attention span, or impairment of ability to add or subtract; 2, lethargy, disorientation with respect to time, obvious personality change, or inappropriate behavior; 3, somnolence or semi-stupor, responsiveness to stimuli, confusion, gross disorientation, or bizarre behavior; and 4, coma.

Side effects of rifaximin and other oral therapies assessed in this study were: severe diarrhea, episodes of intense abdominal pain and at least one of the following symptoms: nausea, anorexia and weight loss.

Serum ammonia levels were assessed at the end of the treatment and expressed in mg/dL.

The severity of asterixis was graded according to established criteria as follows: 0, no tremors; 1, few flapping motions; 2, occasional flapping motions; 3, frequent flapping motions; and 4, almost continuous flapping motions[22,23].

Electroencephalogram (EEG) abnormalities recorded in patients with HE were scored according to criteria previously published in the medical literature[24]: 0, well-structured EEG with stable and symmetrical posterior basic rhythm (8 Hz-13 Hz) dominant in the posterior regions medium amplitude without slow activities or epileptic pattern; 1, unstable or suppressed alpha rhythm frequently replaced by high prevalence of diffuse beta rhythm (normal-limit EEG); 2, low frequency alpha rhythm (8 Hz) disturbed by random waves in the theta range over both hemispheres (mild signs of encephalopathy); 3, background activity in the theta range, diffused over both hemispheres, random appearance of high waves in the delta range (distinctive features of encephalopathy); and 4, severe disorganization of EEG activity without any normal element (signs of severe encephalopathy).

Grades of PSE were calculated as the sum of the degree of mental status abnormality scores, the severity of asterixis, level of serum ammonia elevation and the degree of EEG abnormality[25].

Data extraction

Two independent reviewers extracted publication variables and clinical data for each study. The following variables were collected: the name of the primary author, journal and year of publication, country where the study was carried out, number of patients randomized in each arm, daily dosage of oral therapy, duration of the treatment, allocation sequence generation, allocation concealment, power calculation, study design, methods used to deal with missing data, appropriate description of attrition and drop-outs.

Clinical variables extracted were: the proportion of patients that experienced improvement of their neurological function (effectiveness), common side effects, serum ammonia level and psychometric parameters.

Assessment of study quality

The quality of included studies was scored using the Cochrane Collaboration risk assessment tool[26]. The methodological quality was essentially based on the attention that each study design paid to control potential bias based on the available description reported in the methodology of each paper. When in doubt, authors were contacted by digital letters. The randomization methods were classified as the primary way to control bias and the randomization process was evaluated by the allocation sequence generation and allocation concealment. The randomization methods were considered adequate if based on a table of random numbers, computer-generated random numbers or based on similar techniques. Allocation concealment was classified as adequate if based on central randomization, if using identically appearing coded drugs, if serially numbered opaque sealed envelopes were employed or when other equivalent methods were used. Blinding was extracted and appraised for caregivers, patients and assessors. Studies were classified as single-blinded if the patients did not have any opportunity to know the nature of their therapy and double-blinded if the authors described in their methods how they prevented patients and caregivers or assessors knowing the nature of the treatments. In addition, we appraised the risk of attrition bias by assessing the number and reason for dropouts and withdrawals and whether all patients were accounted for in the report and analysis of the study. Quality of the included studies also assessed the way the authors described sample size calculation to power the trial and if the sample size was achieved, whether there was a clear definition of primary outcomes and if they were reported and whether a crossover design was used.

Statistical analysis

All statistical analyses were performed using RevMan Version 5.0.5 software[27] (Nordic Cochrane Centre, Copenhagen, Denmark). The meta-analysis was performed using the random effects model of DerSirmonian and Laird[28] due to expected clinical heterogeneity. The results are reported as pooled odds ratios (OR) for binary and weighted mean differences (WMD) for continuous outcomes, both with 95% CI. Pooled OR and WMD were calculated using the general inverse variance (IV) with random effect model. Measure of the degree of inter-trial heterogeneity was explored with the I^2 test[29]. Heterogeneity was evaluated with a χ^2-based Q statistic of OR and defined at a P value less than 0.1 and potential reasons for heterogeneity were explored. Data on all patients randomized were extracted to allow intention-to-treat analysis. For patients with missing data, carry-forward of the last observed response was used. Only data from the first period of cross-over trials were included. For the primary outcome measure, we performed subgroup analyses of trials stratified by the treatment regimen and methodological quality. The preferred reporting items for systematic reviews and meta-analysis

Table 1 Characteristics of included studies

Authors	Country	Rifaximin (*n*)	Control (*n*)	Rifaximin dose (mg/d)	Comparative agent	Duration of treatment	Outcomes
Bucci *et al*[35]	Italy	30	28	1200	Lactulose 45 mL/d	15 d	Mental status, asterixis, cancellation test, reitan test, EEG, serum ammonia, degree and severity of HE

EEG: Electroencephalogram; HE: Hepatic encephalopathy; PSE: Portosystemic encephalopathy; NCT: Number connection test.

recommendations were used for study reporting[30,31].

RESULTS

Ascertainment of the studies

After initial screening, a total of 220 potentially relevant trials were identified through the electronic searches as summarized in Figure 1. After subsequent evaluation for eligibility, we retained 12 published RCTs that assessed the effectiveness of rifaximin for the treatment of patients with HE. One study was available only in abstract form[32]. The remaining studies were excluded because they were prospective cohort studies or randomized controlled trials assessing the effectiveness of rifaximin for the prevention rather than for the treatment of HE.

Study characteristics

Table 1 lists the characteristics of the included studies. All trials were single-center studies except one which was multicentric[17] with the total number of patients per study ranging from 14 to 136 and with a minimum therapeutic interval of 7 d to a maximum of 6 mo. The majority of studies treated one arm of patients with rifaximin at a dose of 1200 mg/d divided in three doses, although some used 1100 mg in two divided doses. The comparison arm of patients received non-absorbable oral disaccharides (lactulose or lactitol) at doses ranging from 45 to 120 mL/d for lactulose and 60 g/d for lactitol or antibiotic therapy with neomycin or paromomycin. One study[33] was designed as a double cross study where patients received rifaximin in addition to oral disaccharides for one week and were switched to neomycin in

combination with oral disaccharides on the third week of therapy. Festi *et al*[17] carried on a randomized controlled trial that included 4 arms of patients with HE: in one group the effect of rifaximin was compared to non-absorbable disaccharides and in the other group rifaximin was compared to neomycin.

The majority of control patients who received neomycin were treated with a total of 3000 mg/d divided in three doses except for participants in Di Piazza's study[33] who were treated with a total daily dose of 4500 mg divided in three administrations. Paromomycin was used in only one study[2] and administered at a total dose of 1500 mg/d divided in three doses of 500 mg each.

The majority of trials that used non-absorbable oral disaccharides aimed at inducing several soft bowel movements per day although none of the included studies reported how they monitored their participants.

Risk of bias

We assessed the risk of bias for all the included studies based on published reports and information provided by the authors (Table 2). The allocation system was described in five trials[21,25,34-36] and allocation concealment was clearly defined in eight trials[18,21,25,34-38]. The majority of trials were blinded to patients; however, blinding of observers was described only in six studies[18,25,33,36-38]. Methods for handling missing data, description of drop-outs and possible causes of attrition and power calculations were not adequately described in any of the included studies. One study was available only in abstract form and therefore the risk of bias appraisal was not satisfactory.

Primary outcomes

Effectiveness: First, the effectiveness of therapy was assessed by comparing rifaximin to non-adsorbable disaccharides (lactulose or lactitiol) and then to other oral antibiotics (neomycin or paromomycin). After that, the overall effectiveness of rifaximin *vs* other conventional oral therapies was assessed by combining the two subgroups.

Using the random-effect model, the pooled analysis of 7 studies[17,18,21,32,36,37,39] that investigated the efficacy of rifaximin (n = 184) *vs* non-absorbable disaccharides (n = 165) revealed that both groups experienced either full resolution of HE or clinical improvement that was considered significant by the primary investigators without reaching statistical significance (OR = 1.92, 95% CI: 0.79-4.68, P = 0.15).

Similar findings were observed when the data of all 5 RCTs comparing the efficacy of rifaximin *vs* other antibiotics[17,25,33,34,38] were pooled. This confirmed that rifaximin (n = 68) had similar effectiveness to neomycin or paromomycin (n = 60, neomycin or paromomycin) (OR = 2.77, 95% CI: 0.35-21.83, P = 0.21).

The results of the combined analysis with both groups of patients receiving antibiotics or disaccharides showed a trend that favored the use of rifaximin without statistical significance (OR = 1.96, 95% CI: 0.94-4.08, P = 0.07) (Figure 2).

Adverse events: The following were side effects used in our analysis: severe diarrhea beyond the expected cathartic effect of disaccharides, abdominal pain, and the combination of nausea, anorexia and weight loss. First, each of the adverse events experienced by patients was compared separately. Second, all the adverse events were pooled and compared between the group of patients who received rifaximin (n = 980) and the control group (n = 988).

Participants who received rifaximin had less risk of suffering from diarrhea (OR = 0.20, 95% CI: 0.04-0.92, P = 0.04) although the rate of abdominal pain nausea/anorexia/weight loss was similar between the two groups (P = 0.40, P = 0.06, respectively). Yet, combined analysis of all the adverse events favored the use of rifaximin as it was associated with fewer side effects (OR = 0.27, 95% CI: 0.12-0.59, P = 0.001) (Figure 3).

Secondary outcomes

Serum ammonia level: At the end of 7 RCTs[17,21,25,34-36,38], a significant reduction in serum ammonia level was observed in both treatment arms; rifaximin *vs* non-adsorbable disaccharides and rifaximin *vs* neomycin or

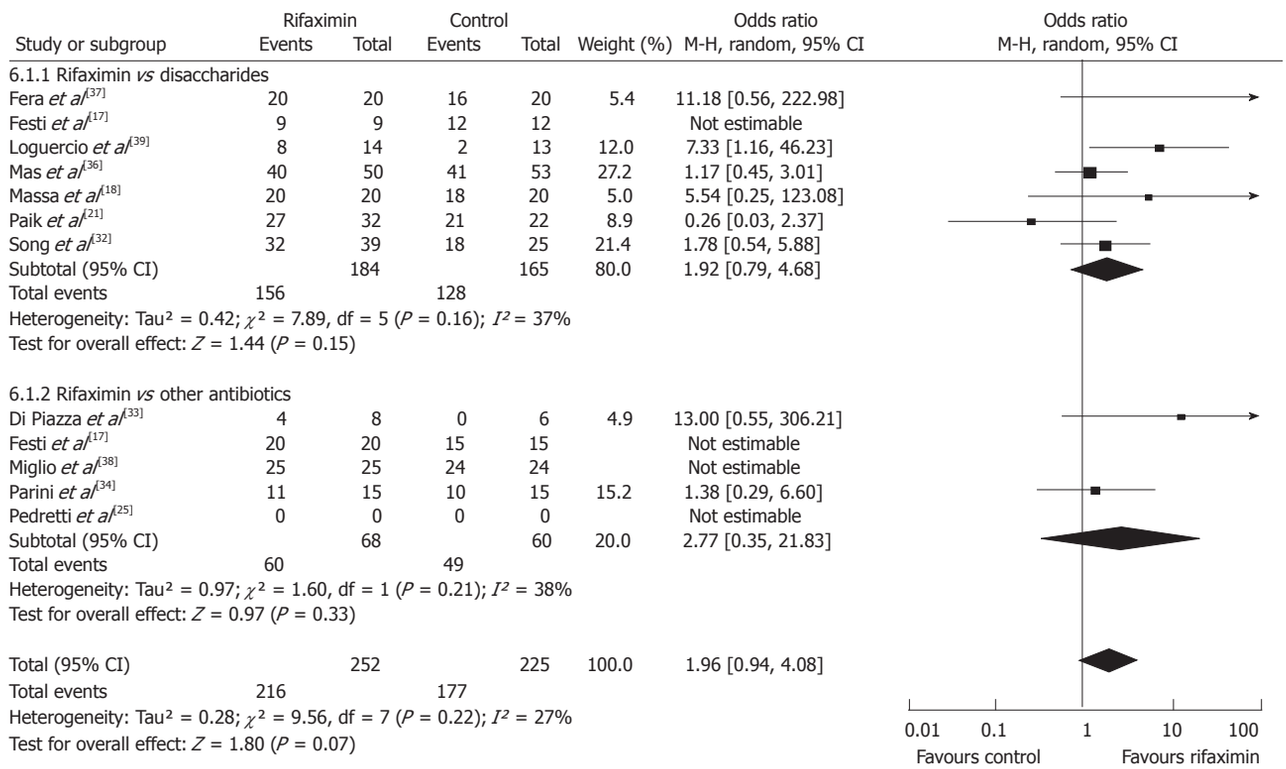

Figure 2 Efficacy of rifaximin *vs* oral disaccharides, rifaximin *vs* other oral antibiotics and rifaximin *vs* control therapy which included the combination of oral disaccharides and other antibiotics. M-H: Mantel Haenszel.

paromomycin. Participants who received rifaximin (n = 138) had lower serum ammonia levels in comparison to patients who received non-adsorbable disaccharides (n = 128) although the difference did not reach statistical significance (P = 0.30). Similar results were observed when comparing rifaximin (n = 60) *vs* other oral antibiotics (n = 60) (P = 0.33) although the differences were not statistically significant. When compared to all the controls (n = 176), patients treated with rifaximin (n = 181) had an overall lower mean serum ammonia level but this, too, was not statistically significant (WMD = -10.65, 95% CI: -23.46-2.17, P = 0.10) (Figure 4).

Psychometric parameters: Improvement in mental status and degree of asterixis after rifaximin therapy were compared to controls in seven trials with no statistically significant results (P = 0.15 and P = 0.25, respectively) (Table 3).

The changes in EEG patterns and PSE sum were studied in 3 trials (rifaximin *vs* control)[18,25,36]. For both parameters, the meta-analysis showed a statistically significant improvement favoring the use of rifaximin (WMD = 0.21, 95% CI: -0.33-0.09, P = 0.0004, and WMD = -2.33, 95% CI: -2.68-1.98, P = 0.00001, respectively) (Table 3). The overall improvement in psychometric parameters measured between the two drug groups was statistically significant favoring the use of rifaximin (P = 0.005) as summarized in Table 3.

Sensitivity analysis

A sensitivity analysis for both primary and secondary outcomes was conducted to explore heterogeneity on the basis of the quality of study design. By excluding studies considered at higher risk of bias according to the Cochrane Collaboration risk assessment tool, we identified consistency of findings and no statistically significant changes were noted for all the comparisons performed.

DISCUSSION

Hepatic encephalopathy represents a challenging clinical complication of liver insufficiency and presents with a wide spectrum of neuropsychiatric symptoms that range from mild disturbances in cognitive function to coma to even death[13,40]. The pathogenesis of this complex syndrome is thought to be multifactorial, but a key role is played by circulating gut-derived toxins such as ammonia[2,40]. With appropriate medical treatment most of the clinical manifestations of HE are reversible when precipitating factors are corrected[2]. The most common known conditions responsible for HE include: gastrointestinal bleeding, infections or systemic inflammation, renal and electrolyte abnormalities, dehydration, use of narcotics and other psychoactive medications, constipation and an excess protein intake[6].

Traditionally, non-absorbable disaccharides have been used as the first-line therapy for patients with HE[13] even if their effectiveness in comparison to placebo has not been proven[19]. Although safe, the need to adjust disaccharide doses to achieve two to three loose bowel movements per day often leads to frequent nausea, vomiting, and flatulence and affects compliance[3]. Poorly absorbed oral antibiotics such as neomycin, vancomycin or paro-

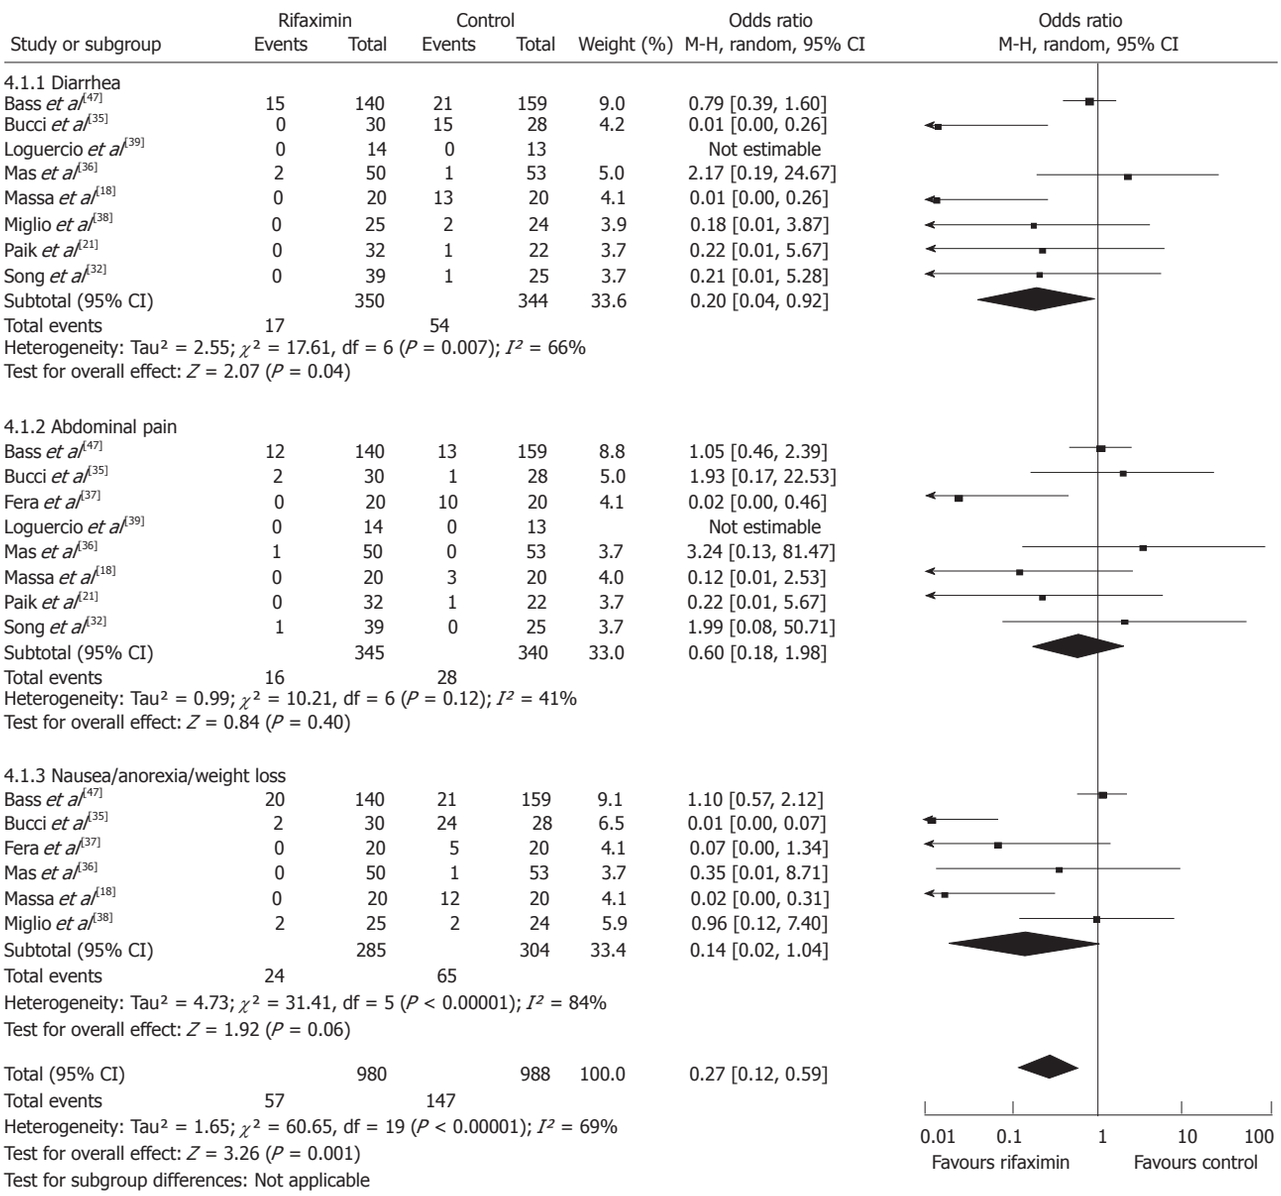

Figure 3 Adverse events experienced by patients treated with rifaximin *vs* control therapy. M-H: Mantel Haenszel.

momycin seem to be more effective than disaccharides[19] with fewer side effects, although ototoxicity[41], nephrotoxicity[42], neurotoxicity and bacterial resistance have been described[20,42]. This significant risk of severe toxicity is the reason why most of these agents are seldom used in modern practice.

On the other hand, rifaximin is an agent that appears to be effective in the treatment of HE without carrying the risk of severe side effects. It has the advantage of being well tolerated and has minimal risk of causing bacterial resistance[43]. It was initially introduced in Italy in 1987[44] and recently approved in the United States for the treatment[45] and prevention[46] of HE. The purported advantages of rifaximin over other oral agents make it a very attractive choice for treatment of HE, although at considerably greater expense[13]. A recent mathematical model has shown that initial disaccharide monotherapy followed by rifaximin as a second-line therapy would be the most cost-effective strategy[47]. So far, the evidence for use of rifaximin as the first-line therapy for HE has been supported only by underpowered randomized controlled trials with conflicting results. A previous meta-analysis of seven randomized controlled trials concluded that rifaximin was not superior to non-absorbable disaccharides, except that it was better tolerated[20]. One of the limitations of that study was that rifaximin was not compared to other established oral therapies and that psychometric functional outcomes were not included in the final analysis.

In this study, we incorporated 12 randomized controlled trials published in the last 20 years assessing the efficacy and adverse events of rifaximin *vs* other oral therapies such as disaccharides and antibiotics. In addition to the effectiveness and safety profile, we also analyzed the effects of these treatments on serum ammonia levels and several other psychometric outcomes.

Table 3 Summary of the meta-analysis on psychometric outcomes measured at the end of each randomized controlled trial

IV: Inverse variance; EEG: Electroencephalogram; PSE: Portosystemic encephalopathy.

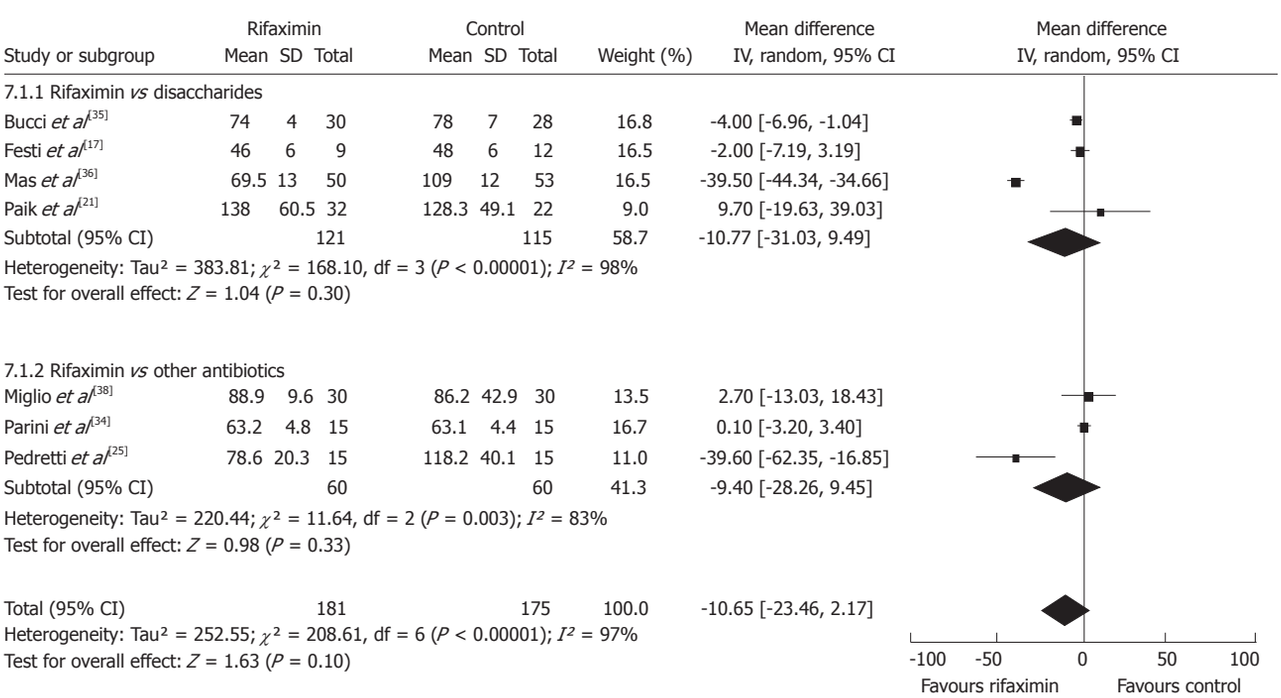

Figure 4 Serum ammonia levels at the end of the treatment protocols: rifaximin *vs* oral disaccharides, rifaximin *vs* other oral antibiotics and rifaximin *vs* control therapy which included the combination of oral disaccharides and other antibiotics. IV: Inverse variance.

Statistical assessment of patients' compliance was not possible as none of the included trials measured attrition or reported any drop-outs as all the included participants appeared to be able to complete the treatment protocols.

The results of this study confirm that rifaximin has similar effectiveness to other oral therapies but with fewer side effects. As such, it is the first new effective treatment for HE in a long time and its impact on patients' quality of life and survival has yet to be fully realized.

With regard to other secondary outcomes measured at completion of treatment protocols, patients receiving rifaximin had lower serum ammonia levels and superior mental status and asterixis profiles in comparison to the control group without reaching statistical significance. On the other hand, the grade of electroencephalographic abnormalities and PSE sums showed better profiles for participants treated with rifaximin when compared to their controls. These findings are of some importance as HE is a syndrome with a wide spectrum of neuropsychiatric abnormalities and it is important to be able to quantify subtle clinical changes during the course of therapy.

All trials in the present review excluded patients with uncorrected precipitating factors causing HE. Nevertheless, we could not obtain individual patient data to determine if response to the treatments varied according to the grade or etiology of liver disease.

One of the major limitations of this study was that the trials that satisfied the inclusion criteria had been performed during a relatively long period of time (1991-2005), the lengths of the treatment protocols varied significantly (5 d to 6 mo) and there was a lack of data on the severity of liver disease or other co-morbidities for each population. These important aspects were most likely responsible for the heterogeneity observed among the pooled studies. Minor imputations were required for some studies specially when considering standard deviations. In addition, pooling may not have been appropriate in all cases because of the heterogeneity between trials, but we attributed heterogeneity to statistical rather than clinical reasons.

On the other hand, this study also has several strengths. An extensive literature search was performed and provided the most up-to-date information on the effects of rifaximin in the treatment of HE. Using two reviewers, the inclusion or exclusion of studies and data extraction were performed independently and therefore more accurately. In addition, we did not exclude potential studies due to language, publication status or year of publication, and the fact that included trials were performed in several countries and in different settings increases the external validity of our results. Another strength of this study is that we assessed not only the efficacy and side effects of the treatments, but we also included other important clinical outcomes that could be measured objectively such as serum ammonia levels, asterixis and electroencephalographic features. Because we used a rigorous search strategy to reduce the introduction of potential publication bias, a funnel plot was not included as the number of trials was moderate and it would not have added any significant information.

In summary, this study has shown that rifaximin is comparable to other oral agents in regard to clinical efficacy for HE and is associated with fewer side effects. These results did not change during sensitivity analysis based on the quality of the trials, and the effect of rifaximin was more favorable in improving psychometric parameters and serum ammonia level measured at the end of the protocols. Given its safety profile, rifaximin should be considered as second-line in the treatment of HE patients who fail disaccharide therapy and as first-line in those intolerant of disaccharides.

COMMENTS

Background

Hepatic encephalopathy (HE) represents a debilitating and even potentially deadly complication occurring in patients with advanced liver disease. The clinical manifestations of encephalopathy range from altered mental status to deep coma. Rifaximin is an oral broad spectrum, non-absorbable antibiotic with very few systemic side effects and is used to treat or prevent hepatic encephalopathy in cirrhotic patients.

Research frontiers

The authors performed a systematic review of the literature and meta-analysis of the effectiveness and safety of rifaximin compared to other conventional oral agents such as non-absorbable disaccharides (lactulose) and other antibiotics (e.g., neomycin, metronidazole). Conventional therapies are known to cause local side effects such as diarrhea and abdominal pain in the case of Lactulose and systemic side effects such as nephrotoxicity and neurotoxicity with neomycin and metronidazole, respectively.

Innovations and breakthroughs

Several studies have shown contradictory results on the effectiveness of rifaximin in comparison to other oral agents.

Applications

The analysis has shown rifaximin to be as effective as non-absorbable disaccharides concerning improvement in the clinical symptoms of patients with hepatic encephalopathy with a lower incidence of side effects such as diarrhea, abdominal pain and nausea.

Terminology

HE: HE is a worsening of brain function that occurs when the liver is no longer able to remove toxic substances in the blood; Systematic review: A literature review focused on a research question that tries to identify, appraise, select and synthesize all high quality research evidence relevant to that question; Meta-analysis: A combination of the results of several studies that address a set of related research hypotheses.

Peer review

Rifaximin is a novel antimicrobial agent with a wide spectrum of activity that has shown promise as an alternative antimicrobial treatment option for HE. Rifaximin appears to be at least as effective as other conventional drug therapy and has been associated with fewer adverse events due to its limited systemic absorption.

Abstract

AIM: To evaluate immunoexpression of cyclooxygenase-2 (COX-2) in primary gastric carcinomas and respective lymph node metastases.

METHODS: Immunohistochemistry to analyze COX-2 expression was performed on tissue microarray slices obtained from 36 specimens of gastrectomy and satellite lymph nodes from patients with gastric carcinoma.

RESULTS: Immunostaining was seen in most cases, and COX-2 expression was higher in lymph node metastases than in corresponding primary gastric tumors of intestinal, diffuse and mixed carcinomas, with a statistically significant difference in the diffuse histotype ($P = 0.0108$).

CONCLUSION: COX-2 immunoexpression occurs frequently in primary gastric carcinomas, but higher expression of this enzyme is observed in lymph node metastases of the diffuse histotype.

Key words: Cyclooxygenase-2; Gastric carcinoma; Immunoexpression; Lymph node metastases; Tissue microarray

INTRODUCTION

Gastric carcinoma is one of the most common malignancies worldwide[1]. Despite improvements in the detection of early gastric cancer and more efficient surgical procedures, mortality remains high. Current challenges include studies on gastric carcinogenesis, tumor progression, and the investigation of possible molecular targets that could be utilized in diagnosis, prevention and therapeutic approaches.

Several recent studies have focused on gastric carcinogenesis. According to a known model, it is a multistep process beginning with chronic gastritis and proceeding to gastric atrophy, intestinal metaplasia, dysplasia and cancer[2]. *Helicobacter pylori* (*H. pylori*), a cause of chronic gastritis, is considered a carcinogenic agent and a link between inflammatory and neoplastic processes in the stomach[3,4].

Cyclooxygenase-2 (COX-2) is an important enzyme that catalyzes arachidonic acid to prostaglandins, which participate in inflammatory and neoplastic processes. *H. pylori*-associated with chronic gastritis induces COX-2 expression in gastric mucosa[5]. Following eradication of bacteria in gastritis, there is a tendency for COX-2 expression to reduce or disappear[5]. COX-2 expression is seen more frequently in intestinal metaplasia than in normal gastric mucosa[6] and is prominent in dysplasias[7].

COX-2 immunostaining levels correlate with the degree of dysplasia in the epithelia and stroma[8]. It is widely accepted that COX-2 immunoexpression occurs in the lamina propria and epithelia in gastritis, in intestinal metaplasia, in dysplasia, and more strongly in adenocarcinomas in a progressive manner according to the degree of the lesion[6,9-11].

In contrast to the many published reports on gastric carcinogenesis, we found few studies on the involvement of COX-2 in gastric cancer progression, all of them concerning local invasion. Results are controversial, with some authors finding a relationship between a higher degree of COX-2 expression and advanced local invasion[12-14] and others finding no correlation[15-17].

Several reports evaluated a possible association between COX-2 expression in primary gastric tumors and the presence or absence of lymph node metastasis, with mixed results. In some reports, COX-2 positivity[14,16,17] and COX-2 overexpression in primary carcinomas[18,19] were associated with the presence of lymph node metastases. Others found no correlation[13,15,20]. None of these studies evaluated COX-2 expression in both primary and metastatic gastric carcinomas. Here, we evaluated the immunoexpression of COX-2 in primary gastric carcinomas and respective lymph node metastases.

MATERIALS AND METHODS

Patients and tissue samples

Thirty-six gastric cancer specimens were obtained from patients surgically treated at the Cancer Institute of Ceará, Brazil. Formalin-fixed, paraffin-embedded tissue samples of primary gastric adenocarcinomas and their respective lymph node metastases were stained with hematoxylin and eosin and histologically analyzed. Gastric carcinomas were classified as intestinal (n = 10), diffuse (n = 12), mixed (n = 8), or unclassified (n = 6) (according to Lauren's classification system)[21].

Tissue microarray

Tissue microarrays (TMAs) were constructed from the primary samples and metastatic lymph node samples. One donor block was identified in each case, and a tissue core 2 mm in diameter representative of the neoplasm without necrotic or hemorrhagic areas was punched (TMA-builder LabVision™ catalog #-TMA 001), then placed into receptor blocks of TMAs (24 samples/block). Sections 2 μm in thickness were obtained from the TMA blocks to perform immunohistochemistry.

Immunohistochemistry

Paraffin sections were dewaxed and rehydrated. Endogenous peroxide was blocked with a 3% H_2O_2 solution in methanol for 10 min, and for unmasking antigens, a retrieval solution (Vector Co™) 1% in hot water (98 ℃) was added and incubated for 20 min. Ultra V block (TA-125-UB, LabVision Co™) was added to the sample and incubated for 10 min to inhibit nonspecific background staining. A rabbit monoclonal antibody against human COX-2 (Clone SP21, pm 70 kDa, LabVision Co™, 1:200) was applied for 60 min. After washing with phosphate buffered saline (PBS), the sections were incubated with a secondary anti-polyvalent biotinylated goat antibody (TP-125-BN, LabVision Co™) for 15 min, washed with PBS, incubated with a streptavidin-coupled peroxidase complex (TS-125-HR, LabVision Co™) for 15 min, then washed again with PBS. Reactions were processed at room temperature (approximately 20 ℃) in an automated immunostainer (Autostainer, LabVision Co™, model 480-2D) at the Institute of Molecular Pathology and Immunology of the University of Porto. A 3% H_2O_2 solution in methanol and 60 mg chromogen diaminobenzidine in PBS were applied for 10 min at 37 ℃ in the dark. After washing with distilled water for 3 min, sections were counterstained with hematoxylin, dehydrated, diaphanized with xylene, mounted and analyzed. Samples containing fewer than 100 cells were excluded from analysis.

Scoring and evaluation

The positivity criterion was cytoplasmic staining of COX-2 in malignant cells. Immunoexpression of COX-2 was evaluated regarding intensity and extension using a modified scoring table based on Rajnakova *et al*[12] (using intensity × extension, rather than intensity + extension). We used the following definitions: Intensity = degree of immunostaining which predominates in the TMA sample (0- absent; 1- mild; 2- moderate; 3- strong); extension = percentage of predominant staining intensity in the sample (0- negative or rare cells; 1- < 25%; 2- 25%-50%; 3- 50%-75%; 4- > 75% of immunoreactive neoplastic cells). A combined score of 0-12 was calculated by intensity × extension. Final COX-2 expression was classified as low (< 6) or high (≥ 6) based on median cut-off. Scores were established by two independent observers without knowledge of previous clinical findings, resulting in a high level of concordance (89%; $P < 0.05$). Cases out of concordance were defined by consensus.

Table 1 Expression of cyclooxygenase-2 in gastric cancer histotypes - stomach

Histotype	COX-2 (combined scores)								
	0	1	2	3	4	6	8	9	12
Intestinal	1	2	-	1	1	3	1	-	1
Diffuse	-	1	-	1	4	2	4	-	-
Mixed: Intestinal component	-	-	-	-	4	-	2	1	1
Diffuse component	-	-	-	-	4	-	3	-	1
Unclassified	1	-	-	1	1	1	1	-	1

Histotype	COX-2 (combined scores)								
	0	1	2	3	4	6	8	9	12
Intestinal	1	1	-	-	2	1	4	-	1
Diffuse	-	1	-	-	1	-	4	-	6
Mixed	1	-	-	1	-	-	1	1	4
Unclassified	2	-	-	-	1	-	1	-	2

COX-2: Cyclooxygenase-2.

Controls

COX-2 positive controls were obtained from colonic adenocarcinoma sections[22]. Gastric non-tumoral mucosa and normal colonic mucosa distant from the tumor were used as negative controls. In known positive cases, there was no background staining when the primary antibody was not included. Stained inflammatory cells in the tumor stroma represented internal positive controls in cancer negative cases and fibroblasts were considered as an internal negative control in samples with positive neoplastic cells.

Statistical analysis

The non-parametric Mann-Whitney unpaired test (two-tailed) was used to compare median scores among different gastric carcinoma histotypes. The non-parametric Wilcoxon paired test (two-tailed) was utilized to test whether the median staining scores were significantly different between each primary gastric histotype sample of carcinoma and respective lymph node metastases. A P value of less than 0.05 was regarded as statistically significant.

Ethics

This study was approved by the Research Ethics Committee of the Cancer Institute of Ceará, Brazil (protocol number 32/2004) and conforms to The Code of Ethics of the World Medical Association (Declaration of Helsinki).

RESULTS

Table 1 shows the primary gastric cancer distribution by histological type and detailed scores. There is a marked concentration of scores at 4 and 8 and dispersion of other scores.

In lymph nodes, the highest score of 12 occurred at a much higher frequency (13 cases) than in primary tumors (only 4 cases), notably in diffuse and mixed carcinomas, while intestinal histotype was given a score of 8 more frequently than in primary carcinomas (Tables 1 and 2).

Analysis of low (< 6) and high (⩾ 6) COX-2 expression levels showed no differences among primary and metastatic respective histotypes (Table 3).

In lymph nodes (Table 4), high COX-2 expression (score ⩾ 6) was found in most cases (25/36 = 69%), mainly in diffuse (10/12 = 83%) and mixed histotypes (6/8 = 75%), but also in intestinal tumors (6/10 = 60%; Table 4). The highest lymph node expression difference was not statistically significant in the whole sample (P = 0.1488).

Nevertheless, in the diffuse histotype, COX-2 immunoexpression in lymph nodes was significantly higher than that in the stomach (P = 0.0108), as shown in Figure 1.

The highest COX-2 expression in metastatic diffuse carcinomas occurred not only in the whole sample of this histotype. Analysis of each case at primary and metastatic sites revealed increased expression in 75% of cases (9/12), similar expression levels in 1/12 cases (8%) and reduced expression levels in only two cases (17%). In five of nine cases with increased immunoexpression, there was a change from low to high COX-2 expression (Figure 2).

Figure 3 shows high COX-2 expression in metastatic tumors compared to respective primary carcinomas in every histological type (except unclassified).

An interesting isolated finding was observed in case 12 (diffuse histotype), shown in Figure 4. The neoplastic cells invading the gastric wall were poorly stained but the cells in the vessel lumina had strong immunoexpression, similar to metastatic lymph node implants. We will comment on these findings in the discussion.

Table 3 Expression of cyclooxygenase-2 (low and high) in gastric cancer histotypes - stomach

All magnifications 400 ×.

DISCUSSION

The study of simultaneous COX-2 immunoexpression in the primary tumor and its metastasis is rarely seen in the current literature. In a case report recently published, Scheer *et al*[23] revealed a strong multifocal COX-2 expression in about 80% of cells in the primary hypopharyngeal carcinoma and 10% in the frontotemporal bone metastasis. In addition to that, Kasper *et al*[24] found various degrees of cytoplasmic COX-2 expression in

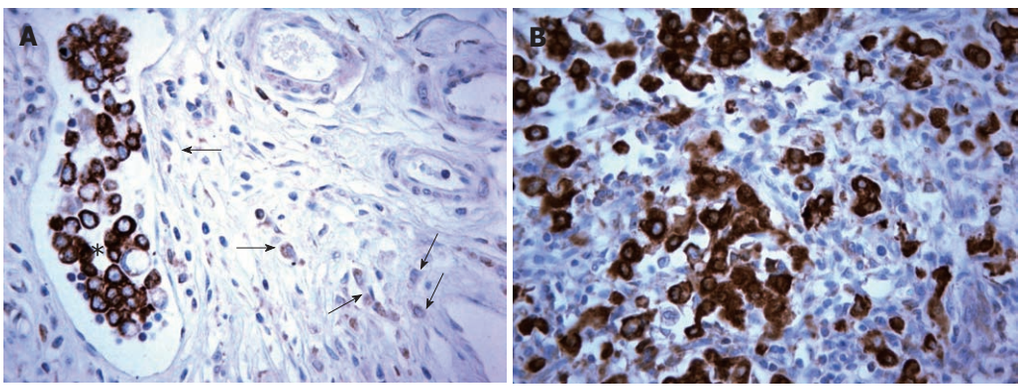

Figure 4 Cyclooxygenase-2 expression in gastric cancer and diffuse type: primary tumor, emboli and metastasis. A: Stomach: Low cyclooxygenase-2 (COX-2) expression in perivascular malignant cells (arrows). Tumor embolus with strongly stained neoplastic cells (*); B: Lymph node: High COX-2 expression at the same intensity seen in the embolus. Case 3, diffuse histotype, 400 ×.

57 colorectal carcinomas and in the corresponding liver metastases. As far as we know, there is no report regarding the simultaneous COX-2 expression in gastric cancer and in its respective lymph node metastasis.

In our study, we verified that COX-2 was expressed in 34/36 (94%) of the primary gastric carcinoma cases, similar to our results from a larger sampling (data not shown) and according to the frequency reported by other authors[14,20]. There is a broad variation in the frequency of COX-2 expression in gastric carcinomas, ranging from 43% to 100%[10,20]. In most reports, however, the frequency lies in the range of 60% to 80%[8,12,13,15,19,25].

Possible explanations for this variation are differences in sample characteristics, for instance, heterogeneity of sampling areas (inflammatory or ulcerated areas near cancer increase COX-2 expression) and variation in the usage of anti-inflammatory non-steroidal drugs, which reduce COX-2 expression. Other possibilities are methodological and technical procedures like time of fixation, sensitivity and specificity of monoclonal/polyclonal antibodies, and criteria for evaluation of immunoexpression. In many studies, including our own, separate scores were applied to intensity and extension and scores were then multiplied or added[8,10,12,19,20,25]. We used a scoring system ranging from 0 to 12 with a cut-off in the middle (low expression < 6; high expression ⩾ 6), based on median.

When scores are sufficiently simplified, defined for example as low and high expression, reproducible results must be obtained. In our sample, elevated COX-2 expression was found in 50% of primary gastric carcinoma cases, similar to the findings of Sun *et al*[19] (55%), both with a cut-off based on median. Other reports with similar score criteria showed high COX-2 expression in 61% and 62%[8,25], percentages not so different from ours.

This study showed high COX-2 expression in primary gastric carcinomas in half of the cases and without significant differences between histotypes, in agreement with other reports[9,20]. Nevertheless, other authors have found a significantly higher frequency of positive cases[6,25,26] or cases with higher expression of COX-2[10,26] in the intestinal carcinomas than in diffuse tumors.

The importance of COX-2 expression on cancer biology, in different malignant tumors including gastric carcinomas, must be emphasized. COX-2 influences neoplastic behavior in many ways, primarily through prostaglandin E_2 (PGE_2) synthesis promoting cellular proliferation[27-29], invasiveness[30-32], angiogenesis and inhibition of apoptosis[33,34]. These effects undoubtedly contribute to the process of tumor survival and progression.

In a larger series (intestinal and diffuse histotypes, results not shown), we found strong COX-2 immunostaining in 58% of tumors at stage T1 and in 48% of more advanced lesions (T2 to T4), in both histotypes (intestinal = 42%; diffuse = 55%). These percentages were higher in mixed carcinomas (data not shown). These findings reinforce the importance of COX-2 presence in local tumor progression of gastric carcinomas in all histological types.

In the lymph nodes, our results clearly showed higher COX-2 expression in metastatic tumors than in respective primary gastric carcinomas of the diffuse histotype. Diffuse carcinomas showed a strong increase in COX-2 lymph node immunostaining compared to primary gastric tumors, not only in the whole group but in most individual cases (Figure 2). To the best of our knowledge, this is the first report to evaluate COX-2 expression simultaneously in both sites and to demonstrate the strongest enzyme marking in a more advanced stage of gastric cancer compared to primary invasive tumors. Recently, Kim *et al*[35] compared COX-2 (and many other proteins) expression levels in primary gastric carcinomas and respective lymph node metastases and found no differences. Further investigation is needed to resolve this discrepancy.

We have no answer as to why, in the present study, the diffuse histotype showed the higher staining difference in metastatic lesions. Another question is "at what level of local invasion through the gastric wall does COX-2 expression increase?" There is an interesting finding in Figure 4 in which we show that neoplastic cells invading the gastric wall, near a vessel, were poorly stained while cells presented in the tumor embolus had a strong COX-2 immunoexpression, similar to the expression

found in the respective lymph node metastases.

This is an isolated finding and we cannot make definitive conclusions. However, this observation does raise further questions: do the neoplastic cells in the neighboring vessel first increase COX-2 expression and, as a consequence, invade the vessel? Or, alternatively, do the cells invade the vessel wall and then the vessel microenvironment would induce COX-2 expression? Perhaps the latter would be a suitable answer, since there are no strongly stained cells in tissue around the vessel. These questions are outside the scope of this study and must be investigated using a larger sample size with many histopathological sections for vessel immunohistochemical markers and even better addressed with experimental models.

In summary, we have shown that COX-2 immunoexpression occurs frequently in primary gastric carcinomas and higher expression is seen in lymph node metastases of the diffuse histotype. These findings emphasize the importance of COX-2 as a potential marker of tumor progression and its possible use in diagnosis, prognosis or development of therapeutic tools against gastric cancer. The role of COX-2 in neoplastic invasion through the gastric wall, in vessel tumor emboli formation and in establishing distant metastases requires further study.

ACKNOWLEDGMENTS

We thank Professor Manuel Sobrinho-Simões and Dr. Fátima Carneiro who made possible this international cooperation and Mrs. Dina Leitão for her excellent technical assistance. We are indebted to the Hospital of Cancer, Cancer Institute of Ceará (Brazil) for providing patient information and tissue blocks for the study.

COMMENTS

Background

Gastric carcinoma is one of the most common malignancies worldwide. It is widely accepted that cyclooxygenase-2 (COX-2) immunoexpression occurs in the lamina propria and epithelia in gastritis, in the intestinal metaplasia, in dysplasia, and more strongly in adenocarcinomas in a progressive manner according to the degree of the lesion. However, there is a lack of studies exploring the immunoexpression of COX-2 in primary gastric carcinomas and respective lymph node metastases.

Research frontiers

In some reports, COX-2 positivity and COX-2 overexpression in primary carcinomas were associated with the presence of lymph node metastases, but some others found no correlation. In this study, the authors evaluated the immunoexpression of COX-2 in primary gastric carcinomas and respective lymph node metastases.

Innovations and breakthroughs

This study reports that COX-2 immunoexpression occurs frequently in primary gastric carcinomas and higher expression is seen in lymph node metastases of the diffuse histotype.

Applications

The importance of COX-2 expression on cancer biology, including gastric carcinomas, must be emphasized. COX-2 influences neoplastic behavior by promoting cellular proliferation, invasiveness, angiogenesis and inhibition of apoptosis, which contribute to the process of tumor survival and progression. The differential expression of molecular markers among cancer histotypes is of high importance regarding a possible improved therapeutic approach.

Terminology

Gastric carcinomas are classified as intestinal, diffuse and mixed histotypes. The molecular characterization of these histotypes might provide a better knowledge concerning metastatic potential.

Peer review

The authors performed immunohistochemistry on COX2 in primary gastric cancer and respective lymph node metastases, and found a higher COX2 expression in metastatic tumors compared to respective primary tumors, especially in diffuse type gastric cancer. Since the study on COX2 expression in the primary and its metastases is rarely seen, this work is significant.

Abstract

AIM: To explore dendritic cells (DCs) multiple functions in immune modulation.

METHODS: We used bone-marrow derived dendritic cells from BALB/c mice pulsed with pseudo particles from the hepatitis C virus to vaccinate naive BALB/c mice. Hepatitis C virus (HCV) pseudo particles consist of the genotype 1b derived envelope proteins E1 and E2, covering a non-HCV core structure. Thus, not a single epitope, but the whole "viral surface" induces immunogenicity. For vaccination, mature and activated DC were injected subcutaneously twice.

RESULTS: Humoral and cellular immune responses measured by enzyme-linked immunosorbent assay and interferon-gamma enzyme-linked immunosorbent spot test showed antibody production as well as T-cells directed against HCV. Furthermore, T-cell responses confirmed two highly immunogenic regions in E1 and E2 outside the hypervariable region 1.

CONCLUSION: Our results indicate dendritic cells as a promising vaccination model for HCV infection that should be evaluated further.

INTRODUCTION

Despite many developments and improving results in treating hepatitis C virus (HCV) infection, chronic hepatitis C stays a severe medical health problem world wide with over 170 million people infected[1,2]. Even though treatment of chronic infected patients with pegylated interferon and ribavirin currently results in a sustained virological response in 40%-80%[3,4], there remains a large number of HCV positive patients, non-responders and relapsers. Until development of an effective vaccine, chronic hepatitis C remains one of the most important infectious diseases.

The main problem in developing such a vaccine is the limited understanding of the type of immune response that is necessary for viral clearance and the occurrence of various genotypes and quasispecies of HCV, evolving rapidly under selection pressure by the immune response[5-7]. So most likely a vaccine must induce a broad immune response to clear HCV infection[5,8,9]. And indeed, humoral and cellular immune responses to several of the viral proteins have been shown to be associated with clearance of HCV infection in experimental settings[10-14]. Infected people develop variant-specific neutralizing antibodies[15]. A main target of these antibodies is considered to be the hypervariable region 1 (HVR1) of the envelope glycoprotein E2[7,11,16,17] but also other regions in the envelope protein[18,19]. E2 covalently linked to E1, the second envelope glycoprotein of HCV, forms the virus envelope[20]. Chimpanzees immunized by recombinant E1 and E2 protein, synthesized in mammalian cells, showed protection against HCV challenge[21,22]. Anti-HVR1 antibodies even have some cross-reactive activity to different HVR1 sequences[23] and may persist up to 7 years[24]. Still, re-infection and viral persistence occurs even in the presence of these antibodies[25,26]. Besides this humoral immune response, cellular immune responses appear to be critical for HCV clearance. Development of an early class 1 restricted $CD8^+$ cytotoxic T lymphocyte (CTL) response to HCV structural and non-structural proteins is associated with HCV clearance[27,28]. Human leukocyte antigen-A2, -A3 and -B7 restricted CTL responses have been identified to regions of HCV core, E1, nonstructural (NS)3, NS4 and NS5 proteins[29,30]. The additional inclusion of T helper epitopes has been shown to produce even stronger $CD8^+$ responses[10,12]. It seems likely that an effective vaccine against HCV should therefore be capable of inducing a T helper cell, CTL and neutralizing antibody response in multiple major histocompatibility complex (MHC) types.

Considering that, key players could be dendritic cells (DCs). DC are the most potent type of antigen presenting cells and induce immune antiviral responses[31-33]. Found within the peripheral tissues and lymphoid organs, DC are perfectly suited to detect and capture pathogens. Their antigen presenting capability is crucial for generation of $CD4^+$ T-cells priming B-cells for antibody production. By production of CD40 and interleukin-2 (IL-2), DC provide help to $CD8^+$ cells. To fulfill their function, DC have to mature, normally triggered by exposure to viruses or other pathogens[5]. Interestingly DC from HCV carriers show impaired maturation, determined by absence of cell surface molecules[34,35], as well as reduced IL-2 production[36]. Loss of DC function is probably a direct consequence of HCV infection[14]. Ex vivo generated and matured DC therefore might be the most potent candidate for a cell based HCV vaccine. In fact, there are some promising results published for immunization with DC against the human immunodeficiency virus and HCV[32,33,37,38].

In sera of patients with chronic HCV infection antibodies directed towards E1 and E2 can be found as mentioned above[39]. Chimpanzees immunized with recombinant HCV E1 and E2 showed protection against HCV infection[40]. Peptide immunizations have been successful in producing humoral and cellular immune responses[41,42]. But peptides do not deliver a great number of epitopes and are not folded in the native protein form. To overcome these limitations virus like particles have been created, consisting of both envelope proteins E1 and E2 on an HCV core or retroviral core protein, the latter termed HCV pseudo particles (HCVpp)[43-45]. These particles mimic HCV virions in the best possible way and are therefore an interesting stimulant. In this study, we investigated if HCVpp are able to activate mature murine DCs *ex vivo* and if so, if vaccination with these DC induces specific immune responses against HCV *in vivo*.

MATERIALS AND METHODS

Cells and culture conditions

293T cells and Huh-7 cells were maintained in Dulbecco's Modified Eagle Medium (Invitrogen, Karlsruhe, Germany) supplemented with 10% fetal calf serum (FCS) (Invitrogen, Karlsruhe, Germany), 2 mmol/L L-glutamine (Invitrogen, Karlsruhe, Germany), 100 units/mL penicillin and 100 units/mL streptomycin (Invitrogen, Karlsruhe, Germany). Bone marrow derived dendritic cells were maintained in RPMI 1640 medium (Invitrogen, Karlsruhe, Germany) supplemented with 10 % FCS, 2 mmol/L L-glutamine, 100 U/mL Penicillin, 100 mg/mL streptomycin and 50 μmol/L 2-mercaptoethanol (Invitrogen, Karlsruhe, Germany).

Preparation of HCVpp

Pseudoparticles were generated as described previously[45]. Briefly, 293T cells were transfected using a calcium phosphate-based transfection kit with three expression vectors encoding an envelope glycoprotein, viral core components, and a viral genome containing a green fluorescent protein marker gene. The plasmids used in our laboratory are the following: Cytomegalovirus (CMV)-Gag-Pol murine leukemia virus (MLV) packaging construct, encoding the MLV gag and pol genes; the MLV-green fluorescent protein (GFP) plasmid, encoding an MLV-based transfer vector containing a CMV-GFP internal transcriptional unit and the plasmid phCMV-E1E2-HCV, encoding the HCV E1 and E2 glycoproteins of Con1-isolate, genotype 1b. After 40-46 h supernatants containing pseudoparticles were filtered through 0.45 μm pore size membrane and for further concentration a centrifugation with Amicon Ultra-15 centrifugal filter units (MWCO 100K) was done. Infectious titers of the concentrated supernatants were then determined by infection of Huh7 cells as previously described[45]. The infectious titers, expressed as transducing units per milliliter, were deduced from the transduction efficien-

cies, determined as the percentage of GFP-positive cells measured by fluorescence activated cell sorting (FACS) analysis[46].

Generation of bone-marrow derived dendritic cells

For preparation of bone-marrow derived DC, we used 6-10 wk old BALB/c mice (Charles River Breeding Laboratories, Sulzfeld, Germany). They were maintained under barrier-sustained conditions and handled according to international guidelines. After sacrificing the animals, the tibia and femur bones were used to prepare bone marrow cells. With minor adaptations, cultivation of bone marrow cells was done following the Inaba protocol[47]. On day 7 we pooled non-adherent and loosely adherent cells. The isolated cell suspensions were either taken for FACS analysis or plated into 12 well culture plates (Greiner Labortechnik, Kremsmuenster, Germany) at a density of 1.5×10^6 cells per well in one ml of complete bone marrow-derived dendritic cell (BMdDC) medium.

FACS analysis of BMdDC

Flow cytometry analysis for measuring the expression of different surface molecules was performed with a FACSCalibur® cytometer and data was analysed with Cell Quest Pro software (Beckton Dickinson, Franklin Lakes, United States). For staining, 2×10^5 cells were incubated in staining buffer [phosphate buffer solution (PBS) and 0.5% body surface area, Invitrogen, Paisley, United Kingdom] with either 1 μL of specific antibodies or the corresponding isotype control (APC anti-mouse CCR-7 (Biozol, Eching, Germany), R-PE anti-mouse CD 11c, FITC anti-mouse CD 86, FITC anti-mouse MHC Ⅱ (I-Ad) (all from BD Bioscience, Heidelberg, Germany) for 30 min on ice in the dark. Stained cells were pelleted for 3 min at 2000 r/mim (Biofuge pico; Kendro, Hanau, Germany) and were washed twice with staining buffer. A negative control with unstained cells was run first to determine the baseline fluorescence. Checking for unspecific binding, marker setting was done with isotype controls. For instrument settings and compensation of R-PE and FITC, samples stained with individual fluorescent probes were used.

Activation of BMdDC

On day 7, FACS analysis revealed 60%-70% mature DC, which were placed in a 12-well culture plate with a concentration of 1.5×10^6 cells per mL. Twenty-four hours later, the DC were activated by adding nothing (negative control), HCVpp (7.5×10^5), 1 μg/mL *E. coli* lipopolysaccharide (LPS) (Sigma, St. Louis, MO), or HCVpp together with LPS into the culture medium. LPS is a known co-stimulatory factor for DC[48]. Cells were harvested on day 9 (24 h after activation) and washed extensively. Activation of DC was measured by FACS analysis. For immunization, 1.0×10^6 DC were collected in 75 μL of 0.9% sodium chloride per mouse.

Table 1 Different vaccination groups with 8 mice each

No.	Vaccine	Purpose
1	Sodium chloride	Negative control
2	DC 293T-supernatant, concentrated with Amicon filtration as the HCVpp	Negative control to rule out immunogenic components of Amicon filter and 293T supernatant
3	HCVpp	Immunogenic impact of HCVpp
4	DC activated with HCVpp	Treatment group without adjuvant
5	DC activated with HCVpp + LPS	Treatment group with adjuvant

DC: Dendritic cell; HCVpp: Hepatitis C virus pseudo particles; LPS: Lipopolysaccharide.

Vaccination schedule of the mice

Different groups of 8 mice each were subcutaneously injected with vaccines on day 1 and day 15 (Table 1). In all experiments HCVpp were used at a concentration of 7.5×10^5/mL after amicon filtration. Two weeks after the second vaccination, sera and spleen cells were collected for immunological analysis. Sera were centrifuged at 13 000 r/min for 30 min and plasma was collected and stored at -80 ℃.

Isolation of splenocytes

Collected spleens were ground on ice in complete RPMI medium (Invitrogen, Paisley, United Kingdom), centrifuged (1000 r/min, 5 min) and resuspended in PBS twice. The purified cells were treated with erythrocyte lysis buffer, centrifuged, washed and resuspended in complete RPMI medium. The isolated cells were counted with a Neubauer chamber. Splenocytes were used for immunological analysis at a concentration of 3×10^6 cells per mL.

Immunological analysis

Interferon-gamma (IFN-γ) enzyme-linked immunosorbent spot test (ELISPOT) assay was performed using 3×10^5 splenocytes per well (96 well plates, Millipore, Bedford, United States) from each vaccination group precoated with anti-IFN-γ antibodies (5 μg/mL; Beckton Dickinson, Franklin Lakes, United States). HCV specific T-cell responses were examined after stimulation with either HCVpp or overlapping peptides from PepSet ™ (Mimotopes, Clayton Victoria, Australia) of the E1 and E2 Protein of the Con1 HCV sequence which was used for HCVpp production. Altogether, 69 peptides (24 covering the E1 protein and 45 covering the E2 protein) consisting of 20 amino acids each with an offset of 8, were pooled by 7 peptides for better handling as described earlier[49]. As a positive control, concanavalin A (1 μg/mL, Sigma, St. Louis, United States) was added. Following standard protocol IFN-γ spot-forming cells (SFC) were counted by a computer-based image analyser (Zeiss-Vision, Eching, Germany). All results were expressed as mean SFC/3×10^5 splenocytes of quadruplicate measurements.

Enzyme-linked immunosorbent assay (ELISA) was

used to determine the levels of anti-HCV-immunoglobulin in the sera of the different immunization groups. Following standard protocol 96-well microtiter plates (Millipore, Bedford, United States) were coated with either HCVpp or PepSet™ (Mimotopes, Clayton Victoria, Australia) containing biotinylated overlapping peptides (offset by 8) of the E1 and E2 Protein of the Con1 HCV sequence (Table 2). Again the 69 peptides were pooled by 7 peptides. Mouse serum was added in a 1:100 dilution. Colour development, using an HRP conjugated goat anti-mouse-IgG antibody (Santa Cruz Biotech, Santa Cruz, United States), was read in an automated reader at 450 nm (Microplate Reader 2001, Whittaker Bioproducts, Walkersville, United States).

RESULTS

Dendritic cells are strongly activated by HCVpp

As shown in Figure 1, CD11c positive DC that were used in our study were activated by HCVpp *in vitro*. In the FACS analysis non-activated DC expressed CD86 in 10% and CCR7 in 10%. After 24 h of incubation with HCVpp and the costimulatory factor LPS, HCVpp only, or LPS alone CD86 rates were increased to 41%, 40% or 49%, respectively. Thus, DC were strongly activated. Regarding the more specific migration marker CCR7, incubation with LPS resulted in low levels of expression (12%). In contrast, priming with HCVpp or HCVpp and LPS resulted in a stronger upregulation. Here, CCR7 was found in 25% and 39%, respectively. In all our experiments CCR7 receptor expression was more enhanced whenever we used HCVpp for activation of the DC.

DC treatment is well tolerated in mice

We immunized different groups of BALB/c mice, each consisting of 8 animals (Table 1). For immunization details see Materials and Methods section. All mice were checked daily. Treatment was well tolerated and no mouse was considered ill, lost weight or died.

BALB/c mice immunized with DC pulsed with HCVpp can induce antibody response

Humoral immune responses against HCVpp were assessed by ELISA. Antibody titers were highest in groups of mice vaccinated with HCVpp pulsed DC. However, only slightly significant antibody binding could be demonstrated in the overlapping peptides (PepSets™) spanning the E1 and E2 protein of the HCV Con 1 isolate (Figure 2). Mice vaccinated with HCVpp showed lower antibody binding of the overlapping peptides compared to mice vaccinated with HCVpp pulsed DC. However, using HCVpp as read-out antigen, the measured antibody binding was comparably high in HCVpp pulsed DC and HCVpp vaccinated animals. Overall, highly significant antibody binding ($P < 0.001$) was only observed with HCVpp as read-out antigen, indicating the importance of correct three dimensional folding.

ELISPOT demonstrates a specific T-cell response in BALB/c mice immunized with DC previously incubated with HCVpp

Specific T-cell responses were assessed by IFNγ-ELISPOT analysis. Results are shown as mean SFC/3 × 10^5 splenocytes (Figure 3). T-cells from mice vaccinated with DC pulsed by the combination of HCVpp and LPS showed the highest amount of IFN-γ when stimulated with the peptide pools or HCVpp itself. The responses were significantly higher compared to T-cells from mice vaccinated with HCVpp only. As expected, the two negative control groups (mice vaccinated with saline or 293T supernatant) showed the lowest number of spots. Peak results with SFC/3 × 10^5 splenocytes above 80 were seen in cells stimulated with pools 3 and 7 in the analysis. Pool 3 (85.8 spots/well) represents amino acids 312-379 of the E1 protein and pool 7 (86.3 spots/well) represents amino acids 544-611 of the E2 protein, regarding the sequence of the HCV polyprotein. In contrast to the ELISA assay, there was no significant difference between the read-out antigens used (peptide pools *vs* HCVpp).

DISCUSSION

The hepatitis C virus inhibits intracellular interferon pathways, impairs DC activation and T-cell responses[34-36,50]. In addition, it induces a state of T-cell exhaustion and selects escape variants with mutations in immunodominant T-cell epitopes[51]. This is especially important since

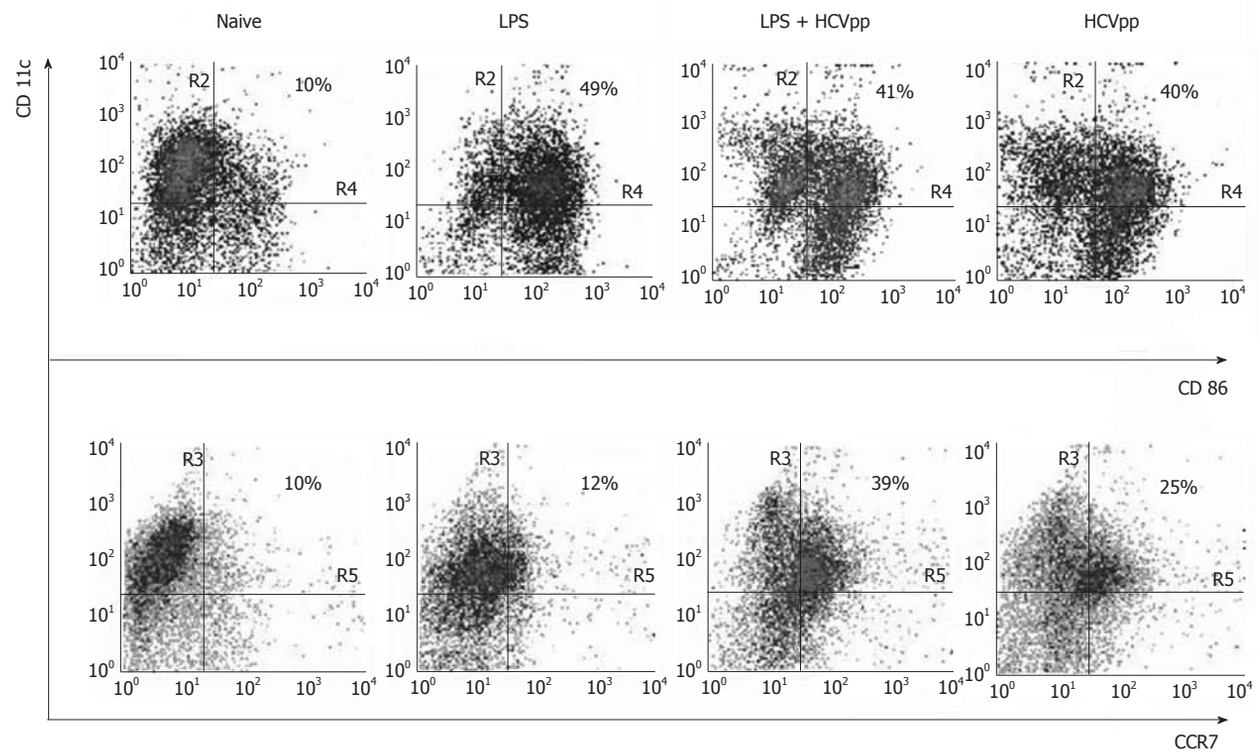

Figure 1 Fluorescence activated cell sorting analysis of bone-marrow derived dendritic cell of BALB/c mice, identified by expression of CD11c, after 7 d of maturation, followed by incubation with different agents. Column one shows the negative control, columns two and three show dendritic cell (DC) incubated with only lipopolysaccharide (LPS) or hepatitis C virus pseudo particles (HCVpp) with the co-stimulator LPS, respectively, and column four shows DC incubated with HCVpp only. Expression of the surface markers CD86 and CCR7 after pulsion of the DC with HCVpp and/or LPS is shown in percent.

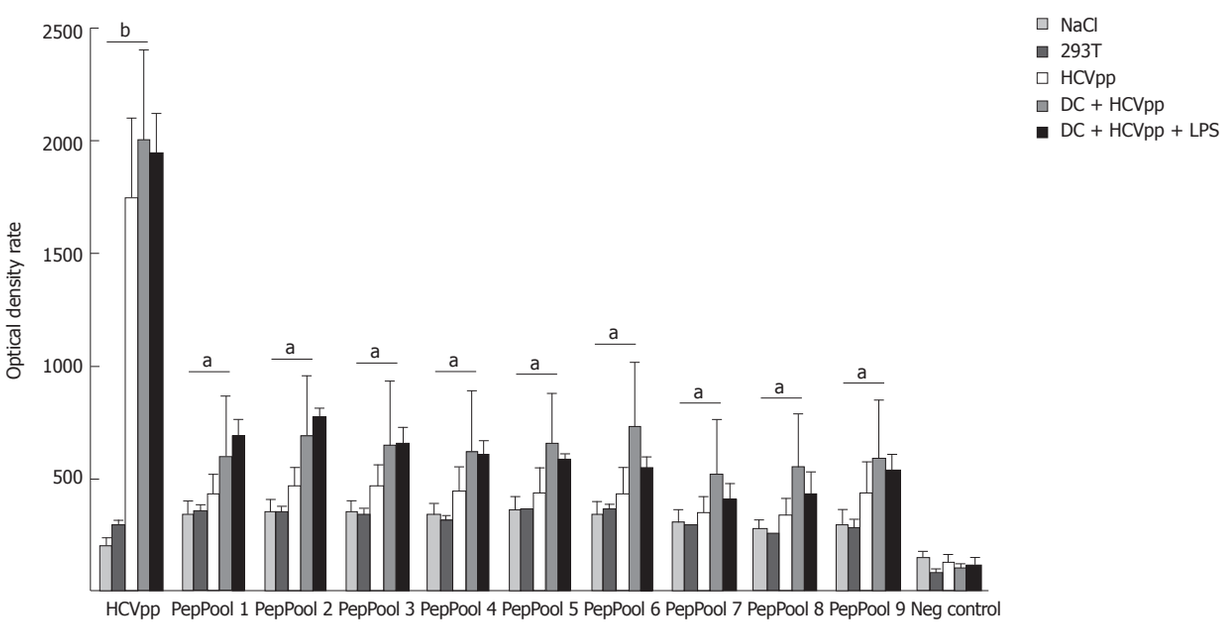

Figure 2 Induction of anti-E1 and anti-E2 antibodies following s.c. immunization of BALB/c mice. All animals specifically vaccinated developed specific antibodies. Highest antibody titers were observed in the two groups of mice which received the dendritic cell (DC) based vaccines. The negative control with phosphate buffered saline showed only very little unspecific binding. PepSets™ Pools 1-9 spanning the E1 and E2 protein of the hepatitis C virus (HCV) Con1 isolate showed considerably lower binding activity in the treatment groups, whereas the negative control groups did not show any differences between the different antigens. Through serial dilutions OD was calculated for HCV pseudo particles (HCVpp) group to be OD 1755, for the DC + HCVpp group OD 2013 and for the DC + HCVpp+ lipopolysaccharide (LPS) group OD 1944. For significance, NaCl groups were compared with DC + HCVpp groups. Pool 1-3 covers most of the E1 protein, pool 4 comprises the last 24 amino acids of the E1 protein and the first 32 amino acids of the E2 protein, and pool 5-9 enclose the rest of the E2 protein. NaCl: Saline; 293T: Cell culture supernatant of 293T-cells. Results are given as means of quadruplicate measurements of eight mice each group. $^{a}P < 0.05$, $^{b}P < 0.001$.

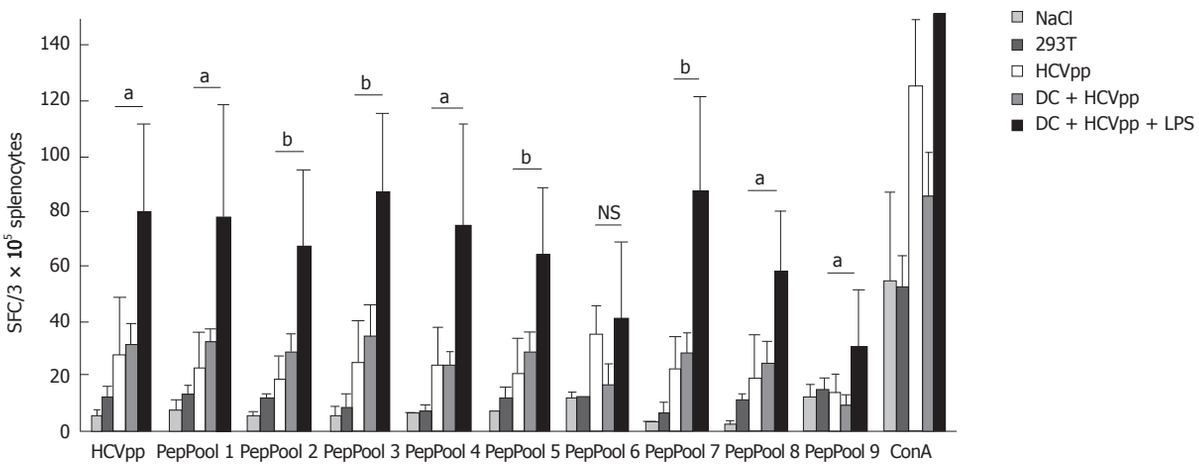

Figure 3 Antigen specific T-cell responses detected by interferon-gamma enzyme-linked immunosorbent spot test. Immune responses were induced by vaccination of different BALB/c mice with different agents. The two negative control groups were vaccinated with saline or 239T supernatant. The third group were mice vaccinated with hepatitis C virus pseudo particles (HCVpp) only. The treatment groups were mice vaccinated with dendritic cell (DC) prior pulsed with HCVpp with or without lipopolysaccharide (LPS). For detection of specific T-cells, spleenocytes were incubated with HCVpp or pooled overlapping peptides covering the E1 and E2 proteins of the HCV Con1 sequence. Convacalin A (ConA) was used as a positive control. Best results were achieved in the group of mice vaccinated with DC prior pulsed with HCVpp and LPS as an adjuvant. For significance HCVpp groups were compared with DC + HCV + LPS groups. NaCl: Saline; 293T: Cell culture supernatant of 293T-cells; NS: Not significant. Results are shown as mean values of 8 mice each group. $^{a}P < 0.05$, $^{b}P < 0.001$.

the clearance of HCV infection requires strong and broadly cross-reactive T-cell and neutralizing antibody responses[52-54]. It has been shown that the development of a multi-specific T-cell response during acute HCV infection is associated with spontaneous clearance of infection[55]. A successful immune response against HCV is therefore based on sufficient innate and adaptive immune responses.

Several approaches in HCV vaccine development have been studied. In chimpanzees it has been shown that the inclusion of structural HCV proteins was more significantly associated with protective immune responses compared to vaccines based on non-structural proteins of HCV[56]. Immunization with recombinant HCV E1 and E2 glycoproteins has been shown to prevent development of chronic infection in chimpanzees[40]. Distinct epitopes in certain regions of the E1 and E2 protein have been shown to drive the production of neutralizing antibodies[11,18,57,58].

We have shown recently that *in vitro* activation of DC followed by immunization with these DC leads to the induction of strong and specific antibody and T-cell responses in the hepatitis B context[59]. For HCV it has been shown that activation of DC by the core or the NS3 protein leads to maturation and stimulation of T-cells[60,61]. In addition, it was shown that DC function was restored in chronic HCV infected patients by the use of IL-10 inhibitors[62]. Thus, re-activation of DC may be an important tool in fighting HCV infection. We activated DC derived from BALB/c mice with HCVpp and were able to induce HCV specific antibodies and T-cells after immunization of mice with these DC. HCVpp were chosen to activate the DC for several reasons. They contain the E1 and E2 proteins and present them as closely to mature virions as possible. Due to that, neutralizing epitopes of the E1 and E2 proteins are potentially presented in the natural three-dimensional fashion. We intended to improve the immune responses using this approach. Immunization with recombinant E1 and E2 proteins as well as synthetic peptides led to limited humoral and cell mediated responses due to the limited number of viral epitopes and the inclusion of incorrectly folded recombinant proteins.

DC were chosen since we and others showed that they can be used to strongly induce immune responses which exceed the responses achieved by immunization with proteins or peptides only[59]. There are many challenges to face using DC as a therapeutic vaccine. The DC must be in the correct maturation state to be sufficiently activated, which may be different regarding the focused target[63]. Early used DC were immunogenic, but suboptimal with regard to their lymph-node homing ability and T-cell stimulatory potential[64]. Besides the maturation state the inflammatory cytokine milieu and the area of origin (plasmacytoid or myeloid) seems to play an important role. Furthermore, a challenge is the site of injection. In some studies intradermally or subcutaneous injected DC only migrated at low levels to the lymph nodes[65]. Reaching the lymph-node DC must show full ability to produce bioactive cytokines to properly activate T- and B-cells[64]. Many DC-based vaccines do not work due to these hurdles and the challenge is to find the right approach for the specific target.

In the present study, we were able to demonstrate that mouse DC can efficiently be activated *in vitro* using HCVpp. Reinjection of these DC into BALB/c mice led to humoral and cellular immune responses, demonstrating that in the HCV context *in vitro* activation of DC induces immune responses. These data lead to the hypothesis that impaired DC function/activation of HCV patients could be restored *in vitro*. This hypothesis is supported by the fact that immunization of the mice with

HCVpp only resulted in less antibody and significantly less IFN-γ production compared to immunization with HCVpp pulsed DC. Interestingly, *in vitro* co-stimulation with LPS led to enhanced T-cell responses but not to enhanced antibody production. The reason for this difference remains elusive. It may be due to a stronger cross-talk between DC and T-cells compared to B-cells. Furthermore, we could not detect significant specific binding of antibodies to recombinant HCV peptides in our experiments. We believe this is due to the lack of a three dimensional read-out using overlapping peptides and not folded proteins. This is supported by the fact that the use of HCVpp as read-out antigen resulted in very strong specific antibody binding. However, HCVpp priming of DC only resulted in slightly higher HCV specific antibody production.

We found relatively few differences between the overlapping peptide pools used for read-out. This is interesting, since we expected to find strong differences between the hypervariable regions in the E proteins compared to other regions. The homogeneity observed in our model suggests that sufficient broad-range immune responses were induced and therefore DC vaccination may be more suitable to potentially match the emergence of escape variants during HCV infection. Moreover, the HCVpp could be engineered for different sub- and quasispecies and thereby even widen the developed immune response after pulsion of DC.

When analyzing T-cell responses, we found two peaks in the immune response. These peaks were seen in pools 3 and 7 of the used overlapping peptides, corresponding to amino acids (aa) 312-379 of the E1 protein and 544-611 of the E2 protein, respectively (Table 2). This is consistent with the described regions aa174-337 and aa527-560, outside the hypervariable region 1[11,17], that have been shown to act as targets of especial interest for the natural immune system fighting HCV infection[18,39].

In conclusion, the data presented in the present study demonstrates that vaccination with HCVpp pulsed DC strongly enhances immune reactions against the structural proteins of HCV in mice. Both specific antibody production and T-cell immunity were enhanced. Furthermore, our data confirms that aa312-379 and aa544-611 of the HCV polyprotein are interesting and strong immunodominant sequences within the structural proteins of HCV. We believe that use of DC as a cellular based therapy is of great interest and should be evaluated further to sufficiently fight chronic HCV infection.

ACKNOWLEDGMENTS

We want to thank Ralf Bartenschlager for providing us with the three plasmids used for the production of the HCVpp and his group for helping us to establish this model in our laboratory. We further want to thank Stefan Urban and his group for providing the basic stock of 293T and Huh-7 cells.

COMMENTS

Background

Due to various genotypes and rapidly evolving quasispecies of the hepatitis C virus (HCV) under selection pressure persistent immune responses are hard to achieve. Most promising to achieve long-term immune responses are cell-based approaches.

Research frontiers

In chronic HCV infection the function of T-cells, B-cells and dendritic cells (DCs) are impaired. Re-activation of DC is probably needed for eradication and long-term immunity against HCV. In this study the authors demonstrate in a mouse model that DC can be re-activated *in vitro* and induce specific T- and B-cell responses *in vivo*.

Innovations and breakthroughs

DC from BALB/c mice were pulsed with pseudo particles from the hepatitis C virus (HCVpp). HCVpp consist of the genotype 1b derived envelope proteins E1 and E2, so the whole "viral surface" is presented to DC to induce immunogenicity. In this study broad-range humoral and cellular immune responses were measured. Furthermore, T-cell responses confirmed two highly immunogenic regions in E1 and E2 outside the hypervariable region 1.

Applications

This study indicates DC as promising vaccination tool to treat chronic HCV infection that should be evaluated further.

Terminology

DCs are antigen-presenting cells involved as key players in the immune response. By up-taking, processing and presentation of proteins/peptides they stimulate T- and B-cells, resulting in cellular and humoral immune response. The envelope proteins are two or three of the structural proteins of the HCV. Together with a lipid layer they form the surface of the HCV particle and are most likely the first proteins of the virus to be recognized by DC. HCVpp are artificial empty particles, consisting mainly of the lipid layer and the envelope proteins, not encapsidating the non-structural proteins of HCV.

Peer review

It describes an immunotherapeutic approach with DC immunization. The study is well organized and written.

Abstract

AIM: To study the long-term effects of endoscopic sphincterotomy on biliary epithelium.

METHODS: This is a prospective case-control study. A total of 25 patients with a median age of 71 years (range 49-89 years) and prior endoscopic sphincterotomy (ES) for benign disease formed the first group. The median time from ES was 42 mo (range 8-144 mo). Another 25 patients with a median age of 76 years (range 44-94 mo) and similar characteristics who underwent current endoscopic retrograde cholangiopancreatography (ERCP) and ES for benign disease formed the second group (control group). Brush cytology of the biliary tree with *p53* immunocytology was performed in all patients of both groups. ERCPs and recruitment were conducted at the Endoscopic Unit of Aretaieion University Hospital and Tzaneio Hospital, Athens, from October 2006 to June 2010.

RESULTS: No cases were positive or suspicious for malignancy. Epithelial atypia was higher in the first group (32% *vs* 8% in the second group, $P = 0.034$). Acute cholangitis and previous biliary operation rates were also higher in the first group (acute cholangitis, 60% *vs* 24% in the second group, $P = 0.01$; previous biliary operation, 76% *vs* 24% in the second group, $P = 0.001$). Subgroup analysis showed that previous ES was the main causal factor for atypia, which was not related to the time interval from the ES ($P = 0.407$). Two patients (8%) with atypia in the first group were *p53*-positive.

CONCLUSION: ES causes biliary epithelial atypia that represents mostly reactive/proliferative rather than premalignant changes. The role of *p53* immunoreactivity in biliary atypia needs to be further studied.

Key words: Endoscopic sphincterotomy; Brush cytology; Atypia; Cholangiocarcinoma; *p53* immunocytology

INTRODUCTION

The introduction of endoscopic retrograde cholangiopancreatography (ERCP) with endoscopic sphincterotomy (ES) in 1974 changed the treatment of choledocholithiasis[1]. Today, ES is a widely available endoscopic technique that is used not only for the removal of common bile duct stones but also in the treatment of a wide variety of biliary and pancreatic diseases[2]. An increasing number of young patients with a long life expectancy will undergo ES, and this raises concern for the long-term complications of the procedure and especially the late development of cholangiocarcinoma[3].

Carcinogenesis after surgical sphincteroplasty and biliary-enteric anastomosis has been well documented. Numerous case reports and large series have described a causal association between biliary-enteric drainage procedures for benign disease and the late development of cholangiocarcinoma[4-6]. The hypothesis is that the disruption of the sphincter of Oddi causes prolonged pancreatobiliary and duodenobiliary reflux, bacterial overgrowth and chronic inflammation of the bile ducts. Chronic inflammatory irritation induces hyperplasia, dysplasia and atypia of the epithelium that ultimately can lead to carcinogenesis[5].

ES also causes ablation of sphincter function, which raises concern about the late development of cholangiocarcinoma by the same mechanism as previously mentioned. In a study of long-term consequences of ES, 410 patients were followed for an average of 10 years after ES, and late development of cholangiocarcinoma was documented in 3 patients, which represents an elevated risk of malignancy[7]. Furthermore, the long-term effects of ES on sphincter function are not clear. In a small trial, the function of the biliary sphincter was permanently lost, and this was associated with bacterial colonisation and chronic inflammation of the biliary system[8]. In another study, pancreatobiliary reflux was present for the first year after ES and was minimised after wards[9]. Recently, two large population-based studies demonstrated an increase in the cholangiocarcinoma rate after ERCP mostly in the first five years, but there was no causal association between sphincterotomy and cholangiocarcinoma[10,11].

In the present study, we performed cytological evaluation with additional *p53* immunocytology of the biliary epithelium one to twelve years after ES for benign disease.

MATERIALS AND METHODS

Ethics

The trial was approved by the Science Board of Aretaieion University Hospital and Tzaneio General Hospital and was registered at ClinicalTrials.org (protocol number NCT01135732). All patients gave informed consent for the ERCP procedure and for participation in the trial.

Study design

This was a prospective case-control study. ERCPs and recruitment of the patients were conducted at the Endoscopic Unit of Aretaieion University Hospital and Tzaneio General Hospital, Athens, from October 2006 to June 2010. Cytological evaluation and *p53* immunocytology were performed at the Cytology Department of Tzaneio General Hospital. Analysis and interpretation of the data were completed in January 2011.

Dilated bile ducts (ultrasound)	14 (56)	18 (72)	0.23[3]
Median time from ES (mo)[2]	42 (range 8-144)	-	

[1]Previous biliary operations were laparoscopic or open cholecystectomies; [2]This is the median time since prior endoscopic sphincterotomy (ES) that cytology brushing was performed; [3]Estimated *P* values were calculated using the χ^2 test; [4]Estimated *P* value was calculated using the Mann-Whitney test. ERCP: Endoscopic retrograde cholangiopancreatography.

The patients were enrolled in two groups. A total cohort of twenty-five patients who underwent ERCP for benign disease and had a prior ES formed the first group (Table 1). Cytology brushing was performed at a median time of 42 mo from ES within a range of 8 to 144 mo. Exclusion criteria were biliary stricture, liver cirrhosis, viral hepatitis infection, sclerosing cholangitis, choledochal cysts, malignancy of the liver, bile ducts and pancreas, and any other known or suspected malignancy. To provide comparable data, a second group (control group) was formed of twenty-five patients of similar age and gender as the first group who underwent current ES for benign disease. The difference between the two groups was that the patients of the first group had a prior ES, while those of the control group had a current ES. The endoscopic procedures were performed by two specialised endoscopists (Vezakis A and Polydorou A).

Brush cytology

Brush cytology was performed in all patients of the first group to evaluate the biliary epithelium. After cannulation of the common bile duct through the previous sphincterotomy, a 3.0-mm standard endoscopic cytology brush with a catheter sheath (Hobbs Medical, United States) was passed through the endoscope into the biliary tree under fluoroscopy. The brush was then pushed out of the catheter, and cellular material was obtained by moving it back and forth across the common and left or right hepatic ducts approximately ten times. The brush was then withdrawn into the catheter, and the catheter and brush were withdrawn from the endoscope as a unit. Similarly, brush cytology was performed in all patients of

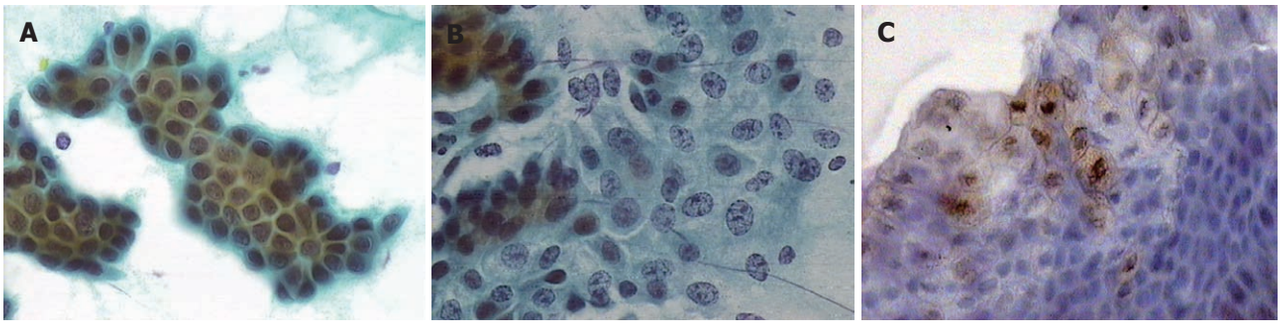

Figure 1 Brush cytology samples. A: This is a sample that was evaluated as negative for malignancy. Note the smooth nuclear shape, the low nuclear/cytoplasmic ratio and the absence of nucleoli (Papanicolaou stain, x 400); B: This is a sample that was classified as atypical-indeterminate. Note the moderate nuclear/cytoplasmic ratio, the granular chromatin pattern with mild clumping and the presence of 1 or 2 small but distinct nucleoli (Papanicolaou stain, x 400); C: This is a *p53*-positive sample from the first group. There are at least five cells with strong nuclear staining (x 400). (Analysis of photos was performed with ACDSee Pro).

Table 2 Diagnostic categories for cytologic diagnosis

Cytological grade	Definition
Unsatisfactory	No diagnostic specimen: acellular or hypocellular; Smears too thick, containing blood, obscured by inflammation or air-drying artefacts
Negative for malignancy	Adequate cellular specimens containing benign cells consistent with normal elements of the target organ
Atypical/indeterminate	Minimally abnormal cellular findings that most likely represent reactive/reparative and inflammatory type changes; Malignancy is unlikely but cannot be completely ruled out
Suspicious for malignancy	Cytologic specimens exhibit abnormal cellular findings that display some, but not all, of the features of malignancy; Specimens containing highly abnormal cells in very limited numbers
Positive for malignancy	Unquestionable cellular features of malignancy

the control group immediately after performing the ES.

The cellular material obtained from each patient was immediately smeared onto five glass slides. Four slides were fixed with a 95% ethanol solution and one was air-dried. The brush was then fixed in cytospin (a solution composed of 50% ethanol, carbowax, and isopropanol) to obtain additional material if needed. Papanicolaou stain was applied to three out of four ethanol-fixed slides, and May-Grunwald-Giemsa stain was applied to the air-dried slide.

p53 immunocytology

p53 immunostaining was performed on the fourth ethanol-fixed slide for all patients in both groups. The immunocytochemical method involved application of an anti-*p53* primary antibody (monoclonal mouse anti-human *p53*, clone DO-7, Dako Athens, Greece, 1:100 dilution).

Cytological evaluation

Samples were classified based on their morphological characteristics into one of five categories (Table 2)[12]. Positive immunocytochemical staining for *p53* mutation was defined as the detection of more than five cells with strong intranuclear staining of *p53* at high magnification (× 400) (Figure 1). Two specialised cytologists separately examined and evaluated the specimens to achieve more objective results.

Statistical analysis

Results were analysed using the χ^2 test, Mann-Whitney test and regression analysis. Differences were considered significant at $P < 0.05$. Statistical analysis was performed with Minitab 16 statistical software.

RESULTS

Cytological evaluation and subgroup analysis

All of the samples had adequate cellularity, and no case was judged too poor to be analysed. In one case, cytological evaluation by the two specialists was different, and an additional evaluation was then performed. No samples were suspect or positive for malignancy (Table 3). However, patients in the first group had a significantly higher proportion of atypia (32% *vs* 8% in the second group, $P = 0.034$). Acute cholangitis and previous biliary operation rates were also higher in the first group (acute cholangitis, 60% *vs* 24% in the second group, $P = 0.01$; previous biliary operation, 76% *vs* 24% in the second group, $P = 0.001$). On the contrary, the presence of dilated bile ducts detected by ultrasound, the extraction of common bile duct stones and the presence of dilated bile ducts without choledocholithiasis by ERCP did not differ between the two groups. A subgroup analysis of the patients with atypia demonstrated that previous ES was the only predisposing factor (Table 4).

There was no correlation between atypia and the time interval from the previous ES ($P = 0.407$). Furthermore, 7 out of 8 cases of atypia in the first group occurred in the first five years after ES (Figure 2).

p53 immunocytology

There were two samples with positive immunocytological staining for *p53* in the first group and none in the second group; both positive samples were from patients

The cytological grade is according to Table 2. 3: Atypical/indeterminate sample; 2: Negative for malignancy sample. ES: Endoscopic sphincterotomy. (Figure design was prepared with Minitab 16 Statistical software).

with epithelial atypia (Table 5).

DISCUSSION

The main outcome of this trial was that no case was suspect or positive for malignancy for a median period of 42 mo after a previous ES. This finding is in agreement with several retrospective studies that examined the long-term complications of ES and did not report late development of cholangiocarcinoma[13-15].

However, there was a significant difference in the reported atypia of the biliary epithelium between the two groups in the present study. Subgroup analysis showed that only previous ES, and not acute cholangitis as one might expect, was directly connected to these changes. This result is not as controversial as it seems. Acute cholangitis as an indication for ERCP is a factor that represents a clinical condition at a specific moment that cannot express chronic subclinical inflammatory irritation of the epithelium. Furthermore, possible previous episodes of acute cholangitis were not included in the present study, as it is extremely difficult to have an accurate estimation. On the contrary, previous ES is a factor that includes and expresses these possible conditions, and the fact that it is

Table 4 Subgroup analysis of the patients with atypia *vs* all others *n* (%)

	Atypical/ indeterminate	Negative for malignancy	*P* value
Patients	10	40	
Median age (yr)	69.5 (SD = 11.3)	74.5 (SD = 12.1)	0.26[2]
Sex, male/female	3/7	20/20	0.25[1]
Previous ES	8 (80)	17 (42)	0.034[1]
Acute cholangitis	5 (50)	16 (40)	0.56[1]
Previous biliary operation	6 (60)	19 (47)	0.48[1]

Positive	2	0	
Negative	8	40	

[1]Estimated *P* values were calculated using the χ^2 test; [2]Estimated *P* value was calculated using the Mann-Whitney test. ES: Endoscopic sphincterotomy; ERCP: Endoscopic retrograde cholangiopancreatography.

associated with epithelial atypia demonstrates that these epithelial changes are possibly the result of a chronic process.

The reported difference in previous biliary operations between the two groups can be easily explained by the fact that a cholecystectomy was performed after ES for gallbladder lithiasis in most of the patients in the first group.

Cellular atypia may also represent premalignant changes of the biliary epithelium[16]. It is known that carcinogenesis of the bile ducts is a very slow process that involves several cellular pathways such as growth autonomy, escape from senescence, unlimited replication, blockade of growth inhibitory signals, altered microenvironment and evasion of cell death[17]. One of the most commonly affected genes is the *p53* tumour suppressor gene, which is inactivated in 21.7% to 76% of all cholangiocarcinomas[18]. Alterations in *p53* have also been demonstrated in premalignant biliary lesions[19]. For these reasons and because of the availability of its use, *p53* immunocytology was performed in all patients in both groups to assess possible premalignant lesions.

Immunocytological staining with *p53* was positive in two young women who both had cellular atypia and also a clinical history that was negative for malignancy. False-positive *p53* immunocytology results in biliary strictures are not known, as it is a relatively new method with only a few series reported, but it seems that *p53* detection increases the sensitivity of brush cytology in cholangiocarcinoma detection[20,21]. Stewart *et al*[22] reported only one case that was *p53*-positive with cytological features of atypia, in whom clinical follow-up revealed no evidence of malignancy. Villanacci *et al*[21] reported two patients with mild dysplasia who were *p53*-positive and submitted to clinical follow-up. The two *p53*-positive cases in our study had a negative clinical follow-up at approximately 3.5 years. Nevertheless, these changes might represent premalignant conditions, and follow-up should continue.

Another important finding in this study is that the atypia of the biliary epithelium was not related to the

Table 5 Patients with positive p53 immunocytology

	Sex	Age (yr)	Indication ERCP	Previous biliary operation	Stone extraction	Cytological evaluation	Time from ES (mo)	Negative[1] follow-up
Patient 1	Female	49	Acute cholangitis	Yes (open cholecystectomy)	No	Atypia	18	3 yr 5 mo
Patient 2	Female	54	Stent removal	Yes (open cholecystectomy)	Yes	Atypia	25	3 yr 6 mo

[1]No clinical or laboratory findings of bile duct malignancy. ES: Endoscopic sphincterotomy; ERCP: Endoscopic retrograde cholangiopancreatography.

time interval from ES as one could expect. In fact, seven out of eight cases of atypia were noticed in the first five years after ES. It seems that the causal factor for these epithelial changes ceases after a certain period of time. These data are in accordance with the results from the study by Sugiyama *et al*[9], in which the sphincterotomy length, pancreatobiliary reflux and pneumobilia gradually decreased at one and five years after ES. Interestingly, Mortensen *et al*[10], in their population-based study found elevated rates of cholangiocarcinoma within the first five years after ES, with percentage declination afterwards.

A major strength of this trial is the presence of a control group with almost matched sex and age. Brush cytology is an easy and safe technique with minimal complications[23]. A major limitation of this method is the relatively low sensitivity in detecting cholangiocarcinoma (30% to 57% in most published series)[23]. However, in this study, the intention was to collect cells from many sites of the biliary tree and not from a focal stenosis. In addition, *p53* immunocytology is a method that seems to increase the sensitivity of brush cytology[21,22]. Finally, one could argue that the patients of the first group had recurrent biliary complications, and so the results cannot be fully extrapolated in asymptomatic patients with prior ES. The result is that many of these pathologic conditions are long-term complications of the ES. Furthermore, a human clinical trial with asymptomatic patients undergoing ERCP is not ethical.

In conclusion, no cases were positive or suspect for malignancy after a median period of 42 mo (range 8-144 mo) after ES for benign disease. Biliary epithelial atypia is likely to occur as a result of previous ES, primarily during the first five years after the procedure. Cytological findings represent reactive/proliferative rather than premalignant changes, but this must be confirmed by additional future studies. In addition, the role of *p53*-positive immunocytology in epithelial atypia needs to be further studied.

COMMENTS

Background

Carcinogenesis after surgical sphincteroplasty and biliary-enteric anastomosis has been well documented. Endoscopic sphincterotomy (ES) also causes ablation of sphincter function, and this raises concerns about the late development of cholangiocarcinoma.

Research frontiers

Long-term effects of ES on biliary epithelium are not very clear. It seems that the biliary sphincter function is permanently lost, which results in duodenobiliary reflux. This study examines the effects of possible reflux on biliary epithelium and demonstrates that biliary atypia is most likely to occur after ES.

Innovations and breakthroughs

Several retrospective studies have examined the late complications of ES. This is the first prospective, case-control study that examines possible premalignant changes of biliary epithelium after ES using brush cytology and *p53* immunocytology.

Applications

By understanding whether and how ES causes changes in biliary epithelium, tha authors contribute to a better knowledge of this commonly used procedure with emphasis on possible future adverse effects.

Terminology

Brush cytology is an easy and safe technique of cytological examination. Mutation in the *p53* oncogene is one of the most common mutations in the malignancy of biliary epithelium, thus *p53* immunocytology indicates possible mutations in cytological samples that could represent premalignant changes.

Peer review

The authors examined the long-term effects of ES on biliary epithelium. It is an interesting paper on a well-known subject. The results showed that reactive or proliferative change in biliary epithelium primarily occurred by ES.

Abstract

AIM: To examine whether vitamin D improved viral response and predicted treatment outcome in patients with hepatitis C virus (HCV) genotype 2-3.

METHODS: Fifty patients with chronic HCV genotype 2-3 were randomized consecutively into two groups: Treatment group [20 subjects, age 48 ± 14 years, body mass index (BMI) 30 ± 6, 65% male], who received 180 μg pegylated α-interferon-2a plus oral ribavirin 800 mg/d (Peg/RBV), together with oral vitamin D3 (Vitamidyne D drops; 2000 IU/d, 10 drops/d, normal serum level > 32 ng/mL) for 24 wk; and control group (30 subjects, age 45 ± 10 years, BMI 26 ± 3, 60% male), who received identical therapy without vitamin D. HCV RNA was assessed by reverse transcription polymerase chain reaction. Undetectable HCV RNA at 4, 12 and 24 wk after treatment was considered as rapid virological response, complete early virological response, and sustained virological response (SVR), respectively. Biomarkers of inflammation were measured.

RESULTS: The treatment group with vitamin D had higher BMI (30 ± 6 *vs* 26 ± 3, $P < 0.02$), and high viral load (> 400 000 IU/mL, 65% *vs* 40%, $P < 0.01$) than controls. Ninety-five percent of treated patients were HCV RNA negative at week 4 and 12. At 24 wk after treatment (SVR), 19/20 (95%) treated patients and 23/30 (77%) controls were HCV RNA negative ($P < 0.001$). Baseline serum vitamin D levels were lower at baseline (20 ± 8 ng/mL) and increased after 12 wk vitamin D treatment, to a mean level of (34 ± 11 ng/mL). Logistic regression analysis identified vitamin D supplement [odds ratio (OR) 3.0, 95% CI 2.0-4.9, $P < 0.001$], serum vitamin D levels (< 15 or > 15 ng/mL, OR 2.2, $P < 0.01$), and BMI (< 30 or > 30, OR 2.6, $P < 0.01$) as independent predictors of viral response. Adverse events were mild and typical of Peg/RBV.

CONCLUSION: Low vitamin D levels predicts negative treatment outcome, and adding vitamin D to conventional Peg/RBV therapy for patients with HCV genotype 2-3 significantly improves viral response.

Key words: Hepatitis C; Genotype 2-3; Vitamin D; Sustained viral response; Peg-interferon alpha 2a

INTRODUCTION

The current treatment for chronic hepatitis C virus (HCV) infection is pegylated interferon α combined with ribavi-

rin (Peg/RBV), administered for 24 wk for HCV genotype 2 or 3 or 48 wk for HCV genotype 1[1]. The aim of HCV therapy is a sustained viral response (SVR), which is defined as undetectable serum HCV RNA level at 24 wk after cessation of therapy. For patients with HCV genotype 1, the rate of SVR ranges between 38% and 46%[2,3]. For patients with HCV genotype 2 or 3, the rate of SVR ranges between 74% and 77%. In subgroups of this population (e.g., Hispanics and African Americans), the rate of SVR is even lower, reaching only 19% in genotype 1 and 57% in genotype 2 or 3[4]. These differences in the rate of viral response are not explained by baseline viral load or adherence to treatment. Recent efforts to improve patient outcomes have focused on adding new antiviral therapies that specifically target HCV, including polymerase or protease inhibitors[5]. However, few studies have addressed the issue of improving host factors with immunomodulators.

Vitamin D is a potent immunomodulator that favors innate immunity and cell differentiation[6,7]. Increased production of 1,25-dihydroxy vitamin D3 results in the synthesis of cathelicidin, a peptide capable of destroying many viral infectious agents as well as *Mycobacterium tuberculosis*. Low serum levels of 25-hydroxyvitamin D (< 20 ng/mL) prevent macrophages from initiating this innate immune response, which may explain why African Americans, who are often vitamin D deficient, are more prone to contracting viral infections and tuberculosis than Caucasians are[8]. Moreover, vitamin D improves insulin sensitivity[9], suppresses proinflammatory cytokines, increases anti-inflammatory cytokines, and improves CD4 T cell hyper-responsiveness[10]. Vitamin D deficiency is very common (92%) among patients with chronic liver disease, and at least one-third of them suffer from severe vitamin D deficiency (< 12 ng/mL)[11]. Israeli subjects from various ethnic backgrounds are at higher risk of vitamin D deficiency[12]. Petta *et al*[13] have recently shown a low serum vitamin D level to be related to severe fibrosis and low responsiveness to interferon-based therapy in genotype 1 chronic hepatitis C. More recently, we have shown that adding vitamin D to conventional Peg/RBV therapy for naïve, genotype 1 patients with chronic HCV infection significantly improves SVR[14]. Southern *et al*[15] have retrospectively shown that vitamin D supplementation improves the SVR in patients with HCV genotype 2-3, with mild-to-moderate fibrosis.

The aim of the present study was to assess prospectively the influence of vitamin D supplementation on outcome (SVR) in the treatment of patients with chronic hepatitis C with HCV genotype 2-3.

MATERIALS AND METHODS

Subjects

Study inclusion criteria were age 18-65 years, a chronic genotype 2 or 3 HCV infection, no previous treatment for hepatitis C, seronegative for hepatitis B virus, hepatitis A virus, and HIV infection, an absolute neutrophil count of > 1500/mm^3, a platelet count of > 90 000/mm^3, and a normal hemoglobin level. Liver biopsies were not required prior to study entrance. Exclusion criteria were decompensated liver disease (cirrhosis with Child-Pugh score > 9), another cause of clinically significant liver disease, or the presence of hepatocellular carcinoma. The protocol was approved by the two institutional review boards of both study centers (Ziv Medical Center, and Hilel Yafe Medical Center, Israel), and all patients provided written informed consent to participate in the study.

Study design and organization

This was an intention to treat prospective randomized study. Fifty consecutive chronic hepatitis C (genotype 2-3) treatment-naïve patients were stratified according to ethnic group (i.e., Russian/Jewish/Arab) due to possible difference in vitamin D levels, and alanine aminotransferase levels were enrolled. They were consecutively and randomly assigned to one of two study groups. The treatment group comprised 20 patients [mean age 48 ± 14 years, body mass index (BMI) 30 ± 6, 65% male], who received pegylated interferon α2a (180 μg once weekly by subcutaneous injection) plus ribavirin orally at a dose of 800 mg/d, with vitamin D [Vitamidyne 2000 IU/d (Fischer, Israel), 10 oral drops, target serum level > 32 ng/mL] for 24 wk. The control group of 30 patients (mean age 45 ± 10 years, BMI 26 ± 3, 60% male) received pegylated interferon α2a (180 μg once weekly) plus ribavirin (800 mg/d) without vitamin D for 24 wk. Vitamin D3 was given by oral drops at a dose of (2000 IU/d, 10 drops) to the treatment group for 12 wk before the initiation of antiviral treatment until serum levels reached > 32 ng/mL. The adherence to vitamin D treatment was excellent during the entire course and the vast majority of patients in the treatment group achieved the target level. Vitamin D supplement was maintained during the course of therapy and during follow-up.

Efficacy assessments

Plasma HCV-RNA levels were measured using the COBAS Taq Man HCV assay, version 1.0 (Roche Molecular Systems, Israel), with a lower limit of quantification of 50 IU/mL and a lower limit of detection of 10 IU/mL. HCV-RNA levels were measured at the time of screening and during the treatment period at weeks 4, 12 and 24 for the treatment group, and at 24 wk after treatment. HCV RNA was not measured at weeks 4 and 12 in the control group because this was not included in the health package at the time of study. Subjects had a safety follow-up visit after the completion of treatment. Those who had undetectable HCV RNA levels at the time of treatment completion had follow-up visits 24 wk later, at which time, HCV-RNA levels were measured again. Assessment of efficacy was SVR, i.e., undetectable HCV RNA at 24 wk after treatment. Clearance of HCV RNA was assessed at week 4 (rapid virological response), week 12 (complete early virological response), and at week 24 at the end of treatment response (ETR) for the treat-

Table 1 Baseline demographic, clinical, and virological characteristics of all patients

Baseline demographics	Peg/RBV (n = 30)	Vitamin D + Peg/RBV (n = 20)	P value

ment group. Patients with ETR who tested positive for HCV RNA during follow-up were classified as relapsers. Breakthrough was defined as an increase in HCV RNA level of 1 $\log_{10}$ unit, as compared with the lowest value[3].

Safety assessment

Biochemical assessments were performed at each visit during the treatment period and after treatment a follow-up visits. Data on adverse events were collected and physical examinations were also performed each time. The safety assessment included complete blood count, antinuclear antibody and thyroid stimulating hormone levels. Pegylated interferon α2a was reduced to 90 μg/wk in patients with neutrophil count < 750 cells/μL, and withdrawn temporarily in patients with counts < 500 cells/μL. The same dose reduction was applied if platelet levels fell under 50 000 cells/mm^3, with pegylated interferon being discontinued when the 25 000 cell/mm^3 threshold was reached. In both treatment arms, the ribavirin dose was tapered by 200 mg/d in patients with hemoglobin < 10 g/dL, and discontinued altogether in patients with hemoglobin level < 8.0 g/dL.

Clinical and laboratory measurements

25(OH) vitamin D3 levels were determined by ^{125}I radioimmunoassay (Dia-Sorin, Stillwater, MN, United States)[16]. 25-OH vitamin D is the major circulating form of vitamin D and is used as an indicator of vitamin D status. Vitamin D deficiency was defined as a 25(OH) D serum level < 12 ng/mL, vitamin D insufficiency as 25(OH) D level 12-32 ng/mL, and vitamin D sufficiency as > 32 ng/mL[12]. BMI was calculated as weight in kilograms divided by the square of height in meters [17]. Obesity was defined as BMI > 30 kg/m^2. C-reactive protein (CRP) was determined by the nephlometric method[18]. Thyroid stimulating hormone, antinuclear antibody, glucose, liver enzymes, albumin, bilirubin, prothrombin time, and creatinine were measured by standard biochemical tests.

Statistical analysis

Results were expressed as the mean ± SD. The difference between two groups was assessed by χ^2 test for categorical variables and by Mann-Whitney rank for continuous variables. The Spearman correlation was used to express correlations between variables. The primary study endpoint was evidence of the influence of vitamin D on viral response at week 24 after treatment. Logistic regression analysis was used to document independent variables that predicted SVR. The significance level was set at $P < 0.05$. The statistical analysis was carried out with the WINSTAT software program (Kalmia, San Diego, CA, United States).

RESULTS

Twenty percent of the patients in the treatment group had severe baseline vitamin D deficiency (< 12 ng/mL), 60% showed insufficiency, and 20% had sufficient vitamin D levels. In the control group, 30% of the patients had baseline vitamin D deficiency, 50% had insufficiency, and 20% had sufficient vitamin D levels. Table 1 shows the clinical and biochemical parameters of the patient populations. The treatment group with vitamin D had higher BMI (30 ± 6 *vs* 26 ± 3, $P < 0.02$), and high viral load (> 400 000 IU/mL, 65% *vs* 40%, $P < 0.01$) than patients in the control group. There were no significant differences between the groups in terms of age, HCV genotype, ethnic background, aminotransferases, or CRP levels. Figure 1 shows the rates of viral response in the treatment and control groups: 19/20 (95%) patients in the treated group were HCV-RNA negative at weeks 4 and 12. At 24 wk after treatment (SVR), 19/20 (95%) patients in the treatment group and 23/30 (77%) in the control group were HCV RNA negative ($P < 0.001$). The rate of viral breakthrough and relapse was nill. The rates of non-response were significantly lower in the treatment group compared to the control group [1/20 (5%) *vs* 7/30 (23%), $P < 0.001$]. Figure 2 shows the baseline and week 12 vitamin D levels in the treatment group before the initiation of antiviral therapy. Serum vitamin D levels were significantly lower at base line (20 ± 8 ng/mL) and increased after 12 wk of vitamin D treatment to a mean level of 34 ± 11 ng/mL. Adherence to vitamin D treatment was excellent during the entire course, and all patients in the treatment group achieved the target level. Vitamin D supplementation was maintained during the course of therapy with the same amount (2000 IU/d) as in the lead in phase.

Predictive factors for SVR in patients treated with Peg/RBV combination therapy are shown in Table 2. Logistic regression analysis identified vitamin D supplementation (OR 3.0, 95% CI 2-4.9, $P < 0.001$), serum vitamin D levels (< 15 or > 15 ng/mL; OR 2.2, $P < 0.01$) and BMI (< 30 or > 30, OR 2.6, $P < 0.01$) as independent predictors of viral response. Thus, vitamin D

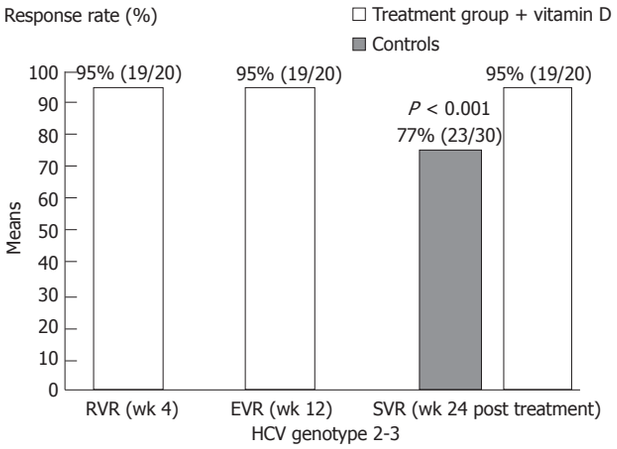

Figure 1 Rate of rapid virologic response, early virologic response and sustained viral response in the treatment (*n* = 20) and control (*n* = 30) groups. Rapid virologic response (RVR) was defined as undetectable hepatitis C virus (HCV) RNA at 4 wk during treatment. Early virologic response (EVR) was defined as undetectable HCV RNA at 12 wk during treatment. Sustained viral response (SVR) was defined as undetectable HCV RNA at 24 wk after cessation of therapy.

Table 2 Viral response, vitamin D levels and biomarkers of inflammation, insulin resistance and oxidative stress in all patients

	OR	95% CI	*P* value
Received vitamin D supplementation (yes *vs* no)	3.0	2.0-4.9	< 0.001
Base line vitamin D (< 15 or > 15 ng/mL)	2.2	1.1-4.3	0.01
Genotype (2 *vs* 3)	2.0	1.2-3.8	0.01
High viral load (< 400 000 or > 400 000 IU/mL)	2.8	1.2-4.0	0.001
Baseline CRP (< 0.5 or > 0.5 mg/dL)	1.0	0.5-1.9	0.5
BMI > 30 (kg/m^2) (yes *vs* no)	2.6	0.8-3.5	0.01

CRP: C-reactive protein; BMI: Body mass index; OR: Odds ratio.

supplementation emerged as being more responsible for higher SVR than the baseline vitamin D level. The SVR rate was significantly different between patients with HCV genotype 2/3 in the treated group versus those in the control group (100%/89% *vs* 90%/64%, $P < 0.01$).

The most common adverse events were mild, similar in both groups, and consistent with typical interferon–ribavirin induced systemic symptoms including nausea, headache, insomnia, myalgia, pyrexia, mild neutropenia, thrombocytopenia, and mild anemia. No serious adverse events were seen. Adherence to Peg/RBV therapy was excellent and there was no difference in dose reduction for Peg/RBV therapy due to adverse events in both groups. No patients discontinued treatment. Changes in laboratory values during the study were consistent with those reported in association with the combined use of Peg/RBV[3].

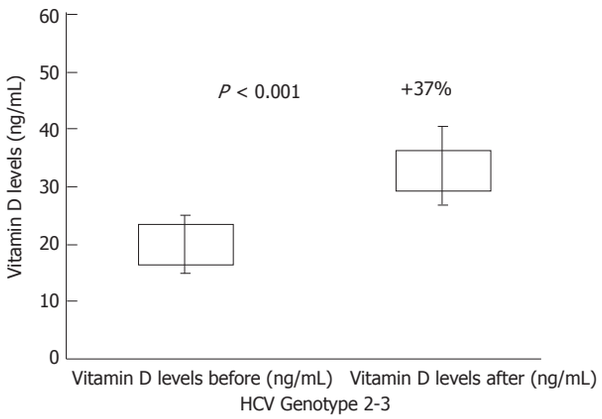

Figure 2 Vitamin D serum levels before and 12 wk after initiation of antiviral treatment (*n* = 30) and vitamin D supplementation (*n* = 20). Percentage change was +37%.

DISCUSSION

The results of this study suggest that the addition of a vitamin D supplement to current standard therapy can significantly improve the rate of SVR in treatment-naïve patients with HCV genotype 2-3, compared to the rates with standard therapy alone. The observed SVR rate in the control group (77%) is consistent with previous reports[2,3]. The overall responses reflect a marked increase in the rate of virological response at week 24 after cessation of therapy (95% *vs* 77%) and a low rate of non-response (5% *vs* 23%) with vitamin-D-based treatment, as compared to the control group[19].

There are only two reports dealing with the association between vitamin D status and outcome of antiviral therapy for chronic HCV viral infection. Petta *et al*[13] have retrospectively analyzed a cohort of 167 patients treated with peg-interferon and ribavirin for hepatitis C, and detected an association between lower vitamin D serum levels and failure to achieve SVR. Our results provide further support to these data. The second study by Bitetto *et al*[20] has shown that vitamin D supplementation improves response to antiviral treatment for recurrent hepatitis C in liver transplant recipients. Several differences between those two studies should be noted. Their HCV patients were immunocompromised and they were supplemented by low-dose vitamin D (800 IU/d) after liver transplantation. In addition, most of their HCV patients (75%) had low vitamin D levels despite treatment. Finally, that study was retrospective and focused on the prevention of osteoporosis and not on the treatment of hepatitis C. Very recently, Southern *et al*[15] have shown the beneficial effect of vitamin D supplementation on the outcome in patients with chronic HCV genotype 2-3 infection. However, this study was retrospective and the authors used Calcichew D3 Forte during the course of treatment without indicating the dose or serum levels of vitamin D.

The exact mechanism of action leading to improved

response to antiviral treatment is unknown in patients receiving vitamin D. Vitamin D is metabolized by the liver and is converted to 1,25 dihydroxyvitamin D3, which is the active form of the vitamin[6,7]. Those with chronic liver disease may have poor conversion from vitamin D3 or any of its other biologically active metabolites[11]. 1,25 vitamin D3 appears to modulate immunity principally via regulating T-cell function[21]. The vitamin D receptor (VDR) is expressed on virtually every type of cell involved in immunity[22]. The immunomodulatory actions of vitamin D are elicited through its direct action on T-cell antigen-presenting cell function[23]. T helper cell type 1 (Th1) cell actions are intensified when vitamin D is insufficient, as in the majority of our patient population, or when signals through VDR are weak. Regulatory T cells and Th2 cells are diminished, thus favoring an autoimmune Th1 response[24]. This is a proinflammatory response that may impair interferon and insulin signaling, thus decreasing viral response[25,26]. A recent study, comprised of 120 patients with chronic infection with HCV genotype 1 reported a Th1 to Th2 ratio < 15.5 (OR, 9.6) was significantly associated with SVR[27]. The overall effect is a switch from the Th1/Th17 response to the Th2/Treg profile[28]. However, Th1 and Th2 measurement was not performed in the present study. Persistent HCV infection modulates the balance between immunostimulatory and inhibitory cytokines that can prolong inflammation and lead to fibrosis and chronic liver diseases[29]. More recently, Gutierrez *et al*[30] have shown that vitamin D3 increases VDR protein expression and inhibits viral replication in cell culture.

It is well known that people of African and Hispanic descent are less likely to respond to standard therapy[31]. This may be due to a polymorphism of the *IL28B* gene and to vitamin D deficiency[13,32]. The vast majority of subjects in the present study had vitamin D insufficiency that was possibly related to low exposure to the sun and/or to a low supply of vitamin D from the diet. Recently, an important study by Lange *et al*[33] has confirmed the association of response to therapy with vitamin D levels and, even more significantly, by describing novel associations between genetic polymorphisms within VDR; especially in the α-hydroxylase promoter region (CYP27B1-1260), and vitamin D levels in HCV patients. The authors showed also that fibrosis alone is not the key to understanding the impact of chronic hepatitis C on vitamin D metabolism.

The role of insulin resistance and supplementation of vitamin D with regards to chronic HCV infection has been investigated previously by our group[14]. Insulin resistance has emerged as one of the most important host factors in the prediction of response in non-diabetic HCV-infected patients treated with Peg/RBV, and is a common denominator to the majority of features associated with difficult-to-treat patients[34]. Vitamin D is also known to help prevent type 2 diabetes and it is possible that low levels of vitamin D lead to insulin resistance[9]. The direct effect of vitamin D may be mediated by binding of its circulating active form to the pancreatic B cell VDR[35,36]. Moreover, oxidative stress leaches calcium, and vitamin D helps absorb calcium[37]. In the current study, increasing levels of vitamin D to > 32 ng/mL increased the response to antiviral therapy. The calcium levels were normal in our patient population.

Multivariate analysis revealed that vitamin D supplementation, baseline vitamin D levels, viral load, and hepatitis C genotype remained as independent predictors. Thus, it can be concluded that vitamin D supplementation is responsible for a higher SVR, rather than the baseline vitamin D level. Limitations of the present study include the small number of patients, and the lack of Th1 and Th2 immune response. The identification of determinants of response such as polymorphisms of the *IL28B* gene and within the VDR may explain the difference in response rates between patients with different ethnic backgrounds. This was not done in our study because data on *IL-28B* and VDR polymorphism were not available. Because of the small number of patients in the present study, a multicenter study with a larger number of patients is warranted. Another limitation was the lack of results that documented the viral response at weeks 4 and 12 in the control group. This test was not included in the health package at the time of study recruitment. Finally, we did not have a dose-response relationship for vitamin D supplementation. The dose of 2000 IU/d was based on previous investigations[38].

In conclusion, the addition of vitamin D to pegylated interferon α2b and ribavirin in naïve patients infected with HCV genotype 2-3 significantly increased the rate of viral response. We suggest routine testing of vitamin D levels prior to combination therapy and replacement during treatment for chronic hepatitis C.

COMMENTS

Background

Treatment of patients with chronic hepatitis C virus (HCV) infection with pegylated interferon + ribavirin (Peg/RBV) achieves virus clearance in < 50% of cases. Thus, there is a need to find new medication.

Research frontiers

Recent efforts have focused on adding new antiviral therapies including polymerase or protease inhibitors to standard therapy. However, these drugs have many side effects like rash and are very expensive. Few studies have addressed the issue of improving the immune system of the patient with immunomodulators, such as vitamin D supplementation.

Innovations and breakthroughs

Adding vitamin D supplements (2000 IU/d) to standard Peg/RBV therapy for patients with HCV genotype 2-3 significantly improves viral response (viral clearance) from 42% to 86% for genotype 1 and from 77% to 95% for genotype 2/3. The addition of vitamin D is cheap and without side effects.

Applications

The authors suggest routine testing of vitamin D levels prior to Peg/RBV therapy and adding vitamin D supplementation for chronic hepatitis C until reaching a blood level > 32 ng/mL.

Terminology

Response rate: Undetectable virus in the blood at 6 mo after discontinuation of therapy; peg-interferon is an immune system modulator that improves immune function and clears virus; ribavirin is a drug that inhibits viral replication.

Peer review

This is an interesting study and supports the previous work from this group on HCV treatment in genotype 1 subjects.

Abstract

AIM: To access the short-term outcomes of simultaneous laparoscopic surgery combined with resection for synchronous lesions in patients with colorectal cancer.

METHODS: Between March 1996 and April 2010 prospectively collected data were reviewed from 93 consecutive patients who had colorectal cancer and underwent simultaneous multiple organ resection (combined group) and 1090 patients who underwent conventional laparoscopic right hemicolectomy or laparoscopic low/anterior resection for colorectal cancer (non-combined group). In the combined group, there were nine gastric resections, three nephrectomies, nine adrenalectomies, 56 cholecystectomies, and 21 gynecologic resections. In addition, five patients underwent simultaneous laparoscopic resection for three organs. The patient demographics, intra-operative outcomes, surgical morbidity, and short-term outcomes were compared between the two groups (the combined and non-combined groups).

RESULTS: There were no significant differences in the clinicopathological variables between the two groups. The operating time was significantly longer in the combined group than in the non-combined group, regardless of tumor location (laparoscopic right hemicolectomy and laparoscopic low/anterior resection groups; $P = 0.048$ and $P < 0.001$, respectively). The other intra-operative outcomes, such as the complications and open conversion rate, were similar in both groups. The rate of post-operative morbidity in the combined group was similar to the non-combined group (combined *vs* non-combined, 15.1% *vs* 13.5%, $P = 0.667$). Oncological safety for the colon and synchronous lesions were obtained in the combined group.

CONCLUSION: Simultaneous laparoscopic multiple organ resection combined with colorectal cancer is a safe and feasible option in selected patients.

Key words: Laparoscopic combined resection; Colorectal cancer; Laparoscopic surgery

INTRODUCTION

The laparoscopic approach for colorectal cancer was in-

troduced during the last decade, and the oncological safety and short-term outcomes have been demonstrated in randomized prospective trials[1-5]. As a result, the laparoscopic approach has been increasingly used to treat colorectal cancer, and this approach for other abdominal organs has also been widely accepted and performed[6-9]. The remarkable development of the laparoscopic approach is due to its unique benefits over open surgery, such as less pain, shorter hospital stay, faster recovery period, and better cosmetic results.

Simultaneous resection of synchronous abdominal lesions requiring surgical intervention is likely to benefit patients by reducing psychological and physiological stress related to re-operation. Some patients with sporadic colorectal cancer have one or more co-existing intra-abdominal diseases that require simultaneous resection with the primary colorectal cancer. This combined surgery could result in increased tissue injury and morbidity related to the longer operative time, as well as a larger or more radical incision, especially when the target organ is distant from the colorectal cancer. Fortunately, the laparoscopic approach can be applied to almost all intra-abdominal surgical procedures. Well-planned positioning of trocars, and a common mini-incision for retrieval of specimens, would maximize the advantages of laparoscopic surgery, even in cases with simultaneous multi-organ resection. However, the laparoscopic approach for greater than two co-existing abdominal disorders, especially colorectal cancer, is rarely performed and is the subject of few case reports in the literature[10-14]. Furthermore, no studies have compared laparoscopic combined resection in colorectal cancer patients with conventional laparoscopic colorectal resection. Therefore, it remains unknown whether or not a laparoscopic approach is safe and beneficial in patients with colorectal cancer undergoing simultaneous combined resection on synchronous abdominal lesions.

In the present study, we clarified the feasibility of simultaneous laparoscopic surgery combined with resection for synchronous lesions in patients with colorectal cancer. The study will elucidate the oncological outcomes in combined resection by comparing findings in patients who underwent conventional laparoscopic non-combined colorectal resection. We also described the technical details related to laparoscopic multiple organ resection combined with colorectal cancer.

MATERIALS AND METHODS

Patients

Between January 1996 and March 2010, 1657 patients underwent laparoscopic resection for colorectal cancer by one surgeon at the Kyungpook National University Hospital in Daegu, South Korea. Three hundred fifteen patients underwent laparoscopic right hemicolectomy and 937 patients underwent laparoscopic anterior or low anterior resection. Patients who had distant metastases, including metastasis of the liver, *en-bloc* regional resection due to T4 serosal invasive lesions, or patients who underwent palliative resection or emergency operations caused by perforation or obstruction of the colon and rectum, were excluded. Patients who underwent transverse colectomy or left hemicolectomy were also excluded because of the absence of simultaneous resection during these surgical procedures. Therefore, 263 patients who underwent laparoscopic right hemicolectomies were matched to 26 patients who underwent combined organ resections with right hemicolectomies. In addition, 827 patients who underwent single low/anterior resections were matched to 67 patients who underwent simultaneous low/anterior resections and other intra-abdominal organ procedures (Figure 1).

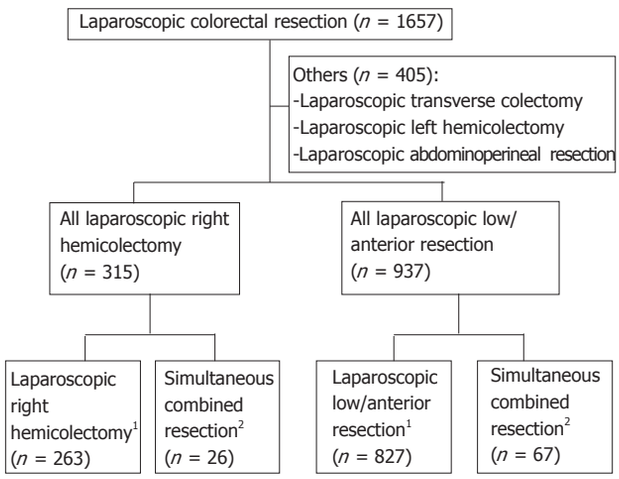

Figure 1 Algorithm of enrolled patients (number of patients). [1]Satisfied with inclusion criteria; [2]Type of combined rection was explained in Figure 2.

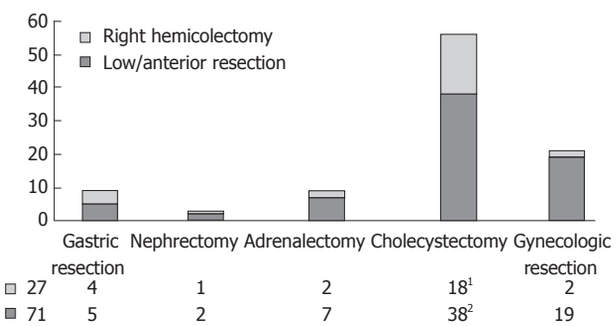

Figure 2 Type of simultaneous combined resection. [1]One case was adrenalectomy with cholecystectomy; [2]Two cases were cholecystectomies with adrenalectomies, 1 case was gastric resection and 1 case was gynecologic resection.

Figure 2 shows the type of simultaneous combined resection according to the location of synchronous abdominal lesions, distinguished between the primary colorectal resections. Five gastric resections were laparoscopically-assisted distal gastrectomies with more than D1+α lymph node dissection for gastric cancer[15], and four were laparoscopic gastric wedge resections for submucosal tumors. Five patients underwent laparoscopic simultaneous resection of three organs.

Data on patient demographics, medical co-morbid-

ities, operative details related to laparoscopic combined resections, short-term post-operative outcomes, and pathological findings were collected prospectively and entered into a database of colorectal malignancies.

The following tests and studies were performed pre-operatively: tumor markers; colonoscopy; abdominal computed tomography; and positron emission tomography. Endocrine function tests, ultrasonography, and gastroduodenoscopy were also performed when synchronous lesions were noted for surgical planning purposes.

Surgical techniques

All surgeries were performed with curative intent, irrespective of the location of the synchronous lesions. All procedures were performed by one surgeon (Choi GS), and the same surgeon performed the combined multiple abdominal resections.

Laparoscopic right hemicolectomy: The patients were placed in the supine or modified lithotomy position in Trendelenburg slightly tilted to the left side. An 11-mm infra-umbilical camera port was placed, two 5-mm trocars were introduced into the right upper and lower quadrants as operating ports, and two additional 5-mm trocars were placed in the left as assistant ports. The surgical technique for the laparoscopic right hemicolectomy was described in a previous report[16]. After D3 lymph node dissection and full mobilization of the right colon, the surgeon moved to the other abdominal lesions. No additional trocars were required. The surgeon changed his position to the right only when performing an operation on left-side lesions. During gastric resections the heads of the patients were elevated, and during nephrectomies the patients were changed to the lateral decubitus position. Ileocolic anastomosis was performed intra- or extra-corporeally, and the other abdominal organs were resected using a routine approach, as described previously[6-8,15,17,18]. Mini-laparotomies were then performed in the upper midline or midline, to extend the umbilical port through which the specimens were extracted and anastomoses were performed.

Laparoscopic low/anterior resection: Initially, the patient was placed in the modified lithotomy position in Trendelenburg with a slight tilt to the right side. An 11-mm infra-umbilical camera port was placed, a 12-mm trocar was placed in the right lower quadrant, and two additional 5-mm trocars were placed in the right upper and left lower quadrant as operating and assistant ports. The surgical technique used at our institution for the laparoscopic anterior and low anterior resections with total mesorectal excision has been previously described[16,19]. Following transection of the rectum, the surgeon approached the other abdominal lesions. In gastric resections and right nephrectomies, an additional trocar was required in the left upper quadrant. The positions of the surgeon and patients were changed in the same way for laparoscopic right hemicolectomies. Then, mini-laparotomies were performed in the upper midline or midline to extend the umbilical port, or the left lower quadrant transversely. The specimen was extracted and an anastomosis was performed.

Statistical analysis

Data analysis was performed using SPSS 17.0 (SPSS, Inc., Chicago, IL, United States). Clinicopathological variables between the groups were compared using the Fisher's exact test for categorical data and the Student's *t* test for continuous variables. A P value < 0.05 was considered statistically significant.

RESULTS

Laparoscopic right hemicolectomy

The clinical characteristics of the patients are summarized in Table 1. All 293 patients underwent elective laparoscopic right hemicolectomy. The two groups (non-combined and combined) were similar with respect to the distribution of age, gender, body mass index and American Society of Anesthesiologists score. Fifty-three (20%) and five patients (19.2%) had a history of previous abdominal surgery in the non-combined and combined groups, respectively ($P = 0.911$).

Table 2 presents data on the surgical aspects and pathological results of primary colon cancer. The mean operating time was significantly longer in the combined group than in the non-combined group [189.6 min (range, 65-397 min) *vs* 166.9 min (range, 210-320 min), $P = 0.048$]. Intra-operative complications and conversion to open surgery were similar in both groups. In the combined group, bile leakage due to gallbladder perforation occurred during cholecystectomy in one patient. Conversion to open surgery was required in one patient to remove common bile duct stones noted during intra-operative cholangiography. In this case, we converted to open surgery followed by choledocolithotomy with T-tube insertion. However, we used a right subcostal incision for biliary surgery as well for retrieval of the specimen and performing an anastomosis. There were no significant differences between the groups in the mean post-operative hospital stay (7.8 d in the non-combined group *vs* 8.6 d in the combined group, $P = 0.363$) or in the overall and major post-operative complications ($P = 0.513$ and $P = 0.910$, respectively).

There were no significant differences between the groups in colon tumor size, proximal and distal margins (all cases had clear resection margins), number of retrieved lymph nodes and American Joint Committee on Cancer stage (6th edition).

Laparoscopic low/anterior resection

The non-combined and combined groups were similar with respect to clinical characteristics of patients who underwent laparoscopic low/anterior resections (Table 1). In laparoscopic resection for primary colorectal cancer, 350 (42.3%) and 29 patients (43.3%) underwent anterior

Ⅱ	119 (45.2)	14 (53.8)		282 (34.1)	25 (37.3)	
Ⅲ	81 (30.8)	9 (34.6)		268 (32.4)	22 (32.8)	

[1]Values are expressed as the mean (range). NC: Non-combined; C: Combined; LN: Lymph node; AJCC: American Joint Committee on Cancer stage (6th edition).

resections, 397 (48%) and 34 patients (50.7%) underwent low anterior resections, and the remaining 80 (9.7%) and four patients (6%) underwent low anterior resections with colo-anal anastomoses, respectively. No significant differences existed between the two groups ($P = 0.602$).

The mean operating time was significantly longer in the combined group than in the non-combined group [228.1 min (range, 80-480 min) *vs* 178 min (range, 60-430 min), $P \leqslant 0.001$]. The rate of intra-operative complications and conversion to open surgery was similar in both groups. In the combined group, one patient was converted to open surgery because of massive intra-abdominal adhesions associated with two previous operations. There were no cases requiring protective diverting stoma in the combined group. In contrast, 18 patients in the non-combined group required protective diverting stomas ($P = 0.282$). There were no significant differences between the groups in the mean post-operative hospital stay (7.9 d in the non-combined group *vs* 8.8 d in the combined group, $P = 0.104$) or in the overall and major post-operative complications ($P = 0.953$ and $P = 0.335$, respectively).

The two groups were similar regarding primary colorectal pathology. All cases were performed safely in terms of oncological outcomes.

Post-operative morbidity

The post-operative complications in both groups are

Table 3 Perioperative complications

	Non-combined group (n = 1090)	Combined group (n = 93)	P value
Postoperative complication (%)	147 (13.5)	14 (15.1)	0.667
Bleeding	7	0	
Anastomosis leakage	27	3	
Intra-abdominal abscess	9	1	
Ascites	8	1	
Wound problem	15	4	
Delayed bowel movement	29	2	
Bile leakage	0	1	
Urinary retention	10	0	
Respiratory problem	25	1	
Phlebitis in injection site	13	0	
Cerebral infarction	1	1	
Deep vein thrombosis	1	0	
Acute renal failure	1	0	
Urinary tract infection	1	0	

shown in Table 3. There were no significant differences between the groups (P = 0.667). In the combined group, post-operative complications developed in 14 patients (15.1%). Three patients had anastomosis leakages that were controlled by conservative management without the need to perform a temporary stoma. Two patients underwent percutaneous drainage to resolve pelvic fluid collections or intra-abdominal abscesses. One patient had bile leakage related to combined procedures on post-operative 1 d, but this resolved with a Jackson-Pratt (JP) drainage for 1 d without other surgical interventions. Two patients experienced dietary delay because of post-operative ileus controlled by an nasogastric tube. The remaining patient developed a cerebral infarction without post-operative sequelae. There were no 30-d operative mortalities.

Pathological findings of synchronous lesions

The pathological data of synchronous lesions are summarized in Table 4. Five early gastric cancers (EGCs) were detected in the stomach; three gastrointestinal stromal tumors and one schwannoma were also discovered. In the five EGC cases, the entire tumor was confined to the mucosa with 45, 31, 17, 17 and 16 lymph nodes retrieved, respectively. There were no lymph node metastases. The other synchronous lesions also had clear resection margins. Two patients who underwent nephrectomies were diagnosed with renal cell carcinomas (RCCs) and one lesion, which was diagnosed with RCC pre-operatively, was a leiomyoma. Eight lesions were adrenal adenomas, and the remaining lesion was diagnosed with adrenal metastasis. Fifty-five cholecystectomies involved cholelithiases, and one cholecystectomy was a primary gallbladder cancer confined to the mucosa with a clear resection margin, which did not require additional resection. In 21 gynecological resections, two lesions were leiomyomas of the uterus and four were serous cystadenomas; seven lesions were endometriomas, six were ovarian cysts, one was a teratoma, and one was an ovarian abscess.

Table 4 Pathological findings of synchronous lesion

Synchronous lesion pathology (n = 98)			
Stomach (n = 9)		**Gall bladder (n = 56)**	
EGC	5	Primary malignancy	1
GIST	3	Stone	55

DISCUSSION

In the present study, we report on the laparoscopic approach for synchronous multiple abdominal lesions in colorectal cancer patients. Our data showed that this approach is feasible and safe in terms of peri-operative and oncological outcomes.

Minimally invasive laparoscopic surgery has been introduced as an option for patients with colorectal cancer, and many advantages of this surgery have been reported. Attenuated surgical trauma offers faster bowel recovery compared with open surgery, thus reducing post-operative ileus related to decreased expression of inflammatory cytokines[1-3,20]. Furthermore, this approach offers good cosmetic results, reduced post-operative pain and short-term morbidity, and improved quality of life. Combined surgery for synchronous lesions also has potential advantages[10-13]. The patients may minimize the length of hospital stay and have a single, rather than multiple, hospital admission. Cardiac and pulmonary burden related to multiple anesthetic exposures were reduced by combining surgery. Thus, combined surgery reduces the cost related to the hospital stay. If combined surgery for synchronous lesions is performed with a laparoscopic approach, there are also potential advantages over open combined surgery. This approach is available in multi-quadrant abdominal operations with better visualization of the operative field and without additional skin incisions. Furthermore, this approach may reduce the number of trocar incisions by reusing the ports and improving cosmesis. Therefore, there are reduced concerns about delaying the post-operative recovery and impairing post-operative quality of life according to open combined resections.

Simultaneous laparoscopic resection for co-existing abdominal lesions has been reported in several case series, the benefits of which have been previously described[10-13,21]. Most recently, in relation to colorectal cancer patients, laparoscopic resection for synchronous gastric cancer was reported in seven patients with synchronous double primary cancers[11]. All of these reports suggest that simultaneous laparoscopic combined resection is the best choice in patients with co-existing

abdominal lesions, in terms of technical feasibility and oncological safety. However, the previous studies emphasized the need for large-scale studies related to simultaneous laparoscopic combined resection owing to the study limitations that prevented a demonstration of actual benefit[10-13]. This present study overcomes these limitations by including 93 patients who underwent laparoscopic combined resection with colorectal cancer and 1090 patients who underwent conventional laparoscopic colorectal resections at our institution. The number of patients included thus enables a comparison of peri-operative and oncological outcomes, including the presence of synchronous cancer and the multiple locations of co-existing abdominal lesions.

In relation to the technical aspects of the procedure, an additional port was inserted in cases of gastric resection and right renal cell carcinoma only in patients with left colon cancer. We shared the trocars in resection of synchronous multiple organs. It is very important to plan the position of ports and mini-incisions appropriately to share the trocars and incisions, not only for exposure and removal of synchronous lesions, but also for colorectal cancer to minimize the number of unnecessary trocars. We modified the number and location of the ports so that we could accomplish multiple surgeries with a minimum number of trocars, but with the same ease. For example, in the case of a cholecystectomy with left colon cancer, the left trocar as an assistant port was placed at a higher level than in standard cases.

In the present study, the mean operative time in the combined group was significantly longer than in the non-combined group. However, the mean operative times were only 20 and 40 min, respectively, compared to the non-combined conventional laparoscopic right hemicolectomy and laparoscopic low/anterior resection. This time is acceptable, as surgeries for more than two lesions were performed, thus avoiding the need for additional operations at a later stage.

Intra-operative complications occurred in six patients; in two of the cases, conversion to open surgery was necessary because of a common bile duct stone discovered intra-operatively and a massive adhesion due to previous abdominal surgery. Although complications developed post-operatively in 14 patients, none required surgical intervention. Anastomotic leakage, which occurred in three patients, was treated by conservative management with bowel rest, percutaneous drainage insertion, and rectal tube insertion. Anastomotic leakage was reported to occur in 0.5%-27% of patients in published series[22,23]; in the current study, anastomotic leakage occurred in 2.5% of patients in the non-combined group and 3.2% of the patients in the combined group. Furthermore, there was only one complication associated with the combined resection; specifically, bile leakage occurring on postoperative 1 d in the combined group, which was resolved through JP drainage for 1 d without other surgical interventions. Our data, therefore, show that laparoscopic combined resection does not increase peri-operative complications in selected patients.

The results of histopathological examinations of the mean number of retrieved lymph nodes and the length of the distal margins in the combined group were similar to the non-combined group, suggesting that oncological safety for colorectal cancer was obtained in both groups. Furthermore, nine patients with synchronous malignancies had clear resection margins. The median follow-up of these patients was 36.6 mo; there was one recurrence in a patient undergoing adrenalectomy for adrenal metastasis that metastasized to the brain in nine months. For primary colorectal cancer, the recurrence rate between the both groups was not significantly different in both laparoscopic right hemicolectomy (combined *vs* non-combined, 11.5% *vs* 8.7%, $P = 0.716$) and laparoscopic low/anterior resection (combined *vs*. non-combined, 10.2% *vs* 7.2%, $P = 0.289$). The five-year overall survival was also similar in both groups, regardless of tumor location (laparoscopic right hemicolectomy; combined *vs* non-combined, 93.3% *vs* 86.5%, $P = 0.665$, laparoscopic low/anterior resection groups; combined *vs* non-combined, 96.6% *vs* 96.4%, $P = 0.565$). Our study showed oncological safety for both colorectal and synchronous cancers.

The retrospective nature of our study posed some limitations. It is uncertain whether or not the longer operative time in the combined group accounts for the reason why the combined resection was difficult or why the primary tumor resection was technically difficult. The time required for colorectal and synchronous lesion resections was not shown; therefore, we did not estimate the results according to conventional resections of other abdominal lesions. Thus, a comparison of the time required for conventional resection of other organs is needed with the time required for combined laparoscopic resection of synchronous lesions.

Following the recent introduction of the Da Vinci system, robotic surgery has been attempted in various fields. Colorectal surgery has been considered one indication for robotic surgery because of advantages such as a magnified three-dimensional visual field and articulating instruments[24-27]. However, various disadvantages have also been reported, one of which is motion limitation in multi-quadrant operations. Our study included 10 cases of robotic-assisted laparoscopic combined resections. Although seven patients in our study underwent a hybrid-surgical technique that involved colectomies and a laparoscopic approach for combined resection, the remaining three patients underwent complete robotic-assisted combined resection for synchronous lesions, low anterior resection with left nephrectomy and anterior resection with aderenalectomy, and right hemicolectomy with cholecystectomy. During nephrectomy, we re-docked after the position change, but the total operating time (340 min) and peri-operative outcomes were acceptable. Therefore, we sought to determine the possibility of using the robotic system in multi-quadrant surgery.

In conclusion, we have demonstrated that simultaneous laparoscopic resection for multiple synchronous abdominal lesions in colorectal cancer patients is safe and feasible. The advantages of this approach with co-existing abdominal lesions include a reduced number of sequential operations and a reduction in hospital stay and overall morbidity. Compared to conventional non-combined colorectal resection, the combined approach has acceptable peri-operative outcomes. Based on these findings, we suggest that simultaneous laparoscopic resection is the best choice for managing co-existing abdominal lesions in colorectal cancer patients.

COMMENTS

Background

The laparoscopic approach is now routinely employed for colorectal cancer on basis of its unique benefits over open surgery and can be applied to almost all intra-abdominal surgical procedures. Simultaneous resection of synchronous abdominal lesions requiring surgical intervention is likely to benefit patients by reducing psychological and physiological stress related to re-operation. If so, when patients with colorectal cancer have co-existing abdominal lesions, is a laparoscopic combined resection safe and beneficial?

Research frontiers

The laparoscopic approach for synchronous multiple abdominal lesions in colorectal cancer patients laparoscopic combined resection does not increase peri-operative complications and secures the oncological safety for both colorectal and synchronous cancers. Therefore, in selected patients, laparoscopic combined resection is feasible and safe.

Innovations and breakthroughs

Simultaneous laparoscopic resection for co-existing abdominal lesions has been reported in several case series, the benefits of which have been previously described. However, the previous studies emphasized the need for large-scale studies related to simultaneous laparoscopic combined resection owing to the study limitations that prevented a demonstration of actual benefit. This present study overcame these limitations by including 93 patients who underwent laparoscopic combined resection with colorectal cancer and 1090 patients who underwent conventional laparoscopic colorectal resections at the institution. This enabled a comparison of peri-operative and oncological outcomes, including the presence of synchronous cancer and the multiple locations of co-existing abdominal lesions.

Applications

Simultaneous laparoscopic resection is the best choice for managing co-existing abdominal lesions in colorectal cancer patients.

Peer review

This is a comparative study on retrospective data on a topic of current interest, although studies to date have suggested more complications with combined procedures that have been done as open surgery.

Abstract

AIM: To investigate the protein expression profile of mismatch repair (*MMR*) genes in suspected cases of Lynch syndrome and to characterize the associated germline mutations.

METHODS: Immunohistochemical analysis of tumor samples was performed to determine the protein expression profile of MMR protein. Germline mutation screening was carried out on peripheral blood samples. The entire exon regions of *MLH1* and *MSH2* genes were amplified by polymerase chain reaction, screened by denaturing high performance liquid chromatography (dHPLC) and analyzed by DNA sequencing to characterize the germline mutations.

RESULTS: Three out of 34 tissue samples (8.8%) and four out of 34 tissue samples (11.8%) showed loss of nuclear staining by immunohistochemistry, indicating the absence of MLH1 and MSH2 protein expression in carcinoma cells, respectively. dHPLC analysis followed by DNA sequencing showed these samples to have germline mutations of *MSH2* gene. However, no deleterious mutations were identified in any of the 19 exons or coding regions of *MLH1* gene, but we were able to identify *MLH1* promoter polymorphism, -93G > A (rs1800734), in 21 out of 34 patients (61.8%). We identified one novel mutation, transversion mutation c.2005G > C, which resulted in a missense mutation (Gly669Arg), a transversion mutation in exon 1, c.142G > T, which resulted in a nonsense mutation (Glu48Stop) and splice-site mutation, c.2006-6T > C, which was adjacent to exon 13 of *MSH2* gene.

CONCLUSION: Germline mutations were identified in four Malaysian Lynch syndrome patients. Immunohistochemical analysis of tumor tissue proved to be a good pre-screening test before proceeding to germline mutation analysis of DNA *MMR* genes.

Key words: Denaturing high performance liquid chromatography; DNA sequencing; Germline mutation; Mismatch repair genes; Immunohistochemistry; Lynch syndrome

INTRODUCTION

Colorectal cancer (CRC) is the most common gastrointestinal cancer in Malaysia and Lynch syndrome accounts for approximately 1%-5% of all colorectal cancers[1-3]. Lynch syndrome is generally divided into type I which describes families presenting with colonic cancers at an early age in the absence of multiple colonic adenomas, whereas type Ⅱ describes similar families who also develop extracolonic cancers particularly those of the female reproductive tract[4]. Lynch syndrome is characterized by autosomal dominant inheritance with multiple members affected in families, inheritance of susceptibility genes (mismatch repair genes) with incomplete penetrance (80%-90%), and early onset of CRC and/or extracolonic cancers such as cancers of the endometrium, ovary, stomach, small intestine, hepatobiliary tract, upper urinary tract, brain and skin[5,6].

Germline mutations in a group of DNA mismatch repair (*MMR*) genes (*MLH1*, *MSH2*, *MSH6*, *PMS1* and *PMS2*) have been found to be associated with susceptibility to Lynch syndrome[5-7]. Germline mutations of *MLH1* and *MSH2* genes account for more than 90% of the mutations identified in Lynch syndrome families[5,8]. The loss of MMR function will lead to a phenomenon known as microsatellite instability (MSI) which is the hallmark of Lynch syndrome.

In addition to tumor MSI testing which is available to evaluate the MSI status and germline mutation analysis using peripheral blood, immunohistochemical testing of tumor tissue for the expression status of MMR protein has emerged as another option available in the genetic testing of Lynch syndrome. Data on germline mutations of *MMR* genes are available from different parts of the world in varying frequencies, however, no reports are available from Malaysia. Hence, this study was undertaken to unravel the spectrum of germline mutations in DNA *MMR* genes in Malaysian Lynch syndrome patients. We investigated the protein expression profile of *MMR* genes in suspected cases of Lynch syndrome and characterized the associated germline mutations. This report focuses on the protein expression profile and germline mutations identified in *MLH1* and *MSH2* gene.

MATERIALS AND METHODS

Patients

This study was approved by the Research and Ethics Committee, School of Medical Sciences, Universiti Sains Malaysia and National Institutes of Health for conducting research under the Ministry of Health, Malaysia. Thirty-four patients who fulfilled any of the following revised Bethesda Guidelines were recruited from three collaborating centres in Malaysia namely Hospital Universiti Sains Malaysia, Hospital Alor Star, Kedah and Hospital Queen Elizabeth, Kota Kinabalu, Sabah. (1) CRC with age less than 50 years old; (2) Presence of synchronous or metachronous colorectal or other hereditary nonpolyposis colorectal cancer (HNPCC)-associated tumors regardless of age; (3) CRC with MSI-positive morphology with age less than 60 years old; (4) CRC with one or more first-degree relatives with CRC or other HNPCC-related tumor, with one of the cancers with age less than 50 years old; and (5) CRC with two or more first- or second-degree relatives with CRC or other HNPCC-related tumor (regardless of age), including cancers (endometrial, stomach, ovarian, cervical, esophageal, leukemia, thyroid, bladder, ureter and renal pelvis, biliary tract, small bowel, breast, pancreas, liver, larynx, bronchus, lung and brain (glioblastoma), sebaceous gland adenomas and keratoacanthomas.

Personal and demographic details of the patients including history of CRC in the family were collected and recorded. CRC patients with a strong family history of CRC among first- or second-degree relatives and who met the selection criteria were subjected to detailed pedigree analysis. Detailed pedigrees of these suspected cases of Lynch syndrome were prepared. A 5 mL blood sample was collected from identified Lynch syndrome patients after obtaining informed consent.

Immunohistochemical analysis of tumor tissues

Paraffin-embedded tissue blocks from each resected bowel specimen containing carcinoma and preferably adjacent non-neoplastic colon were selected. Four μm-thick tissue sections were cut, dewaxed in xylene and rehydrated in graded alcohol concentrations to distilled water. Slides were placed in Tris-EDTA buffer at pH 9.0 in a pressure chamber for antigen retrieval for 2 min at 123 ℃. Peroxidase blocking reagent (DakoCytomation) was used to block endogenous peroxidase activity. Slides were incubated with 150-200 μL of primary monoclonal mouse antibodies: MLH1 antibody (BD Biosciences Pharmingen, United States, Cat. No. 550838) at 1/50 dilution and MSH2 antibody (BD Biosciences Pharmingen, United States, Cat. No. 556349) at 1/200 dilution, Horseradish-peroxidase (HRP) labeled polymer, conjugated to secondary antibody and thereafter DAB substrate chromogen (DAKO Envision detection kit, peroxidase/DAB, Rabbit/Mouse) were applied. Slides were counterstained with hematoxylin.

Normal expression of protein was defined as the presence of nuclear staining in colon cancer cells. Loss of staining in carcinoma with concurrent positive staining in nuclei of normal colon epithelial cells indicated absent expression of protein. Adjacent non-neoplastic colon and stromal inflammatory cells served as internal positive controls. The external positive control was normal colon.

Germline mutation analysis

Genomic DNA was extracted from blood using the commercially available DNA extraction kit, QIAamp DNA Blood Mini kit (Qiagen, Hilden, Germany). Specific primers were designed by using Primer3 software[9] to amplify all 19 exons of *MLH1* gene and 16 exons of *MSH2* gene. DNA was subjected to polymerase chain reaction (PCR) amplification of 19 exons of *MLH1* gene and 16 exons of *MSH2* gene using specific primers as listed in Tables 1 and 2, respectively, in a total reaction volume of 20 μL, consisting of 1X PCR reaction buffer (Applied Biosystem, Foster City, CA, United States), 1.875 μmol/L $MgCl_2$ (Applied Biosystem, Foster City, CA, United States), 0.375 μmol/L dNTPs (Applied Biosystem, Foster City, CA, United States), 0.4 μmol/L each of forward and reverse primers, about 100 ng genomic DNA and 1 unit of Ampli*Taq* Gold DNA Polymerase (Applied Biosystem, Foster City, CA, United States). PCR was performed with an initial denaturation step at 96 ℃ for 5 min, followed by 40 cycles of denaturation at 95 ℃ for 1 min, annealing at temperatures as listed in Tables 1 and 2 for 1 min and extension at 72 ℃ for 1 min, followed by a final extension step at 72 ℃ for 7 min.

Amplicons were then visualized by gel electrophoresis in a 2% agarose gel. Three μL of each amplicon was mixed with 3 μL of wild-type sample, denatured at 95 ℃ for 3 min and then gradually reannealed by decreasing the sample temperature from 95 ℃ to 65 ℃ over a period of 30 min to allow the formation of heteroduplex. Mutation analysis was performed employing denaturing high performance liquid chromatography (dHPLC) using ProStar Helix System, Varian Inc, United States and samples were analyzed under the optimum melting temperature determined by using the melting program available online, http://insertion.stanford.edu/melt.html. The wild-type sample for all the exon regions was randomly selected and confirmed by DNA sequencing.

Samples which showed heteroduplex peaks were subjected to DNA sequencing to characterize the mutation. For this, amplicons were purified using the QIAGEN QIAamp PCR purification kit (Qiagen, Hilden, Ger-

many). Purified amplicons were sequenced using BigDye Terminator v3.1 kit (Applied Biosystem, Foster City, CA, United States) on the automated ABI PRISM 3100 Genetic Analyzer (Applied Biosystem Inc, United States).

RESULTS

Immunohistochemical analysis of tumor tissues

Protein expression of MLH1 and MSH2 antigens were evaluated in tissue samples from 34 Malaysian Lynch syndrome patients. Three out of 34 tissue samples (8.8%) showed absence of nuclear staining for MLH1 and four out of 34 tissue samples (11.8%) showed loss of nuclear staining for MSH2 in cancer epithelium cells. Figure 1A and 1B show the loss of nuclear staining in MLH1 and MSH2 protein, respectively, observed in tumor samples. Patients whose samples showed absence of MLH1 and MSH2 protein expression were subjected to mutation analysis of *MLH1* and *MSH2* genes to detect and characterize germline mutations, if present.

Germline mutation analysis

Nineteen exons of *MLH1* gene and 16 exons of *MSH2* gene were successfully amplified and screened by dHPLC. Samples which showed heteroduplex peaks by dHPLC were subjected to DNA sequencing to characterize the germline mutations. All four Lynch syndrome patients who showed absence of MSH2 protein expression by immunohistochemical analysis were found to harbor germline mutations. Three different types of mutations were identified in *MSH2* gene among these four patients (Table 3). Of these, one was a substitution in exon 1 of *MSH2* gene, c.142G > T, which resulted in a nonsense mutation (Glu48Stop) and is considered a deleterious mutation (Figure 2A). The second type was a transversion mutation, c.2005G > C (Figure 2B), which resulted in a missense mutation (Gly669Arg). This has not been reported before in any of Lynch syndrome mutation databases namely MMR Genes Variant Database (www.med.mun.ca/MMRvariants), International Society for Gastrointestinal Hereditary Tumours mutation database

Table 3 Germline mutations of *MSH2* gene detected in 4/34 Lynch syndrome patients

Gene	Patients ID	Age	Exon/intron region	Nucleotide change	Consequence
MSH2	LS8	50	Exon 12	c.2005G > C	Missense mutation (G669R)
	LS20	43	Exon 12	c.2005G > C	Missense mutation (G669R)
	LS37	41	Intron 12	c.2006-6T > C	Splice-site mutation
	LS41	49	Exon 1	c.142G > T	Nonsense mutation (E48X)

(www.insight-group.org) and Human Gene Mutation Database (www.hgmd.cf.ac.uk/ac/index.php) and could be considered a novel mutation. This novel mutation was identified in two patients who showed absent expression of MSH2 protein by immunohistochemistry. The fourth patient showed a splice-site mutation, c.2006-6T > C (Figure 2C), which was adjacent to exon 13 of *MSH2* gene in one of the patients.

However, no deleterious mutations were identified in any of the 19 exons or coding regions of *MLH1* gene in the three Lynch syndrome patients who showed absence of MLH1 protein expression by immunohistochemical analysis, but *MLH1* promoter polymorphism, -93G > A (rs1800734), was detected in 21 out of 34 patients (61.8%) (Figure 2D).

DISCUSSION

Germline mutations in DNA *MMR* genes particularly of *MLH1* and *MSH2* genes were reported to be responsible for the majority of Lynch syndrome cases[5,8]. The most crucial procedure in confirming Lynch syndrome is the sequencing analysis of DNA *MMR* genes to unravel the germline mutation harbored by the suspected patients. However, the procedure is problematic and challenging especially in large-scale studies, thus the application of a pre-screening method is essential. MSI analysis as well as immunohistochemical analysis of tumor tissue has been shown to be highly predictive for selecting candidates with defective *MMR* genes[10,11]. Immunohistochemical testing of tumor tissue in particular has been proven to be a good diagnostic tool, since it can pinpoint the *MMR* genes most eligible for germline mutation analysis of DNA *MMR* genes[12].

In our study consisting of 34 Malaysian Lynch syndrome patients, immunohistochemical analysis of tumor tissue was applied as a pre-screening method. Using immunohistochemistry, we identified 4 out of 34 patients (11.8%) who showed absent expression of MSH2 protein. One of them harbored a substitution in exon 1 of *MSH2* gene, c.142G > T, which resulted in a nonsense mutation (Glu48Stop). This mutation can be considered as probably deleterious as it results in a premature stop codon and subsequently a nonfunctional and truncated protein. The mutation has been reported in Dutch hereditary nonpolyposis CRC family members who showed absent expression of MSH2 protein[13].

Interestingly, we identified a novel mutation, transversion mutation c.2005G > C, which resulted in a missense mutation (Gly669Arg) in two patients. Functional studies conducted by Acharya *et al*[14] showed that amino acid residues 658-670 is a highly conserved disordered loop region within Walker boxes in ATPase domain (domain V) which play a role in regulating mismatch binding and ATP-dependent clamp formation. Therefore, we strongly believe that changes in protein conformation and subsequent changes in biological properties of MSH2 protein are possible due to this mutation. Currently, we are unable to comment on the real impact of the novel mutation identified, and further functional studies are warranted to elucidate this issue.

In addition, we identified another splice-site mutation, c.2006-6T > C, which was adjacent to exon 13 of *MSH2* gene in one of the patients. The location of this mutation which was in the region of the polypyrimidine tract prompted us to suggest that it might affect normal MSH2 mRNA splicing. Since the polypyrimidine tract plays a major role in promoting the assembly of spliceosome as well as polypyrimidine tract-binding protein[15], the mutation might result in aberrant mRNA splicing during the process of post-transcriptional modification. The skipping of exon 13 which encompasses the most conserved region of *MSH2* gene might occur, leading to diminished MSH2 protein function. However, the impact of the splice-site mutation, c.2006-6T > C, in the pathogenesis of cancer is still controversial due to conflicting evidence. A few reports have shown that this mutation was associated with an increased risk of CRC in patients with ulcerative colitis[16], sporadic CRC[17] and non-Hodgkin lymphomas[18] as well as being described as a polymorphism[19]. It is also possible that the splice-site mutation is in linkage disequilibrium with the other unknown pathogenic mutation. Thus, further extensive studies are warranted to clarify the real impact of splice-site mutation towards the susceptibility to CRC.

Even though no deleterious mutations were identified in any of the 19 exons or coding regions of *MLH1* gene in the three Lynch syndrome patients who showed absence of MLH1 protein expression by immunohistochemical analysis, the possibility of germline epimutation of *MLH1* gene cannot be ruled out. On the other hand, the promoter polymorphism, -93G > A (rs1800734), which we identified in *MLH1* gene in 61.8% of our patients has been reported to be located in the core promoter region, 93 nucleotides upstream from the transcription start site, in the potential region of transcription factor binding sites[20]. The high frequency of this promoter polymorphism, -93G > A, indicates the predominance of this variation among Malaysians. Functional studies have already demonstrated that the *MLH1* promoter region from nucleotide position -184 to the transcription start site, in which the G > A alteration occurs, is essential for transcription of *MLH1*

gene[20]. The fact that the location of the promoter polymorphism is in the region of two potential transcription factor binding sites, GT-motif 2B and interleukin-6-regulated nuclear factor, could greatly enhance the chances of abnormal *MLH1* transcription and expression and subsequently reduce the DNA repair capability[21,22]. On the other hand, there is a possibility that this promoter polymorphism may alternatively be in linkage disequilibrium with another polymorphism in the coding region or intron or with the *MLH1* germline mutation itself which can affect *MLH1* function.

The function of the MMR system is to maintain the fidelity of the genome during replication. The DNA *MMR* genes *via* its intranuclear protein, namely MMR protein, will correct nucleotide base mispairs and small insertions or deletions generated by slippage errors of DNA polymerase during replication. Germline mutation in one of these genes will cause inactivation of the MMR system where the MMR proteins would no longer be expressed resulting in failure to repair the replication errors that occur spontaneously during DNA replication. This defect leads to the accumulation of errors in repetitive DNA sequences (microsatellites) throughout the genome of tumors resulting in microsatellite instability.

In summary, immunohistochemical analysis for MMR protein expression in suspected cases of Lynch syndrome could be considered a pre-screening method and a good strategy prior to germline mutation screening of DNA *MMR* genes. Since no germline mutations were identified in *MLH1* gene in Lynch syndrome patients who showed absence of MLH1 protein expression by immunohistochemical analysis, it is imperative to determine the methylation status of *MLH1* promoter as it may play a role in the other molecular mechanism of Lynch syndrome. Germline mutation analysis of the other *MMR* genes especially *PMS2* with the aim of characterizing the spectrum of DNA *MMR* gene mutation among Malaysian Lynch syndrome patients is also underway.

ACKNOWLEDGMENTS

We would like to thank the patients and their family members who participated in this project. We would also like to thank the staff at Clinical Research Centre, Hospital Sultanah Bahiyah, Alor Setar, Kedah, Malaysia for their contribution to this study and Mariam Azmi, Advanced Medical and Dental Institute, Universiti Sains Malaysia, for her technical expertise in immunohistochemistry.

COMMENTS

Background

Lynch syndrome, the most common form of hereditary colorectal cancer is mainly due to germline mutations in a group of DNA mismatch repair (*MMR*) genes (*MLH1*, *MSH2*, *MSH6*, *PMS1* and *PMS2*), and mutations in *MLH1* and *MSH2* genes alone account for more than 90% of the mutations identified in Lynch syndrome families. Data on germline mutations of DNA *MMR* genes are available from different parts of the world in varying frequencies but no reports are available from Malaysia.

Research frontiers

Mutational analysis of DNA *MMR* genes is the most pivotal step in confirming Lynch syndrome cases in order to unravel the germline mutation harbored by suspected patients. Immunohistochemical analysis of MMR protein expression in suspected cases of Lynch syndrome can be considered a pre-screening method and a good strategy prior to germline mutation screening of DNA *MMR* genes.

Innovations and breakthroughs

There are a number of previous reports available on germline mutations in *MMR* genes in other populations with varying frequencies, but no reports are available from Malaysia. This is the first study to unravel the spectrum of germline mutations in DNA *MMR* genes in Malaysian Lynch syndrome patients. This study also focuses on the protein expression profile of MMR protein and germline mutations identified in *MLH1* and *MSH2* genes. The authors also identified one novel mutation, transversion mutation c.2005G > C, which resulted in a missense mutation (Gly669Arg). The possibility of germline epimutation of *MLH1* gene cannot be ruled out since no deleterious mutations were identified in any of the 19 exons or coding regions of *MLH1* gene in the three Lynch syndrome patients who showed absence of MLH1 protein expression by immunohistochemical analysis.

Applications

The data generated from this study will help to establish a *MMR* gene mutation database of Malaysian Lynch syndrome kindreds.

Terminology

MLH1 and *MSH2* genes are the genes which code for MMR protein and are major elements in the MMR system. The main function of the MMR system is to maintain the fidelity of the genome during replication, where the MMR protein will correct nucleotide base mispairs and small insertions or deletions generated by slippage errors of DNA polymerase during replication.

Abstract

AIM: To investigate the efficacy and safety of combined antiviral and immunosuppressant therapy in adult hepatitis B virus-associated glomerulonephritis (HBV-GN) patients.

METHODS: A computerized literature search was carried out in the PubMed database, Embase, the Cochrane Library, Chinese BioMedical Literature on disc, Chinese Medical Current Contents, Chinese National Knowledge Infrastructure, Wanfang and VIP (Chinese Technological Journal of Database) to collect articles between June 1980 and December 2010 on therapy with immunosuppressants, e.g., glucorticosteroids, mycophenolate mofetil and leflunomide, combined with antivirals, e.g., interferon, lamivudine, entecavir and adefovir dipivoxil, in adult HBV-GN patients. The primary outcomes were remission of proteinuria, clearance of HBV e-antigen, and elevation of serum albumin. The secondary outcomes were blood levels of alanine aminotransferase, serum creatinine, and HBV-DNA titer. Meta-analysis was performed using Review Manager 5.1. Fixed or random effect models were employed to combine the results after a heterogeneity test. The effects of the combined therapy were analyzed for different doses of glucorticosteroid and different types of HBV-GN.

RESULTS: Twelve clinical trials with 317 patients were included. A significantly higher incidence of HBV-GN was found in male patients (relative risk = 2.40, 95% CI: 1.98-2.93). Combined therapy reduced the proteinuria significantly with a mean difference of 4.19 (95% CI: 3.86-4.53) and increased the serum albumin concentration significantly with a mean difference of -11.95 (95% CI: -12.97-10.93) without significant alterations of liver function (mean difference: 4.62, 95% CI: -2.55-11.79) and renal function (mean difference: 10.29, 95% CI: 0.14-20.45). No significant activation of HBV-DNA replication occurred (mean difference: 0.12, 95% CI: -0.37-0.62). There was no significant difference between the high dose glucorticosteroid group and the low dose glucorticosteroid group in terms of proteinuria remission (P = 0.76) and between different pathological types of HBV-GN [membranous glomerulonephritis (MN) *vs* mesangial proliferative glomerulonephritis, P = 0.68; MN *vs* membranoproliferative glomerulonephritis, P = 0.27].

CONCLUSION: Combined antiviral and immunosuppressant therapy can improve the proteinuria in HBV-GN patients without altering HBV replication or damaging liver and renal functions.

INTRODUCTION

Hepatitis B virus (HBV) infection is an important public health problem worldwide and especially in developing countries such as China. It is estimated that there are up to 112 million chronic HBV carriers in China, and hepatitis B virus-associated glomerulonephritis (HBV-GN) remains one of the most common secondary glomerular diseases among the Chinese population[1]. Most HBV-GN patients present with the nephrotic syndrome and some show mild to moderate proteinuria with hematuria. The most common histological type of HBV-GN is membranous nephropathy[2,3]. Although spontaneous remission of HBV-GN has been reported in pediatric patients, it is not as successful for adult HBV-GN patients as for children[3]. There is still considerable morbidity and significant mortality in the world; about 30% of adult patients may progress to renal failure, and as many as 10% of these will require maintenance dialysis[2].

HBV-GN treatment includes antiviral drugs, e.g., interferon (IFN), lamivudine (LAM), entecavir (ETV) and adefovir dipivoxil (ADV), or immunosuppressants, e.g., glucocorticosteroids, mycophenolate mofetil (MMF) and leflunomide (LEF). Although antivirals have proven to be effective in clearing the viral antigens and abrogating the proteinuria[2,4], the safety and efficacy of immunosuppressants are still controversial. It has been argued that immunosuppressants are not appropriate for HBV-GN because of concerns such as induction of HBV replication, liver damage, and even deterioration of renal lesions[5-7].

In a recent meta-analysis study, Zhang *et al*[8] showed that treatment of HBV-GN with corticosteroids only (monotherapy) was not effective with regard to proteinuria remission. However, this conclusion was drawn by analyses of data from both adult and pediatric patients, and because spontaneous remission can occur in children, this could have confounded the effectiveness of corticosteroid treatment in adult patients. In addition, the number of adult patients treated with glucorticosteroids in that study was only thirteen. The efficacy of combined therapy was not evaluated[8].

On the other hand, treatment of HBV-GN without immunosuppressants has been reported to lead to progressive kidney disease[9]. In fact, along with antivirals, glucorticosteroids are being widely and empirically used for patients with HBV-GN, especially those in the Asia-Pacific regions[10]. However, to date, there has not been a meta-analysis on the efficacy and safety of this combined therapy in adults.

Thus the purpose of this study was to analyze the published data on the efficacy and safety of combined therapy with antivirals and immunosuppressants for adult patients with HBV-GN. To accomplish this, we performed a systematic review and meta-analysis of all published clinical trials that met our entry criteria.

MATERIALS AND METHODS

Search strategy and data extraction

We searched MEDLINE, EMBASE, Cochrane Library, and the Chinese BioMedical Literature on disc (CBM), Chinese Medical Current Contents (CMCC), Chinese National Knowledge Infrastructure (CNKI), Wanfang and VIP (Chinese Technological Journal of Database). The key words were; "hepatitis B virus", "glomerulonephritis", "prednisolone", "nephrotic syndrome", "mycophenolate mofetil", "immunosuppressants", "drug therapy", and their synonyms and related terms. All articles were identified by searching from June 1980 to December 2010. In addition, manual searches of selected specialty journals were performed to identify all pertinent literature. Qualitative reviews and published clinical trials were also searched.

Criteria for inclusion

Eligible patients had to be adults (age > 18 years) with renal biopsy-proven HBV-GN. We included randomized controlled trials (RCTs), controlled clinical trials (CCTs), prospective and retrospective self-controlled studies, and cohort studies that used immunosuppressants and antivirals to treat HBV-GN. The data had to be published in a full length paper, and all had a follow-up period of at least 6 mo. The primary and secondary outcomes were a decrease of proteinuria, levels of serum albumin and alanine aminotransferase (ALT), renal function, and HBV-DNA titer.

Criteria for exclusion

Studies were excluded if the data on the measurements of the responses were incomplete or the HBV-GN was treated with Chinese herbal drugs. Trials published as abstracts or as interim reports were excluded, but letters and review articles were not excluded. For serial reports of the same patients, only those articles that provided the most comprehensive information were included. Trials with immunosuppressants only were also excluded.

Definitions of outcome measures

The primary outcome measures were proteinuria remission and HBV reactivation. Secondary outcome measures were elevations of ALT, serum creatinine (Scr), serum albumin, and other adverse effects such as a transient increase in transaminases, dizziness, fatigue, and gastrointestinal symptoms. A complete remission (CR) was de-

fined as disappearance of proteinuria after treatment, and partial remission was defined as a 24 h urinary protein decreased more than 50% of the previous value[11]. Cases that had no improvement of symptoms and laboratory tests were classified as non-responsive.

HBV reactivation was defined as the presence of detectable serum HBV DNA, and an ALT elevation was defined as an increase to > 50 U/L[12]. A relapse was defined as the reappearance of > 1+ albuminuria on urinalysis. A low-dose glucorticosteroid (prednisone or prednisolone) was defined as ⩽ 0.5 mg/kg per day, and high-dose glucorticosteroid was defined as ⩾ 1.0 mg/kg per day.

Data extraction and quality assessment

Two reviewers (Zheng XY and Wei RB) independently selected the studies and extracted the data and outcomes according to the inclusion criteria. In cases of disagreement between the two reviewers, a third reviewer (Tang L) examined the data and discussed the choices with the two initial reviewers. The data were incorporated only when the three reviewers reached a consensus.

Statistical analysis

For dichotomous outcomes, the results are expressed as relative risk (RR) with 95% confidence intervals (CI) for individual studies. When the outcomes were measured on a continuous scale, the mean difference (MD) was used to evaluate the difference in the change from the beginning to the end of treatment. The meta-analysis was performed using the fixed-effect or random-effect methods depending on the absence or presence of significant heterogeneity. Heterogeneity was measured using Chi-square (χ^2) and I^2 tests, and statistical significance was considered to be present when $P < 0.05$. In the absence of heterogeneity, the Mantel-Haenszel method of the fixed-effect model was used for the meta-analysis. Otherwise, the DerSimonian and Laird method for the random-effect model was selected[13]. The RR with 95% CI was used to assess the treatment efficacy. The combined results were the average RR and 95% CI weighted according to the standard error of the RR of the trial. A $P < 0.05$ was considered statistically significant. Funnel plots were used to assess the publication bias, and funnel plot asymmetry was tested using the Egger's test and Begg's test[14,15]. All analyses were performed with the Review Manager version 5.1 (RevMan, Cochrane Collaboration, Oxford, England).

RESULTS

Description of trials included in meta-analysis

Our electronic and manual searches identified 774 studies. After a review of the titles and abstracts or full text, 762 articles were excluded and 12 articles[9,16-26] with 317 patients were included based on the criteria mentioned (Cheng CL 2005, Dang YM 2004, Fang YQ 2009, He LS 2007, Liu J 2010, Liu ZH 2008, Sun LL 2005, Sun XP 2010, Tang L 2005, Tang Y 2005, Wu SB 2008 and Xia DQ 2009; Figure 1 and Tables 1-3). The numbers of patients studied in each trial were 20, 24, 58, 13, 25, 30, 11, 29, 9, 21, 35 and 42, respectively. One of these studies was a RCT[23], three were CCT[9,18,24], and the others were prospective and retrospective self-controlled studies[16,17,19-22,25,26]. The characteristics of the 12 clinical trials included are shown in Table 1, and detailed information of the interventions such as dose and duration of medication, main outcomes, and follow-up periods are summarized and tabulated in Tables 2 and 3.

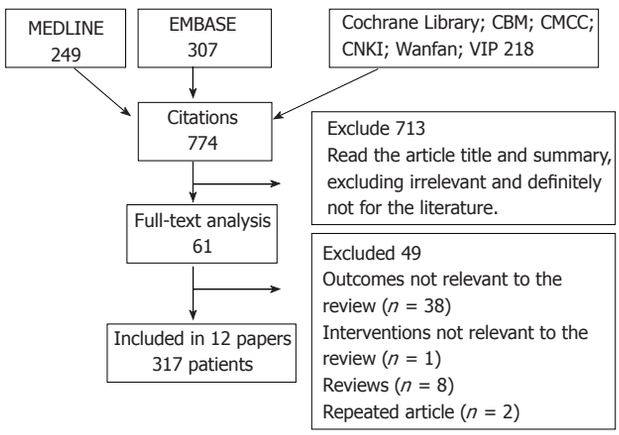

Figure 1 Flowchart showing the abstract screening and study selection process. CBM: Chinese BioMedical Literature on disc; CMCC: Chinese Medical Current Contents; CNKI: Chinese National Knowledge Infrastructure.

Clinical characteristics of gender differences

Gender differences in the incidence of HBV-GN were assessed from the results of 10 trials[16,17,19-26] including 1 RCT[23], 1 CCT[24], and 8 self-controlled studies[16,17,19-22,25,26]. The total number of patients was 286, including 202 male patients and 84 female patients. The χ^2 test of heterogeneity was not significant ($P = 0.37$), therefore the fixed-effect model was selected. A significantly larger number of male patients than female patients had HBV-GN (RR = 2.40, 95% CI: 1.98-2.93; Figure 2).

Efficacy of combined therapy for proteinuria

The efficacy of combined therapy for proteinuria of six months duration was assessed from the results of 8 trials[16,18-21,23-25] including 1 RCT[23], 2 CCT[18,24], and 5 self-controlled studies[16,19-21,25]. The total number of patients was 170, and the χ^2 test of heterogeneity was not significant ($P = 0.62$). Therefore, the fixed-effect model was used. There was a significant decrease in the level of proteinuria after the treatments (mean difference: 4.19, 95% CI: 3.86-4.53, Figure 3).

Efficacy of combined therapy on serum albumin concentration

The efficacy of combined therapy on serum albumin concentration was assessed from the results of 8 trials[16-20,22-24] of 209 patients including 1 RCT[23], 2 CCT[18,24], and 5 self-controlled studies[16,17,19,20,22]. The χ^2 test of heterogeneity was not significant ($P = 0.11$), therefore the fixed-effect

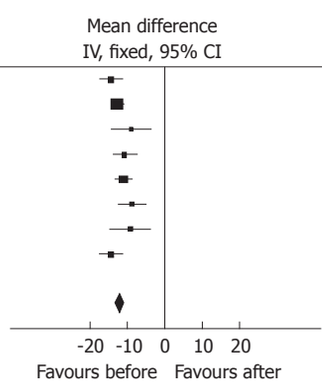

Figure 4 Serum albumin change in combination therapy group. IV: Inverse variance.

model was selected. A significant increase in the level of serum albumin was found after the treatments (mean difference: -11.95, 95% CI: -12.97-10.93, Figure 4).

Safety of combined therapy regarding liver function

Liver function was evaluated by assessing the level of ALT. The change in the ALT level after steroid combined therapy for HBV-GN was assessed from the results of 4 trials[17,19,20,23] including 1 RCT[23] and 3 self-controlled studies[17,19,20]. The total number of patients was 122. The χ^2 test of heterogeneity was significant (P = 0.03), therefore the random-effect model was selected. There was no significant difference after the treatment (P = 0.21, Figure 5); a transient elevation of ALT was noted in 14 patients during the treatment but the treatment was not stopped. Elevation of ALT was the most common side effect of combined therapy and accounted for 4.4% (14/317) of all the participants. These findings demonstrate the ne-

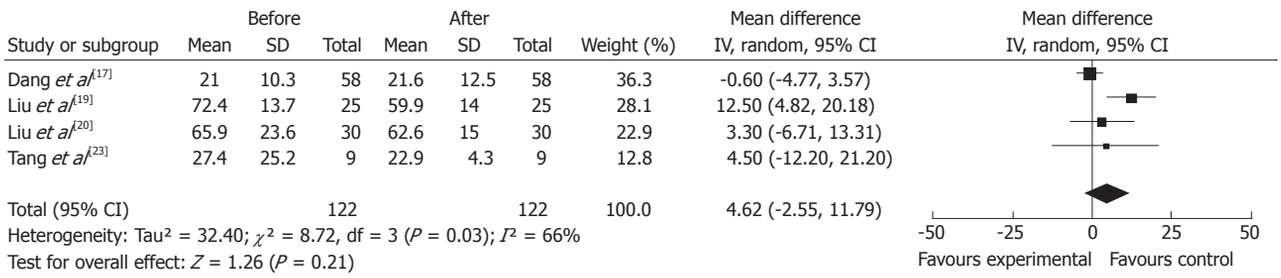

Figure 5 Alanine aminotransferase change in combination therapy group. IV: Inverse variance.

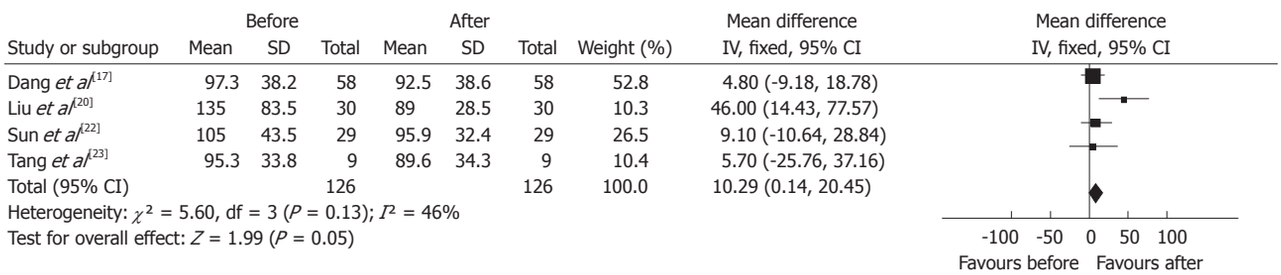

Figure 6 Scr change in combination therapy group. IV: Inverse variance.

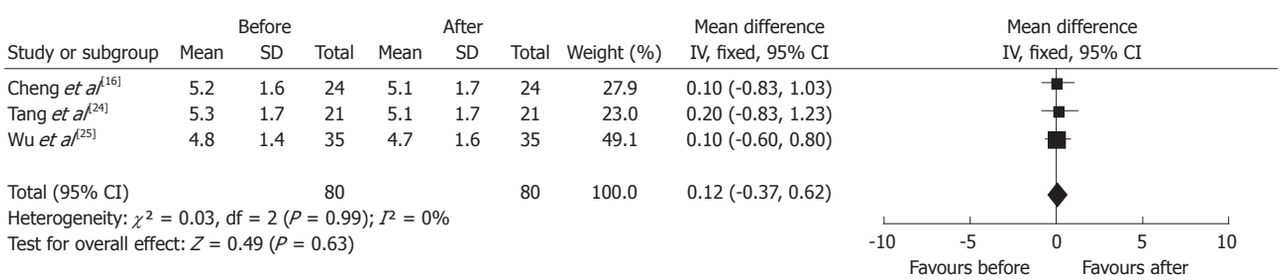

Figure 7 Hepatitis B virus-DNA titer change in combination therapy group. IV: Inverse variance.

cessity of monitoring liver function during the treatment.

Safety of combined therapy regarding renal function

Renal function was assessed by evaluating the change in the serum creatinine (Scr) level. The level of Scr after combined therapy for HBV-GN was assessed from the results of 4 trials[17,20,22,23], including 1 RCT[23] and 3 self-controlled studies[17,20,22]. The total number of patients was 126, and the χ^2 test of heterogeneity was not significant ($P = 0.13$). Therefore, the fixed-effect model was used. There was no significant increase in the level of Scr after the treatments ($P = 0.05$, Figure 6).

HBV-DNA titer

A change in the HBV-DNA titer after combined therapy for HBV-GN was assessed from the results of 3 trials[16,24,25] including 1 CCT[24] and 2 self-controlled studies[16,25]. The total number of patients was 80. The χ^2 test of heterogeneity was not significant ($P = 0.99$), and the fixed-effect model was used. There was no significant difference in the HBV-DNA titer before and after the treatments ($P = 0.63$, Figure 7). However, in one of the 12 articles included in this meta-analysis, one patient was reported to have an increase in the HBV-DNA titer after 5 mo of treatment, but the titer was stabilized following treatment with ADV[9].

Proteinuria in high-dose steroid subgroup vs low-dose steroid subgroup

The change in the proteinuria level in the high-dose steroid therapy group was assessed from the results of 3 trials[18,19,23] including 1 RCT[23], 1 CCT[18], and 1 self-controlled study[19]. The total number of patients was 47, and the χ^2 test of heterogeneity was not significant ($P = 0.77$). Therefore, the fixed-effect model was used. High-dose steroid was found to reduce the proteinuria significantly (mean difference: 4.08, 95% CI: 3.06-5.11, Figure 8). Low-dose steroid therapy was assessed from the results of 4 trials[16,21,24,25] including 1 CCT[24] and 3 self-controlled studies[16,21,25]. The total number of patients was 93, and the χ^2 test of heterogeneity was not significant ($P = 0.25$). Therefore, the fixed-effect model was used. Low-dose steroid was also found to significantly reduce proteinuria (mean difference: 4.25, 95% CI: 3.88-4.61, Figure 8).

The two subgroups were merged for analysis, and the χ^2 test of heterogeneity of the two subgroups was not

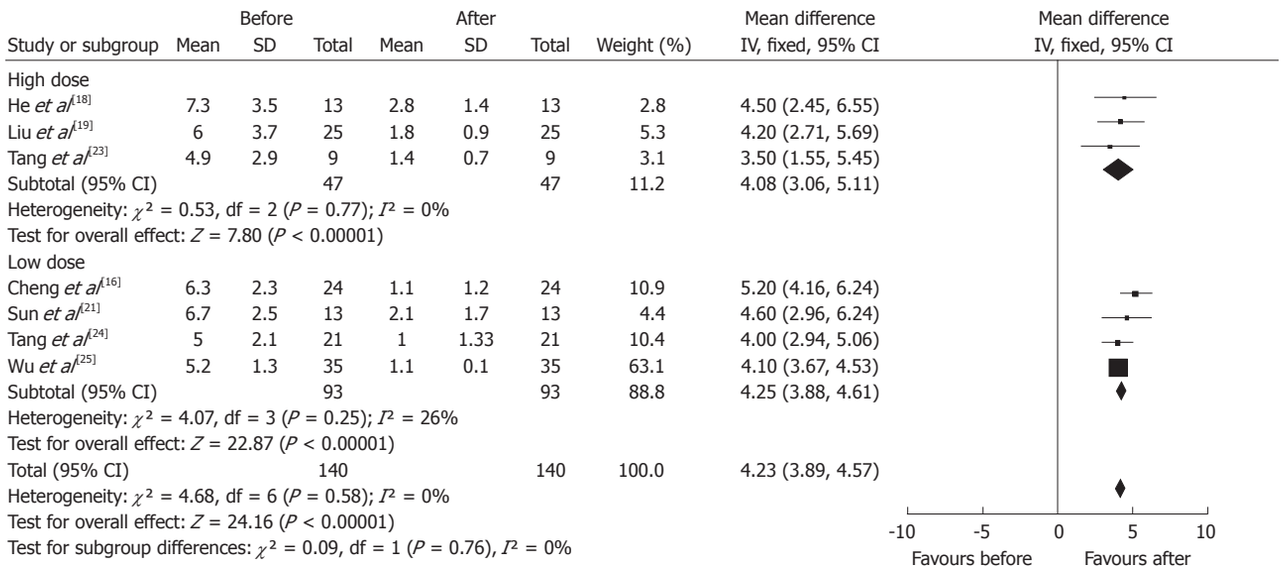

Figure 8 Proteinuria remission rate in different dose glucorticosteroids subgroups. IV: Inverse variance.

significant (P = 0.58). Therefore, the fixed-effect model was used. The combined therapy reduced proteinuria significantly after treatment (mean difference: 4.23, 95% CI: 3.89-4.57, Figure 8), and there was no significant difference between the two subgroups (P = 0.76, Figure 8).

Proteinuria changes in membranous glomerulonephritis subgroup vs mesangial proliferative glomerulonephritis subgroup

Comparisons of the rate of remission or the rate of complete remission in proteinuria between the membranous glomerulonephritis (MN) and mesangial proliferative glomerulonephritis (MsPGN) subgroups were assessed from the results of 6 trials[16,19,21,22,24,26] including 1 CCT[24] and 5 self-controlled studies[16,19,21,22,26]. The total number of patients was 73 for the MN group and 35 for the MsPGN group (Table 4). The χ^2 test of heterogeneity was not significant (P = 0.79 and P = 0.62, respectively), therefore the fixed-effect model was selected. The proteinuria remission rate did not differ between the two subgroups (RR = 0.94, 95% CI: 0.78-1.12, Figure 9). Also the complete remission rate of proteinuria did not differ between the two subgroups (RR = 0.84, 95% CI: 0.51-1.37, Figure 9).

Change in level of proteinuria in MN subgroup vs membranoproliferative glomerulonephritis subgroup

Comparisons of the remission rate and the complete remission rate of proteinuria between MN and membranoproliferative glomerulonephritis (MPGN) subgroups were assessed from the results of 5 trials[16,21,22,24,26] including 1 CCT[24] and 4 self-controlled studies[16,21,22,26]. The total number of patients was 79; 58 in the MN subgroup and 21 in the MPGN subgroup (Table 4). The χ^2 test of heterogeneity was not significant (P = 0.73 and 0.94, respectively), and therefore the fixed-effect model was used. The proteinuria remission rate did not differ between the two subgroups (RR = 1.13, 95% CI: 0.81-1.56, Figure 10), and also the complete remission rate did not differ between the two subgroups (RR = 1.84, 95% CI: 0.81-4.19, Figure 10).

Other adverse events

None of the studies assessed any other serious adverse events associated with the combined treatments. Almost all patients showed good tolerance although some patients had a transient increase in transaminases (4.4%), diarrhea (1.9%), loss of appetite (1.26%), influenza-like illness (0.3%), dizziness (0.3%), and anemia (1.26%). These side effects did not affect the completion and follow-up of the treatments.

Risk of bias in included studies

The overall quality of the studies included in this meta-analysis was suboptimal. Three studies had adequate allocation concealment and in all the rest the allocation concealment method was unclear. No study masked the participants or investigators to the intervention. Masking of the outcome assessors was done in only two studies and almost all the studies included did not analyze the results on an intention-to-treat basis. Because different outcomes and different comparisons were reported, and often without full statistical details, it was not possible to meta-analyze all the data. Risk of bias graph and summary are shown in Figures 11 and 12.

Publication bias

The funnel plots of the study results against precision are shown in Figure 13 with the 95% confidence limits. No obvious publication bias was found in our meta-analysis.

DISCUSSION

HBV-GN is an uncommon but a well-described complication of chronic hepatitis B. There is a high incidence of morbidity and mortality although remission with

adults[32]. Case reports and small scale reports have been published, but unfortunately a standardized treatment protocol and justification for the current therapeutic regimen are lacking.

Antiviral drugs have been recommended for treatment of HBV-GN because they can inhibit HBV replication and reduce proteinuria[31,33-35]. The mechanisms by which antivirals including IFN and the nucleoside analogues, e.g., lamivudine and entecavir, reduce the nephrotic syndrome and decrease the proteinuria are known to be by their viral suppression and HBeAg seroconversion, reduction of serum HBV DNA, normalization of serum alanine transaminase[36]. On the other hand, the virological features of HBV, i.e., the genotype or viral load, genetic barrier, drug potency, patient adherence, and the duration of HBV infection, could play important roles in viral resistance even with nucleoside analogues that target the HBV DNA polymerase[37]. For patients who do not respond well to the antiviral therapy or/and have little signs of proteinuria remission, immunosuppressants, especially the glucorticosteroids, are often empirically used in clinics. This is even true for cases treated in developing countries such as China[38]. In fact, immune complexes have been identified in the kidney indicating that the pathogenesis of HBV-GN may be associated with an immune reaction. This could be supportive for the use of immunosuppressants. However, the use of steroids is still controversial because of the risk of activating viral infec-

Figure 13 Publication bias analysis. tions[3]. In addition, the efficacy of steroids has not been definitively determined.

It has been claimed that HBV-GN occurs predominantly in children and mainly in male patients[39]. The incidence of male patients has been reported to be about 1.5 to 2 times that of female patients[40]. Our meta-analysis of 286 adult patients from 10 studies showed that there were 2.4 times more male patients than female patients. Because all of the trials in this study were from China and considering the fact that China has a relatively larger population of men than women (Census Bureau released in 2011: Chinese male to female population ratio = 120:100), our analysis showed a still higher incidence of male patients.

The use of prednisone has been reported to cause a significant increase in the levels of HBeAg and HBV-DNA[5]. One recent meta-analysis also claimed that glucocorticoid monotherapy did not significantly improve proteinuria[8]. However, favorable effects of glucocorticoids have also been reported in reduction of proteinuria in MsPGN/MN cases following HBV infection[10]. In addition, the proteinuria remission rate of HBV-GN after glucocorticoid treatment in adults has been reported to be 75% which is much higher than that for antiviral treatment (28.6%)[10].

Our analysis showed that most patients with HBV-

GN were successfully treated with combined antiviral and immunosuppressant therapy with an overall estimated rate for proteinuria remission of 83%. Only 2 patients in the treated group dropped out but both were due to economic reasons. Our analyses also demonstrated that the combined therapy can effectively elevate the level of serum albumin. To the best of our knowledge, few reports exist in literature regarding the comparison of combined therapy with monotherapy of either antivirals or immunosuppressants. Thus, it could be an overstatement to conclude that the combined therapy is superior to antivirals or steroids. However, at least our meta-analysis provides evidence showing the efficacy and safety of this combined therapy of antivirals and immunosuppressants, which is actually a widespread practice in China.

Low-dose steroid therapy is aimed at reducing HBV replication while minimizing the risk of HBV activation. Both high-dose and low-dose groups showed similar efficacy of proteinuria reduction following treatment, indicating that low-dose steroid is effective and should be recommended for its safety. In addition, all of the reviewed patients tolerated steroid therapy well without occurrence of liver dysfunction or renal insufficiency.

Our analysis also revealed that no significant increase in the viral titers was observed after combined therapy. However, because the observation time was relatively short, long term effects of the combined therapy should be evaluated in the future.

The most common pathological type of HBV-GN is membranous nephropathy (MN; 50%), followed by MPGN and MsPGN[3]. Our study of 6 trials (152 patients) showed that MN accounted for 48% and MPGN + MsPGN for 36.8% of the phenotypes of HBV-GN. To determine the efficacy of combined therapy for the different pathological types, the trials were divided into three subgroups: MN, MsPGN, and MPGN. The proteinuria remission rate and complete remission rate were compared between the MN group and the MPGN group. There was no significant difference between the two groups. Comparisons of other pathological types could not be included in this analysis because the number of patients was small. Further studies of larger sample sizes are needed to solve this question.

As with all meta-analyses, our study had some biases. Firstly, negative trials are sometimes less likely to be published. To overcome this, we tried to obtain data from as many sources as possible. We used Funnel plots to test our review for publication bias. The risk of having missed trials was acceptably low. Secondly, the number of high quality clinical trials and number of studied patients were limited. Thirdly, we found that randomization and masking were not satisfactory and the allocation concealment of many studies was not available. Therefore, selection bias cannot be completely ruled out. More adequately powered RCTs with sufficient follow-up periods are definitely needed in future studies. Such RCTs should assess clinically important outcomes such as mortality, long-term relapse rate, and long-term HBV-DNA titer. Furthermore, the antiviral therapy should also be in a standard format in conformity with the APASL guidelines (Seoul 2008)[41], which would be beneficial for future analysis.

In summary, our meta-analysis of 12 clinical trials showed that combined therapy with antivirals and immunosuppressants is an effective and safe regimen for adult patients diagnosed with HBV-GN. Low-dose steroid is effective and can be recommended.

COMMENTS

Background

Hepatitis B virus-associated glomerulonephritis (HBV-GN) is one of the most common secondary glomerular diseases in developing countries such as China. To clear the viral antigen and abrogate the proteinuria is crucial for liver and renal function preservation and for decreasing the morbidity and mortality of this disease.

Research frontiers

HBV-GN treatment includes antiviral drugs, e.g., interferon and lamivudine, or immunosuppressants, e.g., glucocorticosteroids and mycophenolate mofetil. Although antivirals have been proven to be effective in clearing the viral antigens and attenuating the proteinuria, the safety and efficacy of immunosuppressants are still controversial.

Innovations and breakthroughs

A recent meta-analysis study showed that treatment of HBV-GN with corticosteroids only was not effective in proteinuria remission. However, this conclusion was drawn by analysis of data from both adult and pediatric patients, and because spontaneous remission can occur in children, this could have confounded the effectiveness of corticosteroid treatment in adult patients. To date, the current meta-analysis is the first to study the efficacy and safety of combined therapy with antivirals and immunosuppressants in adult HBV-GN patients.

Applications

The results of this meta-analysis should be beneficial for investigators and clinicians for obtaining information for the therapy of HBV-GN. Antivirals combined with immunosuppressants are effective and safe for adult patients and low-dose steroid can be recommended. All of the evidence in this paper supports the use of immunosuppressants which are being empirically used in the Asia-Pacific regions.

Terminology

HBV-GN is a clinical entity in which viral antigen and immune complexes have been identified in kidney, indicating that the pathogenesis of this disease may be associated with immune reaction. HBV-GN can be mainly separated into membranous glomerulonephritis, mesangial proliferative glomerulonephritis and membranoproliferative glomerulonephritis subgroups.

Abstract

AIM: To evaluate the radicalness and safety of laparoscopic D2 dissection for gastric cancer.

METHODS: Clinicopathological data from 209 patients with gastric cancer, who underwent radical gastrectomy with D2 dissection between January 2007 and February 2011, were analyzed retrospectively. Among these patients, 131 patients underwent laparoscopy-assisted gastrectomy (LAG) and 78 underwent open gastrectomy (OG). The parameters analyzed included operative time, blood loss, blood transfusion, morbidity, mortality, the number of harvested lymph nodes (HLNs), and pathological stage.

RESULTS: There were no significant differences in sex, age, types of radical resection [radical proximal gastrectomy (PG + D2), radical distal gastrectomy (DG + D2) and radical total gastrectomy (TG + D2)], and stages between the LAG and OG groups ($P > 0.05$). Among the two groups, 127 cases (96.9%) and 76 cases (97.4%) had 15 or more HLNs, respectively. The average number of HLNs was 26.1 ± 11.4 in the LAG group and 24.2 ± 9.3 in the OG group ($P = 0.233$). In the same type of radical resection, there were no significant differences in the number of HLNs between the two groups (PG + D2: 21.7 ± 7.5 *vs* 22.4 ± 9.3; DG + D2: 25.7 ± 11.0 *vs* 22.3 ± 7.9; TG + D2: 30.9 ± 13.4 *vs* 29.3 ± 10.4; $P > 0.05$ for all comparisons). Tumor free margins were obtained in all cases. Compared with OG group, the LAG group had significantly less blood loss, but a longer operation time ($P < 0.001$). The morbidity of the LAG group was 9.9%, which was not significantly different from the OG group (7.7%) ($P = 0.587$). The mortality was zero in both groups.

CONCLUSION: Laparoscopic D2 dissection is equivalent to OG in the number of HLNs, regardless of tumor location. Thus, this procedure can achieve the same radicalness as OG.

Key words: Gastric cancer; Laparoscopy; Gastrectomy; D2 dissection; Lymph node

INTRODUCTION

Gastric cancer is the fourth most common cancer and the second leading cause of cancer-related deaths worldwide[1,2]. In the Far East countries such as China[3], Korea[4] and Japan[5], gastric cancer is the most prevalent malignancy, and the leading cause of cancer-related deaths. Since the first report of laparoscopic gastrectomy in 1992[6], laparoscopy-assisted gastrectomy (LAG) has been carried out not only in distal gastrectomy, but also in proximal gastrectomy and total gastrectomy[7-9]. Several randomized control trials (RCTs) have shown that LAG can be performed in early gastric cancer (EGC)[10-15]. However, LAG for the treatment of advanced gastric cancer (AGC) has remained controversial, mainly due to a lack of evidence from large-scale studies demonstrating that laparoscopic D2 dissection, the standard lymphadenectomy for AGC, is equivalent to open surgery. Recently, some studies have evaluated the outcome of D2 lymph node dissection in LAG and open surgery for gastric cancer[16-19]. The range of lymph node involvement differs due to the tumor location, thereby making the appropriate extent of D2 dissection vary as well[20]. However, little effort has been made to distinguish between tumors in different locations, all being simply regarded as "gastric cancer", or just evaluated as one type of LAG. In this study, we evaluated the overall radicalness of the laparoscopic D2 dissection of gastric cancer, and compared the differences between distal gastrectomy, proximal gastrectomy, and total gastrectomy.

MATERIALS AND METHODS

Patients

This retrospective study involved 221 consecutive patients with gastric cancer treated in the Department of Minimally Invasive Gastrointestinal Surgery, Peking University Cancer Hospital, between January 2007 and February 2011. The exclusion criteria included: (1) invasion of adjacent structures; (2) conglomeration of lymph nodes and no R0 resection; (3) distant metastases; and (4) absence of consent signing before operation. Blood tests, chest X-rays, enhanced computed tomography scans of the abdomen and pelvis, double-contrast upper gastrointestinal X-ray studies, and gastric endoscopy were performed before operation. All tumors were diagnosed as adenocarcinomas by biopsy. Informed consent was signed prior to surgery from each case. Among the 221 patients, 12 were excluded: 7 could not undergo R0 resection (3 with tumor invasion of adjacent structures, 4 with conglomeration of lymph nodes), 4 had distant metastases, and 1 refused operation. The study population thus included 209 cases that successfully underwent radical gastrectomy with D2 dissection. One hundred and thirty-one cases received LAG (LAG group) and 78 cases received open gastrectomy (OG group). All operations were performed by the same surgical team.

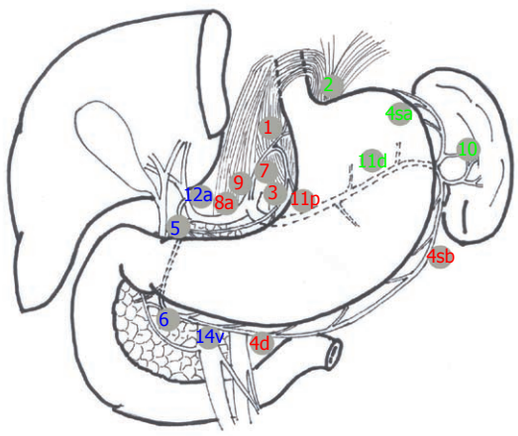

Figure 1 Lymph node stations of the stomach. The groups of lymph node in red, green and blue should be dissected in radical total gastrectomy; the groups of lymph node in red and green should be dissected in radical proximal gastrectomy; the groups of lymph node in red and blue should be dissected in radical distal gastrectomy.

Anesthesia and trocar placement

General anesthesia was administered with epidural analgesia to all the patients. The patients were placed in the supine position with legs apart. A 12-mm trocar for laparoscopy was introduced using the open technique below the umbilicus, and pneumoperitoneum at 10-13 mmHg was induced with carbon dioxide. Another 12-mm trocar was inserted at the left preaxillary line, 2 cm below the costal margin, to serve as a major hand port. Then a 5-mm trocar was placed at the left midclavicular line parallel to the umbilicus, and another 5-mm trocar was inserted at the contralateral site as an accessory port. The last 5-mm trocar was then placed at the right preaxillary line, 2 cm below the costal margin, also serving as another accessory port. The operator stood on the left side of the patient. The first assistant stood on the patient's right. The camera assistant stood between the patient's legs.

Surgical procedures

According to the guidelines of the Japanese Gastric Cancer Association (JGCA), the stomach was divided anatomically into three portions: upper, middle, and lower. The three portions were defined by subdividing both the lesser and greater curvatures into three equal lengths[20]. The type of gastrectomy and extent of D2 dissection were determined by tumor location (Figure 1)[20]. The aim of any oncological resection was to achieve en-bloc resection of gastric segment and surrounding lymph nodes, in order to obtain adequate oncological clearance.

Laparoscopy-assisted radical total gastrectomy with D2 dissection: This procedure was performed for gastric cancer involving more than 2/3 of the stomach. The greater omentum was first dissected, using the ultrasonicactivated scissors (Ultracision-Harmonic Scalpel; Ethicon Endo-Surgery Inc, Cincinnati, OH, United States), along the border of the transverse colon. The

left gastroepiploic vessel was vascularized, clamped with double Hem-o-lok clips (Teleflex Medical RTP, NC, United States) and cut at its origin. The gastrosplenic ligament was then divided and resected along the edge of spleen. These processes allowed the removal of No. 4sb, 4sa, and 10 lymph nodes. Then removal of No. 2 lymph nodes was performed. The next step was to resect the superior leaf of the mesocolon and the anterior leaf of the pancreas rightward the pylorus. The superior mesenteric vein, the Henle's trunk, the right colic vein, and the right gastroepiploic vessel were exposed allowing dissection of No. 14v lymph nodes. Then the right gastroepiploic vessel was clamped at its origin using double Hem-o-lok clips and cut, allowing No. 6 and 4d lymph nodes to be removed. In order to expose the gastropancreatic fold, the stomach was turned headward with the greater omentum folded up on the anterior aspect of the stomach. Along the gastroduodenal artery, the common hepatic artery could be skeletonized easily. The right gastric artery was divided and cut at its origin, using double Hem-o-lok clips, from the proper hepatic artery. Then dissection of No. 8a and 5 lymph nodes was completed. Once No. 8a lymph nodes were dissected, the procedure was continued leftward along the artery in order to remove the lymph nodes located along the celiac trunk (No. 9) and the left gastric artery (No. 7). The left gastric artery was cut from the celiac trunk using triple Hem-o-lok clips. Afterward, the celiac trunk was skeletonized. So, No. 7 and 9 lymph nodes were dissected. Then the splenic artery was skeletonized from its origin to the end in order to remove No. 11 lymph nodes. After returning the stomach and the greater omentum to normal position, the lesser omentum could be resected along the liver edge to the esophagogastric junction, with dissection of No. 1 and 3 lymph nodes. The last step of lymph node dissection was to skeletonize the proper hepatic artery, so No. 12a lymph nodes could be dissected. After standard D2 dissection was completed, an upper midline incision (about 5 cm) was made. The gastrectomy was performed and gastrointestinal continuity was restored in a Roux-en-Y fashion though this incision.

Laparoscopy-assisted radical proximal gastrectomy with D2 dissection: This procedure was performed for lesions located in the upper third of the stomach. The standard D2 dissection, including No. 1, 2, 3, 4, 7, 8a, 9, 10 and 11, was conducted using the same procedure described above. Esophagogastric anastomosis was performed to rebuild gastrointestinal continuity.

Laparoscopy-assisted radical distal gastrectomy with D2 dissection: This procedure was performed for lesions located in the lower third of stomach with or without involving the middle third of the stomach. The standard D2 dissection, including No. 1, 3, 4sb, 4d, 5, 6, 7, 8a, 9, 11p, 12a, and 14v, was conducted using the same procedure described above. Gastroduodenal anastomosis (Billroth Ⅰ) or gastrojejunal anastomosis (Billroth Ⅱ) was performed to rebuild gastrointestinal continuity.

Conventional open operation: The premedication and anesthetic techniques used were similar to the LAG group. Patients lay in the supine position, and the operator stood on the right side of the patient. An upper midline incision (about 20 cm) was made, and a standard gastrectomy with D2 dissection and reconstruction were performed in the same manner as in LAG.

Postoperative management

Nasogastric tube and nasojejunal tube were inserted routinely in operation. Enteral nutrition started through nasojejunal tube on the first postoperative day (POD). Gastroenterography, with the use of compound meglumine diatrizoate, was performed routinely to observe anastomosis on the 7th POD. If there was no evidence of anastomotic leakage by gastroenterography, the nasogastric tube could be removed and liquid diet was taken on the 8th POD.

Outcome evaluation

During surgery, operative time, blood loss (estimated by the volume of suction and the weight of gauze), and the amount of blood transfusion were recorded. Postoperative complications, categorized as surgical and nonsurgical complications, occurred during the hospital stay, and included fluid or abscesses needing drainage, intra-abdominal or anastomotic bleeding needing transfusion or reoperation, ileus, delayed gastric emptying, lymphatic leakage, and anastomotic leakage. Nonsurgical complications included cardiac, pulmonary, urinary, renal and hepatic complications. Mortality was defined as any death that occurred during hospital stay. The depth of tumor invasion, tumor size, margins, the number of harvested lymph nodes (HLNs), and positive lymph nodes were determined by pathological analysis. Histological staging was classified according to the 7th edition of the American Joint Committee on Cancer Staging Manual.

Statistical analysis

The data of patient's age, operation time, blood loss, and the number of lymph nodes were presented as $\chi \pm s$. Differences were compared in sex, type of resection, stage, and complications between the two groups using Chi-square test. Independent-sample *t* test was used to estimate differences in age, operation time, blood loss, and the number of HLNs between the two groups. *P* values less than 0.05 were considered statistically significant. All statistical analyses were performed with SPSS software, version 11.0 (SPSS Inc, Chicago, United States).

RESULTS

Patient clinicopathologic characteristics

Demographic details of the two groups are shown in Table 1. There were 88 males and 43 females in the LAG group, and the mean age of patients was 59.5 (range,

Table 1 Demographic characteristics of the two groups

Variable	LAG (n = 131)	OG (n = 78)	P value
Sex (male:female)	88:43	52:26	0.940
Age (yr)	59.5 ± 12.9	60.6 ± 10.3	0.523
Operation time (min)	259.1 ± 58.6	213.9 ± 37.6	0.000
Blood loss (mL)	111.1 ± 83.7	230.1 ± 96.8	0.000
Types of resections			
PG + D2	33	17	0.856
DG + D2	64	40	
TG + D2	34	21	
Stages			
Ⅰ (Ⅰa:Ⅰb)	29 (9:20)	12 (6:6)	0.253
Ⅱ (Ⅱa:Ⅱb)	28 (14:14)	13 (2:11)	
Ⅲ (Ⅲa:Ⅲb:Ⅲc)	74 (33:21:20)	53 (10:19:24)	

P values were calculated by independent-sample t test or by χ^2 test as appropriate. LAG: Laparoscopy-assisted gastrectomy; OG: Open gastrectomy; PG + D2: Radical proximal gastrectomy with D2 dissection; DG + D2: Radical distal gastrectomy with D2 dissection; TG + D2: Radical total gastrectomy with D2 dissection.

Table 2 Number of harvested lymph nodes in different types of radical resections

Groups	Number	Mean ± SD	P value
LAG	131	26.1 ± 11.4	0.233
OG	78	24.2 ± 9.3	
PG + D2	50	21.9 ± 8.1	0.000
DG + D2	104	24.4 ± 10.0	
TG + D2	55	30.3 ± 12.3	

P values were calculated by independent-sample t test. HLNs: Harvested lymph nodes; LAG: Laparoscopy-assisted gastrectomy; OG: Open gastrectomy; PG + D2: Radical proximal gastrectomy with D2 dissection; DG + D2: Radical distal gastrectomy with D2 dissection; TG + D2: Radical total gastrectomy with D2 dissection.

26-80) years. The OG group included 52 males and 26 females, with a mean age of 60.6 (range, 33-79) years. There were no significant differences in sex and age between the two groups (P = 0.940 and 0.523, respectively). Compared with the OG group, the LAG group had a significantly less blood loss (111.1 ± 83.7 mL in LAG *vs* 230.1 ± 96.8 mL in OG, P < 0.001), and a longer operation time (259.1 ± 58.6 min in LAG *vs* 213.9 ± 37.6 min in OG, P < 0.001). No blood transfusion was administered during surgery in either group.

Radical proximal gastrectomy with D2 dissection (PG + D2) was performed in 50 cases (33 in LAG and 17 in OG), radical distal gastrectomy with D2 dissection (DG + D2) in 104 cases (64 in LAG and 40 in OG), and radical total gastrectomy with D2 dissection (TG + D2) in 55 cases (34 in LAG and 21 in OG). There were no significant differences in the type of radical resection between the two groups (P = 0.856). Tumor free margins were obtained in all the patients. In the LAG group, there were 29 cases in stage Ⅰ, 28 cases in stage Ⅱ, and 74 cases in stage Ⅲ. In the OG group, there were 12 cases in stage Ⅰ, 13 cases in stage Ⅱ, and 53 cases in stage Ⅲ. There were no significant differences in pathological stages between the two groups (P = 0.253).

Table 3 Comparison of number of harvested lymph nodes between laparoscopy-assisted gastrectomy and open gastrectomy

Types of resections	Number	Mean ± SD	P value
PG + D2			
LAG	33	21.7 ± 7.5	0.770
OG	17	22.4 ± 9.3	
DG + D2			
LAG	64	25.7 ± 11.0	0.091
OG	40	22.3 ± 7.9	
TG + D2			
LAG	34	30.9 ± 13.4	0.653
OG	21	29.3 ± 10.4	

P values were calculated by independent-sample t test. HLNs: Harvested lymph nodes; LAG: Laparoscopy-assisted gastrectomy; OG: Open gastrectomy; PG + D2: Radical proximal gastrectomy with D2 dissection; DG + D2: Radical distal gastrectomy with D2 dissection; TG + D2: Radical total gastrectomy with D2 dissection.

Table 4 Postoperative complications in the two groups

Complications	LAG (n = 131)	OG (n = 78)	P value
Delayed gastric emptying	5	3	
Lymphatic leakage	3	2	
Anastomotic leakage	2	1	
Large pleural effusions	1		
Anastomotic bleeding	1		
Acute myocardial infarction	1		
Total (%)	13 (9.9)	6 (7.7)	0.587

P value was calculated by χ^2 test. LAG: Laparoscopy-assisted gastrectomy; OG: Open gastrectomy.

Number of harvested lymph nodes in different types of gastrectomies

Details of the number of HLNs are shown in Tables 2 and 3. In the LAG and OG groups, 127 (96.9%) cases and 76 cases (97.4%) had 15 or more HLNs. The average number of HLNs was 26.1 ± 11.4 in the LAG group and 24.2 ± 9.3 in the OG group (P = 0.233). The number of HLNs was 21.9 ± 8.1 in PG + D2, 24.4 ± 10.0 in DG + D2, and 30.3 ± 12.3 in TG + D2 (P < 0.001) (Table 2). In the same type of resection, there was no significant difference in the number of HLNs between the LAG and OG groups (PG + D2: 21.7 ± 7.5 in LAG *vs* 22.4 ± 9.3 in OG, DG + D2: 25.7 ± 11.0 in LAG *vs* 22.3 ± 7.9 in OG, TG + D2: 30.9 ± 13.4 in LAG *vs* 29.3 ± 10.4 in OG). P value was 0.770, 0.091 and 0.653, respectively (Table 3).

Morbidity and mortality after operation

Postoperative complications are listed in Table 4. Delayed gastric emptying (n = 5), lymphatic leakage (n = 3), anastomotic leakage without reoperation (n = 2), large pleural effusion needed drainage (n = 1), anastomotic bleeding needed transfusion (n = 1), and acute myocardial infarction (n = 1) occurred in the LAG group. Postoperative complications in the OG group included delayed gastric emptying (n = 3), lymphatic leakage (n = 2), and anastomotic leakage without reoperation (n = 1). There

were no significant differences in the morbidity between the two groups (9.9% *vs* 7.7%, $P = 0.587$). Mortality was zero in both groups.

DISCUSSION

For the treatment of AGC, surgical procedures include gastrectomy and lymphadenectomy. However, the extent of lymph node dissection has remained controversial worldwide[21]. In Eastern Asian countries such as Japan, China, and Korea, D2 dissection has been the standard operation[21]. However, in Western countries, D2 dissection is thought to be accompanied by significant mortality and morbidity, with no survival advantage[22,23]. Hartgrink *et al*[23] reported the results of a Dutch gastric cancer group trial in 2004, which included 711 patients who underwent randomly assigned treatment with curative intent (380 in D1 and 331 in D2). Both the postoperative morbidity (25% *vs* 43%, $P < 0.001$) and mortality (4% *vs* 10%, $P = 0.004$) were significantly higher in patients who underwent D2 dissection, while there was no difference in the 11-year overall survival (30% *vs* 35%, $P = 0.53$) between the two groups. Those results were similar to that of the Medical Research Council Gastric Cancer Surgical Trial[22]. However, the conclusions drawn from those two famous RCTs were questioned by Eastern investigators. The main concern was that 80 centers participated in the Dutch gastric cancer group trial, so the mean number of patients who underwent D2 dissection in each center was less than 5. Thus, the discommenders considered it very difficult to perform safe and standard D2 dissections in each center. Unexpectedly, in the 15-year follow-up from the Dutch gastric cancer group trial, published in 2010[24], the gastric-cancer-related death rate of the D2 group was significantly lower than that of the D1 group (37% *vs* 48%, $P = 0.01$), local recurrence was 12% in the D2 group *vs* 22% in D1, and regional recurrence was 13% in D2 *vs* 19% in D1. Thus, the authors recommended D2 dissection as the standard surgical approach for resectable gastric cancer. Currently, more and more evidences have proved D2 dissection as a feasible and safe procedure with survival advantages as compared with the D1 dissection[25-27], and D2 dissection has been gradually accepted by Western investigators. In the 2010 National Comprehensive Cancer Network guidelines, the panel recommended that gastric cancer surgery should remove D2 lymph nodes with the goal of examining 15 or more lymph nodes.

Although D2 dissection is performed in AGC as a standard procedure, more and more investigators have emphasized the need for D2 dissection in EGC because of pre-operative understaging[28-30]. In our hospital, about 90% of gastric cancers were initially diagnosed as AGC, and since endoscopic ultrasonography is not routinely performed, it is difficult to diagnose EGC preoperatively. Therefore, standard D2 dissection is routinely performed in all patients with gastric cancer in our hospital.

Laparoscopic surgery is a minimally invasive operation and is proved to be an acceptable alternative to open surgery in patients with colorectal cancer[31-33]. However, in gastric cancer, laparoscopic surgery has not yet been validated, and thus, was only performed in a limited number of patients with EGC in six small-scale RCTs[10-13,15,34]; this was due to the difficulties in systematic lymph node dissection, especially in the standard D2 dissection.

The number of HLNs is regarded as an important short-term oncological outcome of laparoscopic D2 dissection. Several recent retrospective studies have shown that laparoscopic D2 dissection is both a safe and oncologically feasible procedure, with a similar number of HLNs compared with open dissection[16-19,28,35,36]. Du *et al*[16] evaluated 82 patients with AGC who underwent laparoscopy-assisted total gastrectomy with D2 dissection compared with 94 patients who received open surgery; a similar number of HLNs was obtained in both groups (34.2 ± 13.5 *vs* 36.4 ± 19.1, $P = 0.331$). Huang *et al*[17] analyzed 66 cases of laparoscopy-assisted distal gastrectomy (LADG) with D2 dissection for AGC and 69 cases of open distal gastrectomy (ODG); no significant differences were found in the number of HLNs between the two groups (25.8 ± 12.5 *vs* 27.5 ± 10.3, $P = 0.401$). The morbidity in LADG was lower than that in ODG (6.1% *vs* 15.9%). Lee *et al*[18] evaluated 64 patients who underwent LADG with D2 dissection. The compliance rate, defined as cases with no more than one missing lymph node station according to JGCA lymph node grouping, was similar to that of ODG (67% *vs* 66%). The mean number of HLNs was 50.1 (range, 20-100), and the surgical morbidity and mortality were acceptable (3.1%, 0%, respectively).

There was still debate that the number of HLNs in laparoscopic D2 dissection was less than in the open D2 dissection[37,38]. Jeong *et al*[37] reported a study of 398 patients who underwent radical gastrectomy with R0 resection (261 in LAG and 138 in OG). The number of HLNs was significantly smaller in LAG than in OG (25 ± 13 *vs* 30 ± 14, $P < 0.01$). Lee *et al*[38] reported similar results in the number of HLNs (31.3 ± 11.1 *vs* 40.4 ± 17.9, $P < 0.001$). Unfortunately, in these two studies, the distribution of stages and the extent of lymph node dissection were not balanced between the two groups. The percent of AGC and D2 dissection in OG was higher than in LAG. This variability might explain the different number of HLNs between the two groups.

In this study, all patients successfully underwent radical surgery with D2 dissection. And 127 cases (96.9%) in the LAG group and 76 cases (97.4%) in the OG group had 15 or more HLNs. The mean number of HLNs was comparable between the LAG and OG groups ($P = 0.233$). The extent of D2 dissection should be decided in accordance with tumor location, so the number of HLNs was significantly different in different types of radical gastrectomies ($P < 0.001$). In addition, we analyzed the number of HLNs in different subgroups (PG + D2, DG + D2 and TG + D2) between LAG and OG, and found no significant differences ($P = 0.770$, 0.091

and 0.653, respectively). To our knowledge, this is the first published report that systematically compares the number of HLNs in different types of radical gastrectomies between LAG and OG. Similar to other studies, there was less blood loss, longer operation time, and comparable morbidity in LAG compared with OG.

Our team had completed more than 30 cases of LAG until this study. All operations, including LAG and OG, were performed by the same surgical team, thus allowing consistency of treatment, and all D2 dissections were completed successfully. The stages and types of radical resections were matched between the two groups. These are favorable conditions for comparing the number of HLNs, regardless of tumor location, between LAG and OG in a nonrandomized study.

However, there were some limitations in this study. First, this is a retrospective analysis. Second, there might be a selection bias as a result of comparing these nonrandomized groups to a retrospective profile. Third, there is no survival data. Thus, long-term oncological outcomes of LAG need to be evaluated in future studies.

In conclusion, our data suggests that the number of harvested lymph nodes of laparoscopic D2 dissection is equivalent to open surgery, regardless of the tumor location. Laparoscopic D2 dissection is safe, with less blood loss than open surgery, and can achieve the same radicalness as open surgery for gastric cancer. Large-scale RCTs with a longer follow-up period should be carried out in future studies to prove that LAG with D2 dissection is a good alternative to OG in selected patients.

COMMENTS

Background

Gastric cancer is one of the leading fatal malignancies worldwide, particularly in China and other Far Eastern countries. Laparoscopic surgery is a minimally invasive operation, which can be performed in colorectal cancer, and has been proved by many randomized control trials (RCTs). However, few studies have evaluated the role of laparoscopy-assisted gastrectomy (LAG) in gastric cancer.

Research frontiers

Several RCTs have shown that LAG can be performed in early gastric cancer. However, LAG for the treatment of advanced gastric cancer (AGC) has remained controversial. This is mainly due to a lack of evidence from large-scale studies showing that laparoscopic D2 dissection, the standard lymphadenectomy for AGC, is equivalent in outcome to open surgery.

Innovations and breakthroughs

In recent years, some studies have analyzed D2 dissection in LAG and open surgery for gastric cancer. Although the range of lymph node involvement differs by tumor location, making the extent of D2 dissection differ as well, little effort has been made to distinguish between tumors in various locations, with all simply being regarded as "gastric cancer" or just evaluated as one type of LAG. Thus, this study evaluated the overall radicalness of laparoscopic D2 dissection in gastric cancer, and further compared the difference among distal gastrectomy, proximal gastrectomy, and total gastrectomy.

Applications

This paper confirms the equivalent radicalness of D2 dissection between LAG and open surgery, thus providing preliminary evidence of the feasibility of applying LAG in gastric cancer, even in AGC. Long-term outcomes of LAG should be further studied.

Terminology

D2 dissection is the standard lymphadenectomy for AGC. The regional lymph nodes of the stomach are classified into three groups according to the guidelines of the Japanese Gastric Cancer Association. D2 dissection includes dissection of all Group 1 and Group 2 nodes. The extent of D2 dissection is different due to different tumor locations.

Peer review

The paper can be accepted for publication. The authors compared the radicalness of gastrectomy by laparoscopic and open approaches.

Abstract

AIM: To examine fibroblast activation protein (FAP) expression in pancreatic ductal adenocarcinoma (PDAC) and to analyze its relationship with the clinicopathology of PDAC.

METHODS: FAP expression was examined in 134 PDAC specimens by immunohistochemistry, and in four pancreatic cancer cell lines (SW1990, Miapaca-2, AsPC-1 and BxPC-3) by Western blotting assay. We also analyzed the association between FAP expression in PDAC cells and the clinicopathology of PDAC patients.

RESULTS: The results showed that the FAP was expressed in both stromal fibroblast cells (98/134, 73.1%) and carcinoma cells (102/134, 76.1%). All 4 pancreatic cancer cell lines expressed FAP protein at different levels. Protein bands corresponding to the proteolytically active 170-kDa seprase dimer and its 88-kDa seprase subunit were identified. Higher FAP expression in carcinoma cells was associated with tumor size ($P < 0.001$), fibrotic focus ($P = 0.003$), perineural invasion ($P = 0.009$) and worse clinical outcome ($P = 0.0085$).

CONCLUSION: FAP is highly expressed in carcinoma cells and fibroblasts in PDAC tissues, and its expression is associated with desmoplasia and worse prognosis.

Key words: Pancreatic ductal adenocarcinoma; Cancer-associated fibroblasts; Fibroblast activation protein; Prognosis

INTRODUCTION

Pancreatic carcinoma is one of the most aggressive human malignancies. Currently pancreatic cancer ranks fourth in cancer-related deaths in Western countries and sixth in China[1,2]. As one of the most lethal malignancies, human pancreatic ductal adenocarcinoma (PDAC) results in an overall 5-year survival of the patients of less than 5%, a rate with no substantial improvement over the past 25 years[3,4]. The poor prognosis is mainly associated with early local invasion, a high incidence of recurrence and a

poor response to chemotherapy and radiotherapy. Failure of the conventional therapies for PDAC might be due to our limited understanding of the role of tumor-stromal interactions in cancer progression[5].

In many solid tumors, the stroma is increasingly recognized to be important in promoting tumor proliferation, invasion, metastasis, and chemoresistance[6]. PDAC is one of the most highly invasive of the solid cancers and is characterized by an extensive desmoplastic stromal response. Several studies revealed that the elements in desmoplasia played important roles in tumorigenesis of PDAC[7-9] and was associated with a poor prognosis of the patients[10,11]. Mounting evidence suggests that cancer-associated fibroblasts (CAF), the predominant stromal cell type, actively communicate with and stimulate tumor cells, thereby contributing to tumor development and progression.

Fibroblast activation protein (FAP), or seprase, a cell surface glycoprotein belonging to the serine protease family, is a 170 kDa dimer that is catalytically active and has dipeptidase and gelatinase activities. FAP was identified as being expressed in reactive fibroblasts during embryonic development[12], in healing wounds[13], in chronic inflammation, in liver cirrhosis[14], and most importantly, in the CAFs of many human carcinomas[15-19]. As a marker of CAFs, FAP can enhance stromal cell proliferation and invasiveness, affect cell apoptosis, and is closely correlated with poor prognosis of a variety of tumors[20-23]. Recently, Kraman *et al*[23] reported that stromal cells expressing FAP may be involved in tumor immune system suppression. FAP expression has been described to be present predominantly in the tumor stroma of epithelial malignancies, and its presence has been associated with cancer invasion, tumor angiogenesis, and subsequent growth and metastasis[15-19]. FAP was also reported to be expressed in carcinoma cells of the stomach[20], colorectum[21], breast[22] and uterine cervix[24]. Cohen *et al*[15] found that FAP was expressed predominantly in the fibroblasts in PDAC, and was shown to be statistically highly correlated with a worse clinical outcome. However, there has been no study of the expression of FAP in pancreatic cancer cells and its role in pancreatic cancer development and progression[20]. In the present study, we aimed to investigate the expression of FAP in PDAC carcinoma cells and its association with desmoplasia and patient survival, which may shed light on the role of FAP in desmoplasia in PDAC, and more importantly, signify a potentially new therapeutic target in PDAC.

MATERIALS AND METHODS

Patients and specimens

The PDAC specimens were collected with informed consent from 134 patients undergoing radical resection of primary PDAC in Changhai Hospital, Second Military Medical University during 2005-2007. Of the 134 specimens, 74 were used for tissue array study, and the remaining 60 were used to prepare standard pathological sections. All the experimental procedures were approved by the Research Ethics Committee of the Second Military University. The medical records of the patients were retrospectively reviewed, and the demographic, clinicopathological and treatment data were also collected. Tumor location and size were derived from the surgical report. The patients receiving preoperative chemotherapy or radiotherapy were excluded from the study. All patients were followed up after the operation, and the follow-up of the survivors at the time of analysis ranged from 1-33 (median 12) mo postoperatively. The patients who were alive at the time of the last follow-up were censored for overall survival analysis.

Cell lines

Four pancreatic cancer cell lines (SW1990, Miapaca-2, AsPC-1 and BxPC-3) maintained in our laboratory were incubated in the presence of 5% CO_2 in a humidified atmosphere at 37 ℃. AsPC-1, SW1990 and BxPC-3 cells were maintained in RPMI 1640 supplemented with 10% fetal bovine serum (FBS) (PAA Laboratories GmbH, Linz, Austria), and Miapaca-2 cells were maintained in DMED supplemented with 10% FBS and 2.5% horse serum (Gibco BRL, Invitrogen Corp, CA, United States).

Assessment of fibrotic focus and perineural invasion

Sixty standard slides were observed under the microscope after hematoxylin and eosin staining. A fibrotic focus was defined as a scar-like fibrosclerotic area located within the tumor containing a number of fibroblasts admixed with collagen fibers. The fibroblasts and collagen fibers were arranged in a storiform-like or irregular pattern[25]. The degree of perineural invasion was determined by two independent observers as described previously[26,27].

Immunohistochemistry

Tissue microarrays were constructed using the 74 paraffin-embedded tumor tissue specimens by a precision arraying instrument (Beecher Instruments, Silver Spring, MD, United States). In each case, three tumor cores and two surrounding non-tumor tissues were selected. The standard slices of the other 60 specimens and the sections from the tissue microarray blocks were deparaffinized, rehydrated and then heated in 0.01 mol/L sodium citrate buffer (pH 6.0) for 8 min at 95 ℃. After incubation with 0.3% hydrogen peroxide in methanol for 15 min at room temperature and treatment with normal goat serum (Invitrogen, Carlsbad, CA), the sections were incubated overnight at 4 ℃ with rabbit anti-human FAP polyclonal antibody (LifeSpan BioSciences Inc, United States) at a dilution of 1:70 in solution (Zymed Labroatories, Invitrogen Corp, CA). Slides were rinsed for 10 min in phosphate buffered saline (PBS) wash solution and incubated for 30 min with the horseradish peroxidase (HRP)-labeled polymer conjugated secondary antibody (EnVision+; DakoCytomation, Carpintera, CA, United States) was added according to the manufacturer's instructions. A known positive endometrial cancer tissue

[1]Some records are missing. pTNM: Pathological tumor-node-metastasis.

biopsy sample was used as the positive control. PBS and non-immune serum were used instead of the primary antibody for the blank control and negative control samples, respectively.

Evaluation of FAP staining was carried out by two independent observers, and the stained area and intensity were scored separately. Specifically, a score of 0 was assigned to a stained area with ≤ 10% of the tumor cells, 1 for an area with > 11% to ≤ 25% of tumor cells, 2 for > 26% to ≤ 50% tumor cells, and 3 for > 51% tumor cells. For the staining intensity, a score of 0 was assigned for absent/weak staining (negative control), 1 for a weak staining obviously stronger than the negative control level, 2 for moderately intense staining, and 3 for intense staining. The final grade of the section was derived from the sum of the stained area and intensity scores. A final score ≥ 3 was recognized to indicate positive expression.

Western blotting

Upon reaching 80%-90% confluence, the cultured cells were harvested and lysed in ice-cold lysis buffer (50 mmol/L Tris-HCl (pH8.0), 150 mmol/L NaCl, 0.02% NaN_3, 1% NP-40, 1 mmol/L phenylmethylsulfonyl fluoride, and 1 μg/mL aprotinin), and the protein level was quantified according to the manufacturer's instructions of the BCA protein assay kit (Tiangen Biotech Co, China). Total protein was separated by 8% sodium dodecyl sulfate-polyacrylamide gel electrophoresis and transferred to polyvinylidene fluoride membranes. The membranes were then blocked with 5% skim milk, incubated with 1:1000 rabbit anti-human FAP polyclonal antibody (Abcam, United States) overnight at 4 ℃, washed in Tris-buffered saline Tween-20 buffer, and then incubated with HRP-conjugated goat anti-rabbit IgG (MR Biotech, China) for 1 h at room temperature. The protein bands were visualized by chemiluminescence (Tiangen Biotech Co, China).

Statistical analysis

All the analysis were carried out using SPSS 11.5 software. The χ^2 test was used to analyze the correlation between FAP expression and clinicopathological features of PDAC. The Spearman correlation was used to evaluate the correlation of fibrotic focus and FAP expression. The Kaplan-Meier method was used for survival analysis and the difference in the survival curves was evaluated using the log-rank test. The Cox proportional hazards regression model in a stepwise manner was used to analyze the independent prognostic factors. All the tests were conducted with a 5% type I error.

RESULTS

Clinical data

We examined a total of 134 specimens. The patients consisted of 92 males and 42 females, age range 29-80 (median, 59) years. The patients' characteristics are summarized in Table 1.

Fibrotic focus in PDAC

A fibrotic focus was detected in 47 (78.3%) of the 60 PDAC specimens; in the fibrotic focus, active fibroblasts and collagen fibers were radially aligned around the tumor cells (Figure 1A), a pattern different from that in the surrounding PDAC stroma, where the fibroblasts and collagen fibers were arranged in an orderly fashion (Figure 1B). There was no significant correlation between the presence of a fibrotic focus and other clinicopathological factors.

Patterns of FAP expression in PDAC tissues

FAP was strongly expressed not only in activated fibroblasts within the PDAC tissues (98/134, 73.1%), but also in carcinoma cells in 102 of the 134 specimens (76.1%). Three patterns of FAP immunostaining were found in PDAC tissues, which included carcinoma cells (15/134, Figure 2A), stroma cells (11/134, Figure 2B), both carcinoma and stroma cells (87/134, Figure 2C). FAP immunostaining was localized mainly on the cell membrane and in the cytoplasm, and occasionally in the gland lumens. The expression presented with a diffuse or focal distribution in the carcinoma tissues. The FAP-positive fibroblasts were mainly located adjacent to the carcinoma tissue. The adjacent noncancerous pancreatic ducts showed virtually no positive staining for FAP, and the fibroblasts away from the carcinoma tissues rarely expressed FAP (Figure 2D).

FAP expression in pancreatic cancer cell lines

To further investigate the expression of FAP in pancreatic cancer cells, we performed Western blotting assays

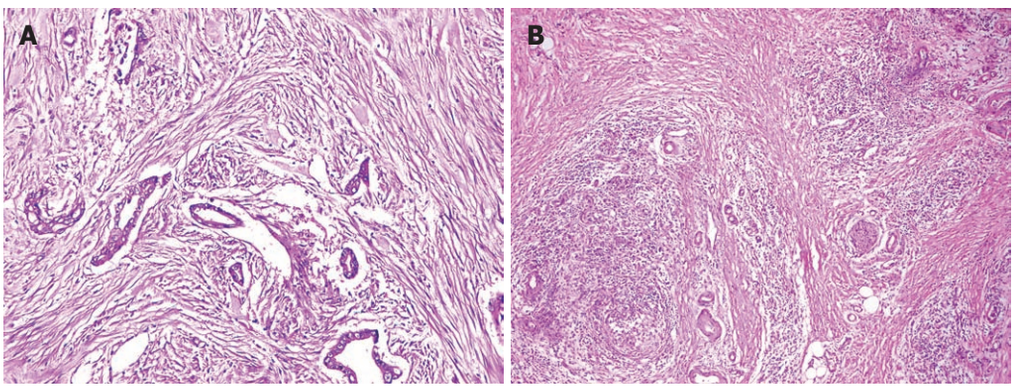

Figure 1 Fibrotic focus in pancreatic ductal adenocarcinoma. A: In the fibrotic focus, fibroblasts and collagen fibers are radially aligned around the tumor cells (× 200); B: A pattern different from that in the surrounding pancreatic ductal adenocarcinoma stroma where the fibroblasts and collagen fibers are arranged in an orderly fashion (× 100).

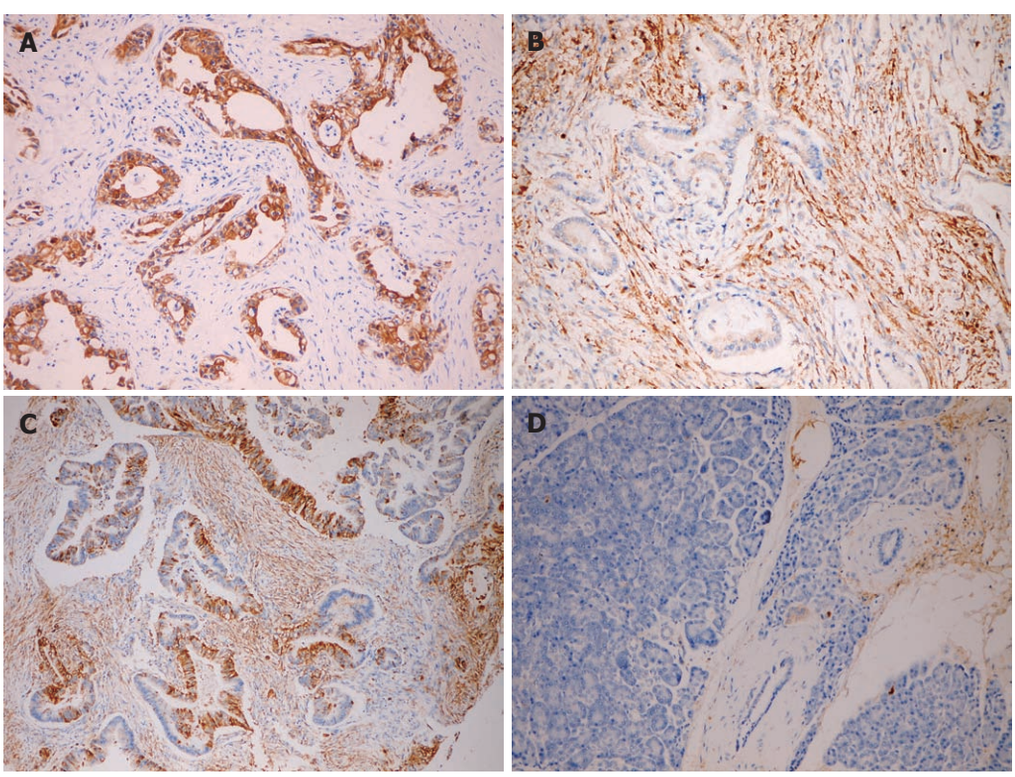

Figure 2 Fibroblast activation protein expression in pancreatic ductal adenocarcinoma. A: Fibroblast activation protein (FAP) expression in carcinoma cells is located mainly on the cell membrane and in the cytoplasm (× 200); B: FAP-positive fibroblasts are mainly located adjacent to carcinoma tissue (× 200); C: FAP is expressed in carcinoma cells and in fibroblasts adjacent to carcinoma tissue (× 100); D: The adjacent noncancerous pancreatic ducts show no positive staining for FAP and fibroblasts away from the tumor tissues rarely express FAP (× 200).

on cancer cells *in vitro*. The results showed that all four pancreatic cancer cell lines expressed FAP protein at different levels. Protein bands corresponding to the proteolytically active 170 kDa seprase dimer and its 97 kDa seprase subunit protein were identified (Figure 3). This result suggests that pancreatic cancer cells can secrete FAP by an autocrine mechanism.

Correlation of FAP expression with clinicopathological features of PDAC patients

The χ^2 test indicated significant correlations of FAP expression in the carcinoma cells from PDAC patients with patient age ($P < 0.001$), tumor size ($P < 0.001$), fibrotic focus ($P = 0.003$) and perineural invasion ($P = 0.009$) (Table 2). The Spearman correlation revealed that FAP expression was positively correlated with fibrotic focus, with a Pearson correlation coefficient of 0.379 ($P = 0.003$). We also found that PDAC patients with high expression of FAP in the carcinoma cells had a significantly shorter median overall survival compared to those with low expression of FAP (10 mo *vs* 33 mo, $P = 0.0085$) (Figure 4). In univariate analyses, the following param-

[1]Some records are missing. pTNM: Pathological tumor-node-metastasis; FAP: Fibroblast activation protein.

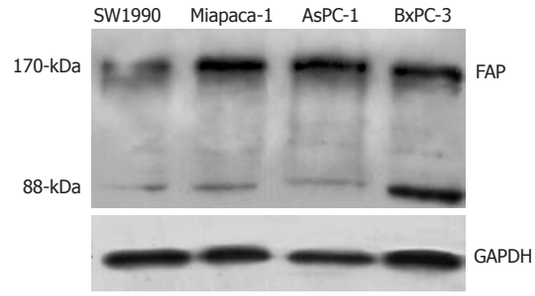

Figure 3 Western blotting analysis of fibroblast activation protein in pancreatic cancer cell lines. All four cell lines express fibroblast activation protein (FAP) with protein bands corresponding to the proteolytically active 170-kDa seprase dimer and its 88-kDa seprase subunit protein. GAPDH: Glyceraldehyde-3-phosphate dehydrogenase.

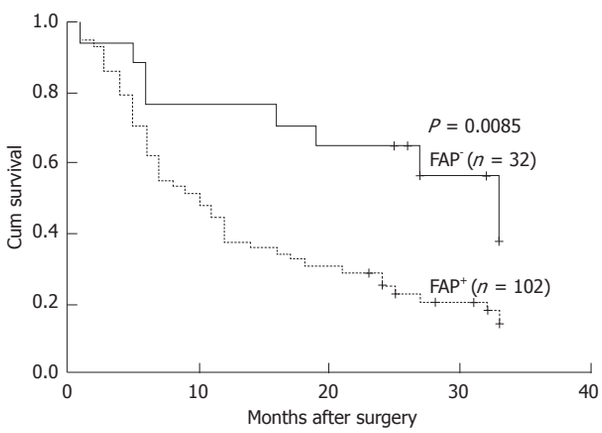

Figure 4 Kaplan-Meier survival curves of pancreatic ductal adenocarcinoma patients. The prognosis was significantly worse in the fibroblast activation protein (FAP)-positive group compared with the FAP-negative group (P = 0.0085).

eters were significantly associated with overall survival in PDAC: patient age (P = 0.013), tumor size (P = 0.008), fibrotic focus (P = 0.023) and perineural invasion (P = 0.009). The multivariate survival analysis further revealed that high expression of FAP was a predictor of overall survival (P = 0.017; relative risk, 2.513) independent of patient age (P = 0.029), tumor size (P = 0.011), fibrotic focus (P = 0.037) or perineural invasion (P = 0.020).

DISCUSSION

In this study, we confirm and extend previous findings that FAP expression is significantly elevated in PDAC tissues. FAP overexpression was positively correlated with patient age, tumor size, fibrotic focus, perineural invasion and poor survival, implying its involvement in PDAC development. Moreover, the protein product of FAP was found in all four pancreatic cancer cell lines and in PDAC tumor cells. To our knowledge, this was a novel finding of interest in the current study.

Solid tumors are a composite of cancer cells, endothelial cells, inflammatory cells, and fibroblasts. Although the relevance of fibroblasts in cancer progression is increasingly being recognized, little is known about their origin. Activated pancreatic stellate cells (myofibroblast-like cells), connective tissue-type fibroblasts, and mesenchymal cells were originally identified as the source of the fibrosis in chronic pancreatitis[9], and are now thought to be responsible for the dense stroma associated with pancreatic adenocarcinoma[9,28]. Cancer cells were surrounded by extremely dense collagen bundles associated with abundant reactive stromal fibroblasts, which were closely related to tumor prognosis[29,30]. The presence of a fibrotic focus correlated positively with disease progression, greater tumor size, the presence of lymph node metastases, and poor outcome in breast[31-33] and pancreatic[29,34] cancers. We found that the fibrotic focus was positive in 78.3% (49/60) of the PDAC tissues examined. Nevertheless, statistical analysis supported no correlation between the fibrotic focus and the prognosis of PDAC, which might be due to the fact that the majority of patients in our study were at an advanced stage, when a fibrotic focus would be common; the high short-term mortality rate of PDAC patients following surgery may also contribute to this result.

FAP expression has been described to be present predominantly in the tumor stroma of epithelial malignancies, and its presence has been associated with epithelial cancer invasion, tumor angiogenesis, and subsequent growth and metastasis[15-19,23]. FAP staining of the epithelial neoplasm has also been seen in some of studies, mainly located in the cytoplasm and the cell membrane

in carcinoma cells of the stomach[20], colorectum[18,21], breast[22], ovaries[35] and uterine cervix[24], and increased expression of FAP was also associated with histological grade, invasion and metastatic progression. Cohen *et al*[15] reported that FAP expression was seen mainly in the fibroblasts immediately adjacent to PDAC tissues, but was extremely rare in the carcinoma cells. In contrast, we found in the present study that FAP was highly expressed in the carcinoma cells (76.1%) as well as in the fibroblasts (73.1%) of PDAC tissues. The results of the Western blotting assay also demonstrated the presence of FAP protein expression in four human pancreatic cancer cell lines. Our findings suggested that PDAC cells might directly contribute to stroma desmoplasia through an autocrine mechanism of the FAP protein. We further analyzed the correlation of FAP expression in PDAC cells with patient survival. As we expected, FAP expression in the tumor cells was correlated with a shorter patient survival and served as an independent prognostic indicator for PDAC. These data suggest that FAP acts through an autocrine and/or paracrine mechanism in human pancreatic cancer, and may be a potential new therapeutic target in the treatment of PDAC.

As noted, we obtained different results concerning FAP expression in PDAC and its relation to desmoplasia from those reported previously[15]. We used a commercial primary antibody, and a non-biotinylated secondary antibody, so there would not be a false impression that FAP was localized to carcinoma cells. Although we do not know the reasons for this difference in expression, it may be related to use of a different source of FAP antibody. According to a recent study, the presence of collagen structures radially aligned with tumor cells was suggested to promote tumor progression and invasion[36]. The difference in FAP expression may reflect distinct biological features of these types of cancer.

To conclude, we found that PDAC cells, as well as CAFs, can also express FAP, which is closely associated with desmoplasia in PDAC. This suggests that PDAC cells may be directly responsible for the desmoplastic reaction through an autocrine mechanism of FAP production, and may partly explain why desmoplasia is particularly conspicuous in PDAC compared with the other carcinomas. This suggests that carcinoma cells may play a direct role, through an autocrine and/or paracrine mechanism, in desmoplasia in PDAC development and progression. Further research is needed to investigate the mechanism and some studies are already in progress. Our findings also provide evidence for ongoing clinical investigations with FAP as a therapeutic target for PDAC.

COMMENTS

Background

Fibroblast activation protein (FAP) is expressed on reactive fibroblasts during embryonic development, in healing wounds, in chronic inflammation, in liver cirrhosis, and in cancer-associated fibroblasts (CAFs) of many human carcinomas.

Research frontiers

FAP can enhance stromal cell proliferation and invasiveness, affect cell apoptosis, and is closely correlated with poor prognosis of a variety of tumors. Stromal cells expressing FAP may be involved in tumor immune system suppression. FAP expression has been found to be present predominantly in the tumor stroma of epithelial malignancies, and its presence has been associated with cancer invasion, tumor angiogenesis, and subsequent growth and metastasis.

Innovations and breakthroughs

FAP was expressed in both stromal fibroblast cells and carcinoma cells. All four pancreatic cancer cell lines expressed FAP protein at different levels. Higher FAP expression in carcinoma cells was associated with tumor size, fibrotic focus, perineural invasion and worse clinical outcome.

Applications

FAP is highly expressed in carcinoma cells and fibroblasts in pancreatic adenocarcinoma tissues, and its expression is associated with desmoplasia and worse prognosis. This suggests that carcinoma cells may play a direct role, through an autocrine and/or paracrine mechanism, in desmoplasia in pancreatic ductal adenocarcinoma (PDAC) development and progression, and FAP may serve as a potential therapeutic target in PDAC.

Terminology

FAP, or seprase, a cell surface glycoprotein belonging to the serine protease family, is a 170 kDa dimer that is catalytically active and has dipeptidase and gelatinase activities; CAF, is a predominant stromal cell type, which actively communicates with and stimulates tumor cells, thereby contributing to tumor development and progression.

Peer review

This is an interesting work.

Abstract

AIM: To investigate the association between interleukin (IL)-10-1082 (G/A) promoter polymorphism and acute rejection (AR) in liver transplant (LT) recipients.

METHODS: Two investigators independently searched the Medline, Embase, China National Knowledge Infrastructure, and Chinese Biomedicine Databases. Summary odds ratios (ORs) and 95% CIs for IL-10-1082 G/A polymorphism and AR were calculated in a fixed- and a random-effects model as appropriate.

RESULTS: This meta-analysis included seven case-control studies, which comprised 652 cases of LT recipients in which 241 cases developed AR and 411 cases did not develop AR. Overall, the variant A allele was not associated with AR risk when compared with the wild-type G allele (OR = 0.94, 95% CI: 0.64-1.39). Moreover, similar results were observed when the AA genotype was compared with the AG/GG genotype (OR = 1.05, 95% CI: 0.55-2.02). When stratifying for ethnicity, no significant association was observed among either Caucasians or Asians. Because only one study was performed in Asian patients, the result of subgroup analysis by ethnicity would not be reliable for Asians. Limiting the analysis to the studies with controls in the Hardy-Weinberg equilibrium, the results were persistent and robust. No publication bias was found in the present study.

CONCLUSION: This meta-analysis suggests that IL-10-1082 G/A polymorphism may be not associated with AR risk in LT recipients among Caucasians.

INTRODUCTION

Liver transplantation is regarded as an effective therapeutic option for end-stage liver disease as survival after liver transplantation has dramatically improved during

the last two decades. Despite this success, graft dysfunction occurs in up to 13% of the patients during the first year after transplantation and rises to 35% in 5 years[1,2]. Acute rejection (AR) and recurrence of disease are two major immunological complications, which may lead to graft dysfunction. The inflammatory microenvironment within the graft may play a role in the precipitation of rejection[3], although the underlying mechanisms involved in such events remain unclear. A network of short-acting cytokines and growth factors in turn determines this environment. Cytokines have a central role in the immunologic events that occur after transplantation and are intimately implicated in graft rejection.

Interleukin-10 (IL-10), whose encoding gene is located on chromosome 1 (1q31-1q32), is an immunoregulatory cytokine produced by Th2 cells, monocytes/macrophages, and regulatory T cells, and is capable of downregulating T-cell activation and major histocompatibility complex expression on antigen-presenting cells *in vitro*[4]. Previous studies have suggested that IL-10 mRNA levels are increased just before a rejection episode[5]. The production of cytokines (including IL-10) is under genetic control and varies among individuals as a function of polymorphisms within the regulatory regions of the various genes that determine the transcriptional activation[6-9]. The promoter of the *IL-10* gene contains three biallelic polymorphisms at positions -1082 (base G to A, dbSNP no. rs1800896), -819 (base C to T, dbSNP no. rs1800871), and -592 (base C to A, dbSNP no. rs1800872) from the transcription start site, and these influence the capacity of cells to produce IL-10[10]. For example, the G-to-A polymorphism at position -1082 of the IL-10 promoter reduces IL-10 production[7]. Alloimmune responses and variations in susceptibility to rejection may be influenced by individual variations in cytokine genes. Associations between cytokine gene polymorphisms and rejection of kidney[11,12], heart[13], and lung[14] have been reported.

Over the last two decades, a number of studies have assessed the association between the IL-10-1082 (G/A) promoter polymorphism and AR in liver transplant (LT) recipients in different populations; however, the results are inconsistent and inconclusive[15-22]. In 2005, Warlé *et al*[23] published findings from a meta-analysis of the IL-10-1082 (G/A) polymorphism and AR risk in LT recipients (based on five studies). The pooled results by Warlé *et al*[23] suggested that the IL-10 polymorphism at position -1082 was a genetic risk factor for acute liver graft rejection, and that LT recipients carrying the IL-10-1082. A allele displayed a lower rejection rate. However, this manuscript had some limitations mainly due to the small sample size and data retrieval. In order to derive a more comprehensive estimation of the association between IL-10-1082 polymorphism and AR risk in LT recipients, we conducted a meta-analysis to re-evaluate the association.

MATERIALS AND METHODS

Literature search strategy

We searched the PubMed, Embase, CNKI (China National Knowledge Infrastructure) and Chinese Biomedicine databases for all articles on the association between IL-10 polymorphisms and AR risk in LT recipients (last search update 20th March 2011). The following key words were used: "interleukin-10" or "IL-10"; "acute rejection" or "early graft rejection"; "liver transplantation". The search was performed without restriction on language, but conducted on human subjects. The reference lists of reviews and retrieved articles were hand searched at the same time. We did not consider abstracts or unpublished reports. If more than one article was published by the same author using the same case series, we selected the study where the most individuals were investigated.

Inclusion and exclusion criteria

We reviewed abstracts of all citations and retrieved studies. The following criteria were used to include published studies: (1) evaluation of the association between IL-10-1082 G/A polymorphism and AR in LT recipients; (2) a case-control or cohort design; and (3) sufficient genotype data presented to calculate the odds ratio (OR) with 95% confidence interval (CI). Major reasons for exclusion of studies were: (1) duplicate data; (2) an abstract, comment, review or editorial; and (3) no sufficient data were reported.

Data extraction

Two investigators (Liu F and Li B) extracted information from all eligible publications independently according to the inclusion criteria listed above. Disagreements were resolved by discussion between the two investigators. The following information was collected from each study: first author, year of publication, transplant period, indication for transplantation, patient characteristics (age, gender, *etc*), definition of AR, immunosuppressive regimen, country of the first or corresponding author, ethnicity, number of AR cases and controls (non-AR), genotyping methods and evidence of Hardy-Weinberg equilibrium (HWE). Ethnicities were categorized as Asian or Caucasian.

Statistical analysis

We first assessed HWE in the controls for each study using the goodness-of-fit test (χ^2 or Fisher's exact test) and a $P < 0.05$ was considered as significant disequilibrium. The strength of the association between AR and the IL-10-1082 G/A polymorphism was estimated using the OR and corresponding 95% CI. For the -1082G/A polymorphism, we estimated the risk of the variant A allele compared with the wild-type G allele, and then evaluated the risk of AA *vs* (AG + GG) which assumed a recessive effect of the variant A allele. We also carried out the stratified analyses by ethnicity (Caucasians/Asians) and HWE in controls (yes/no).

Both the Cochran Q statistic[24] to test for heterogeneity and the I^2 statistic to quantify the proportion of the total variation due to heterogeneity[25] were calculated. A P value of more than the nominal level of 0.10 for the Q

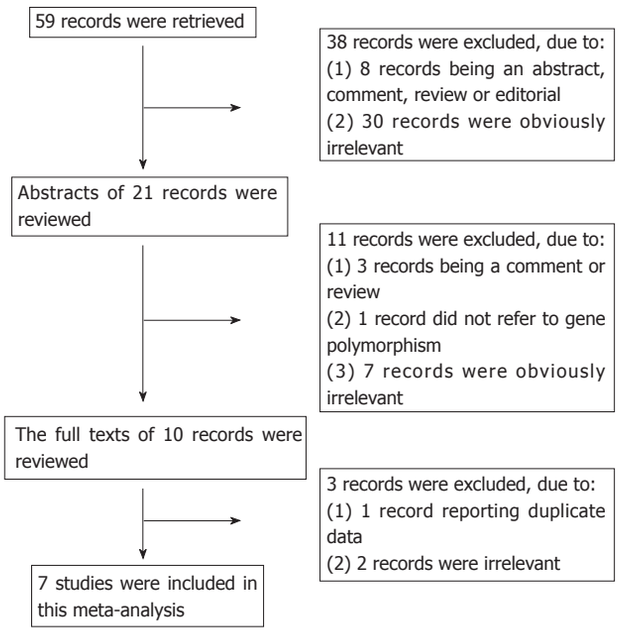

Figure 1 Flow chart of selection of studies and specific reasons for exclusion from the meta-analysis.

statistic indicated a lack of heterogeneity across studies, allowing for the use of a fixed-effects model (the Mantel-Haenszel method)[26]; otherwise, the random-effects model (the DerSimonian and Laird method) was used[27]. Sensitivity analysis was performed to assess the reliability of the results.

Several methods were used to assess potential publication bias. Visual inspection of funnel plot asymmetry was conducted. The Begg's rank correlation method[28] and the Egger's weighted regression method[29] were used to statistically assess publication bias ($P < 0.05$ was considered statistically significant). All analyses were done using STATA software, version 11.0 (STATA Corp., College Station, TX, United States). All the *P* values were two-sided.

RESULTS

Characteristics of studies

There were 59 papers relevant to the search words. *Via* steps of screening the title and reading the abstract, 10 studies were identified[15-22,30,31]. Of these, three studies were excluded (two did not report the association between IL-10-1082 G/A polymorphism and AR in LT recipients[22,30]; two articles[20,31] were published by a different first author using the same case series, and we selected the latest study[20]); thus, seven studies[15-21] which included 241 AR cases and 411 non-AR cases were found to match our inclusion criteria. The flow chart of selection of studies and reasons for exclusion is presented in Figure 1. Characteristics of studies included in the meta-analysis are presented in Tables 1 and 2.

There were six studies of Caucasian descendents, one study of Asian descendents. Studies had been carried out in China, Turkey, the United States, Netherlands, Israel and the United Kingdom. All studies defined rejection as biopsy-proven episodes of AR during the early post-transplant period (AR within first 4-8 wk), treated with high-dose steroids, except for the study of Karasu *et al*[16]. Immunosuppressive regimens in all studies consisted of a calcineurin inhibitor (cyclosporin or tacrolimus) and prednisone with or without azathioprine. Mycophenolate mofetil was only used in a subgroup of patients studied by Xie *et al*[15] and Mas *et al*[17]. Most studies extracted DNA from peripheral blood, and only two studies[15,17] from surgically explant liver tissue from recipients. Several genotyping methods were used, including PCR-RFLP, PCR-SSP, direct sequencing, ARMS-PCR and AS-PCR. The genotype distributions among the controls of all studies were consistent with HWE except for Tambur's study[20].

Quantitative synthesis

Overall, the variant A allele was not associated with AR risk when compared with the wild-type G allele (OR_{random} = 0.94, 95% CI: 0.64-1.39, $P_{heterogeneity}$ = 0.07) (Figure 2). When the AA genotype was compared with AG/GG genotype (recessive model), no significant association was observed (OR_{random} = 1.05, 95% CI: 0.55-2.02, $P_{heterogeneity}$ = 0.01) (Figure 3). When stratified for ethnicity, no significant association was observed among either Caucasians or Asians (for Caucasians: A allele *vs* G allele, OR_{random} = 0.95, 95% CI: 0.61-1.47, $P_{heterogeneity}$ = 0.04; AA *vs* AG/GG, OR_{random} = 1.07, 95% CI: 0.49-2.32, $P_{heterogeneity}$ = 0.01; for Asians: A allele *vs* G allele, OR_{random} = 0.96, 95% CI: 0.34-2.68; AA *vs* AG/GG, OR_{random} = 0.96, 95% CI: 0.33-2.77). Because only one study was performed in Asian patients, the result of subgroup analysis by ethnicity could not be reliable for Asians.

In Tambur's study, the distribution of *IL-10-1082* genotypes among controls was not in HWE. Limiting the analysis to the studies within HWE, the estimated association remained unchanged (A allele *vs* G allele, OR_{fixed} = 0.81, 95% CI: 0.61-1.07, $P_{heterogeneity}$ = 0.13; AA *vs* AG/GG, OR_{random} = 0.98, 95% CI: 0.46-2.11, $P_{heterogeneity}$ = 0.009).

Publication bias

Begg's funnel plot and Egger's test were performed to evaluate the publication bias of studies of AR in LT recipients. Figures 4 and 5 display funnel plots that examined the IL-10-1082 polymorphism and overall AR risk included in the meta-analysis. The shape of funnel plots did not reveal any evidence of funnel plot asymmetry. The statistical results did not show publication bias (A allele *vs* G allele: Begg's test P = 0.55, Egger's test P = 0.26; AA *vs* AG/GG: Begg's test P = 0.76, Egger's test P = 0.67).

DISCUSSION

In spite of major advances in the field of immunosuppressive therapy, acute hepatic allograft rejection remains an important problem after liver transplantation. Almost 30%-50% of patients experience at least one episode of rejection within the first year[32]. Cytokines, a group

of small, soluble, or cell membrane-bound protein or glycoprotein molecules, play an essential role in the regulation of inflammatory and immune responses. Despite the many variables that influence acute rejection, previous reports indicate that cytokine genotypes that result from polymorphisms can sometimes correlate with acute allograft rejection[33,34]. Alloimmune responses and variations in susceptibility to rejection may be influenced by individual variations in cytokine genes. An association between susceptibility to graft rejection and polymorphism in cytokine gene promoters in kidney, heart, lung, and bone marrow recipients has been reported by some centers[11-14,35], although others have not confirmed this[36-38].

IL-10 is an antiinflammatory cytokine, which can inhibit the production of tumor necrosis factor-α, IL-1, IL-6, IL-8, and IL-12 in monocytes/macrophages and interferon-γ in T cells[4]. Therefore, in the context of allograft rejection, local IL-10 release may have inhibitory properties on macrophages, T cells, and cytokines. However, the role of IL-10 in LT patients remains controversial. For example, some studies have suggested that IL-10 *mRNA* levels are increased just before a rejection episode[5], while others have indicated that IL-10 levels are unchanged during rejection of the LT[39]. In animal models, overexpression of IL-10 by gene transfer prolonged graft survival of orthotopic LTs[40]. Since some studies[33,34] reported that cytokine genotypes that result from polymorphisms can sometimes correlate with acute

allograft rejection, a number of studies have assessed the association between the IL-10-1082 promoter polymorphism and AR in LT recipients in different populations. However, some of the results were conflicting, even in the same population, and thus a systematic review and meta-analysis of the association between *IL-10-1082* G/A polymorphism and AR risk was of great value.

A meta-analysis can overcome some problems caused by a single study, such as small sample size, low test power and selection bias; however, some concerns have to be addressed before aggregating data. First, the definition of AR, as the main outcome measure for this analysis, should be consistent among included studies. In six studies, AR was defined as "early" biopsy-proven AR within the first 4-8 wk after liver transplantation, treated with high-dose steroids. However, Karasu *et al*[16] defined AR as an increase in liver enzymes in the absence of vascular or biliary problems, associated with an improvement

after treatment by increasing the dose of immunosuppressive drugs or pulse steroid therapy within the first 8 wk. In the overall meta-analysis performed in this study, the number of patients from the Karasu *et al*[16] study is small, suggesting that this factor probably had little effect on the overall estimates. Moreover, the immunosuppressive regimen among different studies included is also an important factor which should be addressed. All LT patients included in this meta-analysis received more or less the same type of immunosuppression: a calcineurin inhibitor and prednisone, with or without azathioprine. However, there were some differences in the type of induction therapy, dosages and maintenance of target levels in blood, which can provide a possible explanation for significant heterogeneity in a recessive model.

This meta-analysis was based on seven case-control studies and showed that *IL-10-1082* G/A polymorphism was not associated with the risk of AR in LT recipients. Our result is not consistent with a previous systemic review[23]. This is most probably because the previous meta-analysis had a relatively small sample size (the Warlé *et al*[23] meta-analysis included only five studies for *IL-10-1082* G/A polymorphism and AR risk in LT recipients) and may have generated a very rough risk estimate. The G-to-A polymorphism at position -1082 of the IL-10 promoter reduces IL-10 production[7], and individuals with the *IL-10-1082*-GG genotype showed the greatest IL-10 production after *in vitro* stimulation, whereas *IL-10-1082*-GA and -AA showed intermediate and low production, respectively[7,41]. Moreover, previous studies[42,43] showed that Th2 cytokines, such as IL-10, are associated with graft tolerance. Therefore, it can be deduced that patients with an IL-10 genotype corresponding to low IL-10 production are more susceptible to rejection, whereas the IL-10 genotype corresponding to high production is found mainly among nonrejectors. However, our result is inconsistent with the above hypotheses. This is probably because the notion, derived mainly from animal studies, that IL-10 has a role in human allograft tolerance needs re-evaluation. In addition, since the effect of the *IL-10-1082* promoter polymorphism on *in vitro* and thus *in vivo* cytokine production is still inconclusive[7,44,45], its biological effect on acute liver graft rejection remains speculative.

As previously described, ethnicity can strongly influence the distribution of cytokine gene polymorphisms[46]. In Caucasian patients[17], the IL-10 AA genotype at position -1082 occurred in 32.5%, while among Asian patients[15] it occurred in 88.2%. Therefore, there may be different associations between IL-10-1082 promoter polymorphism and AR in LT recipients among different ethnicities. Nevertheless, our results were inconsistent with our hypothesis. When stratifying for ethnicity, no significant association was observed among either Caucasians or Asians. The null result may be due to the limited number of studies with only one study (based on Asian patients) available in this meta-analysis, and there is a very high risk of reporting bias for the relationship of the *IL-10-1082* G/A polymorphism and AR risk in the Asian population. In future, additional studies based on Asian patients should be performed to re-evaluate the association between IL-10-1082 G/A polymorphism and AR risk in this population.

It seemed that selection bias could have played a role because the genotype distribution of -1082 G/A polymorphism among control subjects disobeyed the HWE in one study[20]. It is widely believed that deviation from HWE may be due to genetic reasons including non-random mating, or the alleles reflect recent mutations that have not reached equilibrium, as well as methodological reasons including biased selection of subjects from the population or genotyping errors[47,48]. Apart from the reasons for disequilibrium, the results of genetic association studies might be spurious if the distribution of genotypes in the control groups were not in HWE[49,50]. Thus we carried out subgroup analysis by HWE in controls. When excluding the study that was not within HWE, the estimated pooled OR did not change at all, suggesting that this factor probably had little effect on the overall estimates.

However, there some limitations remain in this meta-analysis: (1) our meta-analysis was based on unadjusted OR estimates because not all published studies presented adjusted ORs or when they did, the ORs were not adjusted by the same potential confounders, such as age, sex, ethnicity and exposures. Lack of the information for the data analysis may cause serious confounding bias; (2) there was significant between-study heterogeneity from studies of the *IL-10-1082* G/A polymorphism, and the genotype distribution also showed deviation from HWE in one study; (3) the number of studies and the number of subjects in the studies included in the meta-analysis were small; (4) we must emphasize the fact that this meta-analysis adds more studies and increases the sample size but that it is an update that is not important because it adds patients (small importance); it is important because the statistical analysis reflects that IL-10 polymorphisms are not relevant in AR in liver transplantation; and (5) meta-analysis is retrospective research that is subject to methodological limitations. In order to minimize bias, we developed a detailed protocol before initiating the study, and performed a meticulous search for published studies by using explicit methods for study selection, data extraction and data analysis. Nevertheless, our results should be interpreted with caution.

In conclusion, this meta-analysis suggests that IL-10 -1082 G/A polymorphism may be not associated with AR risk in LT recipients among Caucasians. Since only one study was from an Asian population, it is critical that larger and well-designed multicenter studies based on Asian patients should be performed to re-evaluate the association.

COMMENTS

Background

Interleukin (IL)-10 is an antiinflammatory cytokine, which can inhibit the production of tumor necrosis factor-alpha, IL-1, IL-6, IL-8 and IL-12 in monocytes/

macrophages and interferon-γ in T cells. Therefore, in the context of allograft rejection, local IL-10 release may have inhibitory properties on macrophages, T cells, and cytokines. The production of cytokines (including IL-10) is under genetic control and varies among individuals as a function of polymorphisms within the regulatory regions of the various genes that determine the transcriptional activation. The G-to-A polymorphism at position -1082 of the IL-10 promoter reduces IL-10 production. Alloimmune responses and variations in susceptibility to rejection may be influenced by individual variations in cytokine genes.

Research frontiers

To date, a number of studies (including meta-analysis) have assessed the association between the IL-10 1082 G/A polymorphism and acute rejection (AR) risk in liver transplant (LT) recipients among different populations; however, the results are inconsistent and inconclusive.

Innovations and breakthroughs

Contrary to the finding of the previous meta-analysis, this study suggests that IL-10-1082 G/A polymorphism may be not associated with AR risk in LT recipients among Caucasians.

Applications

It can be seen from this paper that IL-10-1082 G/A polymorphism could not alter susceptibility to AR risk in LT recipients. It suggests that a common variant in the functional region of a meaningful gene had little effect on human disease.

Peer review

This appears to be a well-done meta-analysis study.

Abstract

AIM: To investigate the copy number variation of *NACO3* gene in colorectal cancer (CRC) and its correlation with tumor progression.

METHODS: A total of 142 samples of case-matched CRC tissues and adjacent normal tissues were obtained from patients undergoing bowel resection. Quantitative real-time polymerase chain reaction method was used to investigate the copy number variations of NCOA3 as well as gene expression in the collected tissues.

RESULTS: Copy number gains of NCOA3 were detected in 39 CRC samples (27.5%) and were correlated with tumor progression (χ^2 = 6.42, P = 0.0112). Moreover, there was a positive correlation between copy number gain and mRNA over-expression of NCOA3 in CRCs (P = 0.0023). Expression level of NCOA3 mRNA was also enhanced in the CRC samples with unaltered copy numbers (3.85 ± 1.23 *vs* 2.71 ± 0.64, P < 0.01).

CONCLUSION: Sporadic colorectal cancers exhibit different mechanisms of NCOA3 regulation.

Key words: Colorectal cancer; *NCOA3*; Gene copy number; Gene expression; Tumor progression

INTRODUCTION

The p160 steroid receptor coactivator (SRC) family is critical to the transcriptional activation function of nuclear hormone receptors. A key member of this family is nuclear receptor coactivator 3 (NCOA3 and also known as AIB1 and SRC-3), initially found to be amplified and expressed in breast cancer, and has subsequently been shown to express in malignant diseases arising from a wide range of other organs[1-3]. Over-expression of NCOA3 has been implicated in tumor proliferation, invasiveness[4], and resistance to chemoradiotherapy[5] in various kinds of tumors. Increased expression of NCOA3 is

also correlated with advanced colorectal carcinoma[6].

Colorectal cancer (CRC) is currently the third most common cancer in Chinese population, responsible for about 130 000 deaths per year. Both genetic and environmental factors contribute to disease etiology, with about one-third of disease variance attributed to inherited genetic factors[7]. The implication of copy-number variations (CNVs) in cancers has become a hot spot over the past few years[8-10]. Studies using SNP arrays and aCGH have suggested that DNA amplification at chromosome position 20q12, also the chromosome locus of NCOA3, is frequent in CRC[11-13]. Moreover, there might be a correlation between CNVs and NCOA3 over-expression in CRCs. However, most of the aCGH experiments focused on the genome-wide screening of CNVs and the data obtained are generally informative but not definitive. Therefore, a study comprehensively examining CNVs in relation to NCOA3 expression or prognosis should be performed using a larger number of tumors.

In the present study, we collected 142 colorectal cancer samples with matched adjacent normal tissues for CNV analysis. Copy number gains of NCOA3 gene were observed in a relatively high percentage of CRC samples and were correlated with cancer lymph node involvement or metastasis. There was also a positive correlation between gene copy number gains and mRNA over-expression of NCOA3. These findings suggested the potential role of CNVs of NCOA3 in CRCs.

MATERIALS AND METHODS

Patients and tissue collection

CRC samples were obtained from 142 patients undergoing bowel resection at the Department of General Surgery, Henan Province Tumor Hospital. Adjacent normal tissue (ANT) samples located at least 2 cm from the macroscopically unaffected margins of the tumor (polyp or carcinoma) were defined as normal controls. The collected samples were stored in liquid nitrogen. There were 133 adenocarcinomas and 9 mucinous carcinomas (when >50% of the tumor volume was composed of mucin). CRCs were staged according to the Dukes classification system: Dukes A (T_1-T_2, N0, and M_0; n = 42), Dukes B (T_3-T_4, N0, and M_0; n = 37), Dukes C (any T, N_{1-2}, M_0; n = 48) and Dukes D (any T and any N and M_1; n = 15). Case-matched samples of colorectal carcinomas (n = 142) and normal colonic mucosa (n = 142) were immediately stored in liquid nitrogen after operation. For each sample, a portion of the tissue was disposed to make frozen sections and then micro-dissected by the Eppendorf Microdissection System (Siskiyou MX160L micromanipulator and PixeLink PL-A662 color Charge Coupled Device firewire camera). Then the dissected tissues were subjected to real-time polymerase chain reaction (PCR) analysis. All patients were informed about the aims of specimen collection and gave signed written consent in accordance with the ethical guidelines of Zhengzhou University. Peripheral blood samples from 152 healthy controls were collected at the Department of Histology and Embryology, Basic Medical College of Zhengzhou University. The study was approved by the Ethics Committee of Zhengzhou University.

DNA extraction and quantification of copy numbers

Genomic DNA was isolated from the tissues using the Genomic DNA Extraction Kit (Innocent, Shenzhen, China) according to the manufacturer's instructions. The concentration of purified DNA was determined by measuring the absorbance at 260 nm and 280 nm in a spectrophotometer. Pure preparations of DNA have A_{260}/A_{280} > 1.8. Quantitative PCR was performed using the BioRad Chromo4 real-time PCR system. The primers for RNAse P are: forward: 5'-AGA CTA GGG TCA GAA GCA A-3' and reverse: 5'-CAT TTC ACT GAA TCC GTT C-3'[14]. The primers for NCOA3 are: forward: 5'-AAA GTA AAC AGA ATG GAT TG-3' and reverse: 5'-AGT GTG CCT TGG AGT TGA AA-3'. The primer sets for *NCOA3* gene were designed by advanced real time PCR primer design tool (GenScript United States Inc.). A melting curve analysis with a temperature gradient of 0.2 K × S^{-1} from 72 ℃ to 95 ℃ was performed following each PCR amplification to confirm that only specific product was amplified.

Average copy numbers of RNAse P in normal candidates (copy numbers = 2) were used as controls[14,15]. The copy numbers of NCOA3 were calculated by the comparative C (T) method[16]. Cut-off values of 0.25, 0.75, 1.25 and 1.75 were used to define the copy numbers as 0, 1, 2 and 3, respectively. Fold change of each sample was presented as follows: fold change = relative expression level/average expression level in the group with 2 copies of DNA.

A standard curve was prepared using 2 μL of crude DNA solutions, including serially diluted samples (original, 2-, 4-, 8-, 16-diluted). The slopes of Ct and efficiency of each primer were calculated by the BioRad Chromo4 real-time PCR system and Microsoft Excel 2007 for Windows. Relative quantification of NCOA3 was performed by the 2^{-ddCt} method[17].

RNA extraction and real-time PCR

Total RNA was isolated from tissues using the AxyPrepTM Blood Total RNA MiniPrep Kit (Axygen) according to the manufacturer's instructions. First strand cDNA was synthesized with the RevertAidTM First Stand cDNA Synthesis Kit (Fermentas). Quantitative PCR was performed through the BioRad Chromo4 real-time PCR system. At the end point of PCR cycles, melt curves were made to check product purity. The mRNA levels of NCOA3 were expressed as a ratio relative to the GAPDH mRNA in each sample. Exploratory data analysis using box plot was applied to visually identify the expression level of target mRNA.

Statistical analysis

Statistical analysis was performed with the SPSS Software

Table 1 Comparison of copy number variations of *NCOA3* between adjacent normal tissues and healthy normal controls from peripheral blood

Samples	*n*	Copy number					*P* value *vs* HNC
		Deletion			Amplification		
		0	1	2	3	> 3	
HNC	152	2	8	135	6	1	
ANT	142	3	7	124	5	3	0.776

ANT: Adjacent normal tissues; HNC: Healthy normal controls.

Table 2 Copy number variations of *NCOA3* in colorectal cancer tissues and matched adjacent normal tissues

CNVs, population	*n*	Copy numbers Amplification ⩽ 2	Amplification > 2	*P* value (*vs* ANT)	*P* value (*vs* Dukes A and B)
Total					
ANT	142	134	8	-	-

ANT	63	60	3	-	-
CRC		39	24	< 0.0001	0.0112

CRC: Colorectal cancers; CNVs: Copy number variations; ANT: Adjacent normal tissues.

(version 12). Data were analyzed by the χ^2 test or Fisher exact test. *P* values less than 0.05 were considered statistically significant. Results of the NCOA3 mRNA expression in normal and tumor tissue samples were compared using two-way repeated measurement ANOVA. One-way, repeated measurement analysis of variance (ANOVA-RM) was performed at a significance level of $P = 0.05$ to determine differences from controls within each group. Two-way analysis of variance (ANOVA-2) was performed after baseline subtraction, at a significance level of $P = 0.05$, to determine differences between the groups with amplified and unaltered NCOA3 copy number.

RESULTS

Gene copy number gains of NCOA3 in CRC samples

Since no statistical difference of CNVs between ANTs and healthy normal controls was observed, the adjacent normal tissues could be used as controls for the cancer tissues in this study (Table 1). Table 2 shows CNVs of NCOA3 in paired samples of CRCs and ANTs. A total of 142 CRC samples were examined. Thirty-nine (27.5%) of CRC samples showed gains of NCOA3. Less than 20% of the CRC tissue samples from patients with early-stage CRC (Dukes A and B) had either three, four, or more than four copies of the *NCOA3* gene, whereas more than 20% of the samples from patients with advanced (Dukes C and D) had either three, four, or more than four copies of NCOA3. There was a correlation between gene copy number gains and the tumor phenotypes ($P = 0.0112$).

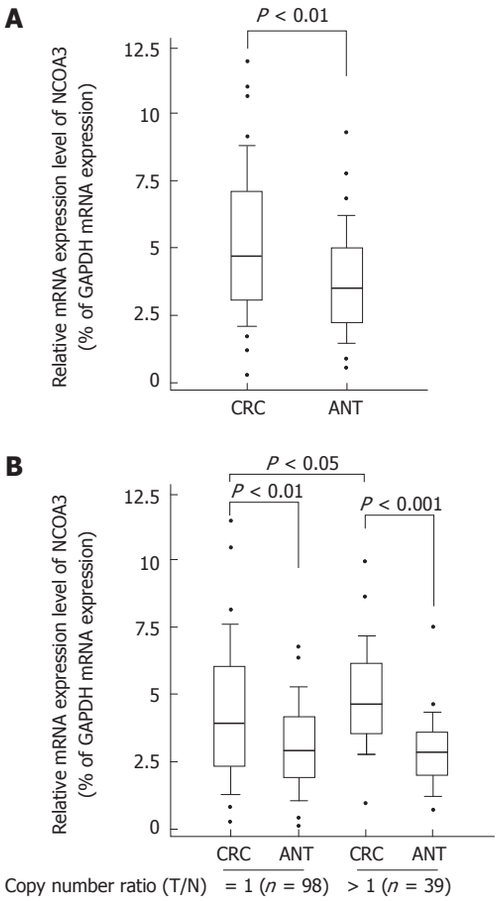

Figure 1 Real-time polymerase chain reaction assay was carried out as described under Materials and Methods section, and the results were obtained from indicated groups of samples. Boxplots of relative copy number of *NCOA3* mRNA measured with real-time polymerase chain reaction analysis showing the median; box: 25th-75th percentile; bars: largest and smallest values within 1.5 box lengths; little circles: outliers. A: mRNA expression level of NCOA3 in all the colorectal cancers (CRC) samples compared with adjacent normal tissues; B: mRNA expression level of NCOA3 in groups with amplified or unaltered DNA copies. ANT: Adjacent normal tissue; GAPDH: Glyceraldehyde-3-phosphate dehydrogenase..

Positive correlation between copy number and mRNA over-expression of NCOA3 in CRCs

To find whether CNVs of NCOA3 have genotype-phenotype correlation, we compared the mRNA expression levels of NCOA3 between the CRC samples and matched adjacent normal tissues by quantitative real-time RT-PCR. As shown in Figure 1A, increased mRNA expression level of NCOA3 was observed in collected CRC tissues, which was consistent with some previous findings[6,18].

Gene CNVs can contribute to qualitative and quantitative diversities to their gene products. Next, we selected the samples with increased or unaltered copies of NCOA3 and tested whether the NCOA3 mRNA expression was correlated with the copy numbers. The samples with decreased copies of NCOA3 (5 of 142) were not included due to the small sample size. As shown in Figure 1B, the CRC samples in the group with increased or

unaltered copies of NCOA3 both showed an increased expression of mRNA compared with adjacent normal tissues ($P < 0.01$). There was a significant statistical difference between the CRC samples in the groups with increased and unaltered copies of NCOA3 ($P = 0.0023$). Thus the DNA copy gain at least plays a partial role in the over-expression of NCOA3 in CRCs.

DISCUSSION

Although cancer is mostly regarded as an acquired disease, familial predisposition plays a significant role in many cancer types. Several highly aggressive cancer predisposing genes correlated with CRC have been identified (DNA mismatch repair genes[19], APC, SMAD4, BMPR1A and MUTYH[20]). As yet, however, these genes explain only a fraction of the familial and/or hereditary cases of cancer. CNVs identified by CGH and array technology have clearly been shown to have the potential to directly or indirectly influence a healthy individual's susceptibility to cancer, for example by varying the gene dosage of tumor suppressors or oncogenes[21,22]. However, there are many discrepancies among previous studies which used high-resolution approaches to screen CNVs[23-27]. Thus, validation of such CNVs by a larger amount of clinical samples is required. In the present study, CNVs of NCOA3 were examined in a relatively high number of case-matched CRC samples. The results obtained here were more definitive than previous reports.

Examination of the CNVs of oncogenes or tumor suppressor genes is a starting point for investigations into the role of gene amplification in the colorectal carcinogenic process. In this study, no differences of NCOA3 gene copy number were found between the healthy normal controls and ANTs from CRC patients. Thus the CNVs of NCOA3 in CRCs were more likely acquired DNA aberrations. The frequency of gains of NACO3 in CRCs was consistent with previous studies, where gains of chromosomes 20q12 were reported in 20%-60% of CRCs, respectively[11,12]. There was a correlation between the frequency of DNA copy-number gains of NCOA3 and Dukes classifications of the CRC samples ($P = 0.0112$), which suggested the potential role of altered copy number of *NCOA3* gene in the progression of CRCs.

It is expected that the CNVs do have a genotype-phenotype correlation. Phenotypic effects of genetic differences, such as CNVs, are supposedly brought about by changes in expression levels[28,29]. We investigated the correlation between the NCOA3 mRNA expression and the copy numbers of its DNA. Contrary to our expectation, the correlation was not as positive as predicted, although a statistical difference was found. mRNA expression of NCOA3 was increased in both the groups of increased and unchanged DNA copies. There was a statistical difference of mRNA expression between the groups of increased and unaltered DNA copies ($P < 0.05$). Thus CNVs did play a role of over-expression of the NCOA3 mRNA in CRCs while there were also other mechanisms involved. This is consistent with two recent reports which assessed an over-representation of differentially expressed genes among CNV-mapping transcripts, showing a weak yet significant positive correlation between relative expression level and gene dosage[30,31].

In a small percentage of samples, the recorded relative expression levels were inversely correlated with copy numbers (data not shown here). Such kinds of inverse correlation were also observed by other previous studies[30,31]. The mechanism of this phenomenon is still poorly understood but may be explained by two models. In the first model, a negative correlation between the number of copies and relative expression is explained by immediate early genes, which induced the expression of a repressor directly or indirectly. This expression, by a negative feedback loop, reduces or even abolishes the expression of the *CNV* gene. In the second model, the extra copies of a gene impair, through steric hinderance, their access to a specific transcription factory, where this particular locus should be transcribed.

Taken together, our findings showed that the CNVs of NCOA3 had a correlation with CRC progression as well as gene expression and might have the potential to serve as a prognostic marker for colorectal malignancies. However, the functional consequences of CNVs, the different features of CNVs between colorectal and other gastrointestinal malignancies and the underlying mechanisms of the heterogeneous expression levels, need to be extensively investigated in the future.

COMMENTS

Background

NCOA3 is a member of the p160 nuclear receptor co-activator family and is considered an important oncogene. The chromosome locus of *NCOA3* gene, 20q12, is frequently amplified in colorectal cancers (CRCs) and the functional impact of such regions needs to be extensively investigated in a large size of clinical samples.

Research frontiers

Fluorescence *in situ* hybridization and array-CGH are the regular methods for the detection of genomic imbalances in tumors. However, the obtained data from these approaches are generally informative but not definitive. Recently, studies using quantitative real-time polymerase chain reaction can provide more precise data on the analysis of gene copy number.

Innovations and breakthroughs

To date, there has been a limited number of studies on the copy number variation (CNV) of *NCOA3* gene in tumors. The present study employed a more sensitive method to investigate the copy number variation of the targeted gene in a larger number of CRC samples. Furthermore, the authors elucidated the potential correlation between gene copy number and tumor progression.

Applications

This study indicated the different mechanisms of NCOA3 regulation in CRCs. This may impact the efficacy of NCOA3 targeted therapies.

Terminology

CNVs are alterations of the DNA of a genome that results in the cell having an abnormal number of copies of one or more sections of the DNA. CNVs cor-

respond to relatively large regions of the genome that have been deleted (fewer than the normal number) or duplicated (more than the normal number) on certain chromosomes.

Peer review

The authors investigated the role *NCOA3* gene in CRC. Authors detected copy number gain of NCOA3 in a relatively high percentage of CRC samples and correlated them with Dukes stage of CRC. Moreover, they observed a positive correlation between CNV gain and mRNA levels of *NCOA3* gene. The study is original and potentially interesting.

Abstract

Cowden syndrome is a rare autosomal dominant disorder that is characterized by multiple hamartomas in a variety of tissues and this is associated with germline mutations in the phosphatase and tensin homologue (*PTEN*) gene, which is the tumor suppressor gene located on chromosome 10q23.3. It is characterized by multiple hamartomatous neoplasms of the skin, oral mucosa, gastrointestinal (GI) tract, bones, central nervous system, eyes, and genitourinary tract. Cowden syndrome does not have increased risk of GI malignancy; however, it has an increased risk of breast, thyroid and endometrial cancer development. Here the authors report a rare case of Cowden syndrome incidentally diagnosed from multiple gastric polyposis. A 29-year-old woman presented with multiple gastric polyps. The laboratory results were normal except for mild anemia, with a hemoglobin level of 11.9 g/dL. Esophagogastroduodenoscopy revealed multiple gastric, duodenal polyps and esophageal acanthosis. Colonoscopy revealed possible hamartomatous polyps in the rectum. Under the suspicion of Cowden syndrome, sonography of the thyroid and breasts was carried out, which revealed multiple thyroid masses. Subsequent fine-needle aspiration biopsy revealed the presence of clusters of follicular epithelial cells, and due to the possibility of malignancy, the patient underwent total thyroidectomy. The pathology was reported as invasive follicular carcinoma. A gene study by direct sequencing showed the presence of a *PTEN* mutation (c.633C > A /p.Cys211*).

Key words: Cowden syndrome; Gastric polyposis; Phosphatase and tensin homologue mutation; Esophageal acanthosis; Thyroid cancer

INTRODUCTION

Cowden syndrome is a rare autosomal dominant disorder that is characterized by multiple hamartomas in a

variety of tissues, and is associated with germline mutations in the phosphatase and tensin homologue (*PTEN*) gene, which is a tumor suppressor gene located on chromosome 10q23.3[1,2]. It is characterized by multiple hamartomatous neoplasms of the skin, oral mucosa, gastrointestinal (GI) tract, bones, central nervous system, eyes and genitourinary tract. Cowden syndrome does not have an increased risk of GI malignancy; however, it has an increased risk of developing breast, thyroid and endometrial cancer[3]. Here we present a case of Cowden syndrome which was confirmed through genetic testing of the *PTEN* gene in a 29-year-old female patient with multiple gastric polyps on esophagogastroduodenoscopy (EGD), and thyroid cancer.

CASE REPORT

A 29-year-old woman presented with multiple gastric polyps, which were detected at a private clinic. On presentation, she complained of no symptoms other than dyspepsia; her vital signs were stable and the laboratory results were normal except for mild anemia, with a hemoglobin level of 11.9 g/dL.

Multiple gastric, duodenal polyps and esophageal acanthosis were observed on EGD, and colonoscopy revealed possible hamartomatous polyps in the rectum and oral mucosal papillomatosis (Figure 1). The polyps, observed through EGD and colonoscopy, were shown upon pathologic analysis to be hamartomatous polyps accompanied by mild inflammation and fibrosis (Figure 2). She also had papillomatous papules around her lips and oral mucosal papillomatosis. Because of a high index of suspicion of Cowden syndrome, ultrasonography (USG) of the thyroid and breasts was carried out, which revealed multiple thyroid masses (Figure 3A). Fine-needle aspiration biopsy revealed the presence of clusters of follicular epithelial cells. Although benign lesions were expected on USG, because of the possibility of malignancy, left lobectomy and right enucleation with ipsilateral central node dissection were carried out. Pathology showed the lesions to be invasive follicular carcinoma, and right lobectomy with ipsilateral central node dissection (completion total thyroidectomy) was carried out (Figure 3B).

Genetic analysis of the *PTEN* genes was performed. Genomic DNA was extracted from the patient's whole blood. Polymerase chain reaction direct sequencing with primers targeting all the coding regions and flanking introns was performed. Sequencing analysis of the *PTEN* gene revealed a heterozygous transition of C to A at nucleotide 633 in exon 6 (NM_000314.4 c.633C > A), which is a nonsense mutation, making a stop codon (p.Cys211*) (Figure 4). This mutation has been previously reported and seems to be the cause of the disorder in this patient[4]. During the course of the evaluation of the patient, the authors investigated other members of the patient's family, and a history of endometrial cancer was identified in the patient's mother. However, she refused further evaluation related to Cowden syndrome, and thus further examination could not be carried out.

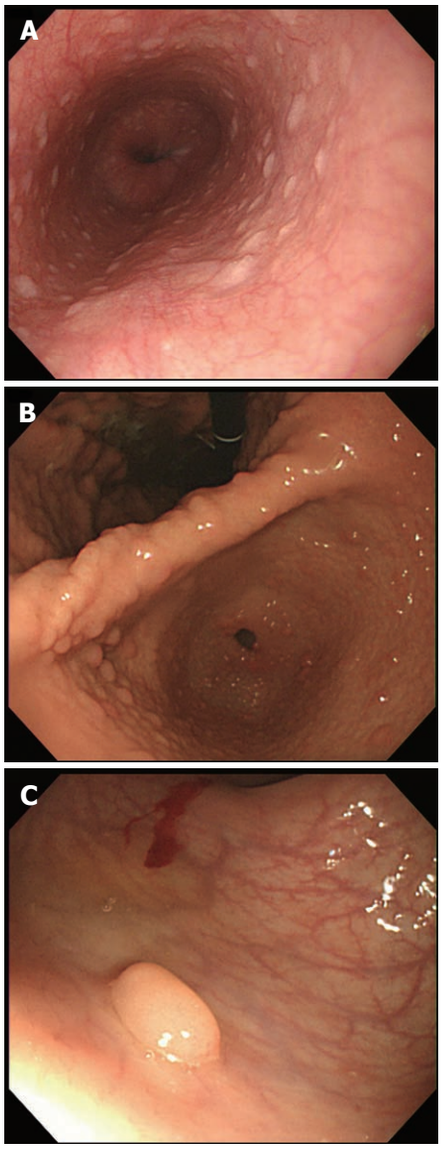

Figure 1 Endoscopic examination. A: Esophageal acanthosis was noted; B: Multiple gastric polyps were noted on entire stomach; C: Several polyps were observed at the rectum.

DISCUSSION

Cowden syndrome was first described by Lloyd and Dennis in 1963 in a case report on a patient named Rachel Cowden[5]. Later, in 1972, Weary *et al*[6] confirmed the existence of this new syndrome through examination of five additional patients with similar clinical findings. The hamartomatous lesions observed in Cowden syndrome can arise in any of the three embryonic germ cell layers and thus it may be ectodermal, mesodermal or endodermal in origin[7]. These lesions can arise in the derivatives of any of the three embryonic germ cell layers[3,7]. The cardinal manifestations of Cowden syndrome include facial trichilemmomas, which are hamartomas

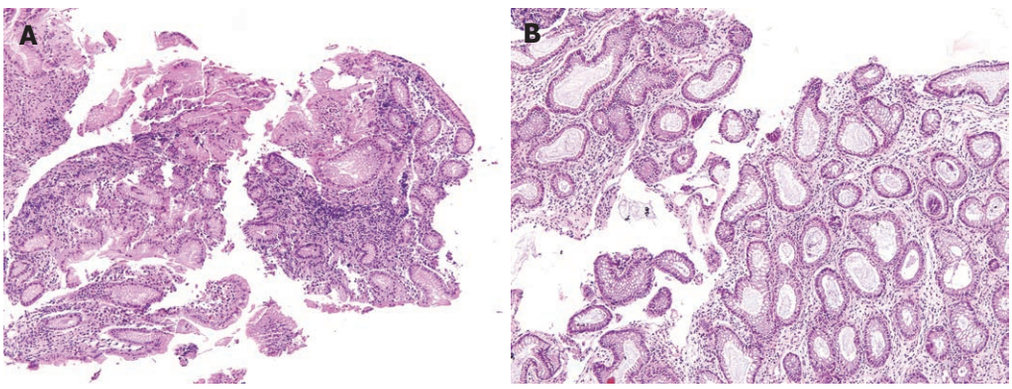

Figure 2 Microscopic examination (hematoxylin and eosin stain, × 100). A: Gastric polyp shows hyperplastic foveolar epithelium; B: Colon polyp exhibits dilated and branched crypts with slightly fibrotic stroma.

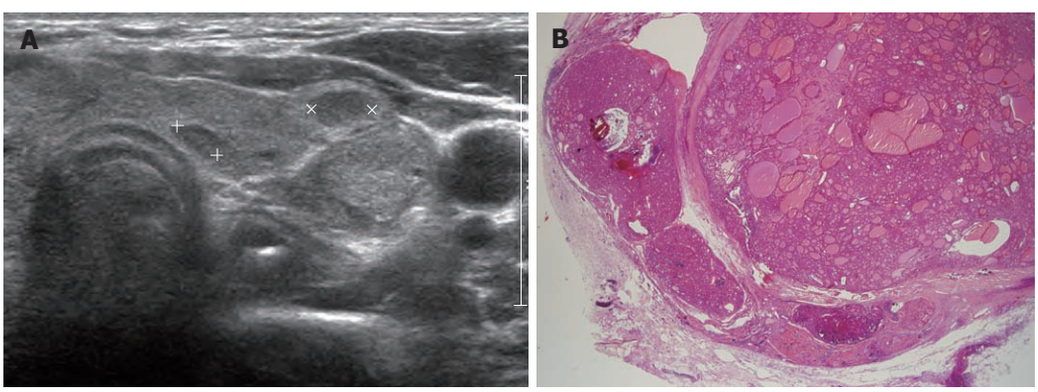

Figure 3 Thyroid masses. A: Multiple thyroid masses in thyroid ultrasonography; B: Postoperative thyroid pathology showed invasive follicular carcinoma (hematoxylin and eosin stain, × 12.5).

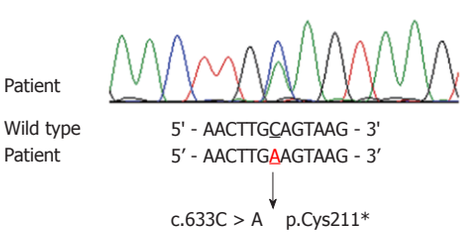

Figure 4 Sequencing result of the phosphatase and tensin homologue mutation. A heterozygous transition of C to A at nucleotide 633 in exon 6 (c.633C > A), making a stop codon (p.Cys211*).

of the infundibulum of the hair follicle, acral keratoses and mucocutaneous papillomatous papules[8-10]. The incidence of Cowden syndrome was estimated to be 1:1 000 000[1]. However, after identification of the relevant gene, the estimate for the prevalence of Cowden syndrome has been increased to between 1 in 200 000 and 1 in 250 000[11,12]. The diagnosis of Cowden syndrome is mainly based on clinical criteria. Nowadays the criteria of the International Cowden Consortium are commonly used for making the diagnosis[7]. The first set of clinical criteria were proposed by Salem *et al*[8], and have subsequently been revised, most recently in the United States by the National Comprehensive Cancer Network, which published the Cowden syndrome testing criteria based on pathognomonic criteria along with major and minor diagnostic criteria. In 1996, the International Cowden Consortium identified germline *PTEN* mutations as being the cause of Cowden syndrome[1,2]. Cowden syndrome is now well recognized as a highly variable, autosomal-dominant hereditary cancer susceptibility syndrome that is characterized by multiple hamartomas and an increased risk of developing malignant transformations.

Cowden syndrome is an autosomal dominant inherited disorder with incomplete penetrance and variable expressivity. Since the first case report of this disorder in Korea in 1997[2], 20 such cases have been reported, but most of these cases involved breast cancer and gynecological cancers, with few involving colon polyps[13]. In this current case study, Cowden syndrome was identified in a patient with multiple gastric polyps, as was reported in 2010, and in addition, thyroid cancer was diagnosed through screening and surgically resecting the tumor, and the *PTEN* mutation was confirmed through genetic testing (c.633C > A/p.Cys211*)[14].

Considering the worldwide prevalence of Cowden syndrome, the number of cases reported in Korea appears to be disproportionately small. Although this difference must be examined in the context of ethnicity, it

may also imply that some cases have gone undetected. However, since Cowden syndrome, as aforementioned, may involve malignancies in several organs, aggressive diagnostic evaluation should be carried out in suspected cases, and screening should be performed in light of the autosomal dominant inheritance of this disorder.

Finally, as was the case with this patient, adequate screening for the organs known to develop malignancies in Cowden syndrome should be carried out in suspected patients. Even when benign lesions are suspected, the potential for malignant lesions must be kept in mind, and further pathologic examination and surgical resection should be aggressively performed without reservation.

In conclusion, this case is a reminder of the importance of early screening for patients suspected of having Cowden syndrome, and female patients should be evaluated for lesions in the breasts and thyroid. Even if benign lesions are suspected, there have been published reports on cases diagnosed with cancer postoperatively; consequently, the possibility of malignancy should always be considered.

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1352 experts in gastroenterology and hepatology from 64 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systemically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensuses and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing
Statistical review is performed after peer review. We invite an expert in Biomedical Statistics from to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Ridit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc*. The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

Conflict-of-interest statement
In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent
Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights
When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www.clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://www.wjgnet.com/1007-9327office. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no less than 256 words) and structured abstracts (no less than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no less than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections.

AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/…"; MATERIALS AND METHODS (no less than 140 words); RESULTS (no less than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 *vs* 3.61 ± 1.67, $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: …*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of *P* values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of *P* values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that...".

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed and http://www.crossref.org/SimpleTextQuery/, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in boldfaced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in boldfaced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*

Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*

Biology: *H. pylori*, *E coli*, *etc.*

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be re-submitted online (http://www.wjgnet.com/1007-9327office/). The author should send the copyright transfer letter, responses to the reviewers, English language Grade B certificate (for non-native speakers of English) and final manuscript checklist to wjg@wjgnet.com.

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

WJG is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1300 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.
