Abstract

Primary sclerosing cholangitis (PSC) is a chronic progressive inflammatory disease affecting the bile ducts, leading to fibrosis and eventually cirrhosis in most patients. Its etiology is unknown and so far no effective medical therapy is available. Liver transplantation (LTX) is the only curative treatment and at present PSC is the main indication for LTX in the Scandinavian countries. Close to half of the PSC patients experience one or more episodes of acute cellular rejection (ACR) following transplantation and approximately 1/5 of the transplanted patients develop recurrent disease in the graft. In addition, some reports indicate that ACR early after LTX for PSC can influence the risk for recurrent disease. For these important post-transplantation entities affecting PSC patients, we have reviewed the current literature on epidemiology, pathogenesis, treatment and the possible influence of rejection on the risk of recurrent disease in the allograft.

Key words: Liver transplantation; Primary sclerosing cholangitis; Rejection; Recurrence

Fosby B, Karlsen TH, Melum E. Recurrence and rejection in liver transplantation for primary sclerosing cholangitis. *World J Gastroenterol* 2012; 18(1): 1-15 Available from: URL: http://www.wjgnet.com/1007-9327/full/v18/i1/1.htm DOI: http://dx.doi.org/10.3748/wjg.v18.i1.1

INTRODUCTION

Primary sclerosing cholangitis (PSC) is a chronic cholestatic liver disease of unknown etiology. Histologically, it is characterized by the existence of intrahepatic and/or extrahepatic concentric, obliterative fibrosis of the biliary ducts. It is a progressive disorder that eventually leads to the development of cirrhosis and hepatic decompensation in the majority of the patients[1,2]. PSC is closely associated with inflammatory bowel disease (IBD), especially ulcerative colitis (UC), which is diagnosed in approximately two-thirds of northern European PSC patients[3-5]. Approximately 2/3 of the PSC patients are male[6] and most affected individuals are less than 40 years of age at the time of diagnosis. There is still no medical treatment with proven efficacy[7] and liver transplantation (LTX) is currently considered as the only curative option for end-stage liver disease due to PSC[8]. Although graft and patient survival following LTX has improved dramatically over the last two decades, and is now close to 80% at 5 years[9], it has become increasingly obvious that the disease can recur in the transplanted liver. In the earliest reports, recurrent primary sclerosing cholangitis (rPSC)

did not seem to influence graft and patient survival[10,11]. On the contrary, more recent data have indicated that a significant proportion of the affected patients will develop graft loss[12], thus influencing the long-term patient survival[13]. Therefore, rPSC represents an important condition in a steadily growing cohort of patients, for which little is known regarding its epidemiology, pathogenesis and treatment.

PSC patients are also believed to be at an increased risk of rejection, and probably up to 50% of the patients will experience one or more episodes of acute cellular rejection (ACR) during the first few weeks following transplantation. The need for increased immunosuppression represents a problem in the clinical management of these patients[14-16]. In addition, the immunological reactions related to rejection could influence the risk of developing rPSC in the graft as more reactive lymphocytes are likely to be present. To date, a possible effect of rejection on the risk of developing recurrent disease is supported by three published reports. This deserves increased attention and will be addressed in this review.

EPIDEMIOLOGY OF PSC AND rPSC

The incidence of PSC varies considerably among different parts of the world. Population-based studies of disease frequency from Norway, Great Britain and United States, indicate a comparable incidence (0.9-1.3/100 000 per year) and prevalence (8.5-13.6/100 000)[17-19] while the numbers from southern Europe and Asia have been reported to be 10-100 times lower[20-22]. PSC is today the number one indication for liver transplantation in the Scandinavian countries, while it in the United States is the fifth most common indication[23]. The first report of suspected PSC recurrence in a liver graft was published in 1988 by Lerut *et al*[24] describing a transplanted PSC patient developing intrahepatic biliary strictures in the absence of allograft rejection within the first year after the transplantation. Since then, numerous reports have corroborated rPSC as a clinical entity[25-28]. The incidence of recurrence varies widely in reports from different centers, probably reflecting variation in diagnostic criteria, study design, and length and type of follow-up. We have in this review identified, after exclusion of cohorts duplicated in previous reports[29-32], a total of 22 publications containing data from original studies on the outcome of LTX for PSC, which analyzed the incidence of recurrent disease (Table 1). For studies based on the same clinical material, the most recent and largest study was included. Of the total number of 1399 patients transplanted for PSC in these studies, 259 (18.5%) developed recurrence (range, 5.7%-59.1% in the individual studies). In the largest series reported so far (n = 230), focusing on the risk factors for rPSC, recurrence occurred in 23.5% of the patients at a median of 4.6 years after LTX[13]. This number is in accordance with the overall percentage for the studies we analyzed.

PATHOGENESIS OF PSC AND rPSC

The etiology and pathogenesis of both PSC and rPSC are currently unknown. Most studies have focused on pre-transplant ("primary") pathogenesis, and lessons from these studies may give insight and provide hypotheses for further research even on the pathogenesis of recurrent disease. The primary disease is characterized by chronic inflammation and progressive fibrotic strictures of the bile ducts[33,34]. By the time the patient is diagnosed with PSC, the changes in the liver architecture are already quite advanced. To determine at this stadium, at a cellular level, which observations that can be of primary importance in the pathogenesis of PSC or just a secondary phenomenon for the ongoing disease is difficult to judge. So far, there has been no unified pathogenetic mechanism for PSC development.

It is important to identify risk factors for recurrence, both in the search for mechanisms involved in the pathogenesis and in improving the management of these patients after transplantation. It might also shed light on the pathogenesis of the primary disease. The pathogenesis of rPSC can be considered multifactorial and influenced by pre- and/or post-operative factors in combination with a genetic predisposition. It is also likely that it is partly related to the pathogenesis of the primary disease. Although it is beyond the scope of this review to go into details regarding PSC pathogenesis, we will briefly mention the theories that have gained the most general acceptance in recent years[7], since these mechanisms may also be involved in recurrent disease. Four hypotheses have been put forward, each is potentially relevant at different stages of the disease process.

Strong evidence indicates that genetic variants play an important role in disease susceptibility and siblings of PSC patients are 9-39 times more likely to develop PSC compared with the general population[35]. Family members of PSC patients are also at increased risk of developing UC, indicating the existence of shared genetic risk factors between these two conditions[7]. Furthermore, unbiased genome-wide association studies have demonstrated shared susceptibility loci between UC and PSC[36,37]. PSC associated variants in the human leukocyte antigen (HLA)-region were first reported almost 30 years ago[38] and have since been verified numerous times. It has so far not been possible to pin-point the exact causative genes in the HLA-region, and it is likely that more than one susceptibility gene exists at this locus. A recent genome-wide association study has also provided strong evidence for involvement of two or more non-HLA genes; in particular *BCL2L11* involved in deletion of autoreactive lymphocytes and *MST1* involved in macrophage activation. Variants at the *MST1* locus are also associated with IBD[39,40]. The role of these genes in recurrent disease is currently unknown but it is plausible that some of these variants together with other factors determine the susceptibility to recurrent disease.

LDLT: Live donor liver transplantation; CCA: Cholangiocarcinoma; ND: Not determined; HLA: Human leukocyte antigen; ACR: Acute cellular rejection; LTX: Liver transplantation; EDC: Extended donor criteria; *n*: No. of patients.

In addition to the genetic associations at loci involved in the immune response, the fact that the majority of PSC patients have IBD, an increased frequency of other autoimmune diseases[41] and the presence of multiple autoantibodies[42] further support a role for autoimmune components in the pathogenesis. The most prevalent autoantibody, which is found in more than 90% of PSC patients, is a special type of perinuclear anti-neutrophil cytoplasmatic antibody (pANCA)[43,44]. The same antibody is observed in UC and in type 1 autoimmune hepatitis[44,45]. On the other hand, the male predominance, the lack of demonstration of a specific PSC autoantigen and the missing response to immunosuppressive treatment are atypical for an autoimmune disease[46,47]. The importance of autoantibodies in both PSC and rPSC is unknown, nevertheless mechanisms related to the immune response are likely candidates for overlapping mechanistic themes between the primary and recurrent disease.

Studies in murine models with intestinal bacterial overgrowth suggest that innate immune responses to the

bacterial products could initiate a PSC-like disease process[48-52], and despite the lack of convincing evidence to support a role of infectious agents in human studies[53-57], the presence of an infectious trigger or infectious modifier effects is still possible.

The strong connection to IBD has lead to the hypothesis that long-lived memory cells (lymphocytes) generated in the gut are responsible for the inflammation of the biliary tree in PSC[58]. This hypothesis is supported by the expression, in both liver and intestine in PSC patients, of vascular adhesion protein-1 (VAP-1)[59] and mucosal adressin cell adhesion molecule (MAdCAM)-1[60]. In contrast, MAdCAM-1 and VAP-1 expression in the physiological state is restricted to the gut and liver, respectively. In PSC and other inflammatory liver diseases, MAdCAM-1 may function to recruit intestinally activated T-lymphocytes to the liver[58,61]. It is an intriguing hypothesis that activated lymphocytes generated in this manner in the recipient can attack the new organ in a similar manner, and contribute to the occurrence of recurrent disease in the transplanted liver.

Several studies have focused on the composition of bile in PSC pathogenesis, this is partly based on the findings of a PSC-like disease in mice that lack proteins involved in the transportation of bile components. These changes closely resemble intrahepatic PSC in humans[62-65]. Interestingly, variants in the *ABCB4* gene (also called *MDR3*) influence the progression of PSC[66]. *ABCB4* variants are also of importance in the pathogenesis in some forms of intrahepatic cholestasis of pregnancy and type 3 progressive familiar intrahepatic cholestasis[67,68]. The influence of these variants, on disease progression, is necessarily dependent upon the genotype of the liver and it remains to be verified if variants in the donor liver potentially affect the progression of rPSC in a similar manner.

RISK FACTORS FOR rPSC

It is also important to identify the risk factors for rPSC because it can reveal essential clues in the pathogenesis of both PSC and rPSC, and potentially influence the management of PSC patients after transplantation. Since the first report on suspected recurrence in the liver graft appeared in 1988[24], potential risk factors have been sought. However, the data on specific risk factors are still limited and non-consistent, serving as an illustration of the complexity of the disease.

Several studies have shown one or more risk factors to be significantly associated with increased risk of rPSC as follows: the presence of HLA-DRB1*08 in either recipient or donor[69], absence of donor HLA DR52[70], recipient-donor gender mismatch[71], male recipient[32], older recipient age[72], younger recipient age[70], intact colon before transplantation[13,32], use of related donor[73,74], use of extended donor criteria (EDC) grafts[13], ACR[69,70], steroid-resistant ACR[69,75], use of OKT3[76], presence of UC after LTX[77], maintenance of steroid therapy for UC for more than 3 mo[77], presence of cholangiocarcinoma (CCA) before transplantation[78] and concurrent cytomegalovirus infection in the recipient[70,73]. Differences between various immunosuppressive regimes used after LTX have been hypothesized to be related to the risk of rPSC, however no such effect has been observed[13,77]. Also, no effect has been found according to post-transplant use of ursodeoxycholic acid (UDCA)[13].

Most of the studies on risk factors for rPSC have appropriately performed multivariate analysis and have found one or more factors to be significantly associated with rPSC. Nevertheless, almost none of the findings are reproduced by other groups. The discrepant results are not so surprising, considering that some of the studies included only a limited number of patients and were thus prone to both false positive and negative findings.

One of the risk factors that seem to be best documented is the link between IBD and recurrent disease in the liver allograft. This was first reported in a study by Vera *et al*[32] in 2002, which demonstrated a dramatic reduction in the risk of recurrence if the colon was removed before or at the time of the transplantation. This study evaluated 152 patients and found male gender and intact colon after transplantation to be the strongest predictors of rPSC. Fifty-six (37%) patients developed rPSC during follow-up, but only 1 (6%) of 17 patients who underwent colectomy before or at the time of LTX had recurrence. The importance of IBD in rPSC was considerably strengthened in a study by Cholongitas *et al*[77] in 2007 evaluating 69 patients receiving LTX for PSC. In this series, none of the PSC patients without UC or patients undergoing pre-LTX total colectomy developed rPSC. On the contrary, recurrence occurred in 7 (27%) of 26 patients with post-LTX UC. In their multivariate regression analysis, UC with the need for maintenance steroids for more than three months was the only risk factor significantly associated with rPSC. In 2009, Alabraba *et al*[13] published the largest study to date on risk factors for rPSC, of note, this study was a re-review and extension of the cohort studied by Vera *et al*[32]. A total of 230 consecutive adult patients who underwent liver transplantation for PSC were included. The protective effect of colectomy before or during LTX on the risk of developing rPSC was confirmed, while colectomy after LTX had no beneficial effect on the incidence of recurrent disease[13]. Taken together, these three studies give a relatively strong indication that absence of inflammation in the intestine, either due to absence of concurrent IBD or colectomy before or during LTX has a protective effect against rPSC[13,32,77]. These findings are consistent with the hypothesis of a common T-cell recruitment theme in UC and PSC, as reviewed by Grant *et al*[61], that may also be relevant in rPSC. Importantly, these data should not be interpreted as an advocation for pre-transplant colectomy that may in theory increase the risks for surgical complications during transplantation, but rather as input to understanding the mechanisms of rPSC development.

On the other side of arguments, Alexander *et al*[69] in a study on 69 patients transplanted for PSC, found no cor-

Table 2 Definition of recurrent primary sclerosing cholangitis following liver transplantation (according to Graziadei *et al*[87])

Diagnosis

relation of rPSC to IBD or the presence of an intact colon after transplantation. Neither did Gautam *et al*[28] in a systematic review from 2006 on rPSC, including only studies with available raw data. To investigate how different immunosuppressive regimens affected the natural course of PSC patients after transplantation, Kugelmas *et al*[76] reviewed a cohort of 71 patients with a 21% recurrence rate. No differences in the frequency of rPSC was observed in the patients with and without IBD, however they did find that OKT3 therapy for steroid-resistant ACR was associated with a higher risk of rPSC.

A few other groups have also independently reported an association between ACR and recurrent disease. In a study of 118 consecutive liver transplantations for PSC, Jeyarajah *et al*[70] found a significantly higher incidence of ACR in recipients that later developed rPSC or chronic rejection. Alexander *et al*[69] found ACR and steroid-resistant ACR to be predictive of an increased risk of rPSC and in a study of 49 patients transplanted for PSC evaluated by magnetic resonance cholangiography (MRC), steroid-resistant ACR was the only significant predictor for rPSC[75].

Up to date, the possible mechanism behind the association between ACR and an increased risk of recurrent disease is unknown. The biliary epithelium is one of the components that is attacked and injured in ACR, and it has been postulated that this can result in an increase in autoimmune epitopes, leading to ductal damage mediated by the immune system[70]. Others have suggested the existence of a common factor predisposing to both ACR and recurrent disease. Especially, the fact that PSC patients seem to be more prone to ACR than most other patient groups, has led to the speculation of a common link between the pathophysiology of rPSC and ACR[69]. One hypothesis is the existence of a hyperactive component of the immune system, and another theory is that the increased risk of both ACR and rPSC results from a defective mechanism in the immune regulation.

What is also worth mentioning is a reported higher rate of recurrence in recipients of grafts from living related donors, with rPSC occurring in 55% and 59% of the transplanted PSC patients[73,74]. Both studies involved a relatively low number of patients, but should urgently inspire further investigations in larger cohorts to confirm important pathogenic mechanisms.

DIAGNOSTIC CHALLENGES IN rPSC

Since the report by Lerut *et al*[24], a number of studies have indicated that biliary complications, especially nonanastomotic biliary strictures occurred more frequently after liver transplantation for PSC than for other end-stage liver diseases[79-85].

As with the diagnosis of PSC in the native liver, rPSC is diagnosed based on the combination of radiological, histological and biochemical findings. The diagnosis is considered problematic because of the difficulty in distinguishing rPSC from other conditions with similar biliary changes. A variety of potential insults to the liver graft can all result in biliary injury and stricturing[28,86]. In 1999, Graziadei *et al*[87] established specific criteria for diagnosing rPSC. This is a useful definition that has been followed since (Table 2). Strict biochemical indices or typical clinical symptoms are frequently absent in patients with rPSC. These patients often present with a cholestatic biochemical profile, and further examinations with cholangiography with either endoscopic retrograde cholangiopancreatography (ERCP), MRC or percutaneous cholangiography (PTC) show characteristic changes of the bile ducts with multifocal strictures and segmental dilatations[88]. However, emphasis must be put on exclusion of other causes that can cause similar radiographic and histological changes. Accordingly, the diagnosis is made in patients with a confirmed diagnosis of PSC prior to transplantation, and by either typical histological features on biopsy or by radiological demonstration of multiple nonanastomotic strictures occurring more than 90 d after LTX (Table 2 and Figure 1).

Cholangiographic findings

As PSC affects both the intra- and extra-hepatic bile ducts, most recipients will have a Roux-en-Y loop after

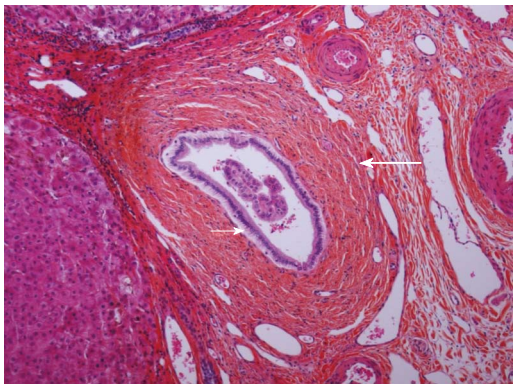

Figure 2 Histological changes demonstrated in a biopsy from a patient with recurrent primary sclerosing cholangitis. Bile duct (small arrow) surrounded by collar of connective tissue with concentric layers of collagen fibers (large arrow) illustrating the typical periductal lamellar fibrosis. (Original magnification, x 100).

LTX[89,90]. This renders access to the bile ducts *via* the endoscopic route technically challenging[91]. Some centers have addressed this challenge using single or double balloon enteroscopy and in this way are able to perform ERCP in patients with complex postsurgical gastrointestinal anatomy[92,93]. It is also worth mentioning that some centers have reported preliminary good results after bile duct reconstruction by direct choledochoduodenostomy[94,95], resulting in an anastomosis that have the advantage of easier access by conventional ERCP. Still, PTC or MRC is most widely used in the post-LTX population[92,96,97]. The typical findings on cholangiography in rPSC involve multifocal nonanastomotic strictures in both intra- and extrahepatic bile ducts, with intervening segments of normal or dilated ducts[86]. Sheng *et al*[85] compared the radiological signs of rPSC with other conditions after LTX. They included 32 patients transplanted for PSC who had developed biliary strictures in the graft and a control group of 32 non-PSC grafts who also had developed biliary strictures. This study demonstrated that intrahepatic strictures were much more common in patients with rPSC and the appearance of the strictures was different, mural irregularity and diverticular outpouchings being more common in rPSC. Even though these changes occurred significantly more frequently in patients with rPSC [15 (47%) patients and 6 (19%) patients, respectively], in the majority of the cases, it was impossible to distinguish rPSC from other conditions based solely on cholangiographic findings.

Several studies have evaluated the diagnostic accuracy of MRC in PSC patients[98-100]. A meta-analysis published last year found that MRC had a sensitivity and specificity of 86% and 94%, respectively in detecting PSC[100]. The latest guidelines by both the European Association for the Study of the Liver (EASL) and the American Association for the Study of Liver Diseases (AASLD) recommend MRC rather than ERCP in patients with suspected PSC[101,102]. Nevertheless, some have raised concerns regarding the sensitivity of MRC when it comes to subtle intrahepatic changes[103] or in detailed characterization of extrahepatic biliary changes[104]. There has been no study so far comparing ERCP or PTC with MRC in rPSC and it is thus not clear whether the sensitivity/specificity figures are similar to those in the primary disease. Importantly, the quality of the MRC imaging is continuously and rapidly evolving and with the noninvasive nature and reduced cost, MRC has become the first choice for most clinicians to evaluate abnormalities of the extra- and intrahepatic bile ducts after LTX.

Histopathological findings

The use of liver biopsies in diagnosing both PSC and rPSC is usually regarded supplementary to cholangiography. This is partly due to the relative lack of specificity and the patchy involvement resulting in a certain degree of sample variability[27]. Histopathologically, the changes in rPSC (Figure 2) are identical to what is described in the native liver with PSC and can be extremely difficult to distinguish from biliary strictures of other causes in allografts, including recurrent biliary infections, ischemia due to arterial problems, chronic rejection, small-for-size syndrome, blood group incompatibility or reperfusion injury[86,105]. The early changes in rPSC are characterized by mild, nonspecific (peri) cholangitis and loss of small bile ducts. As the disease progresses, periductal lamellar edema, increased neutrophil and eosinophil inflammation in the portal tracts, periportal edema and an increased ductular reaction are becoming apparent. Marked deposits of copper with Mallory's hyaline in periportal hepatocytes can often be seen[26]. In medium and small bile ducts, the typical features of fibro-obliterative lesions are observed at this stage together with focal loss of medium and small bile ducts. Lobular changes in the early stages of rPSC include mild nodular regenerative hyperplasia. In the later stages, the characteristic changes of cholestasis, biliary cirrhosis, foam cell clusters and marked deposition of copper in the periportal hepatocytes are observed[105]. In the extrahepatic and large bile ducts of the hilum, ulceration, bile sludge, periductal fibrosis and foam cell accumulation are often seen[105].

The distinction between chronic rejection and rPSC is often challenging, as both conditions can cause loss of bile ducts and a cholestatic pattern of liver enzyme elevation[106]. The diagnosis of both rPSC and chronic rejection should therefore be based on a combination of histopathological, laboratory, radiological and clinical findings. In both conditions, it is important to review prior biopsies combined with the clinical course, and hence for the pathologist to take the clinical history into account. Often there is a history of failed compliance or episodes of severe rejection with unsatisfactory response to treatment in chronic rejection[105].

TREATMENT OF rPSC

Pharmacological therapy

There is currently no proven medical therapy to halt or slow the progression of PSC or rPSC. The major focus

regarding pharmacological treatment in PSC has been a possible effect of UDCA on the disease course. Some of the first studies could document an improvement in both hepatic, biochemical and histological parameters[107-109], but this effect did not significantly benefit transplant-free survival. In the three largest studies[110-112] using UDCA at different doses, no beneficial effect was found on the risk of liver transplantation or death. This conclusion is further supported by a recent meta-analysis by Shi *et al*[113]. In rPSC, no effect has been shown from any specific treatment. Some centers recommend discontinuation of corticosteroid therapy[26] and several centers prescribe UDCA[25]. Patients with coexisting UC may benefit from UDCA in reducing the risk of developing carcinoma in the colon[114], but regarding a possible effect on the progression of rPSC, documentation is so far lacking. The choice of immunosuppression seems to have no influence on the incidence or progression to rPSC[76]. This is, however, a complicated research field and difficult to review in retrospective studies, because detailed information for each patient is needed, including any potential changes in immunosuppressive medication and the disease stage where the change of medication took place. In this study, OKT3 was found associated with a higher risk of recurrence[76], but it is difficult to determine if it is the treatment or the reason for giving the treatment that had a deleterious effect.

Interventional therapy

Three retrospective studies on the effect of endoscopic treatment of dominant strictures in PSC patients have all suggested improved 3- and 5-year survival rates[115-117]. Whether endoscopic treatment influences the progression of rPSC is currently unknown. There have been no published studies with this specific focus in patients with recurrent disease, but based on the effect observed in PSC patients before LTX, further studies of endoscopic treatment modalities should be encouraged.

IMPACT OF rPSC ON GRAFT AND PATIENT SURVIVAL

Earlier studies reported no difference in graft or patient survival among recipients with or without rPSC[10,11]. Long-term data, however, indicate that recurrent disease has a significant impact on graft survival, rate of retransplantations and perhaps also patient survival[12,13]. A study from the United Network for Organ Sharing (UNOS) database on LTX in more than 3000 PSC patients compared with a similar number of patients with primary biliary cirrhosis (PBC), who have a very good outcome after liver transplantation found the retransplantation rate to be significantly higher in PSC patients than in PBC (12.4% *vs* 8.5%). PSC patients had significantly lower graft and patient survival than PBC patients after adjusting for other risk factors and a diagnosis of PSC was an independent predictor for retransplantation[118]. The reduced survival did not become evident until 7 years after the primary operation. In a retrospective study performed by Rowe *et al*[12] analyzing graft loss due to recurrence in 1840 patients undergoing primary LTX between 1982 and 2004, the risk of graft loss from recurrent disease was significantly higher in PSC patients than in PBC patients (hazard ratio 6.0; 95% CI 2.5-14.2). Cholongitas *et al*[77] reported in 2008 a recurrence rate of 13.5% after transplantation for PSC, and 43% of the patients with recurrence required retransplantation. In this study, no difference in survival was seen, but the number was relatively small with a total of 69 patients transplanted for PSC. In the largest series reported to date[13], rPSC developed in 61 grafts in 54 patients, of which, 23 grafts in 20 patients were lost and 13 retransplantations were carried out. After exclusion of all patients surviving less than 6 mo and adjustment for age, there was significantly better survival in patients without rPSC. This is not surprising, considering that retransplantation usually is a much more complicated procedure than the primary operation. A range of reports has shown that retransplantations, independent of the underlying disease, have a significantly worse outcome than the primary procedure[119-124]. In a review of the outcome after retransplantations (for any underlying cause) in 196 patients over a 25-year period at Queen Elisabeth Hospital, the 5- and 10-year survival after retransplantation were 57% and 47%, respectively[119]. The five-year survival after a second retransplantation was 40%. The risk of perioperative death increases significantly from less than 5% in the primary procedure to almost 20% in retransplantations[120,121].

EPIDEMIOLOGY OF REJECTION IN PSC PATIENTS

There is little doubt that the incidence of rejection after liver transplantation has been declining, yet still 20%-40% of the recipients will experience at least one episode of ACR requiring additional immunosuppressive treatment[125]. PSC patients have been suggested to have a higher risk of ACR compared with other liver recipients[10,126,127]. There are nevertheless relatively few published studies with specific focus on the incidence of rejection after LTX according to underlying disease, and the reported incidence varies substantially in different studies. In an attempt to clarify whether this patient population really is at an increased risk of rejection, we identified eleven publications containing specific data on the incidence of acute rejection in patients transplanted for PSC. These studies include a total of 656 patients transplanted for PSC, of whom, 373 (57%) recipients (range, 17%-100% in individual studies) had one or more episodes of acute rejection (Table 3) In the largest study including 150 consecutive transplantations for PSC, at least one episode of acute rejection occurred in 103 (69%) of the recipients, while the incidence in the control group was 59% (261/440)[10]. The reported incidence of ACR after LTX shows a large discrepancy between different centers and time periods. This is the case regarding ACR

Table 3 Studies containing data on the incidence of acute cellular rejection after liver transplantation for primary sclerosing cholangitis

PSC: Primary sclerosing cholangitis; ACR: Acute cellular rejection; ND: Not determined; MMF: Mycophenolate mofetil; ATG: Anti-T-lymphocyte Globulin; CyA: Cyclosporine A; Tac: Tacrolimus; CS: Corticosteroid.

after LTX for PSC, as well as for other underlying diseases. Evolving immunosuppressive strategy clearly has a significant influence. No data regarding immunosuppression trends are currently available from Europe, but based on individual series and data from the UNOS registry, the majority of centers use triple drug therapy, including calcineurin inhibitors (CNIs), corticosteroids and antimetabolite drugs. However, the immunosuppressive regimens vary among centers and the use of induction therapy is inconsistent. Another important factor influencing the reported number of ACR is the use of protocol biopsies or not. An additional confounder is the fact that diagnostic criteria for rejection vary largely in earlier reports. This situation improved considerably with the introduction of the Banff classification in 1997[128]. Based on the current data, and the general difficulties in reporting rejection rates as discussed above, it is hard to state with certainty that transplanted PSC patients carry a higher risk of ACR than other patient groups. There are for instance several publications that show an equally high or even higher incidence of acute rejection in patients transplanted for PBC[84,127,129-131] and autoimmune hepatitis (AIH)[127,130,131]. What seems to be clear though is that there is a tendency that patients with an underlying "autoimmune" condition have an increased risk of ACR after LTX. Whether this is due to a generally more "active" immune system in these patients is unclear. Another interesting and relatively consistent finding in many reports supporting this hypothesis, is that patients treated for non-immunological conditions, like alcoholic liver disease or fulminant hepatic failure from paracetamol intoxication, seem to be at an especially low risk for acute rejection[127,130-133].

PATHOGENESIS AND RISK FACTORS FOR ACR IN PSC PATIENTS

In general, rejection of an allograft can be defined as "an immunologic reaction to the presence of a foreign tissue or organ that has the potential to result in graft dysfunction and failure"[134]. Since the start of experimental solid organ transplantation, it has been obvious that the liver has an immunological advantage over other organs. In several animal transplant models, spontaneous tolerance was achieved after LTX, while skin, heart or kidney transplants were aggressively rejected in the same models[135-139]. Tolerance following liver transplantation is rare in humans, however ACR is usually easily reversed.

Findings in studies on factors that increase the risk of acute rejection after LTX include: use of living donor[140], lack of induction treatment with anti-IL-2 receptor antibody[141,142], severe preservation injury[143], younger age of the recipient[130], lack of renal failure[130], fewer HLA-DR matches[130,144], cold ischemia time greater than 15 h[130] and being transplanted for PSC[10,30,70,87], PBC[129], autoimmune hepatitis[127] or HCV infection[127]. In addition, a meta-analysis of cytokine gene polymorphisms and acute liver graft rejection suggests a role for genetic variation at the *IL-10* locus[145].

For PSC, both disease recurrence and the presumed increased incidence of ACR have been speculated to be caused by a continuum of ongoing immunological attack against the bile ducts and the liver[10]. Whether different immune mechanisms are involved in the rejection process in PSC patients *vs* patients with other underlying disease is not known. To date, no study has focused on characterizing histopathological differences in the inflammatory infiltrates of ACR according to the underlying disease. The typical histological features described in ACR in the liver allograft (Figure 3) are similar to that in other organs, the dominant cell types being CD4+ and CD8+ T cells and macrophages[128,146]. B-cells, neutrophils and eosinophils have been observed in varying proportions, and scattered cells positive for the natural killer (NK) marker CD56+ have been described[147]. NK cells have emerged as a particular focus of interest in the transplant setting because of their ability to recognize allogenic major histo-compatibility complex (MHC) antigens and their potent cytolytic

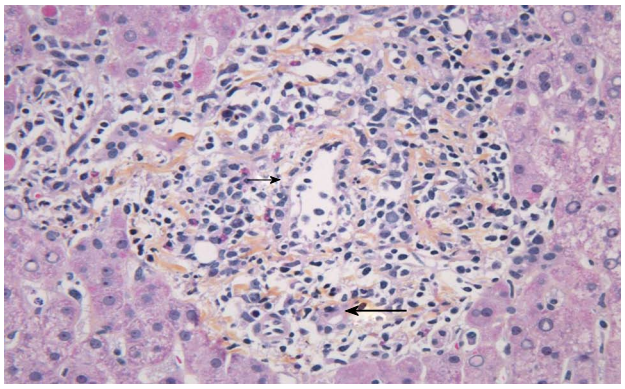

Figure 3 Histological changes seen in a biopsy with acute cellular rejection in a patient with primary sclerosing cholangitis. Portal tract with mixed inflammatory infiltrate containing blastic lymphocytes and eosinophils. Subendothelial localization of the inflammatory cells in a portal vein branch (small arrow). Inflammation of small bile duct (large arrow). (Original magnification, x 400).

activity[148]. They possess a variety of inhibitory and activating receptors, such as killer immunoglobulin-like receptors (KIRs), which recognize MHC class I molecules, and based on the "missing self" hypothesis, kill target cells that display reduced levels of MHC class I antigens. Interestingly, it has been shown that particular combinations of KIRs and HLA class I ligands that reduce NK cell inhibition increase the susceptibility to autoimmune diseases[149], and that certain genetic variants of ligands for NK cell receptors might contribute to the risk of PSC[150,151]. An increase in NK cells in the liver has been observed in PSC as compared with other liver diseases[152,153]. The effect of NK epitope mismatching on acute rejection after liver transplantation is uncertain. The few studies conducted so far have given conflicting results[154-156]. A recent paper by Hanvesakul *et al*[155] on 416 liver transplant recipients showed a striking influence of donor HLA-C genotype on graft survival and chronic rejection, but no effect on ACR. To what extent such phenomena may be restricted to patients with PSC has not been determined.

As previously addressed, there is conflicting data about whether the presence of IBD has an adverse impact on the risk of recurrence of PSC after the transplantation. Some reports also suggest that PSC patients with concomitant IBD may be at increased risk of ACR. In a study by Narumi *et al*[30], the incidence of moderate or severe rejection in patients with IBD was 70% *vs* 36% in PSC patients without IBD, and 37 % in a matched control group. This was further supported by a study by Miki *et al*[3] in which 87% of the patients with IBD developed ACR while only 41% of the patients without IBD developed ACR. Consistent with these studies, Gradziadei *et al*[10] also reported a significantly increased risk of ACR in patients with IBD in their large cohort of 150 transplanted PSC patients. On the other hand, in the study by Jeyarajah *et al*[70], including 118 transplantations for PSC, no association between concomitant IBD and ACR was found.

IMPORTANCE OF ACR AFTER LIVER TRANSPLANTATION FOR PSC

As opposed to kidney transplantation[157-159], there is no convincing data indicating that ACR in the early phase after liver transplantation (for any underlying condition) affects long-term graft or patient survival. After the introduction of more potent and specific immunosuppression, it is easier to prevent episodes of ACR and a major challenge in LTX today is the morbidity and mortality related to side effects of long- term use of immunosuppressive medication[157-160]. In animal models with spontaneous tolerance, the liver allograft undergoes an initial and transient acute rejection-like reaction[161-163], that could indicate that the histopathological diagnosis of ACR does not necessarily always require treatment, but as some argue that it might be a first step on the way to a degree of spontaneous tolerance.

Data regarding the incidence and significance of late acute rejection (LAR) are scarce, but an interpretation might indicate a risk of more serious consequences than with early ACR. LAR has been variably defined in different reports ranging from one, three, six or twelve months after the transplantation. The incidence of LAR after liver transplantation in general varies from 7% to 23% in the published reports[126,164-168]. In a study of more than 1600 LTX patients, where LAR was defined as ACR occurring later than six months after LTX, the incidence was 19%[126]. Interestingly, the study also showed that patients with a primary diagnosis of autoimmune hepatitis, PBC and PSC had the highest incidence of LAR and that patient and graft survival was significantly lower in the LAR group. Another study also reported an increased risk of LAR in PSC patients but did not find any negative effect on patient survival[168].

ACR represents an immunological insult towards the graft and could influence the risk of developing rPSC since more reactive lymphocytes are likely to be present. As previously mentioned, ACR or steroid resistant ACR were found to have a significant effect on the risk of developing recurrent disease[69,70,75,76]. In contrast, most studies evaluating risk factors for rPSC have not found an association with ACR. There is little data supporting the conclusion that mild or moderate ACR, affecting approximately 50% of the transplanted PSC patients, has any effect on the risk of recurrent disease. The question is if severe rejection is associated with recurrence or not. As of today, there is not enough data to answer this question with certainty.

CONCLUSION

Rejection and recurrence of the primary disease in the liver allograft remain as two major challenges in the clinical care of post-transplant PSC patients. Even as there are huge discrepancies in the reported incidence of

rPSC, it is at least present in approximately 1/5 of the transplanted patients. The pathogenesis of rPSC remains enigmatic and is believed to have similar features as the primary disease. There is so far an underutilized potential in studying the pathogenesis of the primary disease in parallel with recurrent disease, an approach that potentially can uncover shared mechanisms relevant to both conditions. Several studies have identified one or more risk factors for rPSC, but few have been confirmed from one study to another. The most convincing data seem to be the link with concurrent IBD and a protective effect on the development of rPSC of colectomy before or at the time of transplantation[13,32,77]. There is, importantly, no reason to advocate colectomy prior to liver transplantation for PSC on this basis. There seems also to be an increased incidence of acute rejection in PSC patients with a potential relevance to the development of recurrence. Rejection and recurrence might therefore represent a continuum of immunological affection of the graft in transplanted PSC patients.

Abstract

Liver metastases synchronously or metachronously occur in approximately 50% of colorectal cancer patients. Multimodality comprehensive treatment is the best therapeutic strategy for these patients. However, the optimal pattern of multimodality therapy is still controversial, and it raises several significant concerns. Liver resection is the most important treatment for colorectal liver metastases. The definition of resectability has shifted to focus on the completion of R0 resection and normal liver function maintenance. The role of neoadjuvant and adjuvant chemotherapy still needs to be clarified. The management of either progression or complete remission during neoadjuvant chemotherapy is challenging. The optimal sequencing of surgery and chemotherapy in synchronous colorectal liver metastases patients is still unclear. Conversional chemotherapy, portal vein embolization, two-stage resection, and tumor ablation are effective approaches to improve resectability for initially unresectable patients. Several technical issues and concerns related to these methods need to be further explored. For patients with definitely unresectable liver disease, the necessity of resecting the primary tumor is still debatable, and evaluating and predicting the efficacy of targeted therapy deserve further investigation. This review discusses different patterns and important concerns of multidisciplinary treatment of colorectal liver metastases.

Key words: Colorectal cancer; Liver metastases; Multimodality therapy

INTRODUCTION

Colorectal cancer is one of the most commonly diagnosed cancers, and it is ranked the third most common globally and fourth in China. Approximately 40% of colorectal cancer patients die of cancer recurrence and metastasis. The liver is the most frequent metastatic site of colorectal cancer. Approximately 15%-25% of colorectal cancer patients have synchronous liver metastases[1-3], and 20%-25% of patients with colorectal cancer develop metachronous hepatic metastases[4-7].

In recent decades, the 5-year overall survival (OS) after curative liver resection of colorectal liver metastases (CRLM) has increased to 35%-58%[8-10]. This improvement is largely due to advancements in CRLM multimodality treatment. Generally, CRLM can be categorized into three subsets: clearly resectable, potentially resectable, or definitely unresectable. This review discusses patterns and key issues of multidisciplinary treatment of these three different CRLM subsets with a focus on the

interactive influence of different therapeutic approaches.

CLEARLY RESECTABLE COLORECTAL LIVER METASTASES

Shifting definition of CRLM resectability

Liver lesions numbering more than three, an estimated resection margin < 1 cm, the presence of extrahepatic disease, or no expected sufficient remnant liver volume used to be deemed as contraindications for CRLM liver resection. According to this definition, only 10%-20% of CRLM patients were resectable. However, this definition has changed in recent years. The report by Malik *et al*[11] has indicated that patients with 4-7 or > 7 CRLMs still had a favorable outcome after liver resection (5-year OS 34.8% and 24.2%, respectively). In the past, it was widely accepted that at least a 1-cm resection margin must be achieved for CRLM resection. However, several studies have indicated that the actual clearance margin did not affect survival as long as R0 resection could be achieved[5,12]. The presence of extrahepatic metastases is also no longer considered an absolute contraindication for liver resection. Some cancer centers have reported that the 5-year OS after combined resection of lung and liver metastases is approximately 30%[13,14]. The CRLM resectability criteria have shifted to focus on whether R0 resection for all tumors can be achieved and if a sufficient volume of residual liver can be preserved. The requirement for residual liver volume can be different for patients receiving intensive chemotherapy. Although at least 20% of total liver volume should be preserved for a healthy liver, it is recommended that at least 30%-60% should be preserved for livers impaired by chemotherapy-associated steatosis or hepatitis[15].

Advantages and disadvantages of perioperative chemotherapy

The combination of surgery and chemotherapy is the most effective multidisciplinary therapeutic paradigm for CRLM with a curative intent. There are two patterns of perioperative chemotherapy for resectable CRLM: preoperative and postoperative chemotherapy. Postoperative chemotherapy is also known as adjuvant chemotherapy, although it is still debatable whether the alternative term adjuvant therapy should be used instead. Postoperative chemotherapy has become a common practice and is intended to reduce the high risk of recurrence after resection of metastases. Preoperative chemotherapy is also called neoadjuvant chemotherapy in the setting of resectable liver metastases. The role of preoperative chemotherapy is more controversial than postoperative chemotherapy because it can give rise to major concerns. Generally, the paradigm of preoperative chemotherapy plus liver resection plus postoperative chemotherapy has become the most prevalent treatment modality in real practice.

Survival benefit of perioperative chemotherapy: Adjuvant chemotherapy for stage Ⅲ colorectal cancer patients has been widely accepted based on solid evidence for survival benefit. Although postoperative chemotherapy after liver metastases resection is also accepted by many oncologists, there have been few prospective randomized clinical studies that have investigated the adjuvant chemotherapy survival benefit after liver resection, and the sample size of these studies has been limited due to difficult accrual. In the Fédération Francophone de la Cancérologie Digestive (FFCD) ACHBTH AURC 9002 clinical trial, CRLM patients receiving adjuvant chemotherapy of 5-fluorouracil (5-FU) and leucovorin (LV) after R0 liver resection had a significantly better 5-year disease-free survival (DFS) compared with the observation group (33.5% *vs* 26.7%, P = 0.028). There was also a trend toward better OS in the adjuvant chemotherapy group, although this was not statistically significant (51.1% *vs* 41.1%, P = 0.13)[16]. This study was prematurely stopped due to slow accrual. A pooled data analysis combined with another study (i.e., European Organisation for Research and Treatment of Cancer/ National Cancer Institute of Canada Clinical Trials Group/ Interdisciplinary Group for Cancer Care Evaluation trial), which had a similar design and stopped ahead of schedule for the same reason, was performed but also could not demonstrate a statistically significant improvement in OS (P = 0.095)[17].

Although the most fascinating benefit of preoperative chemotherapy is the conversion of unresectability to resectability, the role of neoadjuvant chemotherapy in patients with initially resectable CRLM is still controversial. The most important concern about neoadjuvant chemotherapy is whether it can bring about a survival benefit. The only published randomized prospective clinical trial to investigate the role of neoadjuvant chemotherapy in CRLM patients, EORTC 40983[18], indicated that patients with initially resectable CRLM undergoing liver resection plus six cycles of preoperative FOLFOX4 and six cycles of postoperative FOLFOX4 chemotherapy had a better 3-year progression-free survival (PFS) compared to those receiving liver resection alone. However, there was a significant defect in this study: patients in the control group did not undergo chemotherapy after hepatic resection. Therefore, it is difficult to determine whether the PFS improvement is brought about by preoperative chemotherapy, postoperative chemotherapy or both. To investigate the exact role of neoadjuvant chemotherapy, we still need to wait for the results of ongoing clinical studies to compare survival directly in patients undergoing postoperative chemotherapy alone with those undergoing both preoperative and postoperative chemotherapy.

Management of disappearing CRLM: A potential drawback of neoadjuvant chemotherapy in resectable CRLM patients is missing the optimal timing of liver resection because of complete response of liver tumors during chemotherapy. Approximately 4% of patients achieved a radiographic complete response (CR) to chemotherapy, and 9% had a pathological CR[19,20]. Radiographic CR does

not always mean true hepatic metastases remission. Viable cancer cells can be pathologically found in 80% (12/15) of patients with a radiographic CR and undergoing resection according to the prior sites[21]. If these radiographically disappearing liver metastases are kept in place without resection, 41%-75% will have recurrence *in situ*[21,22]. Nevertheless, it is not always easy to perform liver resection according to the previous site of disappearing liver metastases. To avoid such an intractable condition, it is recommended that the evaluation of liver lesions be repeated every 2 mo during preoperative chemotherapy[7,23-25].

Resection of CRLM progressing during neoadjuvant chemotherapy: A second potential risk of neoadjuvant chemotherapy is disease progression. Liver tumor progression may add to the difficulty of liver resection and even deprive patients of the opportunity for hepatic resection. The EORTC 40983 clinical study[18] reported that 7% of initially resectable CRLM patients had progressive disease (PD) during neoadjuvant chemotherapy, and 4% did not complete liver resection due to prior liver disease progression or the presence of new extrahepatic metastases. Another issue concerning liver metastases progression is whether they should be resected even if it is possible. Adam *et al*[26] have suggested that liver PD during chemotherapy indicates poor prognosis after resection and should be considered as a contraindication to liver resection. They reported a dismal 5-year OS (8%) and DFS (3%) after liver resection in patients with tumor progression during neoadjuvant chemotherapy. However, other studies have indicated that the response to neoadjuvant chemotherapy has no prognostic value. Reports from Neumann *et al*[27] and Gallagher *et al*[28] have indicated no difference in survival after liver resection among three groups of CRLM patients with PD, stable disease (SD) or objective response to neoadjuvant chemotherapy.

Impact of chemotherapy-induced hepatotoxicity on the outcome of hepatic resection: Another important concern related to neoadjuvant chemotherapy is whether the hepatotoxicity caused by preoperative chemotherapy increases the perioperative morbidity and mortality of liver surgery. There are two types of chemotherapy-associated hepatotoxicity: non-alcoholic fatty liver disease (i.e., macrovesicular steatosis/steatohepatitis) and vascular sinusoidal obstruction. All three commonly used chemotherapeutic agents for colorectal cancer, 5-FU, oxaliplatin and irinotecan, can induce steatosis with an incidence rate of 30%-40%[29,30]. Steatohepatitis is less common in patients with chemotherapy. Approximately 3.6%-8%[7,31] of patients have chemotherapy-associated steatohepatitis, which is relatively more common in patients receiving irinotecan as compared with those receiving 5-FU[32]. Vascular sinusoidal obstruction is associated with the use of oxaliplatin, and is present in 10%-52% of patients undergoing preoperative oxaliplatin therapy[7,25,33].

The impact of chemotherapy induced hepatic toxicity on the short-term outcome of patients receiving liver resection is still uncertain. A slightly increased morbidity was noted in patients undergoing six cycles of preoperative FOLFOX4 chemotherapy as compared with those without preoperative chemotherapy in the EORTC 40983 study[18]. Nevertheless, there was no difference in the perioperative mortality between these two groups. The study of Kooby *et al*[34] has demonstrated an increase in infection-related complications associated with moderate to severe steatosis in patients undergoing hepatic resection after chemotherapy, but no association with major surgical complications or mortality for preoperative chemotherapy was shown. However, Vauthey *et al*[25] have reported that, after the use of irinotecan, patients with steatohepatitis had a significantly higher 90-d postoperative mortality compared with those without steatohepatitis (15% *vs* 2%, $P = 0.001$). Therefore, it is recommended that irinotecan should be used cautiously in patients with known steatosis or steatohepatitis or those with a high risk for steatosis, such as those with obesity, hypertension or diabetes.

Management of resectable synchronous CRLM

Optimal sequencing of colorectal surgery, liver resection and perioperative chemotherapy: Approximately 15%-25% of patients have synchronous liver metastases at the diagnosis of colorectal cancer[1-3]. The optimal timing of primary tumor and liver metastases resection in synchronous resectable CRLM patients is still controversial. There are three approaches for the sequence of surgical treatment for primary tumor and liver disease: (1) simultaneous resection of primary cancer and liver metastases; (2) resection of primary colorectal tumor first followed by liver resection; and (3) hepatectomy first followed by primary cancer resection. The clinical decision usually depends on many factors, including surgical exposure, colectomy and hepatectomy complexity, surgeon expertise and patient comorbidity[35].

Based on the observation of the possible increased morbidity and mortality using a combination of hepatectomy and colectomy[36-39], a staged approach (i.e., liver resection following primary tumor resection and optional chemotherapy) was widely performed in the past. However, simultaneous resection of the primary cancer and the liver metastases has been increasingly adopted in recent years due to more recent reports that perioperative morbidity and mortality of simultaneous resection are comparable to that of staged resection[40-42]. No significant difference in 5-year survival was found between these two groups in a systemic analysis[43]. However, Reddy *et al*[35] have reported that patients undergoing simultaneous major hepatectomy (i.e., resection of three or more liver segments) had a significantly higher mortality (8.3% *vs* 1.4%) and severe morbidity (36.1% *vs* 17.6%) than those receiving staged resection. Therefore, simultaneous major hepatectomy is not highly recommended at present due to the potentially increased risk of severe complications. A new paradigm has been proposed more recently that is called the "liver-first" strategy[44], and includes first, liver resection, with or without preoperative

chemotherapy, followed by optional chemotherapy after hepatectomy, and finally, primary tumor resection. This approach may be suitable for borderline resectable liver metastases, which may lose the time frame of resection if delayed. Mentha *et al*[44] have reported 20 CRLM patients undergoing such a sequential resection with a resection rate of 80% and 4-year OS of 56%. However, there are some potential defects in the design of this approach. For patients with obstructive symptoms caused by the primary tumor, primary-tumor-directed treatment is more urgent and should be performed first. Another potential disadvantage of this approach is that the primary tumor may progress and require emergency surgery during this process. A decision-making analysis has demonstrated that it is least probable to complete all intended sequential treatment for the liver-first approach among the above three treatment sequences[45].

The role of minimally invasive surgery: It is difficult to perform a one-stage resection of primary and liver disease for rectal cancer liver metastases due to surgical exposure and lengthy incisions. In such a condition, laparoscopic surgery, particularly robot-assisted laparoscopic surgery, is advantageous to perform a simultaneous resection of liver metastases and rectal cancer. This type of surgery has been reported to be safe and feasible in a pilot study by Patriti *et al*[46]. An important concern about the laparoscopic hepatic resection is the oncologic outcome. It has been reported that the laparoscopic approach had a positive resection margin rate (5.6%) and 5-year OS (50%); comparable with open surgery for CRLMs. In a French study[47] comparing CRLM patients undergoing laparoscopic hepatic resection or open resection, the 5-year OS and DFS were similar in these two groups, whereas the laparoscopic surgery group even had a lower rate of positive resection margin than the open surgery group (13% *vs* 28%, $P = 0.04$).

UNRESECTABLE COLORECTAL LIVER METASTASES WITH POTENTIAL CONVERTIBILITY

Some CRLM patients are initially unresectable but have the potential to become resectable through conversion therapeutic strategies including chemotherapy, embolization, two-staged operation or the combination of ablation therapy.

Conversion chemotherapy

It is estimated that 80%-90% of CRLMs are considered unresectable at diagnosis. Due to the development of new chemotherapy agents and targeted therapeutic agents, chemotherapy can convert a considerable portion of initially unresectable CRLM into resectable disease, which is called conversion chemotherapy[7,48-50]. It was first reported in 1996 by Bismuth *et al*[49] that preoperative chemotherapy, using oxaliplatin plus 5-FU/LV, enabled 16% (53/330) of initially unresectable CRLM patients to gain the chance of undergoing liver resection with a 5-year OS of 40%. In 2001, Adam *et al*[23] reported that 13.6% (95/701) of initially unresectable CRLM patients underwent liver metastases resection after systemic chemotherapy and achieved a 5-year OS of 34%. Intensified chemotherapy such as FOLFOXIRI (i.e., oxaliplatin, 5-FU/LV and irinotecan) has been shown to have high response and conversion rates (19%)[50]; however, it has not been generally recommended thus far due to its considerable toxicity. In recent years, the addition of targeted agents such as cetuximab to chemotherapy has been shown to further improve the conversion rate to 30%-40%[51]. In the CELIM study[51], 106 patients with initially unresectable CRLM underwent cetuximab plus FOLFOX6 or cetuximab plus FOLFIRI and achieved an objective response rate of 68% and 57%, a liver resection rate of 40% and 38%, and a R0 liver resection rate of 38% and 30%, respectively.

Portal vein embolization and two-stage operation

Preserving at least 20% of future liver remnant is a major obstacle when performing an extended hemihepatectomy for extensive liver metastases. In this situation, Portal vein embolization (PVE) can be helpful to induce hypertrophy of the contralateral liver to fulfill the minimal liver volume requirement[52]. Generally, PVE is usually used before extended right hepatectomy and is seldom used for extended left hepatectomy because the right posterior sector generally provides > 30% of the liver volume. Even after preoperative chemotherapy or PVE, some patients cannot become eligible for complete CRLM resection through a single hepatectomy. PVE combined with a two-stage resection may be helpful in such circumstances. In 2000, Adam *et al*[53] first proposed the two-stage resection strategy when they reported the initial results from 13 patients undergoing two-stage hepatectomy with a 3-year survival rate of 35%. An updated result of a 5-year OS of 42% in 41 patients receiving two-staged resection was reported in 2008[54]. However, > 30% (18/59) of patients could not complete the second hepatectomy, mostly because of disease progression ($n = 17$). Additionally, the second hepatectomy has a significant higher postoperative mortality (7%) and morbidity (59%) than the first hepatectomy (0% and 20%, respectively).

Ablation therapy

The most commonly used approach for ablation therapy is radiofrequency ablation (RFA). Most previous studies have indicated that RFA is inferior to liver resection for CRLM with a high local recurrence rate[55]. However, for patients who cannot undergo liver resection because of extensive liver metastases and inadequate remnant liver volume, RFA can play an important role when combined with liver resection. RFA is generally recommended for CRLM less than 3 cm[56-64]. The local recurrence rate after RFA increases with tumor size in liver lesions > 3 cm[65]. Several studies have reported a significantly higher local

failure rate after ablation for tumors > 5 cm when compared to those 3cm-5 cm[64,66].

There are three approaches for RFA, including percutaneous, open and laparoscopic. Ablation through the open approach seems to be superior to the percutaneous or laparoscopic methods in terms of local failure rate[57,67,68]. However, the reported local recurrence rate of each approach has actually varied and overlapped each other in a range of 6%-40% in different studies[69-77].

DEFINITELY UNRESECTABLE CRLMs

Necessity of primary tumor resection

For patients with incurable metastatic colorectal cancer who have symptoms related to intestinal obstruction, perforation or intractable bleeding, palliative primary tumor resection is generally required and advocated. However, for asymptomatic patients with unresectable metastases, the value of primary tumor resection is still questionable. Early studies have indicated that primary tumor resection may have potential benefits in preventing tumor-related symptoms such as obstruction, which may require emergency operations with a high risk of surgical mortality[78-80]. However, this opinion may become outdated with the application of new efficient chemotherapy agents that have the ability to control intestinal symptoms well. Therefore, the US National Comprehensive Cancer Network guidelines recommend that colon resection should be considered only for impending obstruction risk or intractable bleeding. It is estimated that only 20%-30% of metastatic colorectal cancer patients are eligible for curative resection. Nevertheless, data from the US Surveillance, Epidemiology, and End Results (SEER) database have demonstrated that 66% of stage IV colorectal cancer patients received primary tumor resection[81]. In another study based on 9000 elderly metastatic colorectal cancer patients, 72% underwent primary tumor resection, whereas only 3.9% received metastasectomy and 20% had symptoms of bowel obstruction, perforation or bleeding[82]. It suggests that a considerable portion of incurable colorectal cancer patients receive intestinal resection without a clear and reasonable indication. The Memorial Sloan-Kettering Cancer Center reported 233 metastatic colorectal cancer patients receiving chemotherapy with the primary tumor left in place[83]. Only 7% of the patients required palliative primary tumor resection during the disease course. Thus, the authors recommended chemotherapy without prophylactic primary tumor resection as a standard management of metastatic colorectal cancer without obstruction or bleeding symptoms.

Targeted therapy in combination with chemotherapy

The survival benefit of adding targeted therapeutic agents such as bevacizumab, cetuximab and panitumumab to traditional chemotherapy in patients with unresectable metastatic colorectal cancer has been validated by several randomized clinical trials. The BEAT study[84] collected 1965 metastatic colorectal cancer patients undergoing bevacizumab combined with different types of chemotherapy as the first-line therapy, and demonstrated that the PFS in patients receiving bevacizumab plus FOLFIRI, FOLOFOX or Xelox was > 10 mo and the OS approached or exceeded 24 mo. This study indicated that bevacizumab-based combination chemotherapy is efficient in metastatic colorectal cancer. The PFS and OS were 8.6 and 18.0 mo, respectively, in patients receiving bevacizumab plus 5-FU, which is also comparable to a regimen including 5-FU plus oxaliplatin or 5-FU plus irinotecan.

The efficacy of cetuximab greatly depends on the status of the *KRAS* gene. The CRYSTAL study[85], which compared cetuximab plus FOLFIRI with FOLFIRI alone in the initial treatment of metastatic colorectal cancer patients, indicated that cetuximab improved the response rate (57.3% *vs* 39.7%, $P < 0.0001$), PFS (9.9 mo *vs* 8.4 mo, $P = 0.0012$) and OS (23.5 mo *vs* 20.0 mo, $P = 0.0094$) significantly in patients with wild-type KRAS. However, in a population subset with mutant KRAS, there was no significant difference in the response rate, PFS or OS between the two groups. The OPUS study[86] even exhibited a worse response rate and PFS for the cetuximab plus FOLFOX4 group as compared with FOLFOX4 group in patients with mutant *KRAS*. The status of the *BRAF* gene is another efficient predictor of cetuximab efficacy. Di Nicolantonio *et al*[87] have reported that the *BRAF* gene mutation rate in patients with wild-type *KRAS* was approximately 14% (11/79). None of the *BRAF* mutant patients responded to cetuximab or panitumumab or cetuximab plus chemotherapy. The PFS of patients with wild-type *BRAF* was better than their counterparts ($P < 0.001$). A considerable defect in the *BRAF* gene as a predictor of treatment response is that the mutation rate is low. The incidence rate of mutant *BRAF* is only 6.4%-14% in patients with wild-type *KRAS*, and no *BRAF* mutation has been reported in those with *KRAS* mutations.

In the second or third-line treatment settings, the addition of cetuximab or bevacizumab to chemotherapy, or a single treatment with cetuximab, has also been proven to be effective[88,89]. In a phase Ⅲ clinical trial[90], 463 metastatic colorectal cancer patients received either panitumumab plus best supportive care (BSC) or BSC alone after chemotherapy failure. Patients with panitumumab plus BSC had an objective response rate of 8% and a significantly better median PFS (96 d *vs* 60 d) than those who received BSC alone. In another clinical trial[91], the combination of panitumumab with FOLFIRI as a second treatment for metastatic colorectal cancer patients improved the PFS (5.9 mo *vs* 3.9 mo, $P = 0.004$) and objective response rate (35% *vs* 10%, $P < 0.001$) in patients with wild-type *KRAS* compared to the regimen of FOLFIRI alone.

CONCLUSION

Multidisciplinary treatment has become the standard practice for CRLM management. Nevertheless, the optimal paradigm of multimodality treatment still needs to be further investigated. As the most effective treatment

method, surgical CRLM resection has been rendered an expanded indication in recent years. CRLM patients can be categorized into three subtypes: clearly initially resectable, potentially resectable, or definitely unresectable. For patients with initially resectable CRLM, the survival benefit of neoadjuvant chemotherapy is still unclear. The management of CRLM disappearing or progressing during neoadjuvant chemotherapy is challenging and controversial. The influence of chemotherapy-related toxicity on the outcome of liver resection needs to be further clarified. The optimal sequencing of primary tumor resection and liver lesions and perioperative chemotherapy deserves further investigation in patients with resectable synchronous CRLM. For patients who are initially unresectable but potentially convertible, chemotherapy, PVE, two-staged operation and ablation therapy are effective methods to convert unresectability into resectability. How to utilize these methods in a reasonable and better way needs to be further explored. For definitely unresectable CRLMs, it is still being debated whether the primary tumor should be resected. Targeted therapy, in addition to traditional chemotherapy, has been shown to improve the survival of unresectable CRLM patients. How to accurately predict the tumor response to targeted therapy is an important issue that should be further investigated in consideration of its high cost. A better understanding of these issues will greatly improve the effect of multidisciplinary treatment of CRLM patients.

Abstract

Surgical resection of liver metastases of colorectal cancer greatly improves the clinical outcome of patients with advanced disease. Developments in chemotherapeutic agents and strategies bring hope of a cure to patients with initially unresectable colorectal liver metastases (CLM). Perioperative chemotherapy significantly improves the survival time of patients who receive curative-intent hepatectomy. Even for unresectable CLM, recent studies demonstrated that active preoperative chemotherapy could achieve shrinkage of liver metastasis and thus render some for resection. Furthermore, an increase in tumor resection rate and prolonged survival time among patients with CLM has been observed following the application of monoclonal antibodies in recent years. However, the value of chemotherapy *via* hepatic arterial infusion is still unclear. More trials should be conducted in patients with CLM in order to improve survival.

Key words: Chemotherapy; Colorectal cancer; Liver metastases; Resection rate; Targeted agents

INTRODUCTION

Colorectal carcinoma is one of the most common causes of cancer-related mortalities in both China and the Western world. Almost 50% of patients with colorectal cancer will eventually develop liver metastases during the natural course of the disease and 25% of patients present with liver metastases at the time of diagnosis. One third of patients with liver metastases have an isolated metastatic site limited to the liver, and the survival of this specific population is directly related to the progression of the hepatic lesions[1]. The management of patients with untreated colorectal liver metastases (CLM) remains a common clinical challenge as previous studies reported a median survival time of 4 mo[2].

The treatment goal for patients with limited CLM is to remove all evidence of disease for better long-term survival or even cure. Historically, only a minority of patients (10%-15%) are considered candidates for resection with overall 5-year survival rates ranging between 25% and 40%[3]. Significant advances have been achieved in the management of CLM in recent years, with improvement in the precision of cross-sectional imaging, surgical techniques, locoregional therapeutic options, and the availability of newer effective chemotherapeutic agents. A multimodality treatment approach for patients with resectable CLM results in more patients being considered for resection and better outcome has been noted, where resectability rate increased to 20%-30%, 5-year survival rate increased to 50%, and 25% of patients survived for not less than 10 years[4,5]. For the time being, although there are still many incurable cases in the most advanced stage, the course of progression can be greatly slowed by multimodality treatment encompassing surgery, chemo-

therapy and interventional locoregional therapy.

Even though surgical resection remains the mainstay of potentially curative therapy, the role of systemic preoperative chemotherapy has been gradually recognized. Standard chemotherapy regimens comprising 5-fluorouracil (5-FU) plus leucovorin (LV) in combination with irinotecan (FOLFIRI) or oxaliplatin (FOLFOX) have been reported to facilitate a resection rate of 9%-40% among patients with initially unresectable CLM[6,7]. Perioperative chemotherapy for those with resectable liver lesions confers a potential survival advantage. Moreover, mounting evidence suggests that the addition of targeted agents or a third cytotoxic agent might be even more effective[8].

In this review, we will focus mainly on updates in systemic chemotherapy for CLM, and a short discussion on regional interventional chemotherapy will also be presented.

SYSTEMIC POSTOPERATIVE CHEMOTHERAPY FOR RESECTABLE LIVER METASTASES

Currently, postoperative systemic chemotherapy for resectable CLM, a common practice, carries the same goal as that for stage Ⅲ colorectal cancer to effectively enhance the local disease control rate. However, in contrast to the well-established benefit noted for adjuvant chemotherapy for stage Ⅲ colorectal cancer, there has been few high quality randomized studies to formally evaluate the benefits of adjuvant chemotherapy for CLM, despite the fact that improved survival and reduced recurrence rates have been demonstrated in retrospective studies[9]. In a multicenter, phase Ⅲ Fédération Francophone de la Cancérologie Digestive Association Française de Chirurgie Hépato-Biliaire et de Transplantation Hépatique Association Universitaire de Recherche en Chirurgie (FFCD ACHBTH AURC) 9002 trial, 173 patients who had undergone R0 resection were randomized to surgery followed by bolus 5-FU/LV for 6 mo with interval days of 10-35 or surgery alone[10]. The 5-year disease-free survival (DFS) rates were 33.5% and 26.7% respectively (P = 0.028), suggesting a positive effect of chemotherapy after surgery. There was a trend toward increased 5-year overall survival (OS) in patients who received chemotherapy without statistical significance (51.1% *vs* 41.9%, P = 0.13). The study may have been statistically underpowered to detect a true difference in OS as a result of early termination of accrual due to low accrual rates. An another trial [European Organisation for Research and Treatment of Cancer (EORTC)/National Cancer Institute of Canada Clinical Trials Group (NCIC CTG)/Gruppo Interdisciplinare Valutazione Interventi in Oncologia (GIVIO) trial] with a similar design, also closed prematurely due to slow accrual, but showed a trend towards improved progression-free survival (PFS) and OS in the chemotherapy group. Multivariate analysis identified adjuvant chemotherapy as a significant independent prognostic factor even though between-group comparison was insignificant[11]. Some large United States and European retrospective analyses further suggested an urgent need for patients with recurrent disease to receive adjuvant chemotherapy and showed a better survival in resected CLM patients who received adjuvant therapy[12,13].

The choice of regimen is the key to the success of chemotherapy after tumor resection. The 5-FU/LV regimen is less commonly used nowadays, but the efficacy of combining 5-FU with oxaliplatin or irinotecan as postoperative chemotherapy for patients with resectable CLM remains to be elucidated. A randomized phase Ⅲ study comparing adjuvant 5-FU/LV with FOLFIRI in patients following complete resection of CLM reported a median DFS of 24.7 mo and 21.6 mo for FOLFIRI and 5-FU/LV, respectively, with no significant differences noted for DFS and OS, however, a trend in favor of improved DFS in patients treated with FOLFIRI could not be excluded[14]. At present, evidence to support significant additional benefit using combination therapies for resectable CLM has not been established. Thus, the use of postoperative therapy is individualized based on local practice as well-established data from clinical trials are not yet available. The expert panel of the European Colorectal Metastases Treatment Group recommends that systemic chemotherapy following liver resection should be considered as an option for patients with resected CLM, particularly for those patients who did not receive preoperative chemotherapy[8].

PREOPERATIVE CHEMOTHERAPY FOR RESECTABLE CLM

Rising enthusiasm for the role of perioperative chemotherapy in cases of operable carcinoma originating from the digestive system has been noted, including those with CLM. Convincing benefits of preoperative chemotherapy on long-term survival in patients with CLM is still not well-established, but it is gradually being accepted as the rationale to improve PFS and reduce recurrence rates[15]. A ten-year study on survival and recurrence after neoadjuvant chemotherapy followed by resection of liver metastases showed that the 1-, 3- and 5-year OS reached 90%, 59.2% and 46.1%, respectively and DFS at 1, 3 and 5 years was 68.1%, 34.8% and 27.9%, respectively. In addition, preoperative chemotherapy followed by liver metastases resection is associated with improved survival, low cancer involvement in resection margins and re-resection rates[16]. In 2008, Nordlinger *et al*[17] published the final results of the EORTC 40983 study, which compared perioperative chemotherapy with oxaliplatin, fluorouracil, and folinic acid (FOLFOX4) regimen to surgery alone in patients with resectable CLM. Patients were randomly assigned to six cycles of neoadjuvant FOLFOX4 before and after surgery (n = 182) or to surgery alone (n = 182). The 3-year PFS was improved from 28.1% for the surgery-alone group to 36.2% for the perioperative FOLFOX4 group, an increase of 8.1% [hazard ratio (HR) = 0.77; P = 0.041] for all eligible patients and 9.2% (HR = 0.73; P = 0.025) for all resected patients. Additional reports on the application of neoadjuvant chemotherapy came from a few prospective single-center clinical tri-

als[18,19]. In one trial, 50 patients with resectable liver metastases received neoadjuvant capecitabine plus oxaliplatin (XELOX) or FOLFOX4 for six cycles (3 mo) prior to surgical resection[20]. The results suggest that preoperative oxaliplatin-based chemotherapy provides high response rates (RRs) without increased risk of perioperative morbidity. The recurrence-free survival was significantly influenced by tumor response to neoadjuvant chemotherapy, which may identify the best candidates for a potentially curative treatment.

Perioperative chemotherapy with FOLFOX4 may be a possible treatment option for patients with resectable CLM, as prolonged PFS has been noted as mentioned above. Nevertheless, not all patients can be cured *via* surgery with perioperative chemotherapy. 7% of patients in the chemotherapy group in the EORTC 40 983 trial experienced disease progression after receiving 3-4 cycles of chemotherapy. More active regimens should be tried to provide better results[17]. A recent non-randomized trial revealed that the objective response following preoperative chemotherapy of XELOX plus bevacizumab was 73% for a cohort of 56 patients, the treatment being safely administered until 5 wk prior to surgery in patients with resectable CLM without increasing postoperative complications[19]. Liver regeneration was not affected by preoperative bevacizumab. A large randomized clinical trial to evaluate the efficacy of bevacizumab combined with preoperative chemotherapy would better assess the efficacy of this preoperative regimen in patients with resectable CLM. Another study is currently ongoing in Britain to determine if the combination of cetuximab with perioperative chemotherapy could contribute to better survival.

At present time, no mature data is available to support the combination of FOLFOX6, antibodies targeting both vascular endothelial growth factor (VEGF) and epidermal growth factor receptor (EGFR) in the perioperative setting. Therefore, a large multi-center EORTC 40051 BOS (Biologics, Oxaliplatin and Surgery) trial was launched to evaluate the combination of oxaliplatin-based chemotherapy plus cetuximab with or without bevacizumab in a preoperative (6 cycles) and postoperative (6 cycles) setting in patients with resectable CLM. Patients could have up to ten liver metastases, and up to two pulmonary metastases. The primary endpoints of the BOS trial are preoperative RR and safety. However, based on the disappointing results from the Panitumumab Advanced Colorectal Cancer Evaluation (PACCE) study where the combination of bevacizumab, panitumumab with chemotherapy was first-line therapy for advanced colorectal cancer[20], as well as the discouraging reports from combination chemotherapy with bevacizumab-cetuximab in the CApecitabine, IRinotecan, and Oxaliplatin (CAIRO) 2 study[21], this study is temporarily on hold.

CONVERSION CHEMOTHERAPY FOR INITIALLY UNRESECTABLE LIVER METASTASES

Approximately 80%-90% of patients with metastatic colorectal cancer (mCRC) referred to specialist centers have unresectable metastatic liver disease at presentation[22]. The role of chemotherapy in these patient populations is to downstage the liver lesions in an attempt to convert their disease from unresectable to resectable, while the goal of treatment for patients with little possibility of conversion to resectable disease is to prolong survival and improve quality of life.

Actually, it is more reasonable to use the term "conversion chemotherapy" than true neoadjuvant therapy[23]. The combination of 5-FU/LV with either irinotecan or oxaliplatin, or a triple cytotoxic drug combination such as fluorouracil, leucovorin, oxaliplatin, and irinotecan (FOLFOXIRI), with or without additional targeted agents has also been used as a preoperative strategy to achieve higher resection rates and a better clinical outcome. In a series of 44 patients with initially unresectable CLM, Alberts *et al*[24] reported their results with FOLFOX4 chemotherapy. Periodical reassessment for resectability with a high clinical RR of 60% was observed, consistent with other studies assessing the activity of FOLFOX4 as first-line therapy for colorectal cancer patients with isolated liver metastases, and 40% of these patients were able to undergo complete resection of their residual cancer. The efficacy of FOLFIRI as preoperative chemotherapy has also been demonstrated in terms of both high resection rate and favorable survival times[25-27]. In 2008, a major systematic review on irinotecan and oxaliplatin for the treatment of advanced colorectal cancer published by the United Kingdom Health Technology Assessment Agency evaluated all studies where irinotecan or oxaliplatin were combined with 5-FU to downstage patients with unresectable CLM[27]. The reported resection rates ranged from 9% to 35% for patients receiving irinotecan and 5-FU, while that for those receiving oxaliplatin and 5-FU ranged from 7% to 51%. There is no conclusive evidence that one is superior to the other as first-line therapy for the downstaging of CLM in terms of PFS and OS.

Current practice for patients whose metastases may be rendered resectable by conversion chemotherapy is to treat with the most effective regimen that offers a high RR in terms of resection rate and PFS, coupled with the recommendation that surgery should be conducted as early as possible to minimize chemical damage to the liver[6]. The effectiveness of FOLFIRI/FOLFOX draws the attention of adding a third cytotoxic drug to these regimens as initial chemotherapy in patients with CLM with good performance status for potential surgical intervention. Falcone *et al*[28] reported a phase Ⅲ randomized trial comparing FOLFOXIRI with a standard infusional fluorouracil, leucovorin, and irinotecan (FOLFIRI) regimen. Of a total of 244 patients with initially unresectable mCRC, an improved RR was achieved in the FOLFOXIRI arm (60% *vs* 34%, $P < 0.0001$). The R0 resection rate of metastases was greater in the FOLFOXIRI arm (15% *vs* 6%, $P = 0.033$, among all patients; and 36% *vs* 12%, $P = 0.017$ among patients with liver metastases only). PFS and OS were both significantly improved in the FOLFOXIRI arm (median PFS, 9.8 *vs* 6.9 mo, $P = 0.0006$;

median OS, 22.6 mo *vs* 16.7 mo, $P = 0.032$). A more recent long-term follow-up indicated that this regimen was associated with an increased RR (70.4%). The 5-year PFS for these patients was 16% and the 5-year and 8-year OS were 42% and 33%, respectively[29]. Another group demonstrated that chemotherapy with FOLFIRINOX (the same agents with FOLFOXIRI) shows a high RR (70.6%) in CLM, and further confirmed the high RR of this regimen. The rate of R0 hepatic resection in patients with initially unresectable liver metastases is attractive (26.5%)[30]. The randomized phase Ⅱ METHEP trial was conducted to compare standard double-agent chemotherapy with triple-agent intensified chemotherapy in patients with unresectable CLM. Various induction regimens including FOLFIRI, FOLFOX-4, high dose-FOLFIRI, FOLFOX-7, and FOLFIRINOX were evaluated. In the preliminary analysis after 4 cycles of treatment, the most promising regimens appeared to be FOLFIRINOX and high dose-FOLFIRI with an objective RR of 52% and 50%, respectively. Secondary resection rates of metastases were also highest in the high dose-FOLFIRI and FOLFIRINOX arms (37% and 36%, respectively). The safety profiles of FOLFIRINOX and FOLFOXIRI are generally acceptable[31].

For patients with initially unresectable CLM, disease progression during preoperative chemotherapy predicts poor prognosis, for which a change to other alternative chemotherapy regimens is usually recommended[32]. Liver resection could be reconsidered if the response evaluation shows response or stabilization after second-line chemotherapy. However, objective response rates (ORR) to second-line preoperative chemotherapy are only 4%-28%[33], and the safety of surgery in patients who received multiple lines of chemotherapy is still to be confirmed in larger series of patients. Hence, tumor progression during chemotherapy is considered a contraindication to CLM resection by most oncologists and surgery is seldom performed if patients fail first-line chemotherapy. In a recent prospective study which included the largest study population to evaluate the outcome of patients undergoing resection of CLM after a second-line chemotherapy regimen, a retrospective analysis by Brouquet *et al*[34] demonstrated that hepatectomy is safe and feasible, and associated with a modest survival benefit in these patients who present with advanced CLM who have a suboptimal response to systemic therapy, with 1-year, 3-year, and 5-year OS rates of 83%, 41%, and 22%, respectively. Although a 37% objective radiographic RR still illustrates the challenges in obtaining a tumor response with second-line chemotherapy, this rate remains acceptable compared to data reported previously[35]. This study indicated that liver resection could be considered an appropriate alternative for selected patients following second-line therapy. At the same time, due to the fact that only a few patients receiving second-line chemotherapy will benefit from resection, further investigations should be conducted to define the assessment criteria to identify potential surgical candidates in this challenging therapeutic setting.

TARGETED COMBINATION THERAPY FOR UNRESECTABLE MCRC

Abundant data are emerging from randomized trials of the added benefits conferred by the targeted agents on the prognosis of patients with unresectable mCRC, including those with CLM. Optimistic results from the randomized Cetuximab combined with iRinotecan in first line therapY for metaSTatic colorectAL cancer (CRYSTAL) trial[36] and OxaliPlatin and cetUximab in firSt-line treatment of mCRC (OPUS) trial[37] reinforce the role of cetuximab on the improvement of RRs and resection rates, combined with standard first-line chemotherapy in patients with advanced CRC. According to the published report of the CRYSTAL study, the addition of cetuximab to FOLFIRI significantly reduced the risk of progression (HR = 0.85; $P = 0.048$) and increased the ORR (HR = 1.4; $P = 0.004$), compared with FOLFIRI alone. The rate of R0 resection of secondary metastases was also slightly higher in the cetuximab-FOLFIRI arm ($P = 0.003$). Retrospective analysis suggested that the benefits of cetuximab were limited to patients with *KRAS* wild-type tumors[38]. The OPUS study which compared cetuximab plus FOLFOX to FOLFOX alone obtained similar results[37]. An update of a re-analysis of the CRYSTAL trial showed that greater benefits from the combination with cetuximab would be derived in patients with both wild-type *KRAS* and wild-type *BRAF*[39]. More patients with CLM would be rendered resectable with effective preoperative therapy, as the addition of cetuximab to chemotherapy is feasible in first-line therapy, which has been confirmed in a randomized phase Ⅱ multi-center study of cetuximab plus FOLFOX6 or cetuximab plus FOLFIRI in the preoperative setting for unresectable CLM (the CELIM study) published recently by Folprecht *et al*[40]. Partial or complete response was noted in 68% of 53 patients in the cetuximab plus FOLFOX6 arm, and 57% of 53 patients in the cetuximab plus FOLFIRI arm. In a combined analysis of both arms, 70% of patients with wild-type *KRAS* tumors achieved tumor response *versus* 42% of patients with mutated *KRAS* (OR = 3.42; $P = 0.008$). The R0 resection rates were as high as 34% in patients with wild-type *KRAS*. In retrospect, resectability rates increased from 32% at baseline to 60% after chemotherapy ($P < 0.0001$). It is concluded that cetuximab may increase the possibility of resection for patients with initially unresectable liver metastases and shows a high efficacy in the conversion treatment of CLM when combined with first-line chemotherapy. For patients with unresectable CLM refractory to conventional first-line chemotherapy, combination therapy with cetuximab could also increase resectability rates without increasing surgical mortality or liver injury[41]. A similar effective increase in RR was shown when cetuximab was added to either irinotecan- or oxaliplatin-based combinations[42-44]. However, the latest results from two randomized phase Ⅲ studies unexpectedly questioned the benefit of adding cetuximab to oxaliplatin-based combination chemotherapy[45-47]. In the MRC COIN study, 1394 patients received

oxaliplatin combination (CAPOX/FOLFOX) as standard chemotherapy with or without cetuximab. Analysis according to *KRAS* status did not result in any difference in either OS (median OS 17.9 mo *vs* 17.0 mo, $P = 0.68$) or PFS (median PFS 8.6 mo *vs* 8.6 mo, $P = 0.60$) between patients treated with CAPOX/FOLFOX and CAPOX/FOLFOX plus cetuximab, even in the *KRAS* wild-type group[45]. Only a small benefit was seen in the RR in the *KRAS* wild-type patients who received cetuximab combination therapy (59% *vs* 50%, $P = 0.02$). Further subgroup analysis reported at ASCO 2010 suggested that an interaction existed between the chemotherapy option, (CAPOX *vs* FOLFOX) and a positive effect on PFS was observed with cetuximab ($P = 0.07$), indicating a benefit from cetuximab in FOLFOX-treated patients, but not in CAPOX-treated patients. Currently, cetuximab is not recommended for combination therapies with capecitabine and oxaliplatin based on these data. Similarly, the NORDIC Ⅶ study, with 566 patients randomly assigned to receive 5-FU plus LV plus oxaliplatin (FLOX), FLOX plus cetuximab until disease progression, or FLOX intermittently plus continuous cetuximab, reported a negative result, demonstrating no added benefit when cetuximab was combined with oxaliplatin-based chemotherapy[47]. In the intent-to-treat population analysis, there were no statistically significant differences between the treatment groups in terms of RR, PFS or OS. Furthermore, the lack of benefit was also noted in both *KRAS* mutant and wild-type sub-groups, suggesting that *KRAS* status did not predict the effect of cetuximab in combination with FLOX in this study. The results from these two studies do not support the use of cetuximab in first-line therapy when given together with oxaliplatin-based regimens. Thus, caution should be taken when making decisions on combined chemotherapy regimens as the role of anti-EGFR agents in the first-line treatment of mCRC needs to be explored further.

In addition, cetuximab combined with triple cytotoxic drug therapy is also being evaluated, for potential extra efficacy on RR and clinical outcome[48,49]. Definitive results from the preoperative chemotherapy for hepatic resection (POCHER) study revealed an RR of 79% and a complete resection rate of 63% achieved by FOLFOXIRI plus cetuximab[48]. Preliminary results of another phase Ⅱ trial evaluating cetuximab in combination with FOLFIRINOX demonstrated an ORR as high as 82% and predicted the feasibility of this new therapeutic combination in first-line mCRC patients[49].

KRAS had been broadly accepted as a predictive factor of anti-EGFR antibody therapies prior to the negative results of the NORDIC Ⅶ study, and identification of additional predictors such as *BRAF* has attracted significant interest. A recent meta-analysis based on the CRYSTAL and OPUS trials reported the updated clinical efficacy of cetuximab combination therapy according to *KRAS* and *BRAF* mutation status[50]. This analysis confirmed that in *KRAS* wild-type patients, the addition of cetuximab in first-line treatment achieves a statistically significant improvement in RR, PFS, and OS compared with chemotherapy alone. However, it also concluded that *BRAF* mutation status does not appear to be a strong predictive biomarker for the addition of cetuximab. *BRAF* is more likely to be a prognostic factor as the clinical outcome in *BRAF*-mutant patients is worse than those with *BRAF* wild-type tumors in terms of RR, PFS and OS. Thus, *BRAF* testing is probably not essential when deciding whether cetuximab should be used. Larger clinical trials to further investigate the field of predictive molecular biomarkers are required since the present data are inconsistent.

The role of bevacizumab added to chemotherapy in the perioperative setting for initially unresectable metastases was evaluated in two large multi-center prospective trials (First BEAT and NO16966)[51]. The First BEAT trial reported a 6% R0 hepatic resection in an unselected population and 12.1% among patients with isolated liver metastases only. Resection rates were highest in patients who received oxaliplatin-based combination chemotherapy ($P = 0.002$). In NO16966[52], the addition of bevacizumab to XELOX/FOLFOX significantly improved PFS in the first-line therapy (9.4 mo *vs* 8.0 mo, $P = 0.0023$), but there were no statistically significant differences between resection rates or OS in patients treated with bevacizumab plus XELOX/FOLFOX *vs* placebo (6.3% *vs* 4.9%, $P = 0.24$). Bevacizumab improved RR when added to FOLFIRI regimen but did not improve RRs and resection rates when added to XELOX or FOLFOX. Recent data from a small phase Ⅱ trial by the GONO group revealed that FOLFOXIRI plus bevacizumab yielded an ORR of 76% and a disease control rate of 100%, with a secondary resection of metastases in 17% of patients[53]. It seems that the addition of bevacizumab to FOLFOXIRI regimen is effective with manageable toxicities, however, negative reports on its efficacy in heavily pretreated patients with advanced disease and its role as adjuvant therapy for stage Ⅲ colon cancer in the NSABPC-08 study remind us to be cautious of the optimal stage to start administration and to determine the best treatment sequence[54,55].

Results from the PACCE study[20] and CAIRO2 study[21] failed to demonstrate a biological synergistic effect in antibodies both against the EGFR (cetuximab or panitumumab) and VEGF (bevacizumab). Thus, specific combinations of targeted drugs are not recommended as first-line therapy for patients with mCRC, including CLM. The ongoing CALGB/SWOG 80404 trial which compared the addition of cetuximab, or bevacizumab or both to standard FOLFIRI/FOLFOX should help to define the preferred targeted partner primarily in terms of OS. The RR, PFS and the resection rate will be secondary end points[56].

LOCOREGIONAL CHEMOTHERAPY

Patients with multifocal CLM who are unfit for surgery or have tumor distribution technically unresectable with clear margins, are potential candidates for regional liver chemotherapy. Hepatic arterial infusion (HAI) with chemothera-

peutic agents can provide relatively high concentrations of drugs to micro- or macro-metastases remaining in the liver with less toxicity to extrahepatic organs. The most commonly used agent for HAI is Floxuridine (FUDR) which is an analogue of 5-FU, and has the advantage of having a first-pass extraction rate of over 94% within the liver[57]. For those whose liver metastases were initially unresectable, the use of HAI as pre-operative conversion therapy to downstage the disease for resection was recommended in some early studies, due to the efficacy results obtained[58-60]. A recent Cochrane meta-analysis of ten randomized trials which compared HAI with fluoropyrimidine chemotherapy to systemic chemotherapy or best supportive care in patients with initially unresectable liver metastases suggested that administration of fluoropyrimidines through HAI yielded higher tumor RRs as compared to the systematic chemotherapy regimens (42.9% *vs* 18.4%, $P < 0.0001$). However, this anticancer activity does not translate into a significant survival advantage for patients treated with HAI as compared to those given systemic chemotherapy (15.9 mo *vs* 12.4 mo)[61]. Only one out of ten studies indicated that HAI with 5-FU was superior to systemic bolus 5-FU/LV in terms of RR and survival[62]. Altogether, current data do not support the clinical or investigational use of fluoropyrimidine-based HAI alone in patients with initially unresectable liver metastases. The advantages of systemic oxaliplatin or irinotecan-based chemotherapy over the 5-FU/LV regimen also guided the use of these agents in HAI chemotherapy. Encouraging results were obtained in patients with initially unresectable metastases, with RRs as high as 55%-70% and resection rates of approximately 16%-18% in unresectable liver metastases[63,64].

HAI as post-operative chemotherapy was also investigated in some clinical trials for feasibility in CLM. A Cochrane meta-analysis performed on seven randomized trials with a total of 592 patients did not show improvement on OS in the HAI group even though fewer recurrences were noted in the remaining liver[65]. As early as 1999, Kemeny *et al*[66] reported the results from a single-institution study in which 156 patients were randomized to post-operative HAI with FUDR plus systemic 5-FU ± LV *vs* systemic therapy alone. An increase in two-year survival rate for the combination therapy group was observed (90% *vs* 60%, $P < 0.001$) as compared with the group receiving monotherapy. The liver relapse-free survival also significantly increased in the combination therapy group. Furthermore, an updated analysis with a median follow-up of 10.3 years reports a significantly greater PFS rate (31.3 mo *vs* 17.2 mo, $P = 0.02$) and a trend toward improved OS (68.8 mo *vs* 58.8 mo, $P = 0.10$) in the combined therapy group compared to the monotherapy group[67]. Other similar randomized studies also suggested an improved PFS of the liver in the HAI combination group compared to the control group, but none of these studies showed any advantage in OS and long-term DFS[68,69].

Negative outcomes in terms of OS and significant hepatobiliary toxicity related to HAI as well as the expertise required limit the implementation of this technique. Given the availability of an increasing number of active systemic chemotherapy regimens, especially the biologic agents, the value of HAI chemotherapy is less clear.

CONCLUSION

Surgical resection undoubtedly remains the gold standard for the treatment of resectable CLM. A well coordinated multidisciplinary approach is also necessary to achieve optimal outcomes for patients with CLM. The modality of perioperative chemotherapy over surgery alone has resulted in more patients with initially unresectable metastases receiving a complete resection and enjoying a prolonged survival after surgery. Emerging data has revealed that preoperative chemotherapy, as well as postoperative chemotherapy could be advantageous compared to surgery alone in terms of DFS for patients with resectable CLM. Newly emerging biologic targeted agents when added to the standard chemotherapy regimen have contributed to increased tumor RR, and to a larger extent, higher secondary resection rates. Insight into the molecular markers to predict the outcome of targeted therapy may define subgroups of patients within the same stage.

At present, there is insufficient evidence to demonstrate the efficacy of regional perioperative chemotherapy. Multi-center randomized prospective trials are needed to provide evidence of a survival advantage of regional perioperative chemotherapy with acceptable adverse effects.

Even though the intent of preoperative therapy followed by resection is probably curative, cure is rarely achieved, as the majority of patients who undergo hepatic resection will experience recurrence. More potent agents and strategies have to be developed to provide longer survival time and eventually cure this disease.

Abstract

AIM: To determine the number of regulatory T cells (Tregs) in gastric mucosa of patients with gastritis, peptic ulcers and gastric cancer.

METHODS: This study was a retrospective analysis of gastric antrum biopsy specimens from healthy controls (n = 22) and patients with gastritis (n = 30), peptic ulcer (n = 83), or gastric cancer (n = 32). Expression of CD4, CD25 and Foxp3 was determined by immunohistochemistry in three consecutive sections per sample.

RESULTS: Compared with healthy controls, there was an increased number of $CD25^+$ and $Foxp3^+$ cells in patients with gastritis (P = 0.004 and P = 0.008), peptic ulcer (P < 0.001 and P < 0.001), and gastric cancer (P < 0.001 and P < 0.001). The ratio of $CD25^+/CD4^+$ or $Foxp3^+/CD4^+$ cells was also significantly higher in all disease groups (P < 0.001, respectively). The number of $CD4^+$, $CD25^+$, and $Foxp3^+$ cells, and the ratio of $CD25^+/CD4^+$ and $Foxp3^+/CD4^+$ cells, were associated with the histological grade of the specimens, including acute inflammation, chronic inflammation, lymphoid follicle number, and *Helicobacter pylori* infection. The number of $CD4^+$, $CD25^+$ and $Foxp3^+$ cells, and the ratio of $CD25^+/CD4^+$ and $Foxp3^+/CD4^+$ cells, were negatively associated with intestinal metaplasia among gastritis (P < 0.001, P < 0.001, P < 0.001, P = 0.002 and P = 0.002) and peptic ulcer groups (P = 0.013, P = 0.004, P < 0.001, P = 0.040 and P = 0.003).

CONCLUSION: Tregs are positively associated with endoscopic findings of gastroduodenal diseases and histological grade but negatively associated with intestinal metaplasia in gastritis and peptic ulcer groups.

Key words: T regulatory cells; *Helicobacter pylori*; Gastroduodenal diseases; Intestinal metaplasia; Immunohistochemistry

INTRODUCTION

In 1988, Correa delineated a multistep pathway from active chronic gastritis to atrophic gastritis, intestinal metaplasia (IM), dysplasia and finally gastric adenocarcinoma[1]. The presence of severe gastric atrophy, corpus-predominant gastritis, or IM is suggested to have an increased risk of cancer development[2]. The progression from IM to gastric cancer is supported by studies from animal models[3-5]. Hence, finding markers associated with these early histological changes could improve the prognosis and treatment of the disease. A common pathogen, *Helicobacter pylori* (*H. pylori*), is recognized as a primary etiologic agent in chronic gastritis. Persistent infection by *H. pylori* is associated with peptic ulceration and/or gastric malignancy[6,7]. In 1994, *H. pylori* was categorized as a group I carcinogen by the World Health Organization's International Agency for Research on Cancer owing to its epidemiologic association with gastric adenocarcinoma and gastric mucosa-associated lymphoid tissue lymphoma.

Regulatory T cells are a small population of T lymphocytes that may induce and maintain immunologic self-tolerance to prevent the development of autoimmune diseases[8-10]. Naturally occurring $CD4^+CD25^+$ Tregs frequently co-express cytotoxic T lymphocyte antigen 4 (CTLA-4), glucocorticoid-induced tumor necrosis factor receptor family-related gene (GITR), transforming growth factor β (TGF-β), and forkhead box p3 (Foxp3)[11]. Using a mouse model and other methods, Foxp3 has been identified as a crucial transcription factor that regulates the development of $CD4^+CD25^+$ Tregs function[12,13] and thus may serve as a reliable marker for $CD4^+CD25^+$ Tregs.

The roles of $CD4^+CD25^+$ Tregs in suppressing the immune response to *H. pylori* have been reported recently in several studies[14-17]. $CD4^+CD25^+$ Tregs reduce proinflammatory cytokine production and *H. pylori*-induced gastritis in mice[17-19]. Depletion of Tregs in infected mice results in increased gastric inflammation and reduced colonization by *H. pylori*[16]. Furthermore, there is a higher proportion of $Foxp3^+$ Tregs in tumor-infiltrating lymphocytes in the gastric mucosa of cancers as compared with normal gastric mucosa[15,20,21]. Apart from its positive correlation with tumor specimens, the number of $Foxp3^+$ Tregs is also elevated in *H. pylori*-associated gastritis[21].

These results suggest that Tregs play a pivotal role in persistent *H. pylori* colonization in gastric mucosa, which may then lead to development of gastric cancers. However, the relationship between $CD4^+CD25^+$ Tregs and precancerous lesions of the stomach remain unclear. In the present study, we investigated the association between Tregs, histological grade and clinical sequelae in the context of the multistep progression to gastric cancer by examining histological profiles in healthy controls and patients with chronic gastritis, peptic ulcers or adenocarcinoma. We retrospectively analyzed the number of $CD4^+$, $CD25^+$, or $Foxp3^+$ T cells by immunohistochemistry in the antrum mucosa and examined the relationship between marker expression and precancerous lesions.

MATERIALS AND METHODS

Study subjects

Between January 2008 and June 2009, a total of 4563 patients were examined by upper gastroduodenal endoscopy at Ton-Yen General Hospital, Hsinchu, Taiwan. Among them, 256 patients who had gastric antral biopsy for histological diagnosis were considered for this retrospective study. After medical chart review for these cases, we excluded patients with chronic heart, lung, liver or kidney diseases, patients with a history of prior gastric surgery or anti-*H. pylori* eradication therapy, and patients taking non-steroidal anti-inflammatory drugs within one week prior to endoscopy. This gave us a pool of 135 enrolled non-cancer subjects, including 113 symptomatic patients from our out-patient department (30 patients with gastritis and 83 patients with peptic ulcers) and 22 healthy controls (asymptomatic cases undergoing physical check up). In addition, 32 patients with histologically proven gastric adenocarcinoma diagnosed between 2004 and 2008 were enrolled as the gastric cancer group. The Institutional Review Board of Ton-Yen General Hospital approved this study.

Demographic factors reported for the 167 patients included age and gender. Endoscopic and histological data were reviewed exclusively by Guan-Ying Tseng and Hsiao-Bai Yang, respectively. We defined an ulcer as a circumscribed mucosal break (> 5 mm in diameter, with apparent depth) in the stomach or duodenum, covered with exudates. *H. pylori* status was assessed by histology with hematoxylin and eosin stain and by rapid urease test on biopsies using Pronto Dry (Medical Instruments Corp., Solothurn, Switzerland). Patient was considered *H. pylori* positive if results by one or both diagnostic methods were positive and *H. pylori* negative if results by both methods were negative.

Histological assessment

For diagnosis, the gastric antrum biopsy specimens were obtained from the non-ulcer region adjacent to the ulcer site of the non-cancer subjects, or taken from the tumor region of the cancer patients, fixed in 10% formalin buffer, and stained with hematoxylin-eosin. The histological findings were graded by Yang HB according to the updated Sydney System[22,23]. The parameters included: (1) chronic inflammatory score (CIS; range 1-3 for mild, moderate, or severe lymphocytic and plasma cell infiltration); (2) acute inflammatory score (AIS; range 0-3 for absence or degree of neutrophil infiltration in lamina propia, epithelia, crypt or gland lumens); (3) lymphoid follicle number (LF; range 0-7 for total LF numbers in one slide); (4) *H. pylori* density (HPD; range 0-5); (5) IM (0, absence or < 5% of the upper third of gastric mucosa; 1-2, goblet cells found in the upper third or upper half of gastric mucosa; 3, goblet cells and paneth cells found, also considered complete IM); and (6) atrophic change (AT; 0-3 for absence, mild, moderate or severe).

[a]P < 0.001. Data were analyzed using Kruskal-Wallis H test.

Immunohistochemical staining

Consecutive paraffin-embedded serial sections of gastric biopsies (4 μm) were deparaffinized and rehydrated with xylene and ethanol for single staining of CD25, CD4, and Foxp3. Antigen retrieval was performed in a 95 ℃ water bath using Tris-ethylene diamine tetraacetic acid (EDTA) buffer (10 mmol/L Tris, pH 9.0, 1 mmol/L EDTA, 0.05% w/v Tween 20) for 10 min in CD4, or sodium citrate buffer (10 mmol/L sodium citrate, pH 6.0, 0.05% Tween 20) for 20 min in Foxp3 or 10 min in CD25. Sections were cooled for 20 min, and then endogenous peroxidase was blocked using 3% H_2O_2 for 10 min. Sections were incubated with blocking buffer (1% bovine serum albumin in phosphate-buffered solution) for 1 h at room temperature and then incubated with primary antibody for 2 h at room temperature. The working dilution of the primary antibody was 1:200 for mouse anti-human CD4 (clone 4B12; Novocastra, Newcastle, United Kingdom), 1:400 for mouse anti-human CD25 (clone 4C9; Novocastra), and 1:50 for mouse anti-human Foxp3 (clone 236A/E7; Santa Cruz Biotechnology, Santa Cruz, CA). Sections were stained using NovoLink Polymer Detection Systems (Novocastra) followed by 3,3'-diaminobenzidine (Sigma) for 5 min, and counterstained with hematoxylin (Sigma). Lymph node tissue was used as a positive control. Additional sections were processed without primary antibody as a negative control.

Quantification of the number of immunostained cells was conducted in three consecutive single-stained sections in order of CD25, CD4 and Foxp3. For enumeration of $CD4^+$ T cells, lymphocytes infiltrating the non-IM region were counted at least ten high-powered fields (HPF; 400 ×) from each CD4-stained section. Selected regions of each CD4-stained section were then retraced in the corresponding CD25- and Foxp3-stained sections to enumerate $CD25^+$ and $Foxp3^+$ cells. For each sample, the mean ratio of $CD25^+/CD4^+$ and $Foxp3^+/CD4^+$ cells was also calculated. Results were expressed as the median value and inter-quartile range of all tested patients in each group.

Statistical analysis

χ^2 test or Fisher's exact test was performed to compare groups with categorical variables. Continuous variables were compared between groups using a Mann-Whitney U test or Kruskal-Wallis H test. Correlations between the number of $CD25^+$ cells and $Foxp3^+$ cells were established based on Spearman's rank correlation analysis, and the ratio of $CD25^+/CD4^+$ cells and of $Foxp3^+/CD4^+$ cells was calculated. Statistical tests were two-sided, with $P < 0.05$ considered statistically significant. Statistical analysis was performed using SPSS version 12.0 (SPSS Inc., Chicago, IL).

RESULTS

Patients

The demographic and clinical characteristics of the 167 study subjects are shown in Table 1. On endoscopy, there were 22 normal, 30 gastritis, 83 peptic ulcer and 32 gastric cancer cases. Subjects ranged in age from 27 years to 95 years (59.7 ± 15.9 years). The mean age of the healthy controls (46.4 ± 14.3 years) was substantially lower than that of disease groups. A much higher male ratio was found in the gastric cancer group (93.8%) than in the healthy control group (59.1%, P = 0.004). The prevalence of *H. pylori* infection was significantly higher in the peptic ulcer group (60.2%) than in the gastritis group (33.3%, P = 0.020).

The histological grading of non-cancer subjects (n = 135) is shown in Table 2. The scores of the six parameters, including AIS, CIS, LF, HPD, IM and AT, were significantly associated with the severity of gastroduodenal diseases as determined endoscopically (AIS, $P < 0.001$; CIS, $P < 0.001$; LF: $P < 0.001$; HPD: $P < 0.001$; IM: $P < 0.001$; AT: $P < 0.001$). The number of $CD25^+$, $CD4^+$, or $Foxp3^+$ cells and the ratio of $CD25^+/CD4^+$ and of $Foxp3^+/CD4^+$ had no correlation with respect to age or sex in non-cancer patients.

Number of $Foxp3^+$ Tregs and ratio of $Foxp3^+/CD4^+$ Tregs are higher in gastroduodenal diseases

To enumerate Tregs present in the gastric mucosa of gastroduodenal diseases, we determined the number of

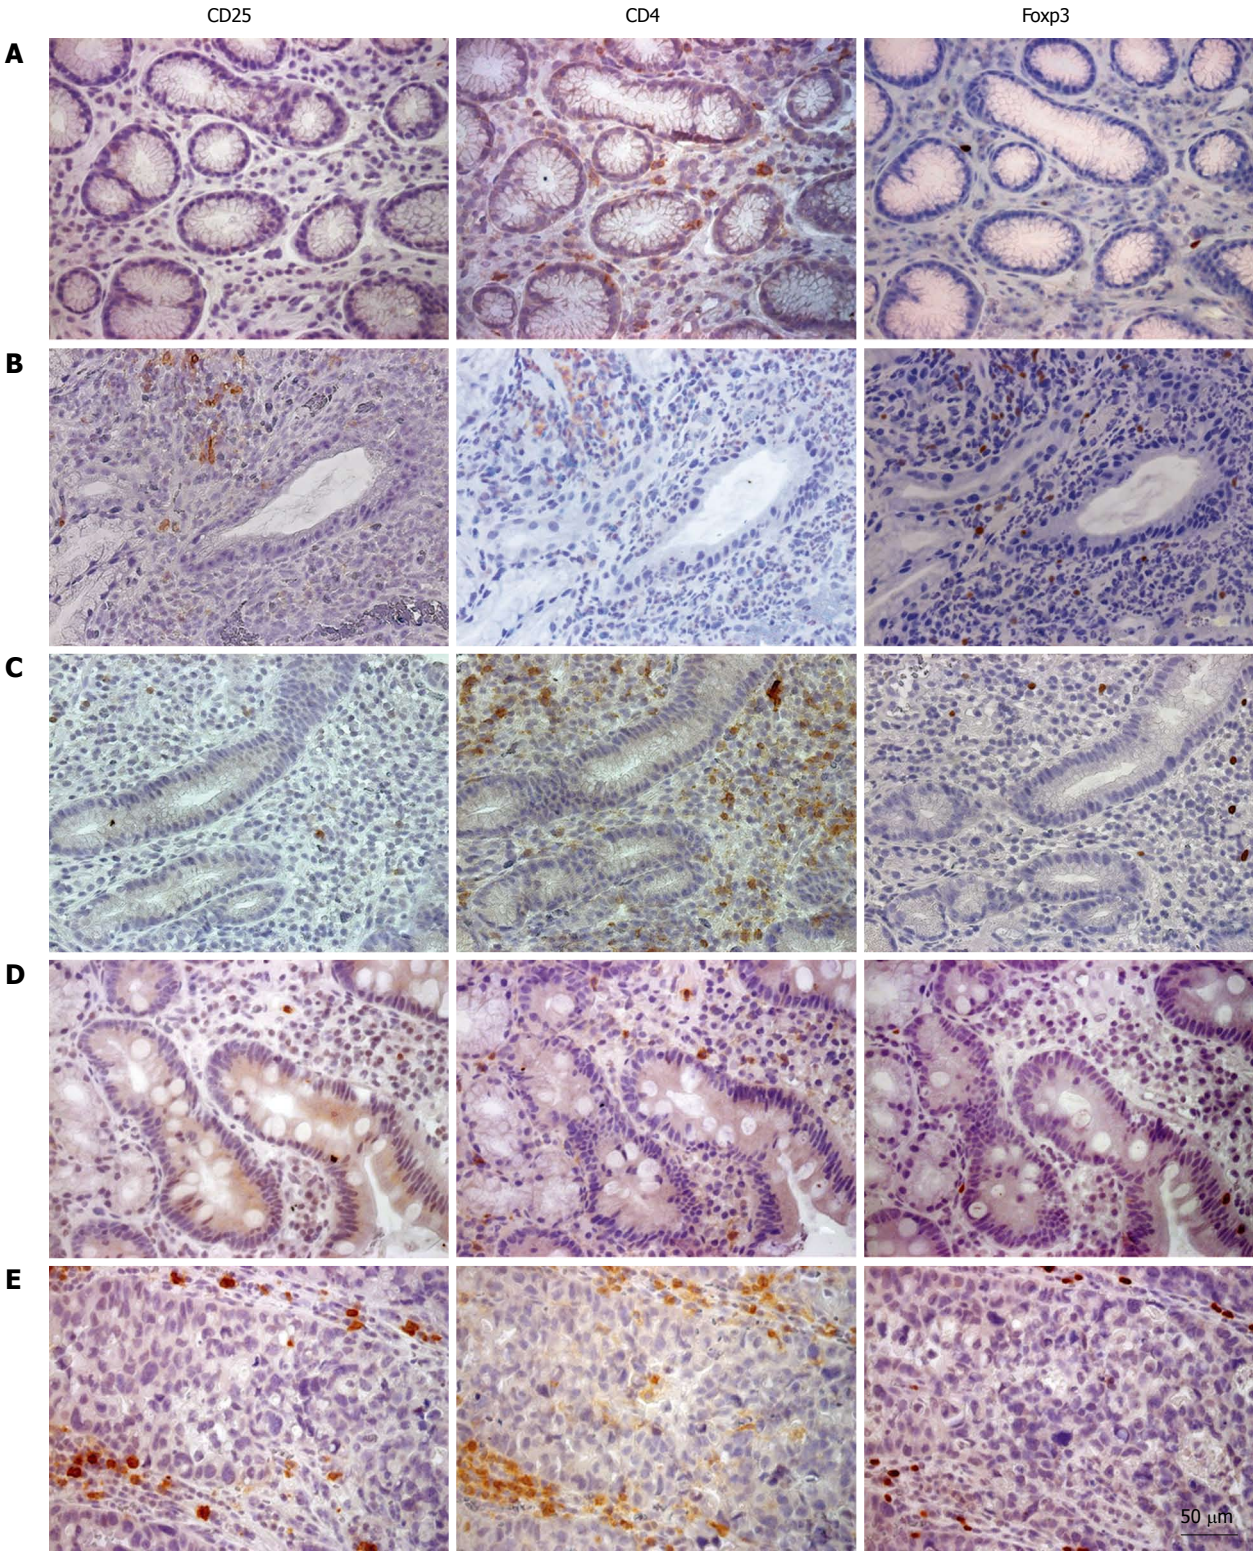

Figure 1 Immunohistochemistry of CD25, CD4, and Foxp3 in healthy controls, acute gastritis, chronic gastritis, intestinal metaplasia, and gastric cancer (original magnification, 400 ×). Immunohistochemistry of CD25 (left), CD4 (middle), and Foxp3 (right) in gastric mucosa from A: Healthy controls; B: Acute gastritis; C: Chronic gastritis; D: Intestinal metaplasia; E: Gastric cancer. CD4 and CD25 staining (brown) were found on the surface of T lymphocytes, and Foxp3 staining (brown) was located in the nucleus of T lymphocytes in lamina propria around glands.

$CD25^+$ cells, $CD4^+$ cells and $Foxp3^+$ cells in three consecutive sections. The expression of CD4 and CD25 was found on the surface of lymphocytes, whereas expression of Foxp3 was seen in the nucleus of lymphocytes (Figure 1).

The number of $CD25^+$ cells was significantly correlated with that of $Foxp3^+$ cells (Figure 2A; $r = 0.876$, $P < 0.001$). Furthermore, the ratio of $CD25^+/CD4^+$ was also significantly correlated with that of $Foxp3^+/CD4^+$ (Figure 2B; r

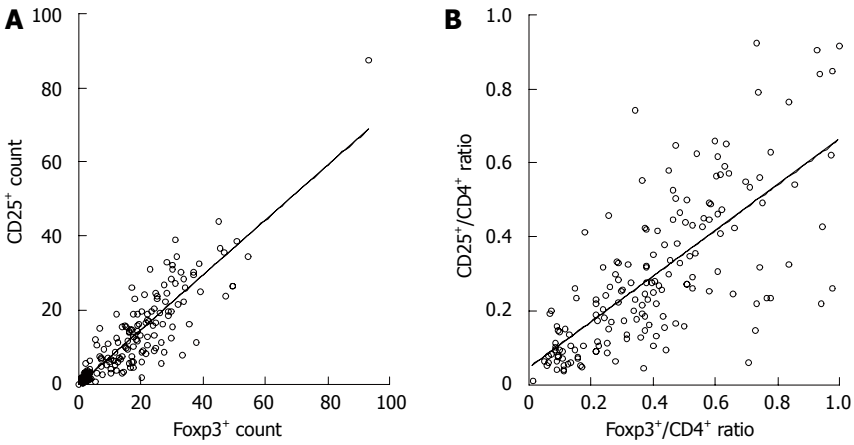

Figure 2 CD25 expression correlates with Foxp3 expression in human T lymphocytes. A: Correlation between $CD25^+$ and $Foxp3^+$ cells from 22 healthy controls and 30 gastritis, 83 peptic ulcer, and 32 gastric cancer patients; B: Correlation between the ratio of $CD25^+/CD4^+$ and of $Foxp3^+/CD4^+$ cells. Data were analyzed by Spearman's rank correlation.

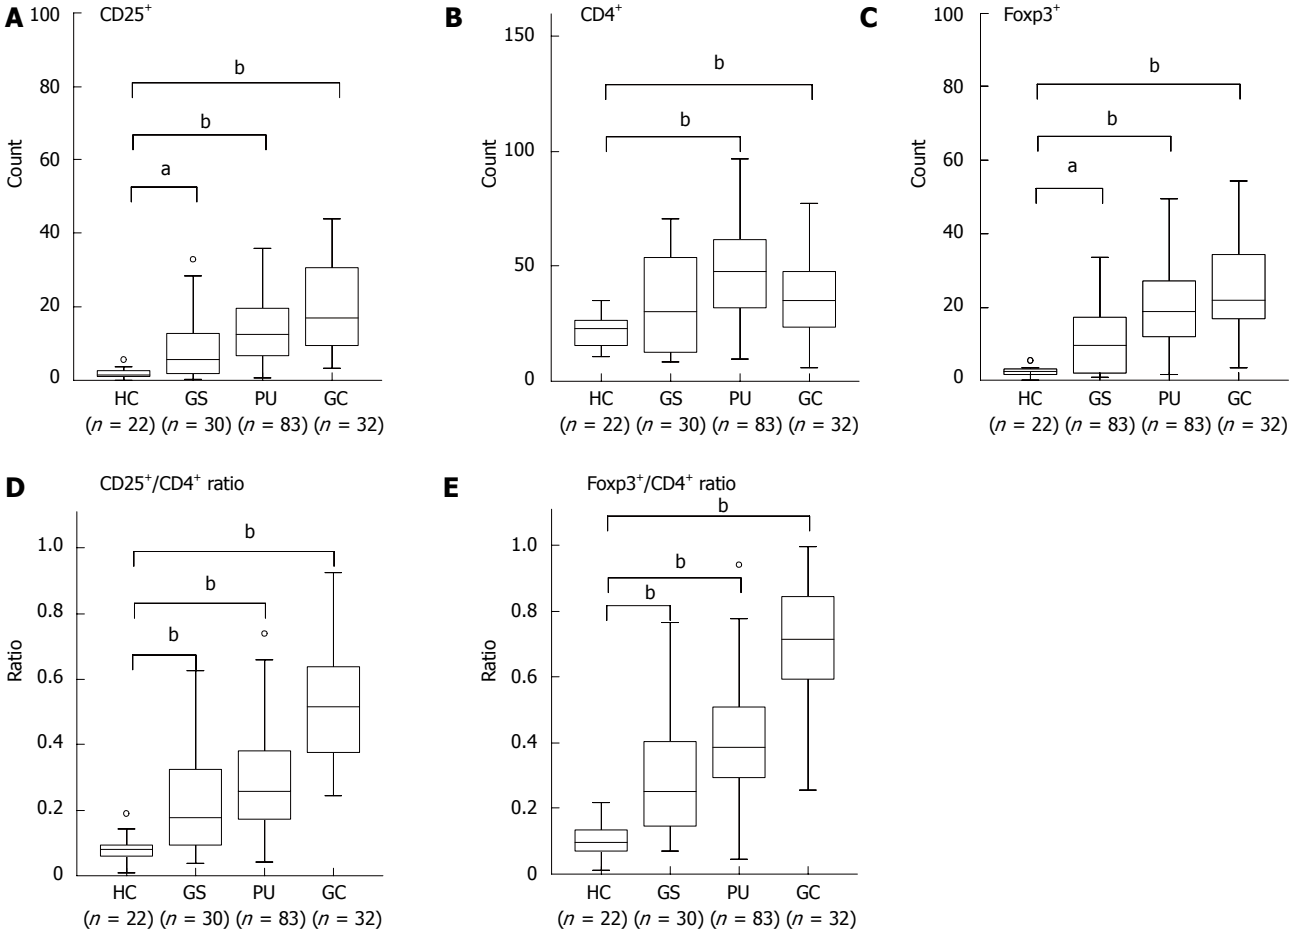

Figure 3 Box plots for the number of $CD25^+$, $CD4^+$, and $Foxp3^+$ cells, and the ratio of $CD25^+/CD4^+$ and $Foxp3^+/CD4^+$ in healthy controls, gastritis, peptic ulcer, and gastric cancer. Box plots for A: The number of $CD25^+$ cells; B: The number of $CD4^+$ cells; C: The number of $Foxp3^+$ cells; D: The ratio of $CD25^+/CD4^+$; E: The ratio of $Foxp3^+/CD4^+$ in non-intestinal metaplasia areas of antral gastric mucosa from healthy controls (HC) and patients with gastritis (GS), peptic ulcer (PU), and gastric cancer (GC). Data were analyzed by the Mann-Whitney *U* test. $^aP < 0.05$ and $^bP < 0.001$.

= 0.717, $P < 0.001$), revealing a strong positive correlation between CD25 and Foxp3.

Peptic ulcer and gastric cancer patients had a significantly higher number of $CD4^+$ cells than the healthy controls (Figure 3B; $P = 0.001$). The number of $CD25^+$ and $Foxp3^+$ cells was lowest in the healthy controls and increased progressively in the more severe disease groups (Figure 3A and 3C; gastritis *vs* healthy control: $CD25^+$, $P = 0.004$ and $Foxp3^+$, $P = 0.008$; peptic ulcer *vs* healthy control: $CD25^+$, $P < 0.001$ and $Foxp3^+$, $P < 0.001$; gastric

cancer *vs* healthy control: $CD25^+$, $P < 0.001$ and $Foxp3^+$, $P < 0.001$; peptic ulcer *vs* gastritis: $CD25^+$, $P = 0.001$ and $Foxp3^+$, $P < 0.001$; gastric cancer *vs* gastritis: $CD25^+$, $P < 0.001$ and $Foxp3^+$, $P < 0.001$; gastric cancer *vs* peptic ulcer: $CD25^+$, $P = 0.018$ and $Foxp3^+$, $P = 0.044$). In addition, the ratio of $CD25^+/CD4^+$ and of $Foxp3^+/CD4^+$ was increased progressively in the more severe disease groups (Figure 3D and 3E; gastritis *vs* healthy control: $CD25^+/CD4^+$, $P < 0.001$ and $Foxp3^+/CD4^+$, $P < 0.001$; peptic ulcer *vs* healthy control: $CD25^+/CD4^+$, $P < 0.001$ and $Foxp3^+/CD4^+$, $P < 0.001$; gastric cancer *vs* healthy control: $CD25^+/CD4^+$, $P < 0.001$ and $Foxp3^+/CD4^+$, $P < 0.001$; peptic ulcer *vs* gastritis: $CD25^+/CD4^+$, $P = 0.012$ and $Foxp3^+/CD4^+$, $P = 0.002$; gastric cancer *vs* gastritis: $CD25^+/CD4^+$, $P < 0.001$ and $Foxp3^+/CD4^+$, $P < 0.001$; gastric cancer *vs* peptic ulcer: $CD25^+/CD4^+$, $P < 0.001$ and $Foxp3^+/CD4^+$, $P < 0.001$). Together, these results suggested that Tregs were associated with gastritis, peptic ulcer and gastric cancer.

Foxp3$^+$/CD4$^+$ ratio is positively associated with degree of inflammation, number of LFs and H. pylori infection

We next analyzed the relationship between Tregs and histological findings in non-cancer subjects ($n = 135$; Figure 4). The ratios $CD25^+/CD4^+$ and $Foxp3^+/CD4^+$ were significantly higher with a higher degree of chronic and acute inflammation (CIS 3, AIS 3-4) than with a lower degree of chronic and acute inflammation (CIS 1-2, AIS 0-1) (Figure 4A and B; CIS 3 *vs* 1: $CD25^+/CD4^+$, $P < 0.001$ and $Foxp3^+/CD4^+$, $P < 0.001$; AIS 2 *vs* 0: $CD25^+/CD4^+$, $P < 0.001$ and $Foxp3^+/CD4^+$, $P < 0.001$; AIS 3 *vs* 0: $CD25^+/CD4^+$, $P < 0.001$ and $Foxp3^+/CD4^+$, $P < 0.001$). The ratios were also significantly higher in patients with higher numbers of LFs (Figure 4C; LF 1-2 *vs* 0: $CD25^+/CD4^+$, $P = 0.005$ and $Foxp3^+/CD4^+$, $P < 0.001$; LF $\geqslant$ 3 *vs* 0: $CD25^+/CD4^+$, $P = 0.013$ and $Foxp3^+/CD4^+$, $P < 0.001$). Moreover, the ratios were significantly higher in gastric mucosa of patients with *H. pylori* infection than in patients without infection (Figure 4D; Hp+ *vs* Hp-: $CD25^+/CD4^+$, $P = 0.001$ and $Foxp3^+/CD4^+$, $P < 0.001$). No significant association was found between Treg number and IM or AT. Together, the presence of Tregs was positively associated with inflammation, LFs, and *H. pylori* infection.

CD25$^+$/CD4$^+$ and Foxp3$^+$/CD4$^+$ ratios are lower in gastritis and peptic ulcer patients with IM than in those without IM

We compared Tregs in gastric mucosa of gastritis and peptic ulcer patients with and without IM (Figure 5). There were significantly fewer $CD4^+$, $CD25^+$, or $Foxp3^+$ cells in gastritis patients with IM than in those without (Figure 5A-C; IM+ *vs* IM-: $CD25^+$, $P < 0.001$; $CD4^+$, $P < 0.001$; $Foxp3^+$, $P < 0.001$). The ratios $CD25^+/CD4^+$ and $Foxp3^+/CD4^+$ were also significantly lower in gastritis patients with IM (Figure 5D and E; IM+ *vs* IM-: $CD25^+/CD4^+$, $P = 0.002$ and $Foxp3^+/CD4^+$, $P = 0.002$). A similar profile was observed in the peptic ulcer patients (Figure 5A-E; IM+ *vs* IM-: $CD25^+$, $P = 0.004$; $CD4^+$, $P = 0.013$; $Foxp3^+$, $P < 0.001$; $CD25^+/CD4^+$, $P = 0.040$; $Foxp3^+/CD4^+$, $P = 0.003$). Thus, IM was associated a reduced number of Tregs in patients with gastroduodenal diseases.

DISCUSSION

Most studies investigating the role of Tregs in gastroduodenal diseases have used fluorescence-activated cell sorting (FACS) to directly identify $CD4^+CD25^+$ Tregs in lymphocytes from peripheral blood or lamina propria[15,24-27]. Recently, Perrone *et al*[28] investigated tumor-infiltrating $Foxp3^+$ Tregs in radically resected (R0) gastric cancer by immunohistochemistry, and suggested that $Foxp3^+$ Tregs may be a novel in situ marker for identifying high-risk gastric cancer patients. In the present study, we investigated the expression of two markers for Tregs, namely Foxp3 and CD25, in relation to CD4 expression by immunohistocytochemistry in three consecutive sections of a panel of normal and diseased specimens. We confirmed a significantly high correlation between the numbers of $CD25^+$ and $Foxp3^+$ T lymphocytes, and between the $CD25^+/CD4^+$ and $Foxp3^+/CD4^+$ ratios.

The retrospective study of 135 non-cancer subjects in a single clinical institute demonstrates a positive correlation between the number of $Foxp3^+$ Tregs and histological grade, including AIS, CIS, and LFs. Furthermore, the presence of *H. pylori* was positively associated with the number of Tregs. These results suggest that gastritis can be induced by *H. pylori* infection, which contributes to the occurrence of lymphoid tissue hyperplasia and recruits Tregs. This result agrees with previous evidences for a positive link between *H. pylori*-induced gastritis and recruitment of $Foxp3^+$ Tregs[21,29-31]. It is interesting that Tregs isolated from gastric adenocarcinoma patients are able to suppress *H. pylori*-induced T cell responses *in vitro*, supporting the role of Tregs in facilitating persistent *H. pylori* colonization and hence gastric carcinogenesis[15].

The number of Tregs in our gastric cancer group was significantly higher than that of the peptic ulcer group or the gastritis group. Additionally, the number of $Foxp3^+$ Tregs and the $Foxp3^+/CD4^+$ ratio in antral mucosa were increased progressively from healthy controls to gastritis patients to gastric cancer patients. Interestingly, this sequential change corresponds to the sequential clinical sequelae of gastric carcinogenesis, or Correa's cascade[32,33]. Increasing evidence has indeed demonstrated the presence of significantly elevated numbers of $CD4^+$ Tregs in various types of cancers[15,24,34-39]. It has been hypothesized that Tregs suppress anti-tumor immunity, which leads to immune tolerance of tumor cells[40]. Recently, advanced tumor/node/metastasis (TNM) stage in gastric cancer patients was found associated with elevated expression of Foxp3 in tumor-infiltrating Treg cells[25]. Of note, cyclooxygenase-2/prostaglandin E_2 production might be involved in Treg-based immune suppression, which may have new implications for gastric cancer therapy.

We further examined the distribution of Tregs in patients with IM, a precancerous lesion of the intestinal-type gastric adenocarcinoma[32,33,41-46]. Notably, gastritis and peptic ulcer patients with IM had significantly fewer

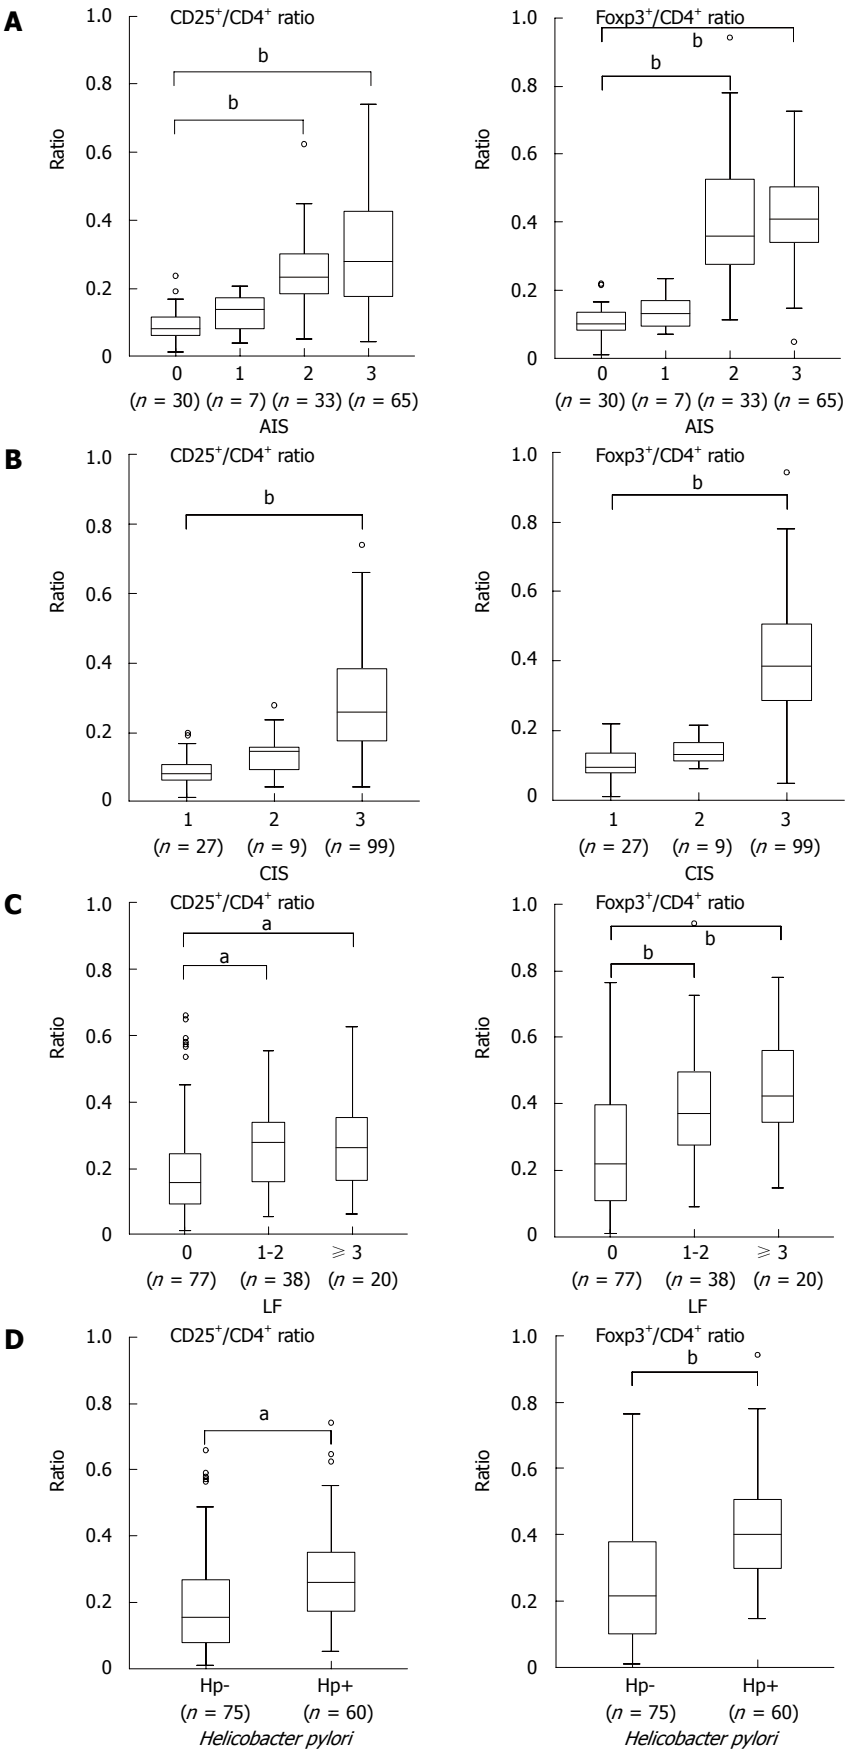

Figure 4 Box plots for the ratio of $CD25^+/CD4^+$ and of $Foxp3^+/CD4^+$ according to acute inflammatory score, chronic inflammatory score, lymphoid follicle number, and *Helicobacter pylori* infection. Box plots for the ratio of $CD25^+/CD4^+$ and of $Foxp3^+/CD4^+$ according to A: Acute inflammatory score (AIS); B: Chronic inflammatory score (CIS); C: Lymphoid follicle number (LF); D: *Helicobacter pylori* infection. Data were analyzed using the Mann-Whitney *U* test. $^aP < 0.05$ and $^bP < 0.001$. HP: *Helicobacter pylori*.

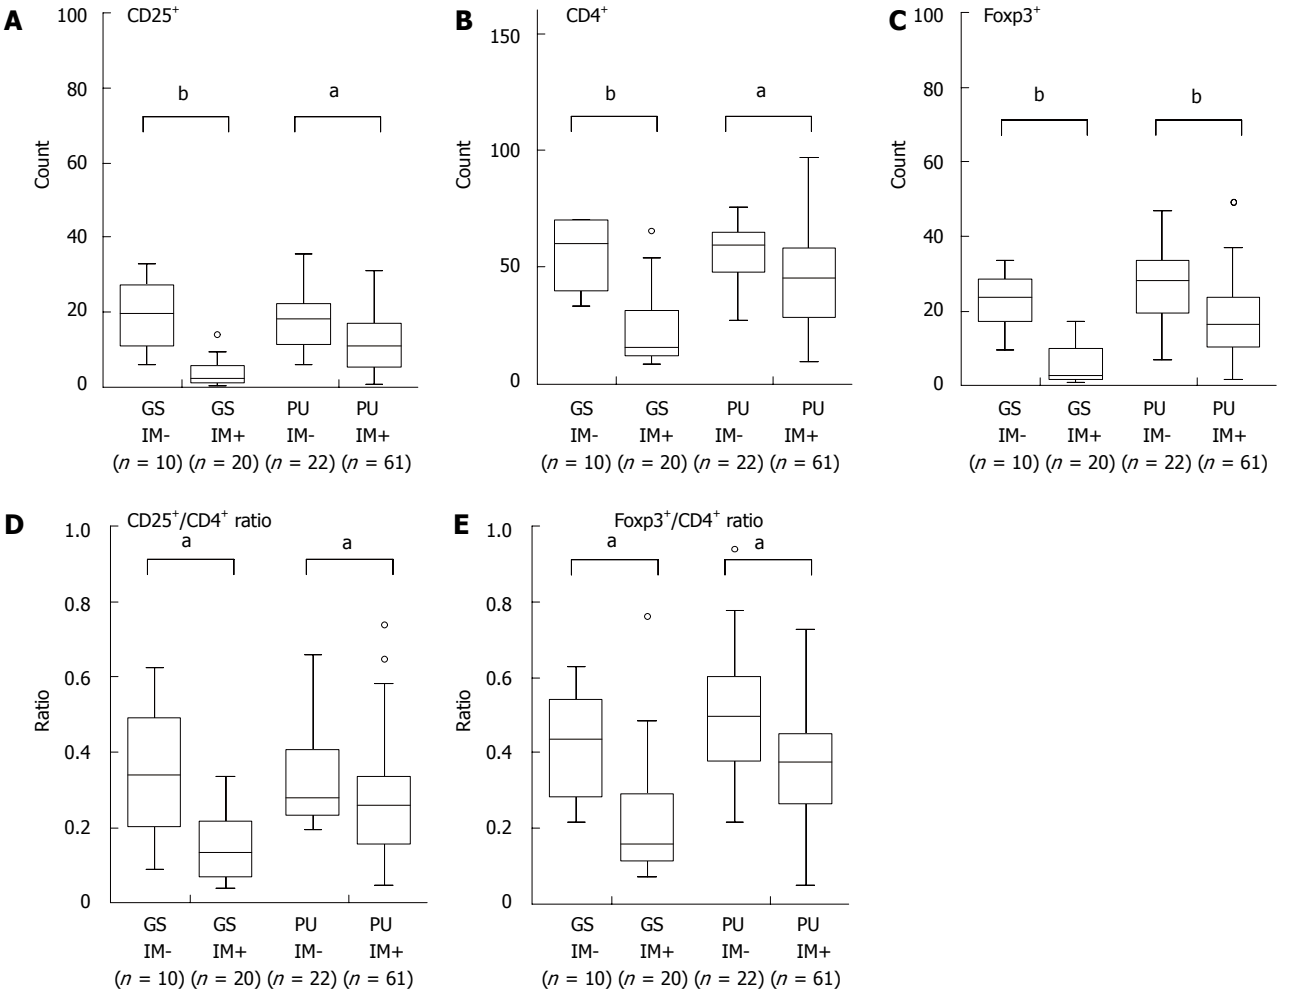

Figure 5 Box plots for the number of CD25$^+$, CD4$^+$, and Foxp3$^+$ cells, and the ratio of CD25$^+$/CD4$^+$ and of Foxp3$^+$/CD4$^+$ in gastritis and peptic ulcer patients with and without intestinal metaplasia. Box plots for A: The number of CD25$^+$ cells; B: The number of CD4$^+$ cells; C: The number of Foxp3$^+$ cells; D: The ratio of CD25$^+$/CD4$^+$; E: The ratio of Foxp3$^+$/CD4$^+$ in non-intestinal metaplasia (IM) areas of antral gastric mucosa from gastritis (GS) and peptic ulcer (PU) patients with and without IM. Data were analyzed using the Mann-Whitney *U* test. $^aP < 0.05$ and $^bP < 0.001$.

Tregs than patients without IM. Previous studies showed an increased level of TGF-β as well as Foxp3$^+$ Tregs in patients with *H. pylori*-induced gastritis[30], which supports the notion that TGF-β is a critical differentiation factor for Treg cells within a local microenvironment[47,48]. It is interesting that Mutoh *et al*[49] recently reported a lower level of TGF-β expression in the IM subjects, which was comparable to that in the normal tissues as opposed to a 6.5-fold increase in gastric carcinoma. Such a lower level of TGF-β expression might contribute to the lesser numbers of Foxp3$^+$ Tregs in GS/PU patients with IM. However, further investigations will be needed to explore this possibility.

There are limitations in our study, all stemming from its retrospective design. First, there is a possible selection bias, even though at least 30 cases were included in each disease group. Second, it is unlikely to rule out the remote NSAIDs used in our enrolled subjects based on reviewing their medical records. The potential effect of NSAIDs on Tregs in our patients thus might be undetermined. Third, it was not possible to use a functional assay for Treg expression to address detailed mechanisms.

In conclusion, the number of Tregs is elevated and positively correlated with histological grade of chronic gastritis, atrophic gastritis and adenocarcinoma, but is decreased and negatively correlated with histological grade of IM.

COMMENTS

Background

Helicobacter pylori (*H. pylori*) are associated with chronic gastroduodenal inflammation, atrophy, intestinal metaplasia, and gastric cancer. The role of CD4$^+$CD25$^+$ Tregs in suppressing the immune response to *H. pylori*, and increased populations of CD4$^+$CD25$^+$ T regulatory cells (Tregs) link to the *H. pylori*-infected pathologies have been reported.

Research frontiers

CD4$^+$CD25$^+$Foxp3$^+$ Tregs are expressed in various types of cancers including gastric cancer. Tregs is also elevated in *H. pylori*-associated gastritis. However, the relationship between Tregs with precancerous lesions of the stomach remains unclear. In this study, the authors analyzed the number of CD4$^+$, CD25$^+$,

or Foxp3$^+$ T cells by immunohistochemistry in the antrum mucosa and examined the relationship between marker expression and precancerous lesions.

Innovations and breakthroughs

Recent reports have highlighted the association between Tregs and precancerous lesions of the stomach. In this study, the authors report that the number of Tregs is positively correlated with histological grade of chronic gastritis, atrophic gastritis and adenocarcinoma, and negatively correlated with histological grade of IM, suggesting that Tregs may play a role in the progression of gastric cancer.

Applications

Foxp3$^+$ Tregs may be a novel *in situ* marker for identifying gastric cancer patients.

Terminology

Tregs are a small population of T lymphocytes that may induce and maintain immunologic self-tolerance to prevent the development of autoimmune diseases. Forkhead box p3 (Foxp3) has been identified as a crucial transcription factor that regulates the development of CD4$^+$CD25$^+$ Tregs function and thus may serve as a reliable marker for CD4$^+$CD25$^+$ Tregs.

Peer review

This manuscript is a well written contribution and the data merit publication. Significant patient material has been collected and relevant data have been retrieved. The immuno-based analysis is well carried out and justifies the conclusions reached by the authors.

Abstract

AIM: To investigate the effects of proton pump inhibitor (PPI) treatment on stool antigen test using the TestMate pylori enzyme immunoassay.

METHODS: This study assessed 28 patients [16 men and 12 women; mean age (63.1 ± 5.9) years; range, 25-84 years] who underwent stool antigen test and urea breath test (UBT) before and after PPI administration.

RESULTS: Using the UBT as the standard, the sensitivity, specificity and agreement of the stool antigen test in all 28 patients were 95.2%, 71.4%, and 89.3%, respectively, before PPI administration, and 88.9%, 90.9%, and 89.3%, respectively, after PPI treatment. Mean UBT values were 23.98% ± 5.33% before and 16.19% ± 4.75% after PPI treatment and, in 15 patients treated for ⩾ 4 wk, were significantly lower after than before 4 wk of PPI treatment (12.58% ± 4.49% *vs* 24.53% ± 8.53%, P = 0.048). The mean optical density ($A_{450/630}$) ratios on the stool antigen test were 1.16 ± 0.20 before and 1.17 ± 0.24 after PPI treatment (P = 0.989), and were 1.02 ± 0.26 and 0.69 ± 0.28, respectively, in the group treated for > 4 wk (P = 0.099).

CONCLUSION: The stool antigen test was equally sensitive to the UBT, making it a useful and reliable diagnostic method, even during PPI administration.

INTRODUCTION

The urea breath test (UBT) has shown high sensitivity

and specificity in the non-invasive diagnosis of *Helicobacter pylori* (*H. pylori*) infection, making the UBT one of the most valuable non-invasive tests for diagnosing *H. pylori* infection and eradication throughout the world[1]. This test has been recommended in the 2005 revision of the guidelines for *H. pylori* diagnosis and treatment of the European *Helicobacter* study group (Maastricht Ⅲ)[2].

The stool antigen test, using polyclonal and monoclonal antibodies, is another non-invasive method for detecting *H. pylori*[3], with comparable sensitivity and specificity to the UBT. Maastricht Ⅲ has also recommended the stool antigen test as a simple, easy and useful method for detecting the presence or eradication of *H. pylori*[2]. Native catalase was recently identified as an antigen produced by *H. pylori*[4]. Catalase is characterized by its stability, and the stool antigen test using a monoclonal antibody to catalase is both rapid, taking only about 70 min, and considered more specific than methods using polyclonal antibodies[4]. Although the UBT is non-invasive and the laboratory procedure is recognized as simple and easy, it requires a longer period of time and trained medical staff. Moreover, the UBT is difficult for some patients, including children, handicapped individuals with deteriorated activities of daily life (ADL) and elderly individuals. The stool antigen test is a simpler analytical process, does not require as many medical staff members and can be more readily applied for patients with reduced ADL, children, and the elderly.

Proton pump inhibitors (PPIs) have strong antigastric secretion effects, as well as being bacteriostatic against *H. pylori*. Since UBT may yield false-negative results in patients being treated with PPIs[5,6], it has been recommended that PPI treatment be suspended for at least 2 wk prior to UBT for *H. pylori* infection. One of the stool antigen tests available is the Testmate pylori antigen enzyme immunoassay (EIA)[7], which uses native catalase as an antigen. Thus, the precision of this test in diagnosing *H. pylori* infection should remain stable even during PPI treatment. To determine their comparative accuracy in patients being treated with PPIs, we compared this stool antigen test and the UBT in patients before and after PPI administration.

MATERIALS AND METHODS

We assessed 28 patients [16 men and 12 women; mean age, (63.1 ± 5.9) years; range, 25-84 years] who had been referred to the Department of Gastroenterology at Oita University Hospital and diagnosed with peptic ulcer, reflux esophagitis, or other diseases requiring PPI treatment.

The UBT and stool antigen test were performed before and after PPI administration. Patients were treated for > 2 wk with the 3 types of PPI commercially available in Japan: omeprazole (10 mg/d or 20 mg/d); lansoprazole (15 mg/d or 30 mg/d); or rabeprazole (10 mg/d or 20 mg/d).

Breath samples for UBT were collected before and 20 min after each subject took a 100 mg UBIT tablet® (Otsuka Pharmaceutical, Tokyo, Japan). $^{13}CO_2/^{12}CO_2$ ratios were analyzed by INIS (UBiT-IR300; Otsuka Electronics, Tokyo, Japan), with a cut-off point of 2.5‰.

Stool samples were collected from each patient before and after PPI treatment, and stored at -80 ℃ until assayed. The stool antigen test was performed using the Testmate pylori antigen EIA (Wakamoto Pharmaceutical, Tokyo, Japan; Kyowa Medex, Tokyo, Japan). An aliquot of 100 mg stool was diluted into 0.4 mL of diluted buffer, and 50 μL, together with peroxidase-conjugated anti-catalase monoclonal antibody, were added to a well and incubated for 1 h at 25 ℃. Absorbance was measured at wavelengths of 450 nm and 630 nm, with a cut-off value of 0.120.

Table 1 Results of urea breath test and stool antigen tests before proton pump inhibitor administration

	Urea breath test		
	Positive	Negative	Total
Stool antigen test			
Positive	20	2	22
Negative	1	5	6
Total	21	7	28

Sensitivity 95.2% (20/21), specificity 71.4% (5/7), agreement 89.3% (25/28).

Statistical analysis

Statistical comparisons were performed using the χ^2 test, the Wilcoxon signed-rank test, and the paired *t*-test.

RESULTS

Prior to PPI administration, both the UBT and stool antigen tests yielded positive results in 20 of 28 patients and negative results in 5. One patient was positive on the UBT and negative on the stool antigen test, and 2 patients were negative on the UBT and positive on the stool antigen test. Using UBT as the standard, the sensitivity, specificity and agreement of the stool antigen test before PPI treatment were 95.2%, 71.4%, and 89.3%, respectively (Table 1).

Following PPI administration, both the UBT and stool antigen test showed positive results in 16 patients and negative results in 9. Two patients were positive on the UBT and negative on the stool antigen test, and one was showed on the UBT and positive on the stool antigen test. Using UBT as the standard, the sensitivity, specificity and agreement of the stool antigen test after PPI treatment were 88.9%, 90.9%, and 89.3%, respectively (Table 2).

Positivity of the UBT and stool antigen test before and after PPI treatment

The UBT positivity rates were 75.0% (21/28) before and 64.3% (18/28) after PPI treatment (P = 0.55; Table 3). The stool antigen test positivity rates were 78.6% (22/28) before and 60.7% (17/28 cases) after PPI treatment (P = 0.15). No significant differences in the positivity ratios of

Table 2 Results of urea breath test and stool antigen tests after proton pump inhibitor administration

	Urea breath test		
	Positive	Negative	Total
Stool antigen test			
Positive	16	1	17
Negative	2	9	11
Total	18	10	28

Sensitivity 88.9% (16/18), specificity 90.9% (9/10), agreement 89.3% (25/28).

Table 3 Differences in positivity rates from before to after proton pump inhibitor treatment

	Before PPI treatment	After PPI treatment	*P* value
Urea breath test	75.0% (21/28)	64.3% (18/28)	0.55
Stool antigen test	78.6% (22/28)	60.7% (17/28)	0.15

PPI: Proton pump inhibitor.

the two assays were observed before ($P = 0.75$) or after ($P = 0.58$) PPI treatment.

Measured values for UBT ($^{13}CO_2/^{12}CO_2$ ratios) and stool antigen test (A values) before and after PPI treatment

The mean UBT values were 23.98% ± 5.33% before and 16.19% ± 4.75% after PPI treatment ($P = 0.068$), and were 24.53% ± 8.53% and 12.58% ± 4.49%, respectively ($P = 0.048$), in the 15 patients treated with PPIs for ≥ 4 wk (Figure 1).

The mean *A* ratios on the stool antigen test were 1.16 ± 0.20 before and 1.17 ± 0.24 after PPI treatment ($P = 0.989$), and were 1.02 ± 0.26 and 0.69 ± 0.28, respectively ($P = 0.099$), in the 15 patients treated with PPI for ≥ 4 wk (Figure 2).

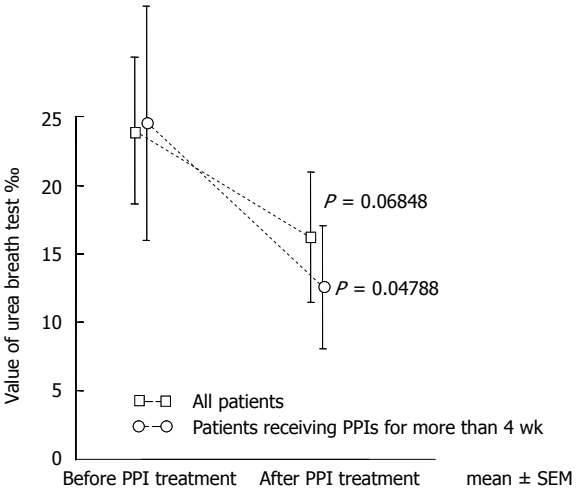

Figure 1 Urea breath test results ($^{13}CO_2/^{12}CO_2$ ratios) before and after proton pump inhibitor treatment. UBT results in all 28 patients were not altered by PPI treatment ($P = 0.068$). However, among patients treated for ≥ 4 wk, UBT results decreased significantly after PPI treatment ($P = 0.048$). UBT: Urea breath test; PPI: Proton pump inhibitor.

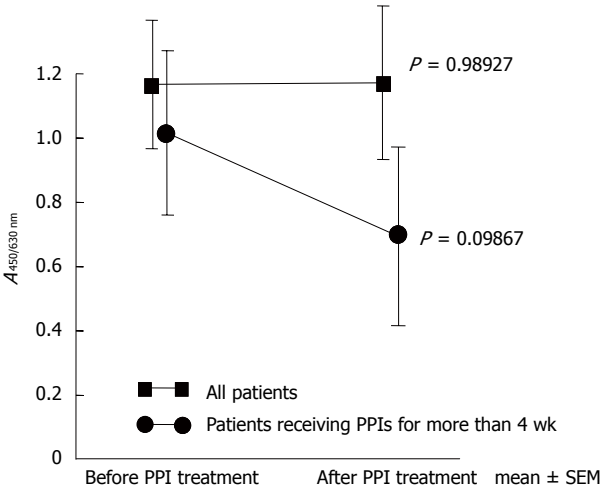

Figure 2 Stool antigen test results (A_{450}/A_{630} ratios) before and after proton pump inhibitor treatment. PPI treatment did not significantly alter stool antigen test results, both in all patients ($P = 0.989$) and in those treated for ≥ 4 wk ($P = 0.099$). PPI: Proton pump inhibitor.

DISCUSSION

The stool antigen test is a non-invasive test for *H. pylori*, similar to the UBT. The test is simple and easy to perform, with good sensitivity and specificity[8]. An analysis of 89 reports found that the mean sensitivity, specificity, positive predictive value and negative predictive value were 91%, 93%, 92%, and 87%, respectively, among 10 858 subjects who were not treated with *H. pylori* eradication therapy[3]. In addition, 8 reports of tests with monoclonal antibody showed significantly better results ($P < 0.001$), with mean sensitivity, specificity, positive predictive value and negative predictive value of 96%, 97%, 96%, and 97%, respectively. The Maastricht Ⅲ guidelines have found that the reliability of the stool antigen test is comparable to that of the UBT[2].

Despite its non-invasive nature, and high sensitivity and specificity, the UBT can lead to false-negative results in patients treated with drugs showing bacteriostatic activity against *H. pylori*, such as PPIs, or inhibiting urease activity[5,6,9-12]. In those studies, the false-negative rates of the UBT in patients treated with omeprazole or lansoprazole for 2 wk or 4 wk were ≥ 50%. We previously observed false-negative UBT results in 1 of 16 patients (6.3%) treated with 30 mg/d lansoprazole for 2 wk[6]. Several studies have also reported that the rate of false-negative results on the stool antigen test also increase in patients treated with PPI[13,14]. A comparison of stool antigen test and UBT results for 9 *H. pylori*-positive patients receiving PPI for 2 wk found a smaller degree of change on the stool antigen test than on the UBT[15].

The authors found that, before PPI treatment, the stool antigen test showed high sensitivity, but lower specificity (71.4%). This was likely due to the small number of patients showing negative results on the UBT ($n = 7$).

Similarly, although many reports have shown high sensitivity and specificity for stool antigen tests, others have reported lower specificity (54%-78%)[3].

The sensitivity of the stool antigen test fell slightly after PPI administration, but its specificity remained high level (90.9%). The concordance rate of UBT and stool antigen test results was high (89.3%) before and after PPI administration. Using the UBT as standard, the stool antigen test showed good sensitivity and specificity both before and after PPI administration. Although stool antigens have generally shown high sensitivity and specificity, divergent sensitivity and specificity between the UBT and stool antigen test have been reported[16]. However, increasing the cut-off for the stool antigen test reduced the percentage of conflicting results[16]. This discrepancy was attributed to the urease-based UBT not detecting the coccoid form of *H. pylori*, as well as the low cut-off index for the stool antigen test. The discrepancies we observed, with positive results on the stool antigen test and negative results on the UBT, were likely due to the same mechanism.

There were no significant differences in positive rates on the UBT and stool antigen test before and after PPI therapy, suggesting that the stool antigen test is a useful and reliable diagnostic test for *H. pylori*, similar to the UBT. The positivity rate for UBT decreased from 75.0% before to 64.3% after PPI administration, and the positivity rate for the stool antigen test decreased from 78.6% to 60.7%. These reductions indicate that the stool antigen test should be performed after limiting PPI administration as much as possible, but that, when PPI treatment cannot be stopped, the stool antigen test shows comparable utility to the UBT. Although both the stool antigen test and UBT results did not change significantly from before to after PPI treatment, the reductions were much less pronounced on the stool antigen test than on the UBT. Moreover, in patients treated for $\geqslant$ 4 wk, UBT, but not stool antigen test, results decreased significantly after PPI treatment. These findings indicate that, while the results of both assays were influenced by the bacteriostatic actions of PPIs, the stool antigen test was less influenced than the UBT.

Although several studies have reported increased false-negative results for the stool antigen test during PPI treatment[13,14], we found that stool antigen test results were more stable than UBT results in patients being treated with PPIs.

Despite the benefits of the UBT as a non-invasive test for *H. pylori*[17] and the slightly lower accuracy of the stool antigen test, the latter has several advantages, including ease, rapidity and lower cost. Others have also reported that the stool antigen test is highly sensitive and specific, with high utility due to the speed and simplicity of testing[18].

The 2005 Maastricht Ⅲ consensus report recommended that the stool antigen test be used for diagnosis when the UBT is unavailable[2]. The numbers of patients receiving PPI therapy have been increasing around the world, and many patients have difficulty undergoing the UBT, such as elderly patients and patients with reduced ADL. In these patients, the stool antigen test should be considered reliable and useful.

In conclusion, the stool antigen test showed stable results even during PPI treatment as well as sensitivity comparable to the UBT. In patients treated with PPI for $\geqslant$ 4 wk, the stool antigen test showed more stable results than the UBT. The stool antigen test is therefore a useful and reliable diagnostic method for *H. pylori* infection.

COMMENTS

Background

Although the urea breath test (UBT) is a reliable, non-invasive diagnostic test for *Helicobacter pylori* (*H. pylori*), it has a potential for false-negative results in patients treated with proton pump inhibitor (PPI). The stool antigen test is another useful, easy to perform, non-invasive assay for *H. pylori*, with high sensitivity and specificity. However, the effects of PPI treatment on stool antigen test results are unclear.

Research frontiers

Due to the increase in patients with gastroesophageal reflux disease and those treated with nonsteroidal anti-inflammatory drugs, the numbers treated with PPIs has increased throughout the world. Thus, reliable diagnostic tests for *H. pylori* are needed for patients treated with PPIs. The study describe the utility of a stool antigen test, using the TestMate pylori enzyme immunoassay, in patients treated with PPIs.

Innovations and breakthroughs

Although many studies have reported results of stool antigen tests in patients treated with PPIs, none has assessed the relationship between measured value of stool antigen test and UBT results. To our knowledge, this study is the first to clarify the stability of the stool antigen test, relative to the UBT, in patients treated with PPIs.

Applications

Elderly patients and those with reduced daily activities who are treated with PPIs have increased. The UBT is somewhat difficult to perform in these patients. The authors found that the stool antigen test may be a useful alternative to the UBT in these patients.

Terminology

The stool antigen test is a diagnostic assay for *H. pylori*. which identifies *H. pylori* antigens in feces using antigen-antibody reactions. This non-invasive assay has equal sensitivity and specificity to the UBT, and may be especially useful for children or elderly patients.

Peer review

The manuscript is well written. The methods are adequate. The results justify the conclusions drawn.

Abstract

AIM: To evaluate the prognosis of type Ⅱ diabetes mellitus (T2DM) after gastrectomy and related factors in gastric cancer patients.

METHODS: 403 gastric cancer patients with T2DM were studied, who underwent gastrectomy between May 2003 and September 2009. A review of medical records and telephone interviews was performed in this cross-sectional study. The factors included in the statistical analysis were as follows: gender, age, type of surgery, preoperative body mass index (BMI), current BMI, BMI reduction ratio, preoperative insulin or oral diabetic medicine requirement, follow-up duration, and current state of diabetes. Assessment of diabetes status after surgery was classified into four categories according to the change in hypoglycemic agents after surgery and present status of T2DM: resolution, improvement, same, and worse.

RESULTS: The mean follow-up duration was 33.7 mo (± 20.6 mo), preoperative BMI was 24.7 kg/m^2 (± 3.0 kg/m^2), and BMI reduction ratio was 9.8% (± 8.6%). After surgery, T2DM was cured in 58 patients (15.1%) and was improved in 117 patients (30.4%). According to the type of surgery, the BMI reduction ratio was significantly higher in the total gastrectomy and Roux-en-Y reconstruction group [14.2% ± 9.2% *vs* 9.2% ± 7.7% (Billroth Ⅱ group), $P < 0.001$] and significantly lower in the subtotal gastrectomy and Billroth Ⅰ reconstruction group [7.6% ± 8.0%, 9.2% ± 7.7% (Billroth Ⅱ group), $P < 0.001$]. The BMI reduction ratio, follow-up duration after surgery, type of surgery, extent of gastrectomy, and performance of duodenal bypass were significantly correlated to the course of T2DM ($P < 0.05$). The BMI reduction ratio was the most influential factor on T2DM status. In a subgroup analysis of patients with a BMI reduction ratio of 10% or less ($n = 206$), T2DM was cured in 15 (7.6%) patients and was improved in 57 (28.8%) patients after surgery, and only the duration of surgery was significantly correlated to T2DM status ($P = 0.022$).

CONCLUSION: The course of T2DM was significantly correlated to the BMI reduction ratio but not to the type of surgery without a significant change in BMI.

Key words: Gastric cancer; Diabetes mellitus; Metabolic surgery; Bariatric surgery

INTRODUCTION

Gastrointestinal surgery has been established as the treatment of choice for patients with inadequately controlled type 2 diabetes mellitus (T2DM) and a body mass index (BMI) greater than or equal to 35 kg/m^2[1]. However, indications for bariatric surgery in the treatment of T2DM are not clear. T2DM is improved by calorie restriction and weight loss, which can be aided by bariatric surgery.

Recently, it was reported that bariatric surgery to treat morbid obesity along with T2DM resulted in amelioration of T2DM, including weight loss[2-6]. In addition, a non-randomized, comparative Swedish Obesity Study showed that regaining weight led to recurrence of diabetes through long-term follow-up[7]. However, bariatric surgery may improve glycemic control in T2DM within days, even before considerable weight loss occurs. The exact mechanism for the dramatic effect of obesity surgery on T2DM remains unknown. T2DM has been approached from a new angle as an intestinal disease, which is increasingly viewed as operable[8-11].

These findings prompted clinicians to extend indications for bariatric surgery to non-obese patients with T2DM. In the 1950s and 60s, amelioration of diabetes following subtotal gastrectomy was reported[12,13]. Since then, there have been few reports with inconsistent results in this area[14,15].

In this study, we compared the effects of gastrointestinal, anatomical rearrangements on diabetes after surgery for gastric cancer.

MATERIALS AND METHODS

Between May 2003 and September 2009, 6848 patients with gastric cancer underwent gastrectomy at Severance Hospital and Gangnam Severance Hospital, the Yonsei University College of Medicine. Of these patients, 576 had diabetes; the diagnosis of diabetes was based on the criteria of the American Diabetes Association and the World Health Organization. We excluded 81 patients who expired or had cancer recurrence and 92 patients who could not be surveyed, leaving 403 patients to be enrolled for this study. To exclude type 1 diabetes, we reviewed patient medical records and interviewed these individuals about their type and history of diabetes, but no patients were diagnosed with or suspected to have type 1 diabetes. Data were collected by a review of medical records and interviews *via* telephone. The following factors were statistically analyzed: gender, age, type of surgery, preoperative BMI, current BMI, BMI reduction ratio, preoperative insulin or oral diabetic medicine requirement, follow-up duration, and current state of diabetes. "Resolution" was defined as a case where the patient became euglycemic or an HbA1c level was maintained below 6% without the use of diabetes medication after surgery. "Improvement" was defined as a case where the patient showed a better fasting glucose level and either used a lower dose of hypoglycemic agents or converted to oral hypoglycemic agents from insulin, compared with preoperative diabetic control. "Same" or "worse" was defined as a case in which no change occurred ("same") or an aggravation in fasting glucose and medication after surgery ("worse") was observed. Patients were divided into three groups by type of surgery: gastroduodenostomy after subtotal gastrectomy [Billroth Ⅰ (B-Ⅰ) group], gastrojejunostomy after subtotal gastrectomy [Billroth Ⅱ (B-Ⅱ) group], and Roux-en-Y esophagojejunostomy after total gastrectomy (R-Y group).

Table 1 Clinical findings [*n* = 403, *n* (%) or mean ± SD]

Gender	Female	96 (23.8)
	Male	307 (76.2)
Age at OP (yr)		63.8 ± 7.6
OP type	B-Ⅰ	165 (40.9)
	B-Ⅱ	134 (33.3)
	R-Y	104 (25.8)
Extent of gastrectomy	Subtotal (B-Ⅰ, B-Ⅱ)	299 (74.2)
	Total (R-Y)	104 (25.8)
Duodenal bypass	Bypass – (B-Ⅰ)	165 (40.9)
	Bypass + (B-Ⅱ, R-Y)	238 (59.1)
Pre-OP BMI (kg/m^2)		24.7 ± 3.0 (18.4-39.9)
Current BMI (kg/m^2)		22.2 ± 2.9 (13.5-35.3)
BMI reduction ratio[1] (%)		9.8 ± 8.6
Pre-OP	Oral diabetic agent	368 (91.3)
diabetic therapy	Insulin	35 (8.7)
F/U duration (mo)		33.7 ± 20.6 (5.5-81.8)
Diabetes course	Worse	38 (9.9)
	Same	172 (44.7)
	Improvement	117 (30.4)
	Resolution	58 (15.1)

[1]BMI reduction ratio (%) = -[(Current BMI - Pre-OP BMI)/Pre-OP BMI] × 100. OP: Operation; BMI: Body mass index; F/U: Follow up; B-Ⅰ: Billroth Ⅰ; B-Ⅱ: Billroth Ⅱ; R-Y: Roux-en-Y.

SPSS version 12.0 for Windows (SPSS Inc., Chicago, IL, United States) was used for all statistical analyses. All data were analyzed using the paired sample *t* test, analysis of variance, and ordinal logistic regression analysis. A *P* value of less than 0.05 was considered significant.

This study was approved by the Institutional Review Board of Gangnam Severance Hospital (approval number 3-2020-0259).

RESULTS

The characteristics of the subjects are summarized in Table 1. Of 403 patients, 58 patients (15.1%) were euglycemic without medication, and 117 patients (30.4%) showed improved metabolic conditions but were still taking medication. In contrast, 172 patients (44.7%) did not change their medication for diabetes, and 38 patients (9.9%) had aggravated conditions (Table 1).

Univariate analyses were carried out to determine the impact of factors contributing to the amelioration of diabetes. The course of diabetes after surgery was significantly different between the R-Y and B-Ⅰ groups (P = 0.001) and between the R-Y and B-Ⅱ groups (P = 0.006), but not between the B-Ⅰ and B-Ⅱ groups (P = 0.161).

Table 2 Univariate analysis [*n* = 403, *n* (%) or mean ± SD]

		Diabetes course				*P* value
		Worse	Same	Improvement	Resolution	
Gender	Female	8 (8.6)	36 (38.7)	34 (36.6)	15 (16.1)	0.180

F/U duration (mo)		36.4 ± 18.2	37.2 ± 21.6	30.0 ± 20.1	28.3 ± 17.8	0.001

[a]*P* = 0.161, B-Ⅰ *vs* B-Ⅱ. [1]BMI reduction ratio (%) = -[(Current BMI - Pre-OP BMI)/Pre-OP BMI] × 100. OP: Operation; BMI: Body mass index; F/U: Follow up; B-Ⅰ: Billroth Ⅰ; B-Ⅱ: Billroth Ⅱ; R-Y: Roux-en-Y.

We categorized patients into two groups by the extent of gastrectomy. Diabetes was significantly improved in the total gastrectomy group compared with the subtotal gastrectomy group ($P < 0.001$) All patients were then categorized into two groups by the presence of duodenal bypass. Patients who received duodenal bypass had significantly improved diabetes compared to those who did not ($P = 0.002$, Table 2). In addition, the course of diabetes was significantly correlated with current BMI and BMI reduction ratio ($P = 0.038$ and $P < 0.001$, respectively). Diabetes was improved immediately after surgery, gradually worsening over a longer term ($P = 0.001$, Table 2).

Ordinal logistic regression analysis was performed to determine significant factors affecting the course of diabetes. Because surgery type, extent of gastrectomy, and duodenal bypass were similar factors, when the three factors were entered simultaneously in multivariate analysis, all were insignificant. Therefore, we performed multivariate analysis three times according to the three types of surgery. In all three multivariate analyses, the BMI reduction ratio and follow-up duration were significantly related to amelioration of diabetes, but current BMI was not. Moreover, the absolute value of contribution degree of the BMI reduction ratio was greatest among significant factors, so the BMI reduction ratio was found to have the biggest impact on diabetic status after three multivariate analyses (Table 3). Performance of B-Ⅰ versus R-Y was a significant factor, but performance of B-Ⅱ versus R-Y was not. We used the extent of gastrectomy or duodenal bypass as a covariate, and these factors were also significant.

Based on these results, we investigated the association between weight change and type of surgery. There was a significant decrease in BMI in the R-Y group, compared with the B-Ⅰ and B-Ⅱ groups (Figure 1A). There was also a significant difference in the BMI reduction ratio between the B-Ⅰ and B-Ⅱ groups. The total gastrectomy group showed significant weight loss compared with the subtotal gastrectomy group ($P < 0.001$, Figure 1B), and duodenal bypass lost significantly more weight than the non-duodenal bypass group ($P < 0.001$, Figure 1C).

Table 3 Multivariate analysis (*n* = 403)

	P value	B-estimation	SE	Contribution degree

These results suggest that the main factor influencing diabetes improvement might be weight loss instead of type of surgery. Therefore, we performed subgroup analysis of the patients whose BMI reduction ratio was less than 10% of the preoperative level. The mean BMI reduction ratio was 3.4% (± 5.4%; Table 4). In univariate analysis, type of surgery was not a significant factor for

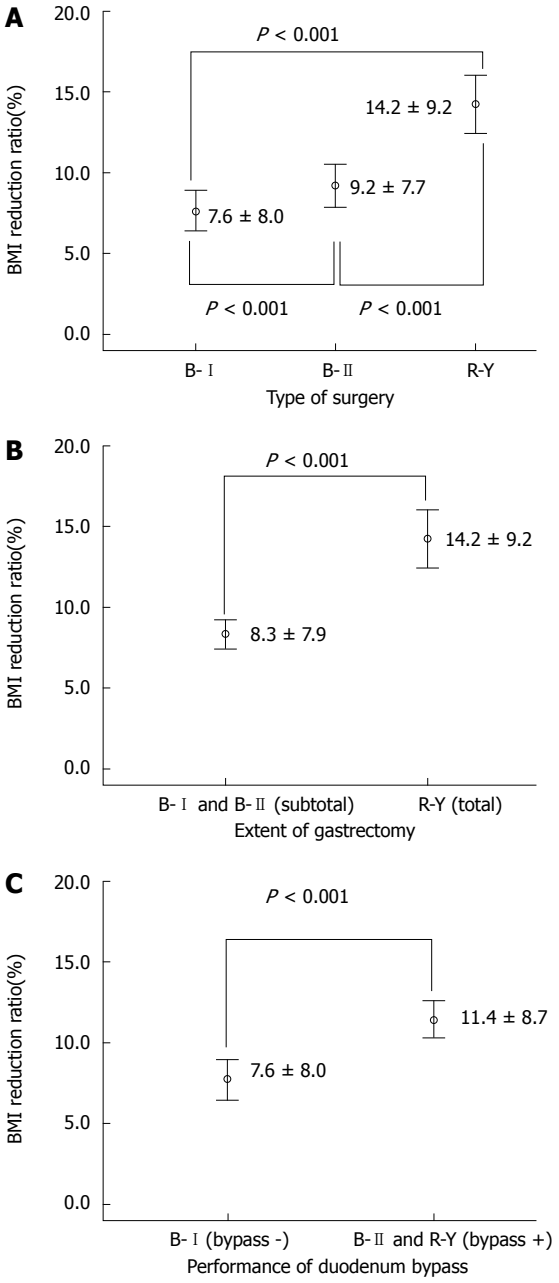

Figure 1 Body mass index reduction ratio according to A: Type of surgery; B: Extent of gastrectomy; C: Performance of duodenum bypass (*n* = 403, mean ± SD). BMI: Body mass index; B- Ⅰ: Billroth Ⅰ; B- Ⅱ: Billroth Ⅱ; R-Y: Roux-en-Y.

the amelioration of diabetes (Table 5). However, in this subgroup of 203 patients, diabetes was resolved without medication in 15 patients (7.6%), and 57 patients (36.4%) improved without significant weight loss.

DISCUSSION

This study was conducted in a retrospective manner. Therefore, the type of diabetes was not evaluated by laboratory testing but by reviewing medical records and interviewing. We interviewed all of the enrolled patients and asked about the type and history of diabetes to exclude type 1 diabetes. There were no patients who were diagnosed with or suspected to have type 1 diabetes. Furthermore, in Korea, the incidence of type 1 diabetes is very low, reported as approximately 0.6-2.2/100 000[16-18]. Considering that type 1 diabetes is extremely rare in Korea and the mean age of the study population was 63.8 years, the results of this study showing that there were no cases of type 1 diabetes in 6848 patients of the study population can be thought acceptable.

Possible mechanisms through which metabolic surgery has led to the resolution of T2DM are a decrease in calorie intake, weight loss, and a rearranged gastrointestinal track, which could modulate hormones that affect glucose metabolism, insulin sensitivity, and beta pancreatic cell proliferation[19]. Several reports support a positive role for duodenojejunal exclusion and/or duodenal bypass for T2DM resolution after bariatric surgery in obese patients[20].

However, it is still unclear whether these effects extend to non-obese patients. One report stressed that gastrectomy and short Roux-en Y reconstruction in non-obese T2DM patients correlate with remission of diabetes in 65% of patients[14]. In that study, the preoperative BMI was 29.1 and the postoperative BMI was 24.6 kg/m^2; such significant weight loss might explain the relatively high rate of T2DM resolution after gastrectomy. Another study reported a resolution rate of 38.1% after gastrectomy with Roux-en Y gastrojejunostomy, which is similar to our results[15]. Early delivery of partially digested foods to the ileum and discrete enteroendocrine cells in the mucosa are suggested to release hormones that contribute to the ileal brake[21]. However, we could not evaluate this point due to procedural limitations.

One of the mainstream T2DM treatments is reduction of calorie intake; restrictive bariatric surgery effectively controls T2DM in obese patients[2]. In this study, univariate and multivariate analyses showed that duodenal bypass and/or duodenojejunal exclusion groups demonstrated a high rate of T2DM resolution compared to other procedures. However, for patients who lost less than 10% of their preoperative weight, the type of surgery was not significantly important for T2DM resolution. These results suggest that the usual procedures after gastrectomy for gastric cancer are ineffective to control T2DM directly. In addition, most gastrectomized patients for gastric cancer are not pathologically obese, and reconstruction should not induce severe weight loss.

Interestingly, diabetes worsened after improvements were observed for a short time after surgery. The limitation of this study, which is retrospective and cross-sectional analysis, should be considered. Moreover, most gastric cancer patients are cautious about maintaining their weight for good nutrition. Therefore, it is possible that weight loss immediately after surgery improves T2DM, and as the patient regains weight, the condition deteriorates. In meta-analysis, the proportion of patients with resolution or improvement was not significantly different at time points less than 2 years or 2 years or more after surgery, although it slightly decreased over time[2].

Several studies demonstrated that T2DM could be resolved after metabolic surgery, irrespective of weight loss, *via* a modification in the enteroinsular axis[2,20,21]. Based on these findings, we tried to establish a new procedure for the resolution of T2DM in non-obese patients. Unfortunately, routine reconstruction surgery after gastrectomy could not control diabetes in non-obese patients, and the main mechanism for gastrectomy-induced resolution of T2DM is possibly weight loss, instead of the type of surgery itself. Thus, a more sophisticated procedure should be developed and prospectively evaluated for its effectiveness in controlling T2DM in gastric cancer patients after gastrectomy.

COMMENTS

Background

It has been frequently reported that bariatric surgery for morbid obesity along with type Ⅱ diabetes mellitus (T2DM) results in amelioration of T2DM, including weight loss. Furthermore, in some reports, bariatric surgery may improve glycemic control in T2DM within days, even before considerable weight loss occurs. These findings prompted clinicians to consider T2DM as an operable gastrointestinal disease and extend indications for bariatric surgery to non-obese patients with T2DM. However, the application of surgery for non-obese T2DM patients has considerable risks. In Korea, many cases of gastric cancer have been performed by gastric cancer surgery. In this study, the effects of gastrointestinal, anatomical rearrangements on diabetes were compared after surgery for gastric cancer.

Research frontiers

This is a retrospective but very large-scale study. The authors interviewed all of the enrolled subjects *via* telephone.

Innovations and breakthroughs

In the 1950s and 60s, amelioration of diabetes following subtotal gastrectomy was reported. Since then, there have been few reports in this area with inconsistent results. In those reports, the numbers of cases were very small. In this study, 403 patients were enrolled, and we evaluated the factors affecting the course of diabetes. The authors demonstrated that 15% of T2DM was cured after gastrectomy with conventional reconstruction. The extent of gastrectomy, type of reconstruction, and change in body mass index (BMI) were related to the course of diabetes. Among these factors, the change in BMI was the strongest. In the subgroup analysis of small BMI changes, the extent of gastrectomy and the type of reconstruction were not statistically related to the course of diabetes, which did not support the foregut hypothesis.

Applications

The results of this study can be used as reference data for further study. In other words, in some study of innovative treatment for diabetes in gastric cancer patients, the results could be used for the calculation of the number of subjects required and provide reference data for comparison. In addition, duodenal bypass itself is not a critical factor in metabolic surgery.

Terminology

The term duodenal bypass means a condition in which ingested food material

does not traverse the duodenum. In both Billroth Ⅱ reconstruction after subtotal gastrectomy and Roux-en-Y reconstruction after total gastrectomy, ingested food materials go directly to the jejunum. Metabolic surgery is a field of surgery that attempts to treat metabolic syndrome, including diabetes. Hormonal changes after metabolic surgery are thought to be important. Both the hindgut hypothesis (the quick transit of nutrients to the distal bowel is important) and the foregut hypothesis (the exclusion of the proximal small intestine induces resolution of T2DM) have been proposed.

Peer review

This paper summarized the effect of gastrectomy on T2DM in a large number of patients.

Abstract

AIM: To assess the efficacy and safety of combined pegylated interferon and ribavirin therapy in hepatitis C virus (HCV) infection in renal transplant recipients.

METHODS: This is a retrospective chart review of post renal transplant patients who were positive for anti-HCV and HCV-RNA, and who have received treatment with combination of pegylated interferon and ribavirin between October 2003 and December 2008. Only patients with stable graft function and absence of evidence of cirrhosis and who received the therapy for continuous 48 wk were included. Nineteen patients (13 male and 6 female) were identified and included. The patient's complete blood count, liver and kidney profile, and calculated glomerular filtration rate (GFR) were monitored every 6-8 wk while on treatment. HCV-RNA was tested at 12 wk for early virological response, at 48 wk for end of treatment response (ETR), and then retested at 24, and 48 wk after completion of therapy for sustained virological response (SVR). Liver biopsies were obtained before treatment from all patients and graft kidney biopsies were performed as required.

RESULTS: Of the entire cohort, 9 patients (47.4%) showed an ETR and 8 had SVR (42.1%). Of the 8 patients with abnormal alanine aminotransferase (ALT) levels at baseline, 78.9% had their ALT normalized (including the virological non responders). ALT was normal in all responders at the end of therapy and at 24 wk post therapy (100%). Only one patient (5.3%) developed an increase in creatinine and decline in GFR from baseline towards the end of treatment. This patient's kidney biopsy revealed borderline rejection. There was no impact on response by HCV-genotype, initial HCV RNA load, age or sex of the patient or duration post transplant before commencement of therapy. All patients tolerated treatment in the same way as non-transplant with no unusual or increased occurrence of side effects.

CONCLUSION: The combination of pegylated interferon and ribavirin is effective in suppressing HCV-RNA,

with a low risk of graft rejection or failure in HCV infected renal transplant recipients.

Key words: Allograft rejection; Hepatitis C; Pegylated interferon; Ribavirin; Renal transplant

INTRODUCTION

Hepatitis C virus (HCV) is the major cause of chronic hepatitis, cirrhosis and hepatocellular carcinoma and is the leading indication for liver transplantation worldwide[1]. There is a marked geographic variation in seroprevalence and genotypes of HCV[2-4]. HCV infection is common among patients with end-stage renal disease. The prevalence of HCV infections in patients that undergo hemodialysis has been described in literature worldwide, reaching as high as 63%[5-8]. After implementation of regulations and routine screening in dialysis centers to prevent spread of infection, the incidence of HCV infection has declined in several countries[9-11]. A considerable number of dialysis patients will eventually undergo renal transplantation, which will ultimately increase the prevalence of HCV infection post renal transplantation. HCV has been recognized as one of the major causes of morbidity and mortality and indicates a poor prognosis of patient and graft survival in renal transplantation[12-15]. Reports on the prevalence of HCV in renal allograft recipients were variable. It has been reported to be from 10% to 49% in some centers, but may reach up to 64% in others[12,15-21]. Renal transplantation in HCV positive patients is associated with an aggressive course of liver disease[5,12,22,23]. Treatment of hepatitis C post renal transplant has been a debatable and controversial issue for a long time. Although there were some case reports of successful therapy with interferon with no serious side effects[24,25] many studies have suggested that interferon is contraindicated in such patients due to high incidence of allograft rejection, severe graft dysfunction and/or intolerance of patients to such therapy[26-33]. Most of the reported studies however, have included a small number of patients. Furthermore conventional interferon has been utilized in these studies and only limited experience with pegylated interferon (PEG-IFN) has been reported. In this retrospective study we report our experience with the largest cohort group of patients with hepatitis C post renal transplant treated with a combination of pegylated interferon and ribavirin, focusing on treatment response and allograft rejection.

MATERIALS AND METHODS

This is a retrospective, chart review study of post renal transplant recipients who were positive for anti-HCV and HCV-RNA, and who have received treatment with a combination of PEG-IFN and ribavirin, between October 2003-the time when pegylated interferon had become available as a formulary drug in our institution-and December 2008. Only patients with stable graft function, and absence of cirrhosis were included. Out of 230 renal transplant recipients followed at our institution, 40 consecutive recipients with positive hepatitis C serology were referred from nephrology to the hepatology clinic. Nineteen such patients (13 male and 6 female) were identified and included. Twenty one patients were excluded, as follows; one patient was anti-HCV positive but his HCV-RNA was negative, 4 patients refused to take therapy after they were told that they may lose their kidneys secondary to treatment, 1 patient had multiple medical problems, 3 patients had developed well established liver cirrhosis with portal hypertension, 4 patients had established rejection and had either considered or already started hemodialysis just before starting treatment, and 8 patients were recipients of double organ (liver and kidney) transplantation.

The patient's white cell count (WBC), hemoglobin, platelets, aspartate aminotransferase (AST), alanine aminotransferase (ALT), albumin, bilirubin, prothrombin time, blood urea nitrogen (BUN), creatinine, and glomerular filtration rate (GFR) (calculated using Cockcroft-Gault Formula)[34] were measured before treatment and repeated every 6-8 wk while on treatment and every 12 wk after completing therapy.

All patients were screened for hepatitis B virus (HBV), human immune deficiency virus (HIV) and autoimmune markers pre and post transplantation. Anti-HCV was tested using either the 3rd generation enzyme immunoassay (AxSYM HCV Version 3.0, Abbott laboratories, Diagnostics Division, Abbott Park, IL 60064, United States) or more recently with ARCHITECT Anti-HCV (Abbott GmbH and Co. KG, Max-Planck-Ring 2, 65205 Wiesbaden, Germany). Quantitative HCV-RNA was performed using Roche COBAS Ampliprep/ COBAS TaqMan System (Roche Molecular Systems, Pleasanton, United States). Qualitative HCV-RNA was performed using Roche Automated COBAS Amplicor Analyzer (Roche Molecular Systems, Pleasanton, United States). The HCV genotype detection assay was performed using m2000 real-time system (Abbott Molecular Diagnostics, Abbott Park, IL, United States). HCV genotype was determined in 14 of the patients. Quantitative HCV-RNA test was carried out in all patients prior to treatment, at 12 wk after starting treatment for early virological response (EVR), at 48 wk for end of treatment response (ETR), and then qualitative

and quantitative assays for HCV-RNA were performed at 24 and 48 wk after completion of therapy for sustained virological response (SVR). All patients had under gone liver biopsy prior to treatment. We used modified Ishak histological grading and staging of chronic hepatitis using the histological activity index (HAI) scoring system for the degree of necroinflammatory activity and a staging system for degree of fibrosis[35]. For simplification purposes, we classified necroinflammatory grading on liver histology into; minimal/mild chronic hepatitis if score is 0-6, moderate chronic hepatitis if score is 7-9, and marked chronic hepatitis, with or without bridging necrosis, if score is 10-18. Fibrosis staging was classified into minimal/mild fibrosis for score 0-3, and moderate/marked fibrosis for score 4-6.

Kidney biopsies were performed on patients who developed abnormal renal function or reduction of GFR, either before or during therapy according to the normal unit indications.

HCV treatment protocol used

This was based on the standard international guidelines for therapy of hepatitis C. However because these are a special group of patients and since there is no agreed-on defined protocol to treat such patients and as our study is a retrospective, the individual treatment protocol was left to the discretion of the treating hepatologist. Pegylated interferon α-2a (Pegasys, F. Hoffmann-la Roche Ltd., Basel, Switzerland) at a dosage of 135-180 μg (135 μg for 2 patients and 180 μg for 13 patients) every week in combination with ribavirin 400 mg (2 patients), 800 mg (11 patients), 1000 mg (1 patient), 1200 mg (1 patient) daily in two divided doses were given to 15 patients. Pegylated interferon α-2b (Peg-intron, Schering-Plough Corporation, Kenilworth, NJ, United States) at a dosage of 80-100 μg every week, in combination with ribavirin 400 mg (1 patients), 800 mg (3 patients) daily in divided doses were given to the remaining 4 patients.

All patients were treated for 48 wk. Patients whose hemoglobin dropped to below 100 mg/dL were given erythropoietin subcutaneously, and those whose absolute neutrophil count dropped to below 800/mm^3 were given granulocyte colony stimulating factor (G-CSF) subcutaneously. The dose and frequency of erythropoietin and G-CSF were given according to our center local guidelines, which are similar to the international protocols. Patients were followed up at the hepatology clinic every 2 wk for the first 6 wk and every 6-8 wk thereafter. Patients were also seen in the nephrology clinic every four to eight weeks.

Immunosuppression

All patients were on maintenance steroid therapy in the form of prednisone. Fifteen patients were on mycophenolate mofetil (CellCept), eight on cyclosporine and nine on tacrolimus. One patient received sirolimus. None of our patients received azathioprine.

Ethical and safety issues

Since there was no available international treatment protocol, the risks and benefits of therapy, including potential graft rejection were explained carefully to all patients by the nephrologists and further reinforced by the hepatologist before commencing therapy as normal precautions which were usually performed in similar conditions outside study protocols. Only those patients who consented received the therapy. The study was passed by the hospital's research committee and approved by the institutional review board.

Statistical analysis

The data was analyzed using SPSS version 17. Descriptive data was obtained for all the parameters tested (mean, median, SD). The change over time in liver profile, renal profile, and viral load were compared using ANOVA and changes between baseline and end of treatment parameters were examined using paired *t*-test. The effect of age, post transplant duration and gender on the response was tested using two-tailed independent *t* test and Pearson Chi square.

RESULTS

Of the nineteen recipients included in the study there were 13 males and 6 females. Age ranged from 20 years to 66 years, with a mean age of 39.9 (± 12.6) years. The time from transplant to initiation of treatment ranged from 14 mo to 156 mo with a mean of 66.3 (± 45.7) mo. All patients had undergone hemodialysis in more than one dialysis unit before renal transplant. Our patients tolerated the treatment fairly well. There were no unusual side effects to therapy. None of our patients were intolerant to therapy requiring discontinuation. None of our patients experienced a serious infection or sepsis during the course of therapy.

Liver biochemical profile

ALT was high in 9 patients at baseline, 15 patients (78.9%) had normal ALT at the end of therapy (including non responders). Nine patients had high AST at baseline, 13 (68.4%) of them had normal AST at end of therapy. ALT and AST were normal in all responders at the end of therapy and at 24 wk follow up post therapy (100%). There was a drop in AST between baseline and 48 wk of therapy but this was not statistically significant. The drop in ALT however was significant ($P = 0.01$) (Tables 1 and 2).

Liver histology profile

The histological activity index (HAI) scoring system revealed minimal/mild hepatitis in 14 patients (73.7%), and moderate hepatitis in 5 patients (26.3%). None of our patients was in the marked grade. The staging system for degree of fibrosis revealed 16 patients (84%) had minimal/mild fibrosis, and 3 patients (16%) had moderate/marked fibrosis.

Virological profile and genotype

All 19 patients had a high HCV-RNA load before treatment with values ranging from 5.1 log10 IU/mL to 7.4

Table 1 Mean ± SD of parameters measured at different stages of therapy (n = 19)

Parameters	Baseline	12 wk	24 wk	48 wk	*P* value (baseline *vs* 48 wk)
AST (U/L)	43.7 (30.4)	32.4 (29.6)	36.8 (35.4)	32.9 (34.3)	0.18
ALT (U/L)	65.4 (56.3)	34.0 (33.7)	34.9 (25.9)	30.8 (21.3)	0.01

log10 IU/mL and a mean of 6.25 log10 IU/mL. Seven patients developed EVR (36.8%) at 12 wk of therapy, while two patients had a low target level at 12 wk of therapy. Nine patients had negative HCV-RNA at 24 wk and at the end of 48 wk of therapy (ETR) (47.4%). HCV-RNA utilizing qualitative and quantitative assays was performed at 24 wk and 48 wk after completion of therapy for SVR. This revealed negative HCV-RNA (SVR) in 8 of the 9 responders (42.1% of total treated patients and 88.9% of responders) and only one patient had relapsed at 24 wk. There was no impact of response by the initial HCV-RNA load. Several genotypes were identified: genotype 1 is the most common and found either alone or in combination with other genotypes (genotype 1 alone in 6 patients; 1 and 2 together in 3 patients; 1 and 3 together in 1 patient; 3 alone in 2 patients; 3 and 4 together in 1 patient; 1, 4, and 5 together in 1 patient). The multiple genotypes in one patient could have been acquired from using multiple dialysis units before transplant. Five patients did not have their genotype tested. Using ANOVA, we found that the genotype did not influence the 24 wk or the end of treatment HCV-RNA load (P = 0.084 and 0.059 respectively). There was a significant fall in the load from 6.3 log10 IU/mL (± 0.69) at baseline to 2.6 log10 IU/mL (± 3.05) at 24 wk, and a further fall at 48 wk to 1.1 log10 IU/mL (± 2.1), (P = 0.0001) (Tables 1 and 2).

Hematological profile

All patients had normal leukocyte count before treatment. One patient developed leucopenia, with an absolute neutrophil count of less than 800/mm³. This patient was given G-CSF and maintained a normal count throughout the course of treatment. Hemoglobin (Hb) level was above 100 mg/dL in all patients except for three who had their Hb between 92-95 mg/dL before treatment. Those patients were given erythropoietin injections to maintain their Hb above 100 mg/dL throughout the treatment course. Platelet count ranged from 108 000/m³ to 403 000/m³. There was no significant drop in platelet count in any of the patients. None of the changes in WBC, hemoglobin or platelets during the treatment period was statistically significant (Table 1).

Renal profile

Six patients had high serum creatinine before treatment. These patients underwent renal biopsies prior to treatment which revealed chronic allograft nephropathy (CAN) in 2 patients, membrano-proliferatve glomurulonephritis (MPGN) probably related to HCV in 2 patients, and calcineurin inhibitors toxicity in 2 patients. Three patients developed renal dysfunction while on treatment; one patient developed an increase in serum creatinine and decline in GFR from baseline towards 24 wk of treatment. This patient's serum creatinine rose from 109 μmol/L before treatment to 153 μmol/L after 24 wk of treatment. Kidney biopsy showed a borderline acute cellular rejection, probably related to interferon. However since he was showing an excellent response and only a mild change in

Table 3 Impact of patient gender on the parameters at the end of therapy

Parameters	Males (n = 13)	Females (n = 6)	P value

WBC (10^9/L)	4.28	6.04	0.53
Hemoglobin (G/L)	109.18	88.75	0.11
Creatinine (Umol/L)	148.73	124.63	0.46
GFR (mL/min)	67.73	68.88	0.92

AST: Aspartate aminotransferase; ALT: Abnormal alanine aminotransferase; HCV: Hepatitis C virus; WBC: White cell count; GFR: Glomerular filtration rate.

his creatinine, and after careful discussion between nephrologist, hepatologist and the patient, it was decided to continue treatment for a further 24 wk. Serum creatinine was 175 μmol/L at the end of treatment. Twelve weeks after completing the treatment, his creatinine went up to 195 μmol/L and then dropped to 172 μmol/L at 24 wk follow up. Although rejection was very mild, we consider this a serious issue and it was taken as a side effect of antiviral therapy. We consider this as a case of therapy related rejection giving a rejection rate of 5.3% in our series. The second patient had attempted treatment twice; initially for 12 wk when the serum creatinine showed a mild but gradual increase. Treatment was held and a kidney biopsy was performed and showed CAN with no features of acute rejection. Her creatinine continued to rise very gradually. The patient and the nephrologist agreed with the hepatologist on retreatment. She was then retreated when her creatinine was 196 μmol/L before treatment. Creatinine went up to 215 μmol/L, 12 wk after starting therapy. The patient showed a virological response and since the nephropathy was not related to interferon it was decided to continue a full course of treatment. The third patient had only a mild elevation of serum creatinine from 168 μmol/L before treatment to 199 μmol/L at the end of treatment; however, he also underwent a kidney biopsy before starting treatment and has shown MPGN, which has no contraindication to treatment, and indeed if HCV related, may respond well to antiviral therapy. These three patients who developed abnormal renal function and underwent kidney biopsies had an excellent ETR and 2 of them had SVR at 24 wk post therapy. There was no significant change in GFR during or after therapy from baseline except in the only patient who had rejection who had a decrease in GFR from 61 mL/min to 38 mL/min at the end of therapy. Serum creatinine and GFR remained stable during the treatment period (Table 1).

Impact of type of immunosuppression

There was no relation observed between response rate and the type of immunosuppression regimen used during therapy. There was no relation between the increase of creatinine or decrease in GFR rate and the type of immunosuppression regimen used.

Impact of gender, duration post transplant and age on the parameters at the end of therapy period

Stratification by gender, duration post transplant and age had no impact on the final post transplant levels of the parameters measured (Tables 3-5).

Table 6 summarises recent reports on the efficacy and rejection rate following the use of interferon in post renal transplant HCV infection. It shows that there is a high rate of response to PEG-IFN especially when it is combined with ribavirin, compared to conventional interferon. Furthermore, the rate of rejection and graft failure with this type of therapy is much lower than that with conventional interferon (Table 6).

DISCUSSION

Several studies have shown a negative impact of HCV on patient and graft survival post renal transplantation[12-15,19,25,26]. Immunosuppressive therapy after renal transplantation usually leads to a flare up of HCV viremia[28]. In the setting of renal and other organ transplantation, HCV infected post transplant patients have an aggressive and rapidly progressive liver disease with cirrhosis, liver failure and death[12,22,23,36,37]. Therefore every effort to suppress HCV and prevent liver and renal

HCV: Hepatitis C virus; CI: Conventional interferon; PEG-IFN: Pegylated interferon; R: Ribavirin; CNI: Calcineurin inhibitors; C: Cellcept; S: Steroids; Aza: azathioprine; ETR: End of treatment response; SVR: Sustained virological response; NR: Not reported; NS: Not specified. [1]Five patients developed acute renal failure, but biopsy did not confirm rejection. [2]CI changed to PEG-IFN in 3 patients but study did not specify these patients. [3]In this study 8 patients received ribavirin alone without interferon, so they were not included. [3]Four patients developed severe renal dysfunction, only one patient biopsied and showed chronic allograft nephropathy.

diseases progression is of paramount clinical importance.

The currently accepted therapy for hepatitis C in immunocompetent patients includes a combination of conventional interferon and ribavirin, and more recently PEG-IFN and ribavirin. Several local and international studies have shown that a combination of PEG-IFN and ribavirin is superior to conventional interferon and ribavirin with a sustained virological response ranging from 41% to 82% depending on several factors including viral load, genotype, liver histology, patient age and weight[38-42].

Ribavirin alone is not recommended in dialysis patients as it is generally not tolerated due to severe hemolysis and aggravation of anemia[43]. Conventional interferon or PEG-IFN alone or in combination with ribavirin were used with varying results in hemodialysis patients with some studies suggesting prolonged durability of response after renal transplantation[44-51].

Treatment of HCV post renal transplant is even more difficult and challenging. Ribavirin alone has been used in recurrence of HCV post liver and kidney transplant but this was not associated with virological response[52-56]. Several studies and case reports have shown that the response rate to a combination of conventional interferon and ribavirin is very low. Furthermore this is associated with severe side effects including allograft rejection[26-33]. Very few studies have reported good efficacy and safety of conventional interferon in renal transplant patients[24,25]. In general, there is a major reluctance to use interferon out of fear of rejection. Fabrizi *et al*[57] have reported the meta-analysis of renal transplant patients treated with conventional interferon and ribavirin between 1994 and 2004 and have concluded that the treatment of HCV in the setting of renal transplant with interferon is contraindicated due to poor safety and efficacy. In a study one patient who was treated with PEG-IFN and ribavirin failed to achieve SVR and has developed graft dysfunction[26]. On the other hand, reports of two cases of HCV in combined liver and kidney transplant recipients treated with a combination of PEG-IFN and ribavirin revealed excellent results[58,59]. Recently eight patients were treated with PEG-IFN either alone or in combination with ribavirin and the results were encouraging, with no episodes of rejection and a SVR of 50%. However in this study there was a high incidence of side effects and intolerance to treatment[60].

The mechanism of rejection induced by interferon in renal transplant recipients is unclear. Interferon is a known strong immune modulator; hence at least theoretically it is highly possible that rejection in this setting involves an immunological reaction. Interferon may produce cell-surface expression of HLA antigens with induction of cytokine gene expression and subsequent stimulation of antibody production[61]. Baid *et al*[27] have found de novo donor-specific human leukocyte antigen

(HLA) antibodies (DSA) in serum and C4d deposits with neutrophils in peritubular capillaries in 2 renal transplanted patients with acute humoral rejection treated with interferon and ribavirin.

The reason why we have less rejection than the other previously published studies is unclear. However, most published studies have a small number of patients and many did not differentiate between biopsy proven kidney rejection and renal dysfunction, unlike our study which has followed these patients carefully and performed kidney biopsies before and during treatment whenever there is decline of renal function. In addition, there are several hypotheses which may have played a role; firstly the fact that we have not used azathioprine in any patient and instead most of our patients were on mycophenolate mofetil, which has been reported to improve graft survival and decrease the incidence of rejection[62-64]; secondly, the average time frame between transplant and initiation of therapy in our patients is relatively long (66 mo). None of our patients had sepsis or severe infection during treatment course or follow up, as sepsis is a well known independent cause for morbidity and mortality in HCV positive renal transplantation[12,13]. All of our patients were on PEG-IFN and ribavirin, with 90% of them being on PEG-IFN α-2a (Pegasys, F.Hoffmann-la Roche Ltd., Basel, Switzerland) which is known for its safety in renal patients including renal failure compared with conventional interferon as its clearance is primarily by the liver[65-68]. Ribavirin has been suggested to have a protective effect against rejection in liver transplantation[69], and this could well be the case in renal transplant. We suggest that it is worth treating such patients with PEG-IFN and ribavirin. However close monitoring is essential. A weakness of our study is that it involves a small number and is retrospective in nature. Nevertheless it has shown that PEG-IFN in combination with ribavirin has a high safety profile and a very good sustained virological response. A prospective protocol involving a larger number of patients is advisable. We think that it would be much better and safer if HCV was treated before the transplant, and indeed this is the current practice at our institution; however even with this protocol there is a chance of recurrence of HCV in the post transplant period.

In conclusion, the combination of pegylated interferon and ribavirin in HCV-RNA positive renal transplant recipients was effective, with ALT normalized in 78% of patients in whom the levels were abnormal before therapy including non responders. ALT was normal in all responders at the end of therapy and at 24 wk post therapy (100%). Virological response was observed in 47.4% of all treated patients at the end of therapy and 42.1% (88.9% of responders) have a sustained virological response at 24 wk of follow up. Rejection occurred in only one patient (5.3%) during therapy. Our study, although retrospective and of small size, has shown that the combination of pegylated interferon and ribavirin has a significant role in suppressing HCV-RNA, without subjecting patients to a high risk of graft rejection or failure in HCV infected patients post renal transplantation. These findings need to be evaluated in large clinical studies. To our knowledge this is the largest reported series of HCV positive renal transplant recipients treated with pegylated interferon and ribavirin.

Part of this work was presented in brief abstract form at the 60th annual meeting of the American Association for the Study of Liver Diseases, 2009, Boston, United States.

COMMENTS

Background

Treatment of hepatitis C post renal transplant has been a debatable and controversial issue for a long time. Many studies have suggested that interferon is contraindicated in such patients due to high incidence of rejection, kidney failure and/or intolerance of patients to such therapy. Limited experience with pegylated interferon has been reported.

Research frontiers

This study reports on the largest group of patients with hepatitis C post renal transplant treated with a combination of pegylated interferon and ribavirin in the world, focusing on treatment response and kidney rejection.

Innovations and breakthroughs

The authors have treated 19 patients, who have hepatitis C and had kidney transplant with pegylated interferon and ribavirin for 48 wk. The virus was cleared in 42.1% and only one patient (5.3%) developed impairment of his kidney function towards the end of treatment period.

Applications

This research has clearly demonstrated the efficacy and safety of pegylated interferon and ribavirin in treating patients with hepatitis C virus (HCV) after renal transplant. This shall open doors for treating such patients, which were in the past left untreated because of a potential risk of kidney failure.

Terminology

Pegylated interferon is an antiviral therapy used for treatment of hepatitis C. Ribavirin is oral antiviral therapy that is used in combination with interferon for treatment of hepatitis C. Rejection is the process by which the human body refuses to accept the transplanted organ, and eventually leads to the organ failure.

Peer review

This is the largest reported series of HCV infected renal transplant recipients treated with pegylated interferon and ribavirin. The paper is generally well written and adds to the current experience regarding hepatitis C treatment in renal transplant patients.

Abstract

AIM: To demonstrate the oncologic outcomes of low rectal cancer and to clarify the risk factors for survival, focusing particularly on the type of surgery performed.

METHODS: Data from patients with low rectal carcinomas who underwent surgery, either sphincter-preserving surgery (SPS) or abdominoperineal resection (APR), at The First Affiliated Hospital of Sun Yat-sen University in China from August 1994 to December 2005 were retrospectively analyzed.

RESULTS: Of 331 patients with low rectal cancer, 159 (48.0%) were treated with SPS. A higher incidence of positive resection margins and a higher 5-year cumulative local recurrence rate (14.7% *vs* 6.8%, $P = 0.041$) were observed in patients after APR compared to SPS. The five-year overall survival (OS) was 54.6% after APR and 66.8% after SPS ($P = 0.018$), and the 5-year disease-free survival (DFS) was 52.9% after APR and 65.5% after SPS ($P = 0.013$). In multivariate analysis, poor OS and DFS were significantly related to positive resection margins, pT3-4, and pTNM Ⅲ-Ⅳ but not to the type of surgery.

CONCLUSION: Despite a higher rate of positive resection margins after APR, the type of surgery was not identified as an independent risk factor for survival.

Key words: Abdominoperineal resection; Prognosis; Rectal neoplasms; Sphincter-preserving surgery; Surgery

INTRODUCTION

Colorectal cancer is the fourth most prevalent malignancy in the world. In 2010, it was estimated that there were approximately 39 670 new rectal cancers in the United States[1]. In China, approximately 70% of rectal cancers are located below the peritoneal reflection[2], an obvious difference from the typical location of rectal cancers in patients in Western countries.

Treatment outcomes for rectal cancer have been dramatically improved by applying the total mesorectum excision (TME) principle[3], the double-stapling technique[4], and the concept of shorter distal margins over the past

few decades[5]. More patients with rectal tumors are being managed with various types of sphincter-preserving surgery (SPS). However, for low rectal cancer, challenges remain for some patients who require abdominoperineal resection (APR) to achieve a safe distal margin. Improvements in survival and control of local tumor recurrence for patients with mid and upper rectal cancers have not been as difficult to achieve as in those patients with lower-third rectal tumors. One of the possible reasons for this discrepancy may be the higher rate of circumferential margin (CRM) and inadvertent bowel perforations in APR[6]. However, whether the type of surgery is a risk factor for oncologic outcomes in patients with low rectal cancers is still controversial[7-10].

Herein, we collected data from a single institute in China and performed a retrospective, consecutive cohort study attempting to demonstrate the oncologic outcomes of low rectal cancer and to clarify risk factors for survival, especially focusing on the type of surgery.

MATERIALS AND METHODS

From August 1994 to December 2005, a total of 353 patients with primary low rectal carcinomas (0 to 7 cm from the anal verge) underwent open surgery at The First Affiliated Hospital of Sun Yat-sen University in China. Patients who underwent local excision (n = 3), the Hartmann procedure (n = 2), palliative colostomy (n = 7) or who were lost follow-up (n = 10) were excluded, resulting in 331 patients enrolled into the final study.

The clinicopathologic features, including gender, age, tumor size (maximum tumor diameter), distance of the tumor from the anal verge, operative procedure, resection margins, histopathologic grade, pathologic stage, mucin production[11], adjuvant therapy, and oncologic outcome, were fully reviewed.

Surgical procedures

All patients underwent surgery according to the principles of TME[3]. APR was performed in cases where the tumor was too close (usually ⩽ 2 cm) to the dentate line or where the differentiation of the tumor was poor (necessitating a longer distal resection margin). Low anterior resection (LAR) was adopted as often as possible, especially for tumors with a distance < 2 cm from the dentate line. To observe the effects of LAR with a colonic J-pouch, we performed a prospective clinical trial from 1998 to 2002 in which 16 out of 331 patients had a J-pouch created. In this study, LAR (with or without the creation of a J-pouch) and Bacon and Parks procedure were combined as SPS.

The Bacon pull-through procedure was performed for some patients with ultra low rectal cancers. In brief, in this procedure the mobilization of the sigmoid colon and the rectum is identical to that in LAR and APR. The anal sphincter is dilated to four to six finger breadths, and then the submucosa is infiltrated with 1:300 000 epinephrine. A circular incision is made in the mucosa at the anoderm at a point 5 mm from the dentate line. Isolation is performed upward beneath the rectal mucosa until reaching the upper limit of the internal sphincter; then the rectum is cut off and moved away from the abdomen. A 2-cm soft plastic pipe is inserted into the proximal colon. The colon is pulled through from the anus, and several sutures are made between the sigmoid colon and the anal canal. The second stage of the procedure is performed 14 to 21 days later. Excess bowel is amputated, and the anastomosis is completed. The Parks procedure is similar to the Bacon pull-through procedure, the difference being that the anastomosis between the colon and the anal canal is accomplished directly in the Parks procedure without the need to pull through the colon.

The CRM was not used at our institute during the study period. Instead, "resection margins" were adopted to record the status of the proximal, distal, and circumferential resection margins. Neoadjuvant chemoradiation therapy (CRT) was not extensively performed at our institute during the study period. Only 5 patients in the SPS group and 12 in the APR group received neoadjuvant therapy.

Follow-up

All of the patients were followed up every three to six months for the first two years, then every six months for the next three years, and then once a year thereafter. Digital palpation, abdominal and pelvic computed tomography (CT) scan, chest X-ray, total colonoscopy and carcinoembryonic antigen (CEA) were routinely measured to exclude local recurrence or metastasis.

Statistical analysis

Statistic analysis was performed using the SPSS 17.0 statistical package (SPSS, Inc., Chicago, IL, United States). The Student t-test and Chi-square test were used to analyze continuous and categorical variables, respectively. Overall survival, cancer-related survival and local recurrence rates were calculated using the Kaplan-Meier method. Potential prognostic factors were investigated using the log-rank test first, and then covariates with P-values < 0.05 were selected for backward multivariate Cox regression analysis. All P-values less than 0.05 with two sides were considered significant.

RESULTS

Clinicopathologic features

Patient characteristics and treatment details are summarized in Table 1. There were 211 male and 120 female patients with a median age of 56 years (range, 17 years-91 years). The median tumor size was 4.0 cm (range, 0.5 cm-15.0 cm). The median distance between the anal verge and the tumor was 4.0 cm (range, 1.0 cm-7.0 cm), and tumors in the APR group were significantly closer to the anus than those in the SPS group (median, 3.0 cm *vs* 5.0 cm, P < 0.001).

Of the 331 patients with low rectal cancer, 172 patients

Table 1 Characteristics of 331 patients with low rectal cancer

Characteristic	APR (%) *n* = 172	SPS (%) *n* = 159	*P* value
Median age (yr)	56.0	58.0	0.334
Median tumor size (cm)	4.0	4.0	0.301
Median distance of tumor from the anal verge (cm)	3.0	5.0	< 0.001
Gender (male)	115 (66.9)	96 (60.4)	0.220
Positive resection margins	23 (13.4)	10 (6.3)	0.032
Histopathologic grade			0.238
Well	34 (19.8)	27 (17.0)	
Moderate	102 (59.3)	108 (67.9)

pTNM stage			0.445
Ⅰ	20 (11.6)	22 (13.8)	
Ⅱ	63 (36.6)	69 (43.4)	
Ⅲ	73 (42.4)	56 (35.2)	
Ⅳ	16 (9.4)	12 (7.6)	
Mucin production	14 (8.1)	10 (6.3)	0.517
Adjuvant chemotherapy	34 (19.8)	29 (18.2)	
Year of surgery			0.001
1994-2001	101 (58.7)	65 (40.9)	
2002-2005	71 (41.3)	94 (59.1)	

APR: Abdominoperineal resection; SPS: Sphincter-preserving surgery.

received the APR procedure and 159 underwent SPS, including 130 APR, 13 Bacon or Parks procedures, and 16 APR with a colonic J-pouch. Before 2001, only 40.9% (65 out of 166) of patients underwent SPS, while after 2001 more (59.1%, 94 out of 165) patients were able to undergo anus-sparing surgery (65/166 *vs* 94/165, $P = 0.001$). Combined resection of organs was performed for 35 patients, including 10 patients who underwent resection of solitary liver metastasis. Only 4 (2.5%) patients had a protective stoma after SPS.

Resection margins were microscopically positive in 33 (10%) patients. More patients in the APR group were diagnosed with "positive resection margins" than in the SPS group (13.4% *vs* 6.3%, $P = 0.032$). Data on tumor stage and tumor differentiation are presented in Table 1.

There was no mortality. Anastomotic leakage occurred in 6 (3.8%, 6 out of 159 SPS) patients, all of whom did not have a protective stoma before, and these patients were treated conservatively. In total, 63 (19.0%) patients received adjuvant chemotherapy with 5-fluorouracil plus leucovorin or FOLFOX (oxaliplatin, 5-fluorouracil, and folinic acid).

Recurrence

Patients were followed up with a median follow-up time of 61 mo (range, 1 mo-194 mo). At the last follow-up in November 2010, 177 patients (53.5%) were alive, and 154 (46.7%) were dead.

A total of 97 (27.3%) patients experienced recurrence, including 34 (10.3%) local, 58 (17.5%) distant, and 5 (1.5%) combined recurrence. Seventy-five patients died of cancer recurrence. The median disease-free interval for the 35 patients with local recurrence was 15.5 mo (range, 4 mo-104 mo). For the 51 patients with distant metastasis, the median time to metastasis was 25 mo (range, 4 mo-123 mo). The overall 5-year cumulative local recurrence rate was 10.9%. The estimated local recurrence rate at 5 years was 14.7% for APR and 6.8% for SPS ($P = 0.041$, Figure 1A).

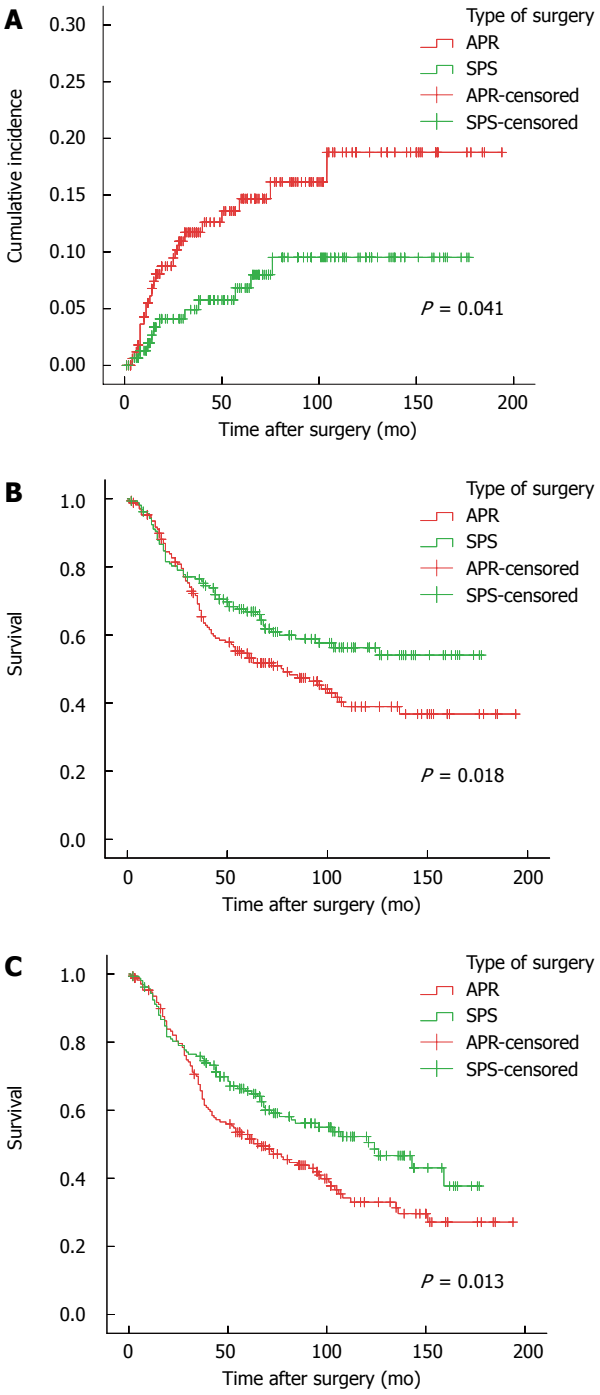

Figure 1 Surgical outcomes among 331 patients who underwent abdominoperineal resection and sphincter-preserving surgery. A: Cumulative local recurrence rate; B: Overall survival rate; C: Disease-free survival rate. APR: Abdominoperineal resection; SPS: Sphincter-preserving surgery.

Survival

The five-year overall (OS) and disease-free survival (DFS) were 60.6% and 59.1%, respectively. The five-year OS was 54.6% after APR and 66.8% after SPS ($P = 0.018$,

Table 2 Univariate analysis of 331 patients with low rectal cancer

Characteristic	No. of patients	5-year OS		5-year DFS	
		%	*P* value	%	*P* value

OS: Overall survival; DFS: Disease-free survival; APR: Abdominoperineal resection; SPS: Sphincter-preserving surgery. [1]Analysis of 159 patients who underwent sphincter-preserving surgery.

Figure 1B). The 5-year DFS was 52.9% after APR and 65.5% after SPS ($P = 0.013$, Figure 1C).

In univariate analysis, OS and DFS were both significantly influenced by tumor size, type of surgery, resection margins, tumor histopathologic grade, pT stage, and pTNM stage (Table 2).

Multivariate analysis was performed for those factors which were statistically significantly associated with OS and DFS in the univariate analysis. In backward multivariate Cox regression analysis, poor OS was significantly related to positive resection margins [hazard ratio (HR) = 1.644, $P = 0.031$], pT3-4 (HR = 1.781, $P = 0.003$), and pTNM Ⅲ-Ⅳ (HR = 2.153, $P < 0.001$). Positive resection margins (HR = 1.728, $P = 0.012$), pT3-4 (HR = 1.669, $P = 0.006$), pTNM Ⅲ-Ⅳ (HR = 1.839, $P < 0.001$), and poor tumor differentiation (HR = 1.665, $P = 0.034$) were significantly associated with poor DFS (Table 3).

DISCUSSION

Curative resection of local rectal cancer consists of complete removal of the primary tumor and its lymphatic drainage by sharp mesorectal excision with or without sphincter preservation. The choice of APR or SPS may be affected by different opinions regarding safe distal margin, views on the functional aspects associated with intersphincteric dissection, a variety of institution-specific cultural features and the availability of staple anastomosis[12-15]. Our study demonstrated that the rate of sphincter-preserving surgery increased from 40.9% before 2001 to 59.1% after 2001. This may be attributed to the acceptance of a shorter distal margin (1-2 cm) and the availability of the double stapling technique.

This study shows that more patients had positive resection margins after APR than after SPS, which is in line with other studies[6,10,16-18]. Nevertheless, a positive margin should lead to a worse prognosis, and this was confirmed by the multivariate analysis in this study. Inadequate resection at the level of the pelvic floor with TME in APR may result in an increased risk for positive resection margins, contributing to the observed higher risk for positive circumferential resection margins and local recurrence after APR than after SPS. The five-year OS and DFS after APR were inferior to those after SPS, and the OS and DFS were both significantly influenced by the type of surgery in the univariate analysis. However, after adjustment for other potential risk factors, we failed to find a significant association between the type of surgery and

survival.

Low rectal cancers lie at the pelvic floor and close to the anal sphincter, which makes completion of a radical operation challenging. To reduce the incidence of circumferential resection margin involvement and intraoperative tumor perforation, some surgeons have made a change in their approach to APR. West *et al*[14] applied cylindrical abdominoperineal excision of the rectum and anus, entailing resection of the levator muscles en bloc with the lower rectum and anal canal, for patients with low rectal cancer, leading to a decrease in circumferential resection margin involvement from 40.6% after traditional APR to 14.8%. They also reduced the rate of intra-operative perforations from 22.8% to 3.7%. The cylindrical technique may possess the potential to improve patient outcomes, and close attention should be paid to the perineal part of the APR surgery.

It has been reported that preoperative CRT has a strong influence on the prognosis in rectal cancer[18,19]. However, only 17 patients in this study received preoperative CRT due to economic considerations and lack of acceptance of it as a major part of the management of rectal cancer. It was not until recently that we began to include preoperative CRT widely for advanced rectal cancers. We also investigated other variables for poor survival outcome and determined that the pathologic TNM stage remained the strongest risk factors for OS and DFS, which is consisted with previous studies[20-21].

In conclusion, this consecutive cohort study from a single institution in China demonstrates that a higher risk of positive resection margins and local failure was observed in patients after APR. The survival after APR is inferior to that after SPS. However, after adjustment for other covariates, we failed to confirm that the type of surgery is an independent risk factor for survival outcome. To reduce positive resection margins and local recurrence, there has been a call to change the approach to APR.

COMMENTS

Background

Risk factors for survival in low rectal cancer patients still need to be clarified. There is evidence that the type of surgery, sphincter-preserving surgery (SPS) or abdominoperineal resection (APR), may influence the prognosis in low rectal cancer.

Research frontiers

A retrospective, consecutive cohort study was conducted, attempting to demonstrate the oncologic outcomes of low rectal cancer and to clarify the risk factors for survival. Univariate and multivariate Cox regression analyses were performed to determine whether gender, age, tumor size, distance of the tumor from the anal verge, operative procedure, resection margins, histopathologic grade, pathologic stage, mucin production, and adjuvant therapy were associated with the prognosis of low rectal cancer.

Innovations and breakthroughs

A higher risk for positive resection margins and local failures were observed in APR. The survival outcome after APR is inferior to that after SPS. However, after adjustment for other covariates, the type of surgery was not identified as an independent risk factor for survival.

Applications

To reduce positive resection margins and local recurrence, there has been a call for a change in the approach to APR.

Terminology

Total mesorectum excision (TME) is the standard technique for the treatment of rectal cancer. It was devised some 20 years ago by Professor Bill Heald at the Basingstoke District Hospital in the United Kingdom. TME is accomplished by precise sharp dissection under direct visualization with the true pelvis around the integral mesentery enveloping the entire mid-rectum and with preservation of the hypogastric plexus.

Peer review

This is an important paper, comparing the outcome of low mesorectal anterior resections for carcinoma of the rectum with abdominoperineal resections.

Abstract

AIM: To explore germline hypermethylation of the tumor suppressor genes *MLH1*, *CDH1* and *P16*^{INK4a} in suspected cases of hereditary gastric cancer (GC).

METHODS: A group of 140 Chinese GC patients in whom the primary cancer had developed before the age of 60 or who had a familial history of cancer were screened for germline hypermethylation of the *MLH1*, *CDH1* and *P16*^{INK4a} tumor suppressor genes. Genomic DNA was extracted from peripheral blood leukocytes and modified by sodium bisulfite. The treated DNA was then subjected to bisulfite DNA sequencing for a specific region of the *MLH1* promoter. The methylation status of *CDH1* or *P16*^{INK4a} was assayed using methylation-specific PCR. Clonal bisulfite allelic sequencing in positive samples was performed to obtain a comprehensive analysis of the CpG island methylation status of these promoter regions.

RESULTS: Methylation of the *MLH1* gene promoter was detected in the peripheral blood DNA of only 1/140 (0.7%) of the GC patient group. However, this methylation pattern was mosaic rather than the allelic pattern which has previously been reported for *MLH1* in hereditary non-polyposis colorectal cancer (HNPCC) patients. We found that 10% of the *MLH1* alleles in the peripheral blood DNA of this patient were methylated, consistent with 20% of cells having one methylated allele. No germline promoter methylation of the *CDH1* or *P16*^{INK4a} genes was detected.

CONCLUSION: Mosaic germline epimutation of the *MLH1* gene is present in suspected hereditary GC patients in China but at a very low level. Germline epimutation of the *CDH1* or *P16*^{INK4a} gene is not a frequent event.

Key words: Gastric cancer; Germline promoter methylation; *MLH1*; *CDH1*; *P16*^{INK4a}

INTRODUCTION

Gastric cancer (GC) is one of the most common malignancies worldwide and is the most frequent form of cancer in East Asian countries. Point mutations or deletions within large genomic segments of tumor suppressor genes have previously been detected in about 30% of individuals with a genetic predisposition to GC[1,2]. However, the underlying genetic abnormalities in more than 70% of GC patients thus remain unknown. The methylation of cytosines in CpG dinucleotides within the promoter regions of tumor suppressor genes can result in transcriptional silencing and this occurs frequently in GC tumors. As one of the major genes in the mismatch repair (MMR) system, *MLH1* is considered to be one of the key causative genes for GC. Hypermethylation of the *MLH1* gene promoter is extremely frequent and often correlates well with loss of the MLH1 protein in tumor cells[3-6]. The epithelial cadherin gene *CDH1* is also associated with GC and shows decreased expression in GC tumors. However, germline mutations in *CDH1* have been found in only some patients with hereditary diffuse gastric cancer (HDGC). A high rate of promoter methylation of *CDH1* is observed in GC tumors and is associated with the inactivation of this gene[7-11]. As an important protein in the cell cycle regulatory pathways, the inactivation of $P16^{INK4a}$ is one of the most commonly observed abnormalities in human cancer. This can occur *via* the hypermethylation of CpG islands within its promoter in many tumor types including gastric cancers and germline mutations in this gene in GC are relatively rare[10,11].

Recent reports have shown that promoter hypermethylation of the *MLH1* gene is not limited to tumor cells but might also occur in the peripheral blood and other tissues of patients with early-onset colorectal cancer (CRC), suggesting a germline origin[12-18]. Importantly however, although the promoters of *MLH1*, *CDH1* and $P16^{INK4a}$ are hypermethylated in GC tumors, it is currently not known whether these epigenetic events exist in the germline and cause a GC predisposition in affected individuals.

In our current study, we characterize the germline promoter methylation of the *MLH1*, *CDH1* and $P16^{INK4a}$ tumor suppressor genes in GC. We screened a selected cohort of Chinese GC cases in whom the cancer had developed before the age of 60 years or in which there was familial history of *MLH1*, *CDH1* and $P16^{INK4a}$ germline epimutations.

MATERIALS AND METHODS

Subjects

A cohort of 140 GC patients from the Jiangsu, Anhui and Zhejiang provinces of China was assembled for this study. The selection of patients was based on the GC family history and onset ages i.e., (1) individuals with GC and two or more first-degree relatives with GC, denoted as high familial cancer history (HF) cases; (2) individuals with GC and one first- or second-degree relative with GC, designated low familial cancer history (LF) cases; and (3) individuals diagnosed with GC prior to 60 years of age, but no family history of this disease, referred to as young onset (Y) patients. Of the 140 GC patients in our selected cohort, we identified 18 HF, 43 LF and 79 Y cases. Thirty age-matched normal controls were also included in the analysis. Informed consent was obtained from each subject who underwent genetic testing, in accordance with the guidelines of the Ethics Committee of the Medical School of Nanjing University.

Methylation screening and bisulfite sequencing

Peripheral blood leukocyte DNA was bisulfite modified using the CpGenome™ DNA Modification Kit (Chemicon International, Temecula, CA, United States) in accordance with the manufacturer's instructions. A specific CpG-rich sequence in the *MLH1* promoter region (from -427 to -53 bp relative to the translation start site for human *MLH1*, a 375 bp fragment containing 20 CpG sites; Figure 1A) was selected. This region is purported to be strongly associated with *MLH1* silencing[19-22]. Bisulfite DNA sequencing (BSP) of this region was performed to determine the comprehensive CpG island methylation status of the *MLH1* gene promoter using an ABI 3100-Avant automated sequencer (Applied Biosystems, Foster City, CA, United States). The primers used for BSP were MLH1-BF, 5'- TAAGGGGAGAGGAGGAGTTTGA-3' (sense) and MLH1-BR, 5'-CAACCAATCACCTCAATACCTC-3' (antisense). The obtained PCR products displaying methylated CpG sites were subcloned into the PMD18-T vector [TaKaRa Biotechnology (Dalian) Co., Ltd., Dalian, China] and at least 10 clones were selected and sequenced for each sample using universal M13 primers to determine the level and extent of gene promoter methylation.

The methylation status of *CDH1* and *P16* was determined by methylation-specific PCR (MSP) after treatment of the DNA with sodium bisulfite. The primer sequences used have been reported previously for *CDH1*[8,11] and *P16*[7,23] and are as follows: CDH1-M-F, 5'-GGTGAATTTTTAGTTAATTAGCGGTAC-3' (sense) and CDH1-M-R, 5'-CATAACTAACCGAAAACGCCG-3' (antisense) for methylated *CDH1*; CDH1-U-F, 5'-GGTAGGTGAATTTTTAGTTAATTAGTGGTA-3' (sense); and CDH1-U-R, 5'-ACCCATAACTAACCAAAAACACCA-3' (antisense) for unmethylated *CDH1*; P16-M-F, 5'-TTATTAGAGGGTGGGGCGGATCGC-3' (sense) and P16-M-R, 5'-GACCCCGAACCGCGACCGTAA-3' (antisense) for methylated *P16*; P16-U-F, 5'-TTATTAGAGGGTGGGGTGGATTGT-3' (sense), and P16-U-R, 5'- CAACCCCAAACCACAACCATAA-3' (antisense) for unmethylated *P16*. The PCR-amplified regions for the methylated (from -78 to +127 bp relative to the transcription initiation site for human *CDH1*, 205 bp) and unmethylated (from -78 to +130 bp relative to the transcription initiation site, 208 bp) *CDH1* alleles contained 19 CpG dinucleotides, including five CpGs at the primer annealing sites (Figure 3A). The primer sets spanned the transcriptional start site and were designed to include methylation sites that best corresponded with the transcriptional

silencing of *CDH1* in the published literature[24].

The PCR-amplified region for the methylated (from -80 to +70 bp relative to the translation initiation site for human *P16*, 150 bp) and unmethylated (from -80 to +71 bp relative to the translation initiation site, 151 bp) *p16* alleles contained 19 CpG dinucleotides, including eight CpGs at the primer annealing sites (Figure 6A).

The positive samples were further amplified using *CDH1* or *p16* gene-specific primers CDH1-BF-5'-TAGTAATTTTAGGTTAGAGGGTTA-3' (sense) and CDH1-BR-5'-AAATACCTACAACAACAACAACAACAAC-3' (anti-sense)[25]; P16-BF-5'-TTTTTAGAGGATTTGAGGGATAGG-3' (sense) and P16-BR-5'-CTACCTAATTCCAATTCCCCTACA-3' (anti-sense)[19]. The amplified fragments (363 bp, from -185 to +178 bp relative to the transcription initiation site of *CDH1*, Figure 3A; 392 bp, from -159 to +233 bp relative to the translation initiation site of *P16*, Figure 6A), were sequenced using an ABI 3100-Avant automated sequencer (Applied Biosystems, Foster City, CA, United States). CpGenome universal methylated and unmethylated DNA (Chemicon International, Temecula, CA, United States) served as a positive control for gene promoter hypermethylation and hypomethylation, respectively.

RESULTS

Methylation analysis of the MLH1 promoter

A stretch of 375 bases incorporating 20 CpG sites in the *MLH1* proximal promoter was analyzed (Figure 1A). In one of the 140 suspected hereditary GC patients in our cohort (patient G46), partial methylation was detected by BSP through the 6th to 20th CpG sites of the *MLH1* promoter from blood DNA (Figure 1B). This individual was a 60-year-old female with no family history of GC. For the remaining samples, partial methylation was evident at the 9th and 10th CpG sites (-269 and -262 bp from the translation initiation site, respectively), but no other CpGs in this region were found to be methylated. The peripheral blood leukocyte DNA of 30 age-matched normal controls was examined for *MLH1* methylation in comparison with the GC patients. None of the control samples showed detectable *MLH1* promoter methylation by bisulfite DNA sequencing apart from the 9th and 10th CpG sites which seemed to have methylated alleles more than 50% for all the patients. However, because this alteration was also found in unmethylated controls and in healthy blood donor samples, it is far less likely to be linked to GC (Figure 1B).

To determine the extent of *MLH1* allele methylation in patient G46, clonal bisulfite allelic sequencing of the *MLH1* promoter in peripheral blood from this individual was performed. Upon analysis of the peripheral blood DNA from patient G46, one of ten clones had a cytosine present through the 6th to 20th CpG sites (Figure 2). All other non-CpG cytosines were converted, indicating that this corresponded to a methylated allele. For one other clone, only one CpG (the 12th) was found to be methylated and this may have been due to an incomplete conversion. Four of these ten clones had a cytosine present at the 9th and 10th CpGs, confirming the methylation pattern evidenced by bisulfite DNA sequencing. This result supported the possibility that mosaic germline *MLH1* methylation could be occurring in this patient. Indeed, 10% of the *MLH1* allele was methylated in this individual, equating to 20% of the cells found with one methylated *MLH1* allele in the peripheral blood. Unfortunately, tumor material was not available from patient G46 to evaluate the methylation profile of the *MLH1* gene in the GC cancer cells.

Methylation analysis of the CDH1 promoter in GC patients

None of the GC cases under study showed detectable *CDH1* promoter methylation in their peripheral blood leukocytes by MSP assay (Figure 3B). Direct sequencing of the *CDH1* promoter region from -185 to +178 bp relative to the transcription initiation site confirmed this result (Figure 4). Several C bases (including the 4th and 9th CpG sites, and at positions -120 and -65 bp relative to the transcription initiation site) were evident (more than 50%) in all patients. However, because this variation was also found in the healthy blood donor samples, it is unlikely to be linked to GC (Figure 5). This result also suggested that the incidence of germline hypermethylation of the *CDH1* promoter is low in Chinese GC patients.

Methylation analysis of the P16 promoter

None of the GC cases under study showed detectable *P16* promoter methylation of the DNA from their peripheral blood leukocytes by MSP assay (Figure 6B). Direct sequencing of the *P16* promoter region from -159 to +233 bp relative to the translation initiation site confirmed that all of the 35 CpG dinucleotides present in the fragment were unmethylated (Figure 7). This result suggested that germline hypermethylation of the *P16* promoter is also rare in Chinese GC patients.

DISCUSSION

In our current study, we demonstrated that a mosaic *MLH1* promoter methylation pattern existed in the peripheral blood of a Chinese GC patient. Deng *et al*[19] previously divided the *MLH1* promoter area into four regions, A–D, and proposed that methylation in region C plays an important role in silencing hMLH1 expression. In our current experiments, we carried out methylation analysis on region C of the *MLH1* promoter. We excluded the 9th and 10th CpG sites of the *MLH1* promoter region as they were found to be methylated in the control samples (Figure 1B). Our analyses also showed that rather than an allelic methylation pattern as has previously been reported for *MLH1* in CRC patients, a mosaic level of *MLH1* methylation was found from the 6th to 20th CpG sites in this promoter region in the germline genomic DNA of GC patient G46 in our study cohort. Clonal sequencing further revealed a

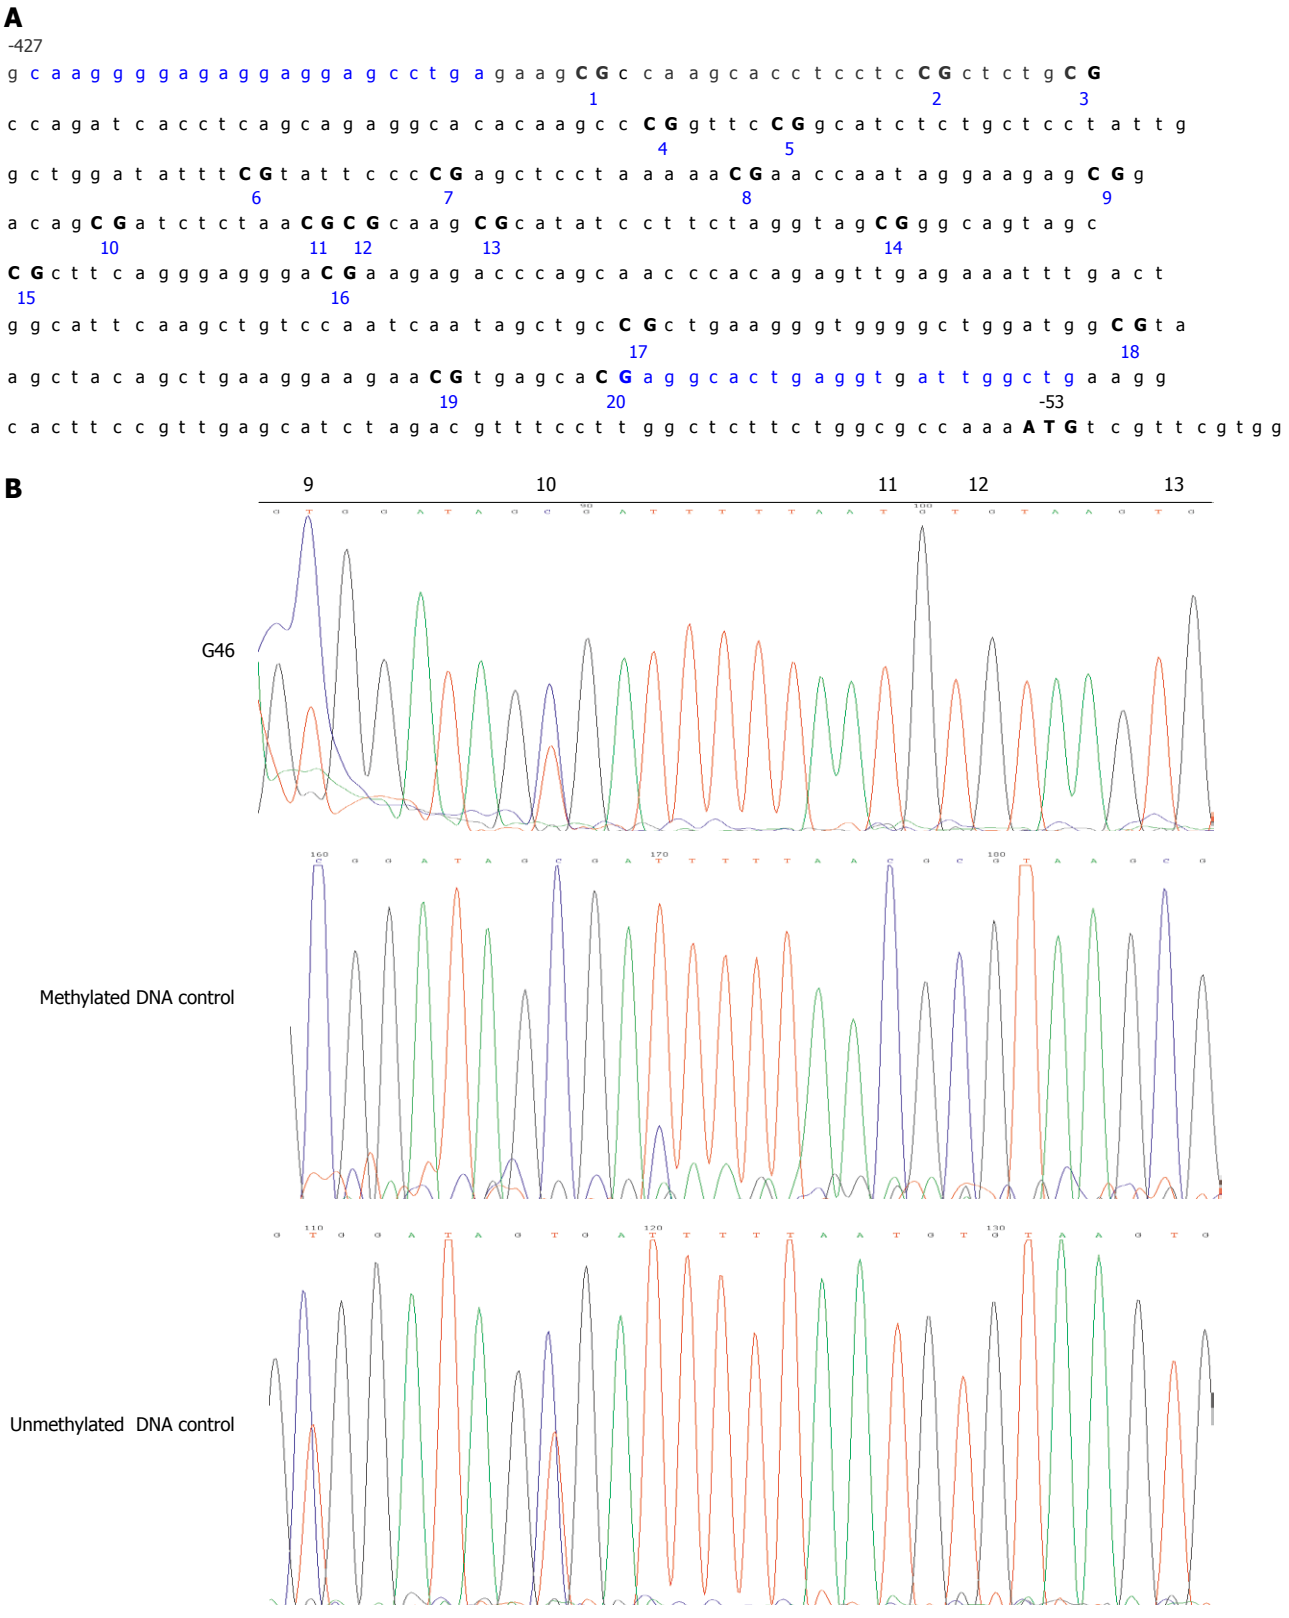

Figure 1 Germline *MLH1* promoter hypermethylation analysis in a gastric cancer patient cohort. A: Map of the CpG island structure in the *MLH1* promoter. The sequence is numbered relative to the translation start site for human *MLH1* (bolded "ATG"). Characters in blue indicate the primer binding sites for bisulfite sequencing. Individual CpG sites in the sequence are numbered consecutively; B: Bisulfite sequencing of *MLH1* promoter sequences. *G46,* DNA isolated from the blood of case G46 showing a mixture of C and T at the 6th to 20th CpG sites attributable to partial modification of the DNA due to partial methylation; *Methylated DNA control*, CpGenome Universal Methylated DNA in which *MLH1* is completely methylated showing a high C content at all CpGs attributable to reduced modification because of complete methylation of the DNA; Unmethylated DNA control, CpGenome Universal Unmethylated DNA showing T bases at all CpGs except the 9th and 10th CpG sites due to almost complete modification of the DNA. The 9th and 10th CpG sites show a high number of Cs in G46, but also in the unmethylated control, suggesting that these sites are uninformative in relation to gastric cancer.

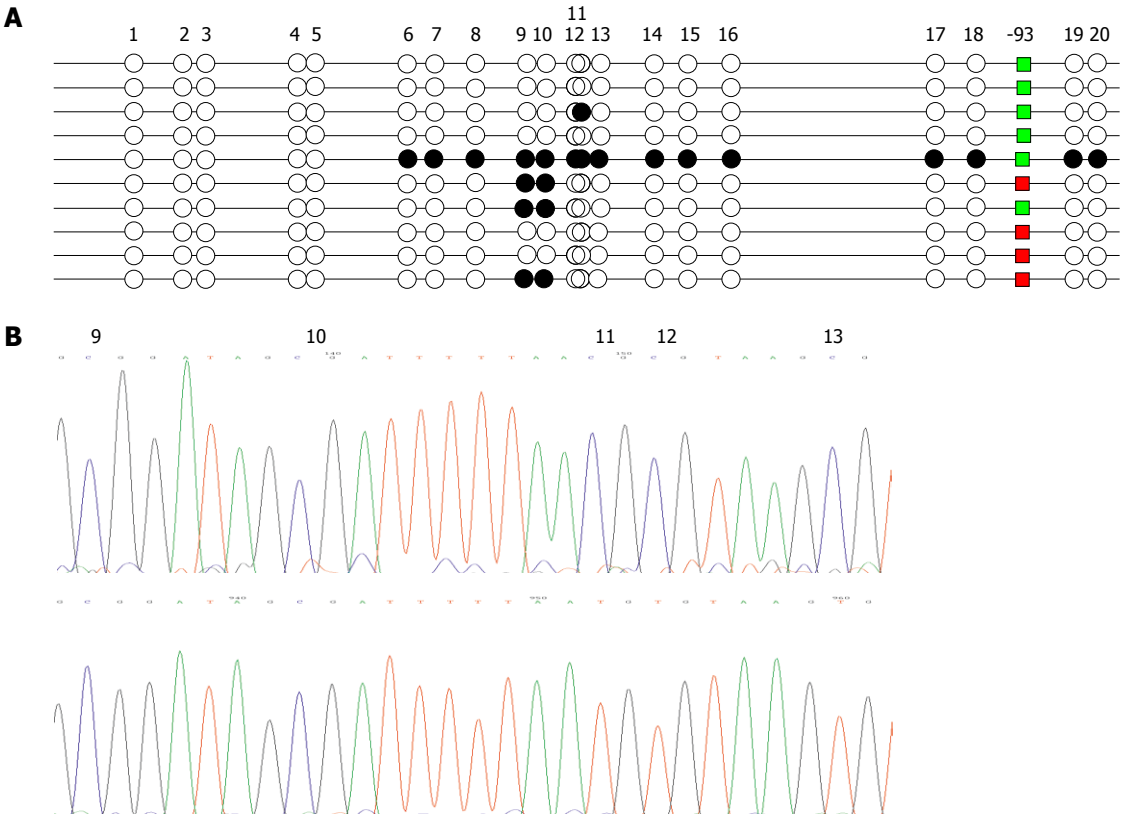

Figure 2 Clonal bisulfite allelic sequencing of the *MLH1* promoter in the peripheral blood from gastric cancer patient G46. A: Each horizontal line of circles represents an isolated allele. The numbering scheme is derived from the map shown in Figure 1A. White circles represent non-methylated CpG sites, and black circles indicate a methylated CpG. This subject displayed 10% methylated alleles at the 6th to 20th CpG sites, suggestive of mosaic allele-specific germline epimutation. Green, -93A; Red, -93G; B: Upper figure, sequencing of clone 5 from case G46 showing methylation at the 6th to 20th CpG sites. Lower figure, sequencing of G46 clone 7 revealing unmethylated CpGs except for the 9th and 10th CpG sites. The numbers above the sequences are derived from the map shown in Figure 1A, indicating the location of the CpG sites.

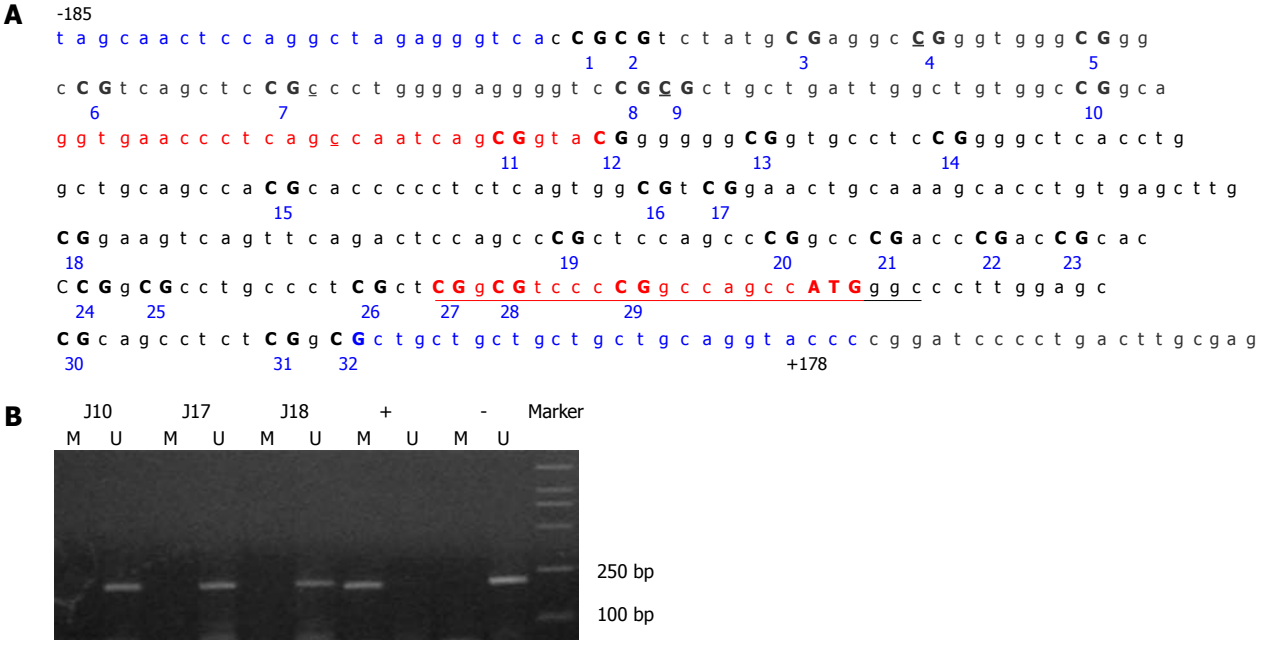

Figure 3 Germline *CDH1* promoter hypermethylation analysis in GC patients. A: Map of the *CDH1* promoter region and primer positions. The sequence is numbered relative to the transcription start site for human *CDH1*. Characters in red indicate the primer binding sites for methylation-specific PCR (MSP), those in blue for bisulfite sequencing. Individual CpG sites in the sequence are numbered consecutively; B: MSP of the *CDH1* promoter from the peripheral blood of GC patients. Marker, DL2000 DNA Markers (TaKaRa); +, CpGenome Universal Methylated DNA control; -, CpGenome Universal Unmethylated DNA control; M, methylated band; U, unmethylated band. As a control, the fragments corresponding to the *CDH1* promoter of fully methylated DNA showed a clear band when amplified with methylated-specific primers and did not display a band when treated with unmethylated primers. The unmethylated DNA control showed the reverse pattern.

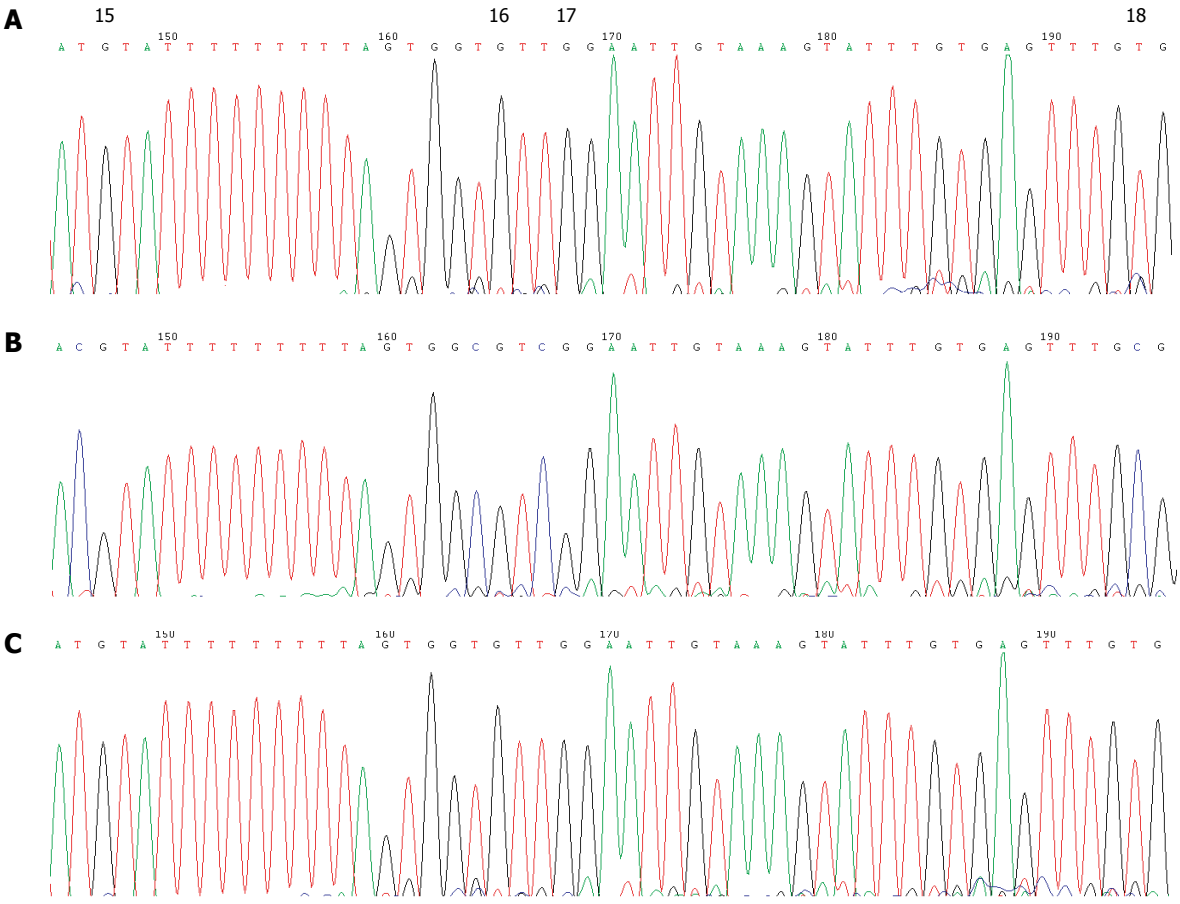

Figure 4 Bisulfite sequencing of *CDH1* promoter sequences from gastric cancer patients. A: DNA isolated from the blood of a gastric cancer patient showing T bases at the CpG sites around the transcription start site due to complete modification of the DNA; B: CpGenome Universal Methylated DNA control in which *CDH1* is completely methylated showing a high level of C at all CpGs due to reduced bisulfite modification; C: CpGenome Universal Unmethylated DNA control showing T bases at the CpG sites around the transcription start site attributable to complete bisulfite modification of the DNA.

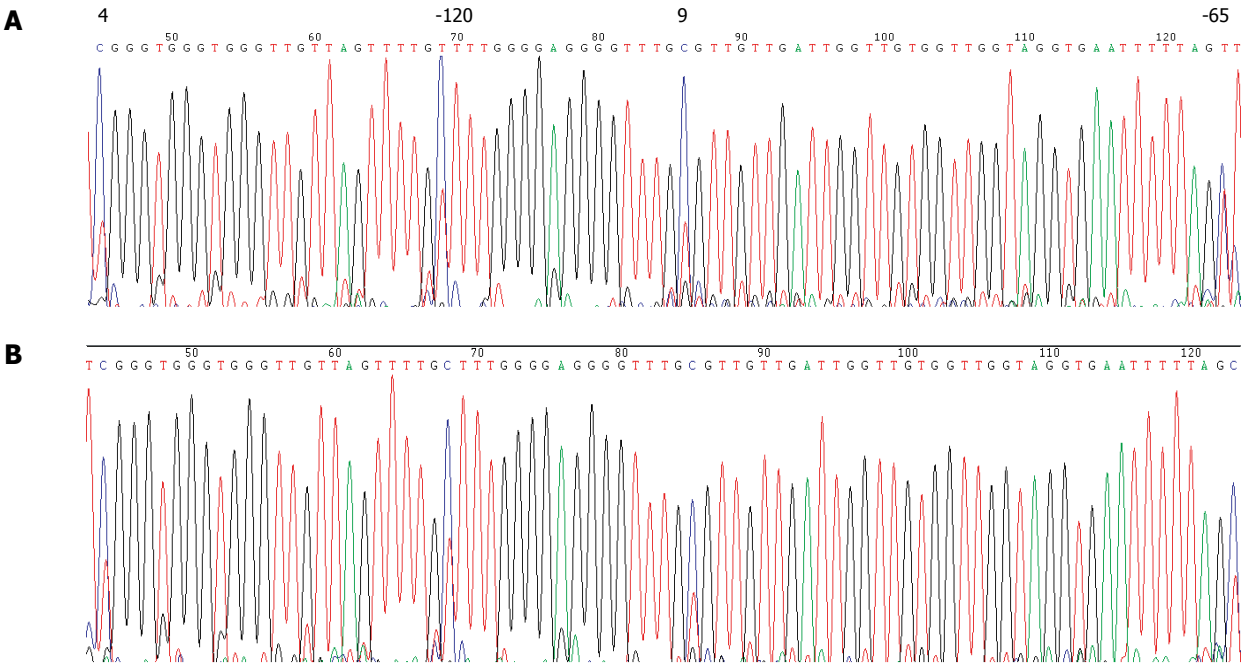

Figure 5 Bisulfite sequencing of the *CDH1* promoter sequences from gastric cancer patients showing uninformative CpG sites. A: DNA isolated from the blood of a gastric cancer (GC) patient; B: DNA isolated from the blood of a normal control. The 4th and 9th CpG sites showed a high C content in all patients, but also in each of the normal controls, suggesting that these sites are not associated with GC.

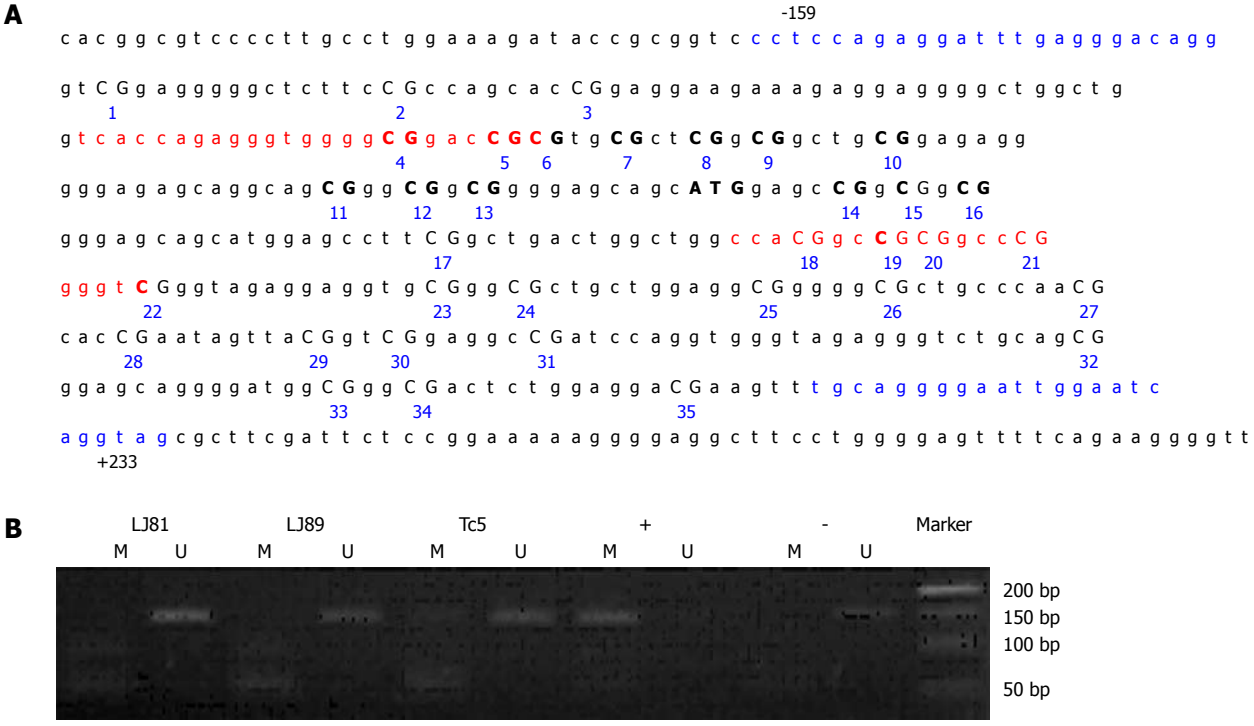

Figure 6 Analysis of the methylation pattern of the *P16* gene in blood cells from gastric cancer patients. A: Map of the *P16* promoter region and positions of the primers used in the analysis. The sequence is numbered relative to the translation start site for human *P16*. Characters in red indicate the primer binding sites for MSP and those in blue for bisulfite sequencing. Individual CpG sites are numbered consecutively; B: MSP of the *P16* promoter in peripheral blood from patients with gastric cancer. Marker, DL500 DNA Marker (TaKaRa); +, fully methylated DNA control; -, fully unmethylated DNA control; M, methylated band; U, unmethylated band. As a control, the fragments corresponding to the *P16* promoter of fully methylated DNA showed a clear band when amplified with methylated-specific primers and did not display a band when treated with unmethylated primers. The fully unmethylated DNA control showed the reverse pattern.

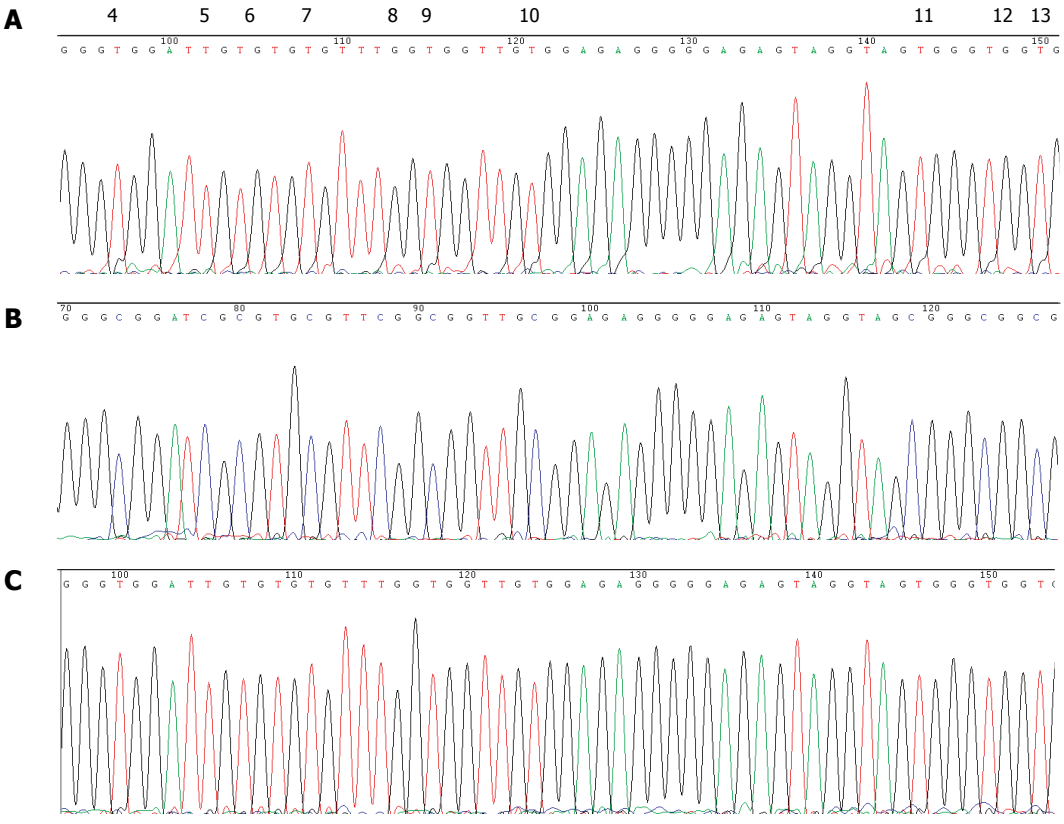

Figure 7 Bisulfite sequencing of *P16* promoter sequences. A: DNA isolated from the blood of a GC patient showing a T at all CpG sites of the *P16* gene promoter region due to complete modification of the DNA; B: CpGenome Universal Methylated DNA control in which a high C content can be found at all CpGs in the *P16* gene; C: CpGenome Universal Unmethylated DNA control showing a T at all CpG sites in the *P16* gene promoter.

10% methylation level at each of these CpG sites. Taken together, our data suggest that a mosaic germline *MLH1* epimutation might be present in some patients who develop gastric cancer. This mosaic methylation of *MLH1* might not be due to disseminated GC cells in the blood because these do not occur at sufficiently high levels to be detected by our assay. In patient G46, aberrant DNA methylation may have occurred after fertilization, when the maternal CpG methylation pattern is established[26]. It is also possible that CpG methylation is not always faithfully replicated during early embryogenesis, and the degree of mosaicism might be influenced by the genetic or epigenetic background. Our results raise the further possibility that silencing of *MLH1* by promoter methylation could occur as a germline or an early somatic event that generates a predisposition to GC.

We did not detect germline *CDH1* or *P16* promoter CpG methylation in any of the 140 GC patients investigated (Figures 3-7), suggesting that germline hypermethylation in the *CDH1* or *P16* promoter is not a common mechanism of *CDH1* or *P16* inactivation leading to GC. A detailed inspection of the bisulfate transformed sequence corresponding to the promoter region of *CDH1* revealed two methylated CpGs (the 4th and 9th), and also two methylated Cs at positions -120 and -65 bp relative to the transcription start site of the *CDH1* gene. However, given that this methylation was found in all of the patients and normal controls, it is unlikely to be associated with GC.

In summary, we report here that germline mosaic hypermethylation of the CpG islands in the *MLH1* promoter region may be the underlying cause of some gastric cancers, while germline hypermethylation of *CDH1* or *P16* gene is not a common mechanism responsible for GC in familial patients.

COMMENTS

Background

Gastric cancer is considered to be one of the leading cancers in East Asia but the underlying genetic abnormalities that lead to more than 70% of these cases remain unknown.

Research frontiers

Epigenetic methylation-associated inactivation of genes is not limited to tumor cells. Monoallelic promoter hypermethylation of the *MLH1* gene in the peripheral blood of patients with early-onset colorectal cancer has recently been reported in the literature. However, it is uncertain whether germline epimutations are responsible for gastric cancer onset in hereditary cases.

Innovations and breakthroughs

In this report, we provide a comprehensive description of germline epimutations of the tumor suppressor genes *MLH1*, *CDH1* and $P16^{INK4a}$ in Chinese gastric cancer cases. We report the rare occurrence of germline mosaic hypermethylation of the CpG islands in the *MLH1* promoter region in gastric cancer. We also demonstrate that germline epimutation of the *CDH1* or $P16^{INK4a}$ gene is not a frequent occurrence in this disease.

Applications

The finding of human *MLH1* gene germline epimutations is of some significance as it not only reveals a possible new mechanism in the tumorigenesis of gastric cancers, but also indicates that germline epimutations may be associated with a wide range of human diseases. On the other hand, germline epimutations show both mosaic and non-Mendelian characteristics, which may explain the phenotypic variability and changes in the genetic penetrance of some complex diseases, and thereby provide new avenues for studying the etiology of such disorders.

Terminology

Germline epimutations not only arise in tumor cells but in nontumor cells of a germline origin.

Peer review

The manuscript is well written and the methods are adequate. The results justify the conclusions drawn.

Abstract

AIM: To investigate the growth effects of 4-phenyl butyric acid (PBA) on human gastric carcinoma cells and their mechanisms.

METHODS: Moderately-differentiated human gastric carcinoma SGC-7901 and lowly-differentiated MGC-803 cells were treated with 5, 10, 20, 40, and 60 μmol/L PBA for 1-4 d. Cell proliferation was detected using the MTT colorimetric assay. Cell cycle distributions were examined using flow cytometry.

RESULTS: The proliferation of gastric carcinoma cells was inhibited by PBA in a dose- and time-dependent fashion. Flow cytometry showed that SGC-7901 cells treated with low concentrations of PBA were arrested at the G_0/G_1 phase, whereas cells treated with high concentrations of PBA were arrested at the G_2/M phase. Although MGC-803 cells treated with low concentrations of PBA were also arrested at the G_0/G_1 phase, cells treated with high concentrations of PBA were arrested at the S phase.

CONCLUSION: The growth inhibitory effect of PBA on gastric cancer cells is associated with alteration of the cell cycle. For moderately-differentiated gastric cancer cells, the cell cycle was arrested at the G_0/G_1 and G_2/M phases. For lowly-differentiated gastric cancer cells, the cell cycle was arrested at the G_0/G_1 and S phases.

INTRODUCTION

Modification of the N-terminal of chromosomal histone

can alter chromatin structure by affecting the affinity between the histone and DNA[1,2]. Histone acetylation is a reversible dynamic process and can be regulated by histone acetyltransferase (HAT) and histone deacetylase (HDAC). Usually, HATs lead to the relaxation of chromatin structures and gene transcriptional activation, while HDACs are associated with chromatin condensation and transcriptional silence. Many studies have shown the close correlation of low histone acetylation or high expression of HDACs with the genesis and development of some tumors[3,4]. The activation of HATs and/or the suppression of HDACs were considered as a new approach to tumor therapy. The antitumor effect of histone deacetylase inhibitors (HDACIs) are attributed mainly to growth inhibition, apoptosis, or the induction of differentiation[5].

Gastric cancer is the second leading cause of cancer death in the world and will likely remain as one of the leading causes of all deaths in the near future[6,7]. In the past few years, evidence has accumulated showing that modification of acetylation status plays a central role in gastric carcinogenesis[8]. 4-phenyl butyric acid (PBA), a short-chain fatty acid, is a commonly used HDACI. However, the antitumor effect of PBA in gastric cancers has not yet been elucidated.

MATERIALS AND METHODS

Cell culture and reagents

Human gastric cancer cell lines, MGC-803 (lowly differentiated) and SGC-7901 (moderately differentiated), were obtained from the Shanghai Institute of Biochemistry and Cell Biology, Chinese Academy of Sciences (Shanghai, China). MGC-803 and SGC-7901 cells were cultured in RPMI-1640 medium (Life Technologies, Grand Island, NY, United States) supplemented with 10% fetal bovine serum, glutamine, 100 U/mL penicillin and 100 μg/mL streptomycin in a humidified, 5% CO_2 in air atmosphere at 37 ℃. Exponentially growing cells were used for the experiments.

MTT assay

To observe the effect of PBA on the growth of gastric carcinoma cells, the MTT assay was used. MGC-803 and SGC-7901 cells (1.5×10^4/mL) were added to 96-well plates. Twenty-four hours later, PBA was added at final concentrations of 5, 10, 20, 40 and 60 μmol/L, respectively. Four wells were used for each dose. After the cells were incubated for 24, 48, 72, and 96 h, 20 μL of 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) solution [2 g/L in phosphate buffered saline (PBS)] was added into each of the 96 wells. The cells were incubated at 37 ℃ for 4 h, the medium was removed, and 150 μL of dimethyl sulfoxide (DMSO) was added to solubilize the formazan. The microplate was shaken on a rotary platform for 10 min. Then, the optical density (OD) values were measured at 490 nm using a Wellscan reader (Labsystems, Santa Fe, NM, United States). The inhibition rate was determined to indicate the suppressive effect of PBA on gastric carcinoma cells. The relative inhibition rate was calculated as a percentage, as follows: $(1-A_{experiment}/A_{control}) \times 100\%$. Three independent experiments were performed.

Cell cycle analysis

MGC-803 and SGC-7901 cells were treated with PBA at the above-mentioned concentrations for 24 h and 48 h. Then, the cells were collected and washed twice with PBS. Cold 70% ethanol was added and the cells were kept at 4 ℃ overnight. Subsequently, the cells were rinsed twice with PBS. Finally, the cells were incubated in propidium iodide/RNase Staining Buffer (BD, San Diego, CA, United States) according to the manufacturer's manual, and the cell cycle was analyzed with a fluorescence-activated cell sorting Calibur Flow Cytometer (BD, San Diego, CA, United States). The percentage of cells in the different phases of the cell cycle (G_0/G_1, S or G_2/M phase) was calculated by the BD FACStation™ Data Management System. Three wells of a 6-well plate were used for each dose. Three independent experiments were performed.

Statistical analysis

Statistical analysis was performed using the Statistical Program for Social Sciences (SPSS) software 13.0 (SPSS Inc, Chicago, IL, United States). Data were expressed as the mean ± SD. One-way analysis of variance (ANOVA) was used to analyze significant differences between control and treatment groups. A P value of less than 0.05 was considered statistically significant.

RESULTS

Effect of 4-phenyl butyric acid on the growth of gastric carcinoma cells

After exposure to PBA for 24, 48, 72, and 96 h, the growth of gastric carcinoma MGC-803 and SGC-7901 cells was inhibited significantly (5 and 10 μmol/L, $P < 0.05$; 20, 40, and 60 μmol/L, $P < 0.01$). The inhibitory effect was dose- and time-dependent (Figure 1).

Effects of cell cycle distribution of 4-phenyl butyric acid on gastric carcinoma cells

To decipher the suppressive mechanisms of PBA on gastric cancer cells, we monitored the changes in the cell cycle distribution by flow cytometry. The results of 48 h treatments showed that gastric carcinoma cells treated with various concentrations of PBA were arrested at different phases. MGC-803 cells treated with low concentrations (5 and 10 μmol/L) of PBA were arrested at the G_0/G_1 phase, while those treated with high concentrations (20-60 μmol/L) were arrested at G_2/M (Figure 2A). There was a big difference in the cell cycle interruption between MGC-803 and SGC-7901. SGC-7901 cells were arrested at the G_0/G_1 phase at low concentrations (5 and 10 μmol/L) and at the S phase with high concentrations (Figure 2B). Based on these observations, we investigated

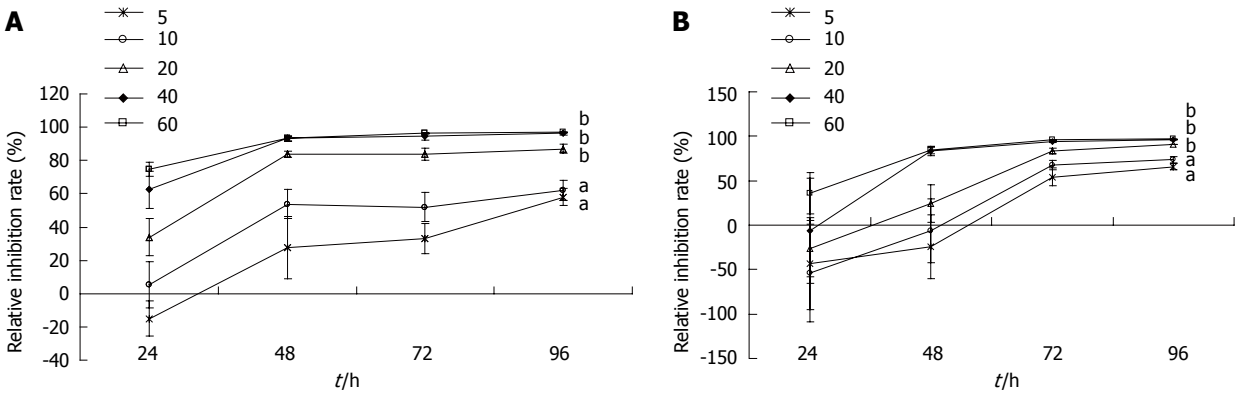

Figure 1 Effects of 4-phenyl butyric acid on the proliferation of gastric carcinoma MGC-803 cells (A) and SGC-7901 cells (B). Cells were incubated with 4-phenyl butyric acid at various concentrations for 24, 48, 72, and 96 h. The proliferation of cells was determined by the MTT assay. $^{a}P < 0.05$, $^{b}P < 0.01$ *vs* control. The relative inhibition rate was calculated as a percentage, as follows: $(1\text{-}A_{experiment}/A_{control}) \times 100\%$.

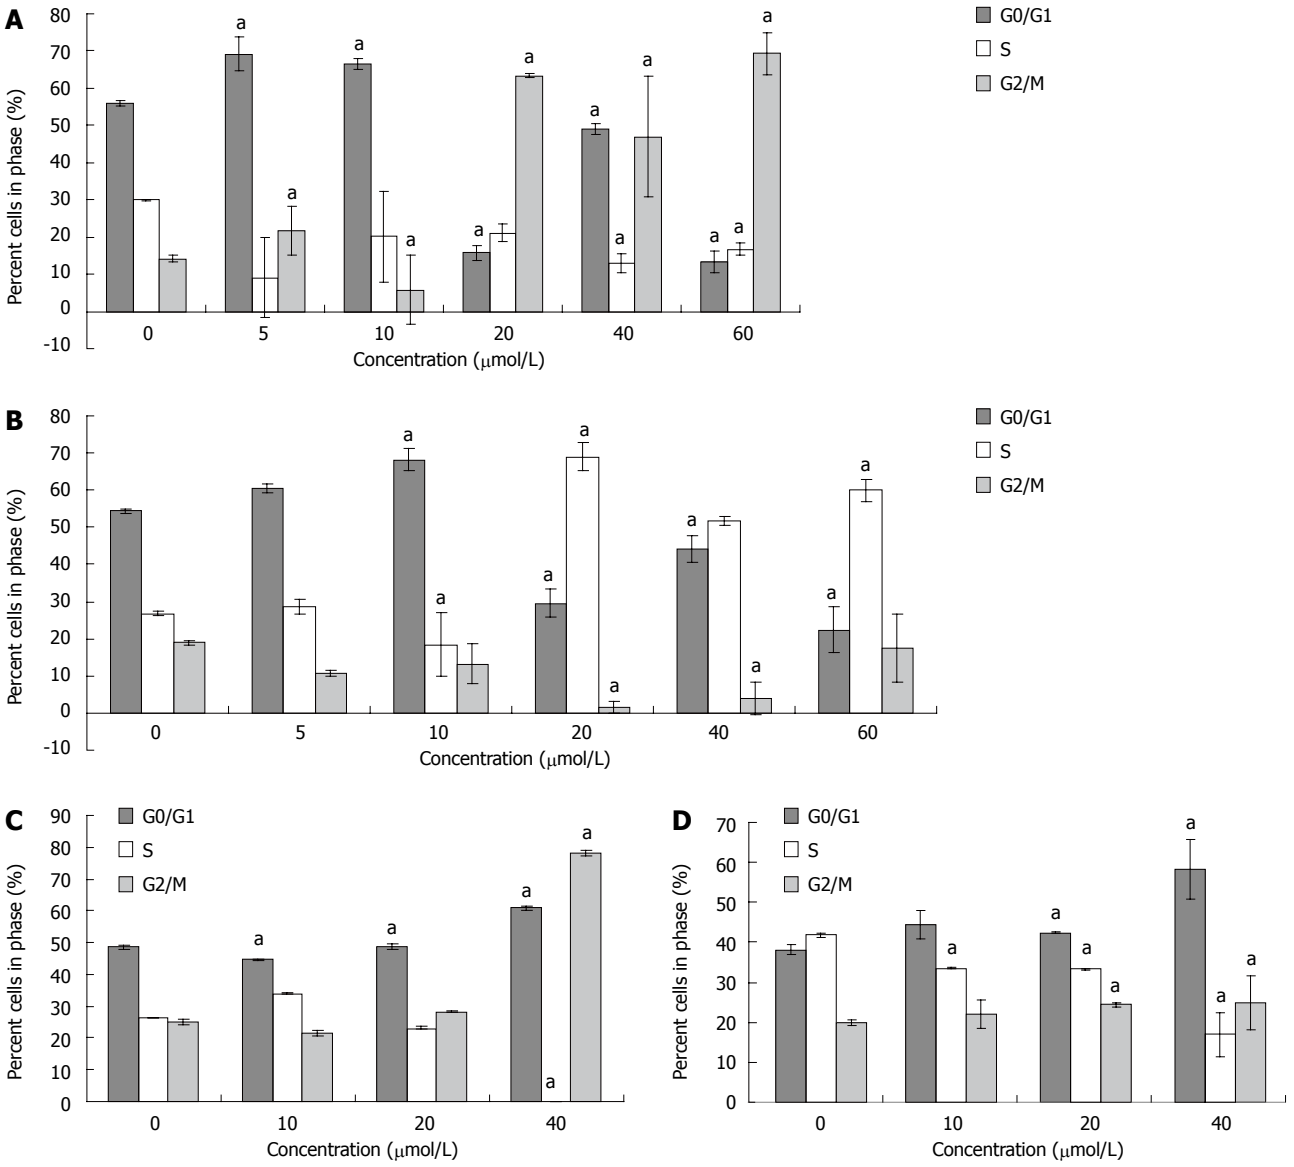

Figure 2 Effects of 4-phenyl butyric acid on cell cycle distribution of gastric carcinoma cells. The cell cycle was measured by propidium iodide staining and fluorescence-activated cell sorting analysis. $^{a}P < 0.05$ *vs* control. MGC-803 cells (A) and SGC-7901 cells (B) were treated for 48 h; and MGC-803 cells (C) and SGC-7901 cells (D) were treated for 24 h.

another time-course effect. Three doses, 10, 20 and 40 μmol/L, which were among the significant concentrations for both cells at the 48 h treatment, were chosen to treat cells for 24 h. As indicated in Figures 2C and D, similar effects were found.

DISCUSSION

PBA is one of the HDACIs already tested in clinical trials in the treatment of recurrent malignant gliomas and myelodysplastic syndrome[9,10]. In addition, it is a FDA-approved, and well-tolerated drug for urea cycle disorders[11]. It is converted into phenylacetate (PA) by β-oxidation in liver and kidney mitochondria[12]. It has recently been demonstrated that PBA has various cellular effects, such as induction of differentiation and apoptosis[13]. PBA has also been proved to be an effective chemical compound in preventing gene mutations and in preventing the aggregation of denatured α-lactalbumin and bovine serum albumin[14,15]. Interestingly, PBA treatment results in the induction of apoptosis in prostate cancer cells, medulloblastoma cells and colon cancer cells[12,13-17]. Furthermore, PBA was found to cause the regression of tumors derived from hepatocarcinoma cells in a rat model system[18].

Histone acetylation and DNA methylation represent epigenetic modifications that are essential for chromatin organization and the regulation of gene expression. Histone acetylation leads to an open chromatin structure favoring gene transcription, whereas deacetylation induces transcriptional repression through chromatin condensation[19]. In addition, the function of nonhistone proteins can be modified by acetylation and deacetylation[20]. Aberrant gene expression resulting from epigenetic alterations is critical for tumor development in many tumors, including gastric cancer, and it is also implicated in response to chemotherapy[21,22]. Modulation of chromatin structure has been suggested to influence the accessibility of DNA-targeting drugs such as short-chain fatty acid, and thus to affect the extent of the DNA damage[23-25]. Enzymes involved in these chromatin modifications with opposing activities are the histone acetyltransferases and HDACs. According to the structure, there are four types of HDACIs: hydroxamic acid and analogs, short-chain fatty acids, circum tetrapeptide, and benzamides[26]. PBA, a short-chain fatty acid, has not been used widely against gastric cancer, and its antineoplastic function has not been studied.

The present study has shown that PBA has a time- and dose-dependent effect on the proliferation of gastric carcinoma cells (Figure 1). These effects are similar to those of PBA on prostate cancer[27]. It is known that chemotherapeutic drugs act on the cell cycle of tumor cells. To decipher the growth suppressive mechanisms of PBA on gastric cancer cells, cell cycle distribution was measured by flow cytometry. The results indicated that the cell cycle distributions of two types of gastric carcinoma cells were interrupted by PBA (Figure 2). It was interesting to find that the modes of cell cycle arrests were different when high concentrations of PBA were used. The state of differentiation of MGC-803 and SGC-7901 cells is very different. MGC-803 cells are lowly differentiated, and SGC-7901 cells are moderately differentiated. These effects are similar to those of lycium barbarum polysaccharide (LBP) on MGC-803 and SGC-7901 cells. Miao *et al*[28] found that LBP treatment inhibited the growth of MGC-803 and SGC-7901 cells, with cell-cycle arrest at the G_0/G_1 and S phase, respectively. The cell cycles are regulated by the cell cycle-associated proteins, cyclin and cyclin-dependent kinase (CDK). Cyclin A binds and activates CDK2, and thus promotes both G_1/S and G_2/M transitions in the cell cycle[29]. For SGC-7901 cells, LBP increased the expression of cyclin A and decreased the expression of CDK2, and thus arrested cells at the S phase[28]. At the G_0/G_1 phase, the main cell cycle regulators are cyclin D, cyclin E, and CDK2[30]. For MGC-803 cells, LBP decreased the expressions of cyclin D, cyclin E, and CDK2[28]. These results are consistent with the effect of LBP on the arrest of the MGC-803 cell cycle at the G_0/G_1 phase.

In summary, our study identified PBA effects on gastric cancer cell growth. These observations may be correlated with the suppression of the cell cycle, and they suggest that an HDAC inhibitor such as PBA may be a potential anti-cancer drug.

COMMENTS

Background

Gastric cancer is the second leading cause of cancer death in the world and will likely remain as one of the leading causes of all deaths in the near future. Evidence has accumulated showing that modification of acetylation status plays a central role in gastric carcinogenesis.

Research frontiers

4-phenyl butyric acid (PBA), a short-chain fatty acid, is a commonly used histone deacetylase inhibitor (HDACI). However, the antitumor effect of PBA in gastric cancer has not yet been elucidated. In this study, the authors demonstrate that the proliferation of gastric carcinoma cells was inhibited by PBA in a dose- and time-dependent fashion.

Innovations and breakthroughs

Recent reports have highlighted the importance of PBA in the growth inhibitory effects on prostate cancer cells. This is the first study to report that PBA also suppresses the growth of gastric cancer cells. Furthermore, our studies show that the cell cycle arrest of PBA in gastric cancer cells is different between differentiated level of cancer cells.

Applications

By understanding how PBA inhibits the growth of gastric cancer cells, this study may represent a future strategy for therapeutic intervention in the treatment of patients with gastric adenocarcinoma.

Terminology

Histone acetylation is a reversible dynamic process which can be regulated by histone acetyltransferase and histone deacetylase (HDAC). Many studies have shown the close correlation of low histone acetylation or high expression of HDACs with the genesis and development of some tumors. Unsurprisingly, the use of PBA, a HDACI, will suppress the growth of gastric cancer cells.

Peer review

The authors assessed the inhibitory effect of PBA on human gastric cancer cells. They showed that PBA had growth inhibitory effects in a dose- and time-dependent manner. They also found cell cycle arrest was different between differentiated levels of gastric cancer cells. Advanced gastric cancer is a high mortality tumor as the result of repeated anti-cancer therapy. A further therapeutic strategy is needed to raise the remission rate of gastric cancer. The approach

of the authors in this study is one of the next generation therapies for gastric cancer. Therefore, the concept of this study is reasonable and important. It is interesting that the inhibitory effect was different between differentiated levels of gastric cancer cells. Also, methodology is interesting to investigate the mechanism of inhibitory effect of HDACIs.

Abstract

AIM: To investigate appropriate therapeutic strategies for graft-*vs*-host disease (GVHD) following liver transplantation.

METHODS: Four patients who developed GVHD after liver transplantation in West China Hospital were included in this study. Therapeutic strategies with augmentation or withdrawal of immunosuppressants combined with supportive therapy were investigated in these patients. In addition, a literature review of patients who developed GVHD after liver transplantation was performed.

RESULTS: Although a transient response to initial treatment was detected, all four patients died of complications from GVHD: one from sepsis with multiple organ failure, one from gastrointestinal bleeding, and the other two from sepsis with gastrointestinal bleeding. Few consensuses for the treatment of GVHD after liver transplantation have been reached.

CONCLUSION: New and effective treatments are required for GVHD after liver transplantation to improve the prognosis of patients with this diagnosis.

Key words: Graft-*vs*-host disease; Immunosuppressant; Immunosuppression; Liver transplantation; Treatment

INTRODUCTION

Although the liver is recognized as an immunologically privileged organ, acute graft-*vs*-host disease (GVHD) may occur in 1%-2% of patients after liver transplantation (LT), and the mortality rate of patients with GVHD is very high (> 85%)[1-3]. The donor lymphocytes remaining in the portal tracts and the parenchyma of the donor liver graft after flushing with cold preservative solution[4,5] colonize the recipient, recognizing the host tissue antigens as foreign and react against the host tissue. The typical clinical presentations of GVHD include fever, skin rash (Figures 1-4), diarrhea, and pancytopenia beginning 2 to 6 wk after LT[1,2,6]. The diagnosis is usually made according to the typical clinical manifestations mentioned above, with the exclusion of other phenomena such as infection, drug allergies or rejection, which share the same clinical features as GVHD. A rapid diagnosis by the detection of lymphocyte macrochimerism through DNA-short tandem repeat (STR) has been recommended[7], while human leukocyte antigen (HLA)-

typing has also proven critical in confirming GVHD and elucidating its cause[8].

Treatment of GVHD typically consists of increasing immunosuppression using antibody preparations, such as OKT3 or antithymocyte globulin, to eliminate the donor lymphocytes and supporting myelopoiesis through the use of cytokines. However, this treatment has been unsuccessful; the majority of GVHD patients died of native bone marrow failure, resulting in fatal sepsis[1,9,10]. In one case, immunosuppressant withdrawal to control GVHD was suggested by Chinnakotla *et al*[11]. In their report, two of three patients exhibited the rapid loss of donor T-cell chimerism and resolution of their symptoms; however, the remaining patient continued to progress to severe GVHD and subsequently died.

In this study, we describe the unsuccessful results of different treatment regimens involving augmentation or withdrawal of immunosuppressant therapy in four patients with established GVHD after LT.

MATERIALS AND METHODS

From January 1999 to December 2010, 836 cases of LT were performed in West China Hospital. A total of four recipients developed postoperative GVHD (Table 1). Each of these patients was given a pathological diagnosis of GVHD following skin rash biopsy; HLA typing and polymerase chain reaction (PCR)-STR were not performed. The various treatments in these patients are shown in Table 2. One patient received increased immunosuppressive therapy (methylprednisolone 500 mg, iv, qd, for 3 d). This therapy was then augmented by consecutive use of cyclosporine A (CsA) and mycophenolate mofetil, while granulocyte colony-stimulating factor (G-CSF) was subsequently administered as a supportive treatment. The other three patients also initially received increased immunosuppressive therapy (methylprednisolone 500 mg, iv, qd, for 2 d); however, this was followed by the complete withdrawal of immunosuppressant therapy combined with the administration of supportive treatment including G-CSF (0.075 mg, bid), intravenous immunoglobulin (20 g, qd) or thymosin α1 (Zadaxin 1.6 mg, qd). Due to immune dysfunction, the patient who received increased immunosuppressive therapy eventually developed a severe infection. *Enterobacter cloacae* (a yeast-like organism) and *Candida albicans* were identified through repeat sputum and buccal swab culture in this patient. Subsequently, many different antibiotics (imipenem/cilastatin sodium, azithromycin, moxifloxacin, meropenem and teicoplanin) and an anti-fungal agent (fluconazole) were administered. Broad-spectrum antibiotics with or without anti-fungal medicines were also administered in the other three patients after GVHD onset to control infection or as a routine prophylaxis (Table 2). A flowchart of treatment is shown in Figure 5.

RESULTS

All patients with confirmed pathological diagnoses of GVHD developed fever, skin rash, diarrhea, severe bone marrow suppression and gastrointestinal bleeding. In response to the initial treatment, the rash faded, the skin underwent desquamation and pigmentation (Figure 2), and the temperature displayed a transient decrease. However, diarrhea persisted, bone marrow failure and gastrointestinal bleeding developed, and the levels of white blood cells (WBC) and platelets dropped. The most conspicuous changes in platelet number and white blood cell count were observed in cases 4 and 3, from a normal

level to 1 × 10^9/L and from a normal level to 0.03 × 10^9/L, respectively (Table 1). All of these patients died of complications from GVHD: one from sepsis with multiple organ failure (MOF), one from gastrointestinal bleeding, and the other two from sepsis with gastrointestinal bleeding (Table 2). The average survival time from onset of GVHD was 14.25 d.

DISCUSSION

GVHD following LT is an uncommon but fatal complication that poses a major diagnostic and therapeutic challenge. Research has shown that GVHD involves activation of donor T lymphocytes by antigen-presenting cells (APCs), causing an alloreactive T-cell response to recipient tissues mediated by cytotoxic T-cells and inflammatory cytokines[12], such as tumor necrosis factor-alpha (TNF-α), interleukins 1, 2, 6 and 10, and interferon γ[13]. Of these cytokines, TNF-α is recognized as the key inflammatory cytokine involved in the pathogenesis of GVHD, which can activate APCs, recruit effector cells, and cause tissue damage[13,14]. Taking the role of TNF-α during GVHD into account, certain anti-TNF-α agents such as etanercept and infliximab have been used in steroid-refractory GVHD following hematopoietic stem cell transplantation (HSCT), and one case who developed GVHD after LT was reported to be successfully treated with infliximab[14,15]. Etanercept, a soluble recombinant human TNF-α receptor type Ⅱ fusion protein, which is usually used to treat rheumatoid arthritis and inflammatory bowel disease, was reported to be used in acute GVHD with steroids. A substantial majority of patients displayed a complete response (CR), which was very promising[15,16].

At present, most cases of GVHD after LT are diagnosed by typical clinical manifestations. However, the following laboratory examinations can help with the diagnosis: (1) biopsy of the skin rash; (2) detection of donor peripheral blood leukocytic chimerism; (3) microsatellite phenotype; (4) detection of donor HLA types in the peripheral blood, mucous membrane, or skin by PCR; and (5) detection of donor lymphocytes using immunohistochemistry on the skin rash[17]. Once diagnosis is confirmed, treatment should follow. Due to the low incidence of the disease and difficulty in evaluating the efficacy of treatment modalities, the therapeutic schedule for GVHD after LT has not yet been standardized. Most treatment methods are derived from those experiences of GVHD management following HSCT. Most treatments focus on increasing immunosuppression, usually in the form of antibody preparations such as antithymocyte globulin (ATG) or OKT3, which are used to treat conventional GVHD in a bone marrow transplant recipient. Unfortunately, these experiences did not demonstrate any survival benefit[9,10,18-21].

CsA is the mainstay of pharmacologic prevention of acute GVHD[22], while high-dose corticosteroid is considered an important part of first-line treatment for acute GVHD after LT[1,3]. The use of corticosteroids for the treatment of GVHD after LT is derived from the HSCT experience: corticosteroids resolve symptoms in many patients. The mechanism by which glucocorticoids ameliorate acute GVHD is not completely clear, but it is likely related primarily to the suppression of lymphocytic activity. However, GVHD after LT is less responsive to corticosteroids than GVHD after stem cell transplantation. The literature includes reports on 12 patients who were treated primarily with corticosteroids and/or increased immunosuppressive medications following the diagnosis of GVHD after LT[1,3,9,10,21,23-27]. Of these patients, all adult patients died of GVHD-related complications during the subsequent 11 d; only two children[28,29] were alive at the time of the report. These results suggest that, at least in the adult patients, treatment of GVHD after LT exclusively with corticosteroids or increasing immunosuppression is an inadequate approach to long-term therapy. Although temporary symptom relief may be available, the resolution of GVHD cannot be expected.

In the first case in our series, high-dose methylprednisolone followed by CsA and mycophenolate mofetil were administered to treat GVHD. Although the fever improved transiently in this patient, diarrhea and bone marrow suppression did not respond to this treatment regimen; continuous diarrhea and bone marrow failure developed, and WBC and platelet counts progressively decreased. Furthermore, hyperpyrexia developed again after two days' amelioration. This patient soon died of severe lung infection and MOF 11 d after GVHD onset. Due to the unsuccessful outcome of acute GVHD in a liver allograft recipient following increased immunosuppression, reduction and even complete withdrawal of immunosuppressant therapy has been proposed as a treatment for GVHD after LT. Theoretically, such an approach should allow the recipient immune system to reject alloreactive donor lymphocytes mediating the GVHD[29-31]. Attempts at implementing this approach were met with an initial worsening of symptoms[2,32] and involved a risk of the donor liver being rejected[30]. These limitations would explain why few patients were treated primarily with the reduction or discontinuation of immunosuppression. Antilymphocyte globulin, ATG and OKT3 were also used in these patients, but there was no evidence that these agents altered the eventual outcome[9,10,8-21].

Six adult patients were reported to have been treated for GVHD after LT primarily by the reduction or discontinuation of immunosuppression before 2004[9,26,33-35]. Two of these patients were reported to be alive at the time of the report, with their recovery attributed to a reduction in immunosuppression[26,30]. Five children have been treated with this approach[1,29,31,33,36]. Of these children, three were alive, one was alive with chronic GVHD, and one child died. Chinnakotla *et al*[11] reported the success of immunosuppression withdrawal in three patients diagnosed with GVHD in 2007. This approach

was successful in two of three cases, but the other patient died. Another successful approach to treatment involving improvement of the immunity of the patient was also reported by Lu *et al*[17].

In our series, three patients were treated first by increasing immunosuppression (high-dose methylprednisolone 500 mg once daily for 2 d + FK506 or CsA) upon the initial appearance of GVHD symptoms, such as hyperpyrexia and skin rash. Because the diagnosis of GVHD was confirmed by skin rash biopsy, the amelioration of fever, and progressive bone marrow cell proliferation suppression, complete withdrawal of the immunosuppressant was proposed. At the same time, supportive therapies such as immunoglobulin, thymosin α1 and G-CSF were administered. Unfortunately, these three patients did not respond effectively to this regimen of immunosuppression withdrawal combined with supportive therapy; one patient died of gastrointestinal bleeding, while two died of sepsis with gastrointestinal bleeding.

In sum, although two major strategies (augmentation or withdrawal of immunosuppressant therapy) have been proposed for the treatment of GVHD after LT, many novel strategies have been reported to be effective: anti-TNF-α with etanercept or infliximab, use of alefacept to elevate the blood cell count[36], pulse cyclophosphamide to treat the steroid-refractory hepatitis form of liver GVHD not associated with gut GVHD[37], interleukin 2-receptor antibody (basiliximab or daclizumab) therapy[7], and the preventive broad-spectrum chemokine-inhibitor NR58-3.14.3 (in animal experiments only)[38]. However, few consensuses have been reached. For non-typical manifestation at an early stage, which involve symptoms similar to those of a drug allergy or mimicking a more common clinical condition such as infection, GVHD can easily be misdiagnosed or even omitted. Moreover, as a rare post-transplant complication with no standardized treatment protocol hitherto, early diagnosis and effective treatment of GVHD would be complex, frustrating and laden with additional difficulties. Although a handful of successful cases have been reported, further research is necessary. It is therefore imperative to develop a *de novo* therapeutic schedule with definite effects.

COMMENTS

Background

Graft-*vs*-host disease (GVHD) following liver transplantation (LT) is a rare but fatal complication. The incidence is about 1%-2%, and the mortality rate is over 85%. People who develop GVHD after LT usually die of serious complications such as multiple organ failure, gastrointestinal bleeding and sepsis. So, a rapid diagnosis and treatment of GVHD is critical. At present, the consensuses of treatment methods for GVHD after LT have not been reached and the therapeutic experiences are derived from those of management following hematopoietic stem cell transplantation.Two major strategies (augmentation or withdrawal of immunosuppressant therapy) have been proposed as the treatment of GVHD after LT. Also, many novel strategies have been reported to be effective.

Research frontiers

A rapid diagnosis by the detection of lymphocyte macrochimerism through DNA-short tandem repeat has been recommended, while human leukocyte antigen-typing has also proven critical in confirming GVHD and elucidating its cause. Tumor necrosis factor-alpha (TNF-α) is recognized as the key inflammatory cytokine involved in the pathogenesis of GVHD, which can activate antigen presenting cells, recruit effector cells and cause tissue damage. So, certain anti-TNF-α agents such as etanercept and infliximab have been used in steroid-refractory GVHD.

Innovations and breakthroughs

The authors herein report four patients who developed GVHD after liver transplantation. Therapeutic strategies with augmentation or withdrawal of immunosuppressant combined with supportive therapy were investigated in these patients and a literature review of patients who developed GVHD after liver transplantation was performed in this article to investigate appropriate therapeutic strategies for GVHD following LT.

Applications

This article describes the clinical manifestations and diagnostic method of GVHD after LT and summarizes different therapeutic strategies, which would be helpful to the diagnosis or cure of this disease.

Terminology

GVHD: An immunological disorder that affects many organ systems, including the gastrointestinal tract, liver, skin and lungs, is a common and serious complication of transplantation where there is a reaction of donated organ/bone marrow against a patient's own tissue. It is an incompatibility reaction when donor lymphocytes or a graft containing lymphocytes that immunologically competent are given to a patient that has low immunological competence. Due to antibodies from the donor against antigens in the host, it can produce lymphocyte clones that will react by a variety of processes against the host and cause damage. Immunosuppressant: The agent administrated by patients who accept organ/bone marrow transplantation that decrease the immunity of the patients.

Peer review

The manuscript is well written and summarizes the treatment methods of GVHD after LT.

Abstract

An inflammatory pseudotumor (IPT) is a relatively rare lesion characterized by chronic infiltration of inflammatory cells and areas of fibrosis. IPTs are difficult to diagnose because of the absence of specific symptoms or of characteristic hematological or radiological findings. In this study, a case of a woman aged over 70 years was reported, who presented with a general malaise lasting more than two months. A computed tomography scan demonstrated a diffusely spread lesion of the liver with a portal vein occlusion and a splenic lesion surrounded by a soft density layer. Since the percutaneous liver biopsy showed findings that suggested an IPT, although the radiological findings did not exclude the possibility of a malignancy, we performed a percutaneous spleen biopsy to enable a more definitive diagnosis. The microscopic findings from the spleen specimen lead us to a diagnosis of IPT involving the liver and spleen. Subsequent steroid pulse therapy was effective, and rapid resolution of the disease was observed.

Key words: Inflammatory pseudotumor; Percutaneous liver biopsy; Percutaneous spleen biopsy; Steroid pulse therapy

INTRODUCTION

Inflammatory pseudotumors (IPT) are unusual lesions from a histological standpoint as they are characterized by nonspecific inflammatory cell infiltration and fibrosis. This tumor type was first described in the lung by Brunn[1] in 1939, and has been reported subsequently in various organs including the liver[2] and spleen[3].

No radiological findings have been found that are characteristics of IPT. This may be because the proportion or the distribution of inflammatory cells and fibrosis differs according to the cause and the period of inflammation[4]. Hence, it is difficult to establish a definite diagnosis by radiological imaging. Moreover, a proper differential

diagnosis of IPT from a malignant tumor could delay vital treatment. As a result of these issues, surgical removal is chosen only when the possibility of malignancy cannot be ruled out and when the treatment can be expected to be effective, particularly if growth of the lesion is observed during the evaluation period. There are some reports emphasizing the importance of undertaking a percutaneous needle biopsy in cases of suspected hepatic IPT to avoid unnecessary surgery, although misdiagnoses of adenocarcinoma[5] or an uncertain type of sarcoma[6] have been reported for some microscopic examinations. However, only one case of a needle biopsy for splenic IPT has been reported to date[7], and it is extremely rare to find IPT of the liver and spleen at the same time[8-10].

We report a rare case of IPT involving the liver and spleen which was difficult to diagnose by hematological examination or radiological study, but was confirmed following a percutaneous liver and spleen biopsy.

CASE REPORT

A woman aged over 70 with a past history of early-stage gastric cancer that had been treated by endoscopic mucosal resection at another hospital four years previously, was being followed annually by upper esophagogastroduodenoscopy. In one examination, compression from outside of the stomach at the fundus was observed, and she was referred to our hospital for further investigation.

At the time of the referral, this patient had been suffering from a general malaise lasting more than two months but did not have any other clinical symptoms such as fever, appetite loss, weight loss, or abdominal pain. The initial physical examination revealed nothing of note. Blood tests further showed a reduction in hemoglobin [8.0 g/dL (normal range 12.0-15.0 g/dL)] and an elevation of the white blood cell count [10 300/mm^3 (normal range 3300-9400/mm^3)], platelet count [549 000/mm^3 (normal range 130 000-320 000/mm^3)], and C-reactive protein level [10.98 mg/dL (normal range < 0.2 mg/dL)]. There was a slight increase in the total protein content [8.2 g/dL (normal range 6.4-8.1 g/dL)], whereas the albumin concentration was 1.9 g/dL (normal range 3.6-4.7 g/dL), indicating a substantial increase in globulin levels, which was consistent with an elevated IgG [3774 mg/dL (normal range 870-1700 mg/dL)]. The serum aspartate aminotransferase (AST) and alanine aminotransferase (ALT) levels were within the normal range, whereas the serum levels of alkaline phosphatase and γ-glutamyl transpeptidase were elevated [507 U/L (normal range 134-359 U/L) and 94 U/L (normal range 8-51 U/L), respectively]. The patient was negative for hepatitis B surface antigen (HBsAg) and hepatitis C virus antibody (anti-HCV). Antinuclear antibodies (ANA) were positive at a titer of 1:40 (normal range < 1:40) whereas other autoantibodies were negative, including antimitochondrial antibody (AMA), cytoplasmic anti-neutrophil cytoplasmic antibody (C-ANCA), and perinuclear anti-neutrophil cytoplasmic antibody (P-ANCA). Carcinoembryonic antigen (CEA), carbohydrate antigen 19-9 (CA19-9), α-fetoprotein (AFP), and des-γ-carboxy prothrombin (DCP) were all found to be within normal limits.

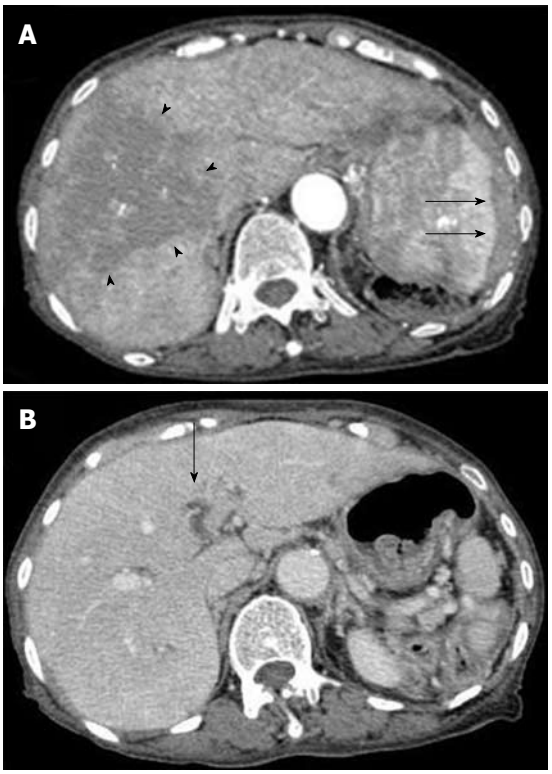

Figure 1 Contrast computed tomography scanning of the arterial phase revealed a diffusely and non-homogeneously enhanced liver, with the anterior compartment showing less enhancement (arrow-head). The spleen was found to be protruding inward, and also showed a diffuse and inhomogeneous enhancement. A: Computed tomography (CT) scans also revealed a soft density layer around the spleen (arrow). B: A CT of the portal phase showed an occlusion (arrow) of the left branch of the portal vein.

Contrast computed tomography (CT) during the arterial phase showed a diffusely and non-homogeneously enhanced liver, with a less enhanced anterior compartment (Figure 1A). The left branch of the portal vein was occluded in the portal phase (Figure 1B). The spleen was protruding inward, with diffuse and inhomogeneous enhancement of the arterial phase, as observed for the liver. CT also revealed a soft density layer around the spleen (Figure 1A). The results of fluorodeoxyglucose positron emission tomography/computed tomography (FDG-PET/CT) exhibited abnormal metabolic activity with a high standardized uptake value (SUV) of 7.1 around the spleen (Figure 2A). This was consistent with previous CT findings, and with a multiple abnormal uptake in segment six of the liver (Figure 2B). There was no abnormal uptake in other body sites. These radiological findings indicated the presence of a malignancy of the area surrounding the spleen and liver, with the possibility of a differential diagnosis of angiosarcoma, malignant lymphoma, hepatocellular carcinoma or metastatic cancer of the liver, with tumor thrombosis of the portal vein and the spleen.

A percutaneous needle liver biopsy was performed

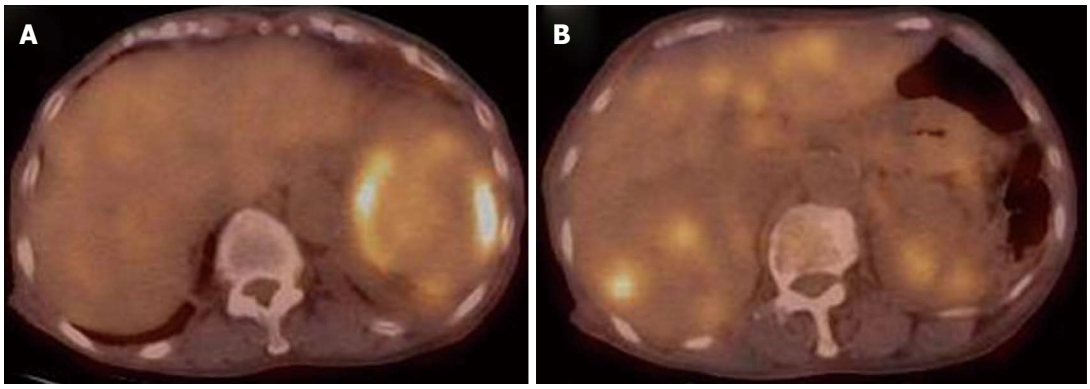

Figure 2 Fluorodeoxyglucose positron emission tomography/computed tomography analysis showing abnormal metabolic activity with a high standardized uptake value of 7.1 surrounding the spleen (A), and multiple abnormal uptakes in segment six of the liver (B).

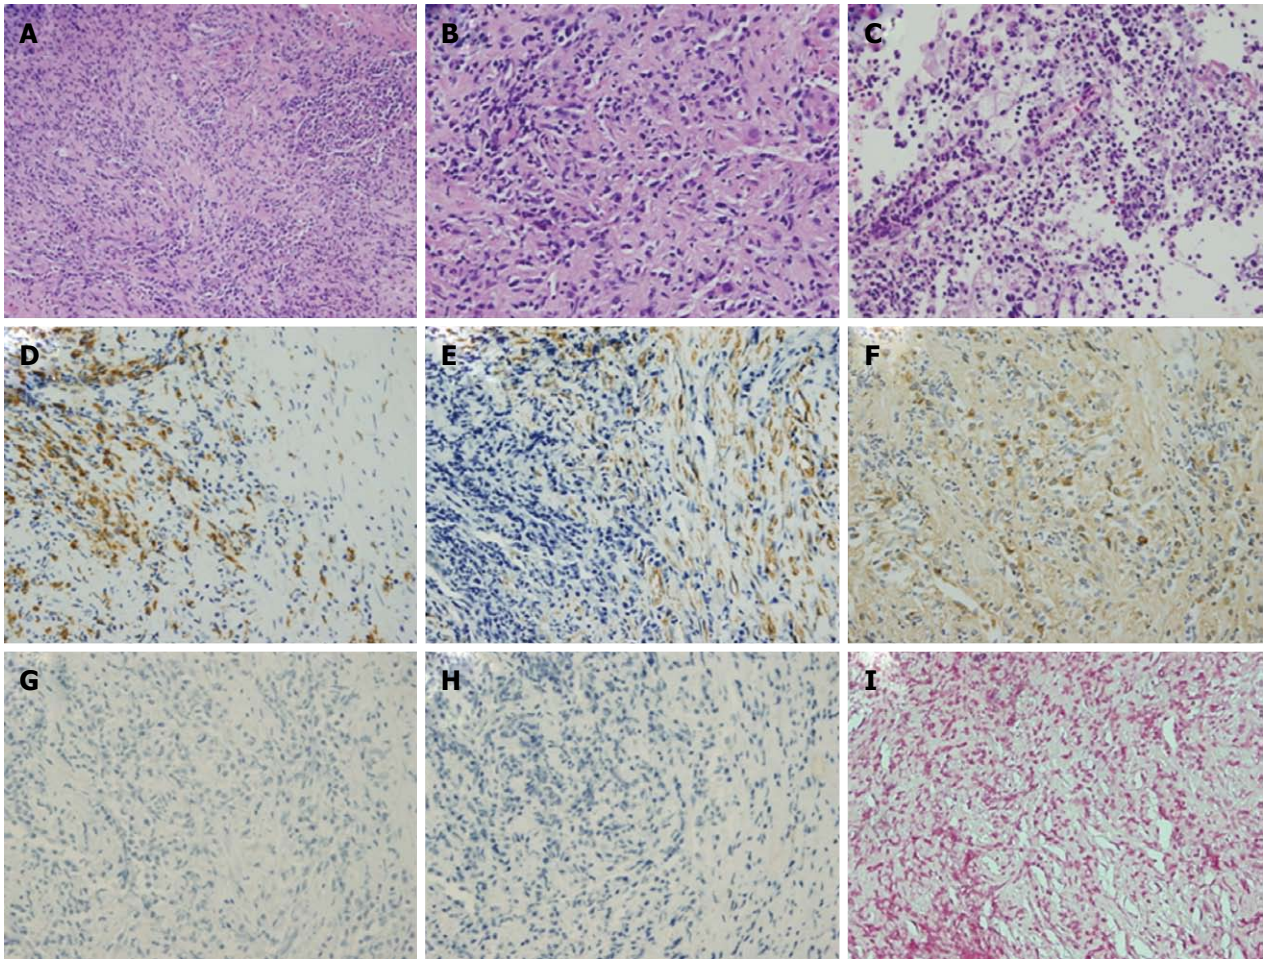

Figure 3 Histological findings for the liver *via* hematoxylin and eosin staining showing patchy fibroses and inflammatory cell infiltration (original magnification × 100). A: Mainly consisting of lymphocytes and plasma cells (original magnification × 200); B and C: Histological findings for the spleen following HE staining showed infiltration by plasma cells (original magnification × 200); D-I: Immunohistochemical analysis of the liver showed that the lesion was positive for CD68 (D), α-smooth muscle actin (SMA) (E), and IgG (F), but not for IgG4 (G), anaplastic lymphoma kinase (ALK) (H), or Epstein-Barr virus (EBV) encoded RNA (EBER) (I). HE: Hematoxylin and eosin.

under ultrasonic guidance to enable a more definite diagnosis. Sonographic examination revealed rough echogenicity of the right hepatic lobe, and a liver biopsy was subsequently performed but did not show a focal liver mass. The sonographic appearance of the spleen was similar to the liver biopsy region. The liver specimen showed a patchy fibrosis and inflammatory cell infiltration, mainly consisting of lymphocytes and plasma cells, but was free of malignant cells (Figure 3A and B). From this point of view, we considered a possible diagnosis of

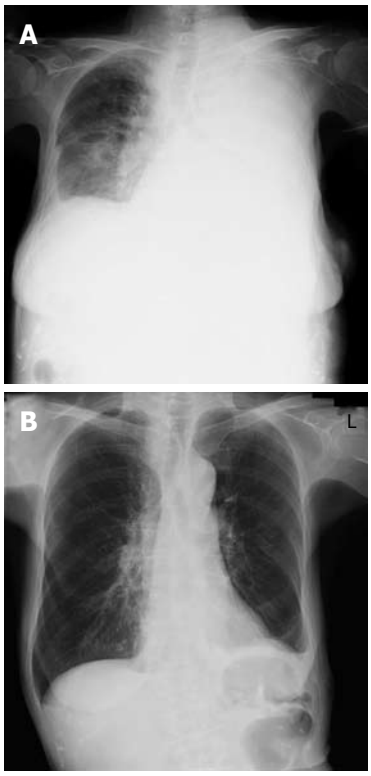

Figure 4 Chest X-ray showing massive pleural effusion of the left side before treatment (A), and full correction following steroid pulse therapy (B).

IPT, but the radiological findings so strongly indicated malignancy that we planned splenectomy for diagnostic confirmation. However, due to the patient's severe shortness of breath, caused by massive pleural effusion, a splenectomy was considered unsafe at that time (Figure 4A). Subsequent cytologic analysis showed that the pleural effusion was transudative and negative for malignancy. Hence, a percutaneous needle biopsy of the splenic lesion was performed as an alternative examination under ultrasonic guidance in the supine position *via* an intracostal approach. Microscopic examination of the spleen specimen revealed infiltration by lymphocytes and plasma cells, but no evidence of malignant cells (Figure 3C), as found in the liver specimen. Immunohistochemical examination of the liver specimen showed that the lesion was positive for CD68, α-smooth muscle actin (SMA) and IgG, but was negative for IgG4, anaplastic lymphoma kinase (ALK), and Epstein-Barr virus (EBV) encoded RNA (EBER) (Figure 3D-I). We were thus able to rule out an IgG4-related lesion, inflammatory myofibroblastic tumor (IMT), and an EBV-associated ITP-like follicular dendritic cell (FDC) tumor.

Finally, based on the results of our microscopic examination of both the liver and the spleen specimens, we diagnosed the pathological status of this patient as an IPT. However, despite an extensive clinical search for the potential cause of this IPT, mainly for infectious diseases including tuberculosis, its etiology could not be identified. As IgG levels were elevated in this patient and the ANA test was positive, we speculated that an autoimmune process could be possible. The patient did not respond for 19 d to intravenous antibiotics, including ampicillin hydrate (ABPC), sultamicillin tosilate hydrate (SBTPC), ciprofloxacin hydrochloride (CPFX), and meropenem hydrate (MEPN) and no underlying disease that could be a possible cause of IPT was detected. Because of the lack of any evidence for infection and her deteriorating clinical condition, we commenced steroid pulse therapy (three days of intravenous methylprednisolone; 1000 mg). C-reactive protein levels decreased immediately from 9.25 mg/dL to 0.93 mg/dL and there was no subsequent flare-up of inflammation during the gradual tapering of the steroid dose. The pleural effusion also decreased gradually (Figure 4B) accompanied by the restoration of normal breathing. Follow-up CT imaging after one month showed a nearly complete resolution of the hepatic and splenic lesions, except for the soft density layer remaining around the spleen (Figure 5). The occlusion of the portal vein remained unresolved however, and was subsequently found to be due to a thrombus which may have resulted from the severe inflammation. At 15 mo after the initial steroid pulse therapy, the patient was in good health and free of recurrence with continuing treatment of 5 mg of oral prednisone.

Figure 5 Follow-up computed tomography showing nearly complete resolution of the hepatic and splenic lesions other than the remaining soft density layer around the spleen (arrow).

DISCUSSION

The sites of predilection for IPT are the lungs and eyes followed by the liver, but involvement of the spleen is rare. The coexistence of IPT of the liver and spleen is therefore unusual.

It is very difficult for a physician to diagnose IPT because of the absence of specific symptoms, hematological abnormalities or anomalous radiological findings. Patients with IPT can present with fever, abdominal pain, abdominal discomfort, or leukocytosis, but these symptoms are not specific to IPT. Radiological results for IPT are also inconsistent, because fatty depositions, tissue inflammation and necrosis, fibrosis and bleeding can affect the imaging[11]. Moreover, the degree and distribution of proliferating capillaries influences the staining patterns

obtained by CT or MRI examination. A further problem is that IPT imaging findings are often similar to those of malignant tumors. For example, delayed enhancement on contrast CT, especially at the periphery of the lesions, is considered to be characteristic of IPT[12,13], but cholangiocellular carcinoma or metastatic tumor shows the same enhancement pattern. IPT sometimes shows an early enhancement pattern followed by a washout in the delayed phase on contrast CT[14], but this is a typical finding also for hepatocellular carcinoma. FDG uptake can be semiquantitatively measured using an SUV, which is generally higher in malignant tumors than in inflammatory disease. However, this method of differentiation is of limited value for IPT as the FDG uptake varies with the proportion of fibrosis and inflammatory cell infiltration. In fact, there have been some FDG-PET studies of IPT that have reported a high SUV[15,16] that is comparable to malignancy.

Due to the difficulty in diagnosing IPT through an assessment of clinical symptoms, blood examinations or radiological imaging, a definitive diagnosis often requires histopathological confirmation. Percutaneous needle liver biopsies are usually performed to diagnose IPT of the liver but may sometimes lead to a misdiagnosis[5,6]. Despite the absence of malignant findings by histological examination, there are also some IPT cases in which the possible existence of malignancy cannot be completely excluded even though various clinical factors are considered in tandem. Exploratory laparotomies or hepatectomies are often then performed[17] for confirmation. In cases of splenic IPT, almost all final diagnoses require surgery since a splenectomy is not only diagnostic but can also be curative. Recently, a less invasive laparoscopic splenectomy has been introduced in clinical settings[18], making it easier to perform. On the other hand, only one case of splenic IPT diagnosed by percutaneous spleen biopsy has been reported to date[7].

Only three cases of the coexistence of IPT of the liver and spleen have been previously reported[8-10]. Each was at first clinically or radiologically believed to be another disease such as lymphoma or metastatic cancer, but was eventually histologically diagnosed as IPT. One case was diagnosed by percutaneous liver biopsy without further radical study including spleen biopsy, as the patient was in the remission stage at the time of the biopsy. In the other two cases, a splenectomy was performed to enable the final diagnosis. In our current case, CT and FDG-PET findings strongly suggested the existence of a malignant tumor of the liver and the spleen with peritoneal dissemination, even though the histological appearance of the liver biopsy sample showed inflammatory cell infiltration and fibrosis indicating IPT. We therefore planned to conduct a splenectomy to confirm the diagnosis, but this became too risky as a massive pleural effusion had reduced the patient's respiratory function and her clinical status was worsening rapidly at that time. We therefore decided to conduct a spleen biopsy after obtaining informed consent from the patient. The results from the earlier liver biopsy were confirmed by the matching evidence obtained from the spleen sample.

IPT is clinically classified into several types according to their etiology, and the treatment options vary. Infections and autoimmune disorders are representative of originally-defined IPT, which is a benign and a reactive lesion. IPT of infectious origin can be caused by *Mycobacterium tuberculosis*[19], non-tuberculous mycobacteria[20], *Escherichia coli*[21], gram-positive cocci[5] and *Klebsiella pneumonia*[22]. Detection of the infecting organism by bacterial cultivation can confirm the existence of such instances of IPT, and the diagnosis can be further validated by the patient's response to administered antibacterial agents.

In our current patient, IMT[23], an EBV associated IPT-like FDC tumor[24], and IgG4-related diseases[25] were all excluded by immunohistochemical staining. In addition, although we obtained blood cultures and analyzed tissue from the lesions, no microorganisms were detected. Furthermore, the patient did not respond to a serial course of treatment with antibiotics, thus excluding the possibility of active infection. There are some reports of IgG4-related IPT[25] indicating the possibility that an autoimmune response contributes to the disease pathogenesis. Although the etiology of IPT remains unclear, based on the deteriorating clinical condition of our patient, we undertook steroid pulse therapy which proved to be very effective. The indication for steroid therapy has not been firmly established, but seems to be appropriate for IPT considering that this disorder was originally attributed to an inflammatory or a reactive process.

In conclusion, we report a rare case of the coexistence of hepatic and splenic IPT which was diagnosed by percutaneous liver and spleen biopsies. We conclude that a percutaneous biopsy can be an effective choice for suspected cases of IPT, even when a laparotomy or splenectomy is clinically difficult to perform.

Abstract

Gastrointestinal stromal tumors (GISTs) are rare gastrointestinal malignancies. They are rarely seen near the urinary tract. In a literature review, only one case of GIST presenting as a left adrenal tumor was reported. We report two documented cases of gastric GISTs mimicking left adrenal tumors which were successfully treated with pure laparoscopic adrenalectomy and wedge resection of the stomach by excising the tumor from the stomach with serial firing of endoscopic gastrointestinal staplers. The surgical margins were clear, and the patients recovered smoothly. No adjuvant therapy with imatinib was prescribed. During the surveillance for 9 mo and 44 mo respectively, no tumor recurrence and metastasis were documented. Laparoscopic tumor excision, when adhering to the principles of surgical oncology, seems feasible and the prognosis is favorable for such tumors.

Key words: Gastrointestinal stromal tumor; Stomach; Laparoscopy

INTRODUCTION

Gastrointestinal stromal tumors (GISTs) are rare neoplasms that account for less than 1% of all GI malignancies. The stomach is the most common site of origin for GISTs, accounting for 50%-60% of these tumors[1,2]. Of these, about 12% arise from the greater curvature[1]. It may mimic an adrenal tumor if no irregular gastric contour is noted. When the tumor is detected at this location incidentally, a patient without gastrointestinal (GI) symptoms may be referred to a urologist and adrenalectomy may be conducted. However, many urologists may be unfamiliar with this disease entity and may encounter difficulty in managing these tumors intra-operatively. Herein, we reported two such cases and detail our management.

CASE REPORT

Case 1

A 56-year-old female presented with microscopic hematuria found during a health examination. She did not

Figure 1 Computed tomography scan showing a soft tissue mass above the upper pole of the left kidney (arrow).

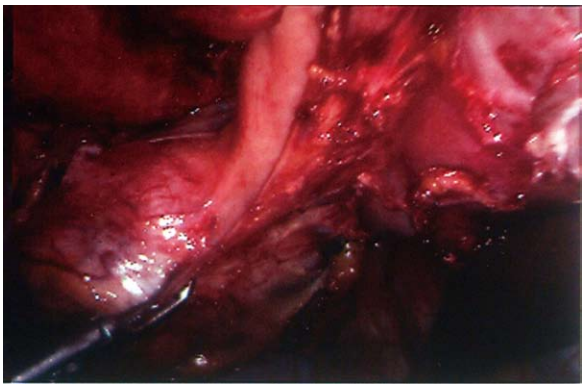

Figure 2 Intra-operative picture of a pedunculated tumor (T) originating from the greater curvature of the stomach (S).

suffer from flank pain, dysuria, epigastralgia, melena or hematemesis. Her medical history was unremarkable. Physical examination revealed no icteric sclera, flank knocking tenderness or palpable abdominal mass. Urine cytology disclosed a negative result for malignancy. Renal ultrasonography showed a left suprarenal mass. Abdominal computed tomography was performed, which showed a soft-tissue density mass 4.5 cm in diameter above the upper pole of the left kidney (Figure 1). This tumor was not enhanced with intravenous contrast and did not have calcification. Laboratory screening did not display anemia, or occult blood in stool. Endocrine examination showed normal adrenal hormonal profiles.

Case 2

A 76-year-old man presented with dyspepsia. A firm tumor in the left epigastrium could be palpated physically. Abdominal ultrasonography showed a large tumor located at the left retroperitoneum. He had a history of peptic ulcer, but no definite tumor had been documented in a panendoscopic examination of the upper gastrointestinal tract. Abdominal computed tomography showed a soft-tissue density mass 8 cm in diameter above the upper pole of the left kidney. Neither hepatic lesions nor lymphadenopathy was found. A bone scan and laboratory screening, including all endocrine survey, were all unremarkable.

Surgical technique: The surgical procedures for these two patients were quite similar and described together as follows. With a preoperative diagnosis of a non-functional adrenal tumor (case 1), and an adrenal mass ruling out adrenal carcinoma (case 2), transperitoneal laparoscopic tumor excision was planned. During surgery the tumors were noted to be undistinguishable from the left adrenal gland; hence no effort was made to dissect the tumor from the adrenal gland. Instead, the tumor along with the whole left adrenal gland was excised *en bloc,* in order to adhere to the principles of surgical oncology. After the main left adrenal vein, several small adrenal arteries and veins, and other surrounding connective tissues were divided, a pedunculated tumor strongly attached to the greater curvature of the stomach was noted (Figure 2). *En bloc* tumor excision was accomplished with wedge resection of the attached stomach by firing 2-3 endoscopic gastrointestinal anastomosis staplers (ENDO-GIA, Tyco HealthCare, Norwalk, CT, United States) consecutively to divide the gastric attachment of the tumor from the normal part of the stomach.

Pathology and follow-up: The pathological examination showed a 4 cm yellowish and elastic tumor beneath the smooth gastric mucosa in patient 1, and a 7 cm yellowish-gray and soft tumor in patient 2. The mitotic counts in both cases were less than 5 mitoses per 50 high power fields. Tumor cells were immunohistochemically positive for c-kit (CD117). Hence the diagnosis of GIST was confirmed for both tumors. The surgical margins in each specimen were free of tumor in either direction. Postoperatively, there was no gastric leakage; the nasogastric tube drainage was removed 2 d later and the patients resumed intake of a soft diet in 2-3 d. No adjuvant therapy with imatinib was prescribed for either patient. Serial follow-up computed tomography during surveillance revealed no local tumor recurrence or metastasis 9 (case 1) and 44 (case 2) mo after their respective operations.

DISCUSSION

The peak age of patients diagnosed with GISTs is around 60 years in most series. In a large series (1765 cases) of gastric GISTs, 54.4% of patients presented with symptoms related to GI bleeding such as anemia, melena or hematemesis[1]. Others had upper abdominal pain (16.8%), while acute abdomen resulted from tumor rupture was very rare (1.7%)[1]. GISTs are often discovered as incidental findings during radiological imaging for unrelated conditions, or as unexpected findings in surgical resections[1].

In the medical literature only one patient with GIST presenting as an adrenal tumor was reported before[3]. In both our patients, it was difficult to differentiate these two GISTs from usual cases of nonfunctional adrenal tumors since there were no clues from their symptoms

(no GI bleeding-related symptoms and normal endoscopy result) or image studies (no irregular intra-luminal contour of the stomach). Mild adhesion of the mass to the stomach might be a clue, but this phenomenon can be frequently observed if the adrenal tumor is big enough and/or the stomach is distended during the imaging studies. However, GISTs were suspected during the operation due to the severe adhesion of the mass to the greater curvature of the stomach wall, and surgery was adapted to achieve *en bloc* resection according to the principles of surgical oncology.

Surgical resection is the mainstay of treatment for localized gastric GISTs. It should be performed very carefully to avoid tumor rupture, which was associated with a high risk of intra-abdominal dissemination, subsequent recurrence and short overall survival[4]. In addition, complete resection of tumors is mandatory. The survival duration was similar between patients with tumor rupture and patients with incomplete surgical resections[4]. Unlike adenocarcinoma of the stomach, metastasis of GISTs to regional lymph nodes is very rare[1,5]. Routine lymphadenectomy is, hence, not indicated[6]. Several scholars had reported successful laparoscopic resection of gastric GISTs[7-9]. However, a large GIST of the stomach sometimes obscured the laparoscopic field. Yano *et al*[10] reported that two patients with large GISTs were successfully treated with hand-assisted laparoscopic surgery. They believed a hand-assisted procedure may offer adequate traction for the resection with sufficient surgical margins. In our patients, although the tumors were also quite large (4 cm and 7 cm in diameter) they had been completely dissected from all the other surrounding tissues except their final attachments from the greater curvature of the stomach, thus there was adequate space for manipulation and they were readily removed from the stomach with laparoscopic GIA staplers. Transperitoneally pure laparoscopic resection was hence feasible and successful in these two cases.

In conclusion, evaluation of patients with left adrenal tumors should include not only endocrine examinations but also GI workups if patients present with concurrent GI symptoms, or with hormonally inactive asymptomatic left adrenal tumors where there is no obvious demarcation between the tumor and the stomach wall in preoperative images[11]. If a GIST is suspected intra-operatively, we need to excise the tumors carefully with adequate safety margin and without causing tumor rupture. Postoperative surveillance is recommended especially in high risk patients (tumor size > 5 cm, mitoses > 5/50 high power fields).

World J Gastroenterol 2012 January 7; 18(1): I-VI
ISSN 1007-9327 (print) ISSN 2219-2840 (online)

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1361 experts in gastroenterology and hepatology from 64 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systemically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensuses and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing
Statistical review is performed after peer review. We invite an expert in Biomedical Statistics from to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Ridit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc*. The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

Conflict-of-interest statement
In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent
Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights
When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www.clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://www.wjgnet.com/1007-9327office. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no less than 256 words) and structured abstracts (no less than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no less than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections.

AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/…"; MATERIALS AND METHODS (no less than 140 words); RESULTS (no less than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 *vs* 3.61 ± 1.67, $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: …*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of *P* values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of *P* values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that...".

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed and http://www.crossref.org/SimpleTextQuery/, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in boldfaced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in boldfaced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*

Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*

Biology: *H. pylori*, *E coli*, *etc.*

Guidelines: http://www.wjgnet.com/1007-9327/g_info_20100312232134.htm

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be re-submitted online (http://www.wjgnet.com/1007-9327office/). The author should send the copyright transfer letter, responses to the reviewers, English language Grade B certificate (for non-native speakers of English) and final manuscript checklist to wjg@wjgnet.com.

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

WJG is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1300 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.

Abstract

Vertical transmission has become the most common mode of transmission of hepatitis C virus (HCV) in children. The rate of perinatal transmission from an HCV-infected mother to her child ranges from 2% to 5% and the prevalence of HCV in children in developed countries ranges between 0.1% and 0.4%. Spontaneous viral clearance seems to be dependent on the genotype and has been reported between 2.4%-25%. For chronically infected patients, treatment with recombinant polyethylene glycol (PEG)-interferon α-2b and daily ribavirin has now been approved as standard treatment for children 2-17 years of age. In five large prospective studies, a total of 318 children and adolescents aged 3-17 years were treated either with subcutaneous PEG-interferon α-2b at a dose of 1-1.5 μg/kg or 60 μg/m² once a week in combination with oral ribavirin (15 mg/kg per day) or PEG-interferon α-2a with ribavirin. Subjects with genotype 1 and 4 received the medication for 48 wk and individuals with genotype 2 and 3 mainly for 24 wk. Overall sustained viral response (SVR) was achieved in 193/318 (60.7%) of treated patients. Stratified for genotype; 120/234 (51%) with genotype 1, 68/73 (93%) with genotype 2/3, and 6/11 (55%) with genotype 4 showed SVR. Relapse rate was between 7.7% and 17%. Overall, treatment was well tolerated; however, notable side effects were present in approximately 20%. According to recent experiences in the treatment of chronic hepatitis C in children and adolescents, a combination of PEG-interferon α with ribavirin has been found to be well tolerated and highly efficacious, particularly in individuals with genotype 2/3. Thus, this treatment can be recommended as standard of care until more effective treatment options will become available for genotype 1 patients.

INTRODUCTION

Combination therapy of polyethylene glycol (PEG)-interferon α-2a or α-2b with ribavirin is standard of care for adults with chronic hepatitis C. Clear benefits in terms of sustained viral response (SVR) and side effect profile have been documented with PEG-interferon α compared with recombinant interferon α with and without ribavirin. An additional advantage of the pegylated form of interferon is the extended serum half-life, which allows a once-weekly administration regimen. Until recently, only recombinant interferon α-2b in combination with ribavirin had been approved by the Food and Drug Administration

(FDA) and European Medicines Agency (EMA) for use in children and adolescents. Since December 2008 and September 2009, respectively, the FDA and EMA approved PEG-interferon α-2b in combination with ribavirin in the United States and Europe for children aged 3 years and older[1]. Although most experts believe treatment is beneficial, due to several factors associated with treating young patients with chronic hepatitis C, this topic remains controversial[2-4]. However, there is no doubt that chronic hepatitis C remains an epidemiologically important health care issue in children and adolescents. Associated costs in the United States are estimated between $17 and $40 million annually[5]. Effective treatment of chronic hepatitis C virus (HCV) at an early age would help to prevent the long-term sequelae of chronic infection, improve the prognosis of patients, and reduce health care expenditure.

The prevalence of HCV in children in developed countries ranges between 0.1% and 0.4% but may even exceed 10% in some regions of Saudi Arabia and Africa[6-8]. The rate of perinatal HCV transmission from an infected mother to her child ranges from 2% to 5%. Clinically most relevant are genotypes 1, 2 and 3; considerably less spread is genotype 4[2]. It is estimated that there are 1 million individuals aged less than 18 years infected with chronic hepatitis C worldwide[9].

Since the early 1990s, transmission of HCV infection has occurred predominantly by parenteral transfusion of blood products or by non-use of disposable syringes. However, transfusion-associated hepatitis C has now become extremely rare in countries with adequate hygienic facilities. Subjects who were particularly at risk such as premature infants, hemophiliacs, patients with thalassemia, and children with malignant diseases or organ transplantations have now reached adulthood and vertical transmission from HCV-infected mothers to their offspring has become the most common cause of chronic hepatitis C in children. Importantly, in the case of vertical infection, the chronicity rate is very high[10].

Children chronically infected with HCV may be at risk for social disintegration and impaired quality of life. A possible psychological burden may be present and some physical impairment has been described. To date, only two rather small studies have been published reporting significantly lower physical and psychosocial scores and worse cognitive functioning compared with non-infected controls[11,12].

NATURAL COURSE

Spontaneous viral clearance in vertically infected children seems to be dependent on genotype and was found to range from 2.4%-25%[13,14]. It may be higher in parenterally infected individuals and was reported to reach 35%-45% by adolescence[15,16]. Children infected with genotype 3 have a higher spontaneous clearance rate than those infected with genotype 1. Beyond the age of 4 years, spontaneous viral clearance seems to become rather unlikely[13]. Patients who do not clear the virus within the first years of life will develop chronic hepatitis C. Overall, the cumulative probability of progression to chronicity is approximately 80%[17,18]. Most children are clinically asymptomatic or show only mild unspecific symptoms. In roughly 10% of patients, hepatomegaly may be present[17]. During the chronic course, alanine aminotransferase (ALT) levels may be normal or intermittently elevated. Only few patients show persistent markedly elevated ALT levels. Inflammatory activity in liver tissue is usually mild and the risk of severe complications is low. However, despite the favourable prognosis during the first and second decade of life, approximately 4%-6% of children will develop evidence of advanced liver fibrosis or cirrhosis[19,20]. A recently published study in pediatric patients with chronic hepatitis C cured of malignancy reported liver cirrhosis in 5% after three decades of observation[21]. Progression of fibrosis depends on age and additional risk factors such as obesity and alcohol consumption. Thus, progression usually starts beyond the second life decade and there is evidence that it seems to proceed more rapidly in patients with genotype 3[22]. Large liver transplantation units have reported on children who needed liver transplantation due to progressive HCV infection[23].

TREATMENT OPTIONS

Many years ago, treatment started in adults with the use of interferons, yielding SVR rates in the 10%-15% range. According to the use of different treatment regimens and small numbers of treated children, it was difficult to compare the response rates in children to those in adults. Overall, SVR seemed to be better in children. Nineteen studies using recombinant α-interferon were published between 1992 and 2003[24]. A meta-analysis of trials with interferon-α monotherapy revealed a wide range (0%-76%, mean 27%) of SVR. Subjects infected with genotype 2 and 3 clearly responded better than patients harbouring genotype 1. Based on an increasing number of randomized controlled trials in adults, ribavirin was added to interferon-α in treatment trials for children. Between 2000 and 2005, six studies were published all demonstrating an SVR from 27% to 64%[25]. The stratification according to genotypes showed a very good response (> 80%) in patients with genotype 2 and 3 and an SVR of approximately 36%-53% in those with genotype 1. Results of an extensive trial in children published by Gonzalez-Peralta led to the approval of recombinant interferon α-2b in combination with ribavirin[26].

However, when PEG-interferon in combination with ribavirin became the standard of care for adults with chronic hepatitis C, trials in children promptly started. Some advantages were present such as a reduced injection frequency to once per week, better SVR, and better interferon tolerance. Interestingly, the sole controlled randomized trial, comparing a pegylated interferon α (PEG-interferon α-2a) with and without additional ribavirin, was only published in 2011. It clearly demonstrated that in the pediatric age group, the addition of ribavirin was necessary to obtain significantly better treatment re-

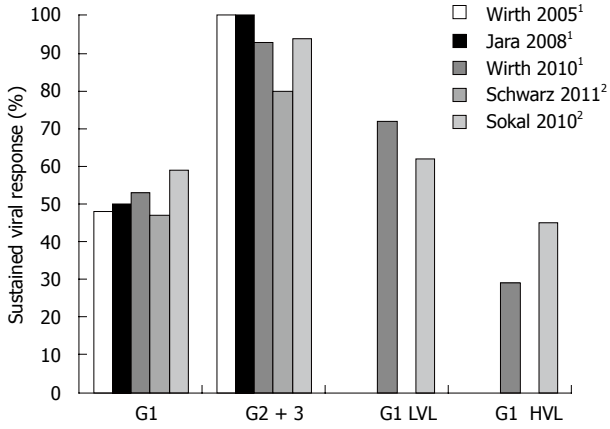

Figure 2 Sustained viral response in five large prospective trials with polyethylene glycol-interferon α-2b[1]/α-2a[2] and ribavirin stratified for genotype and viral load[27,28,30-32]. G: Genotype; HVL: High viral load, > 600 000 U/mL, (Wirth *et al*[32]), > 500 000 U/mL (Sokal *et al*[30]); LVL: Low viral load, < 600 000 U/mL (Wirth *et al*[32]), < 500 000 U/mL (Sokal *et al*[30]).

sults[27]. Specifically, in genotype 1 patients, SVR rate was 17% with PEG-interferon monotherapy compared with 47% in individuals with combination treatment. The difference was also striking in subjects infected with genotype 2 and 3 (36% *vs* 80%).

Up to now, results of seven trials using PEG-interferon α in combination with ribavirin have been reported[27-32]. SVR rates in patients with genotype 1 from 5 trials with more than 30 patients ranged from 44% to 59%. Achieving SVR in children with genotype 2 and 3 was very successful and yielded rates of more than 90%. The relapse rate was between 7.7% and 17%. Four trials used PEG-interferon α-2b and two used PEG-interferon α-2a in combination with ribavirin. An additional report presented the retrospective data in 33 treated Japanese children and young adults[33]. SVR rate in these patients was approximately 82%. Unfortunately, no information regarding genotypes was provided. Table 1 and Figure 1 summarize the characteristics of the five prospective studies. Peg-interferon α-2b and ribavirin were approved for patients aged 3 to 17 years of age by the FDA in December 2008 and the EMA in September 2009.

Baseline viral load

Two studies stratified the results in genotype 1 patients according to the viral load before treatment. In the first study, the cut-off level was 600 000 IU/mL: 32% of children with genotype 1 and high viral load (> 600 000 IU/mL) and 73% with low viral load (< 600 000 IU/mL) achieved SVR[32]. In the second trial, the cut-off value was 500 000 IU/mL: 45% of children with genotype 1 and > 500 000 IU/mL and 62% with < 500 000 IU/mL achieved SVR[30].

Figure 2 summarizes the SVR in relevant pediatric trials using PEG-interferon in combination with ribavirin.

Table 2 Most frequent adverse events during polyethylene glycol-interferon treatment in combination with ribavirin and its appraisal of clinical significance

Interferon α-treatment:
Leukopenia, thrombocytopenia: Frequent, not really significant; if necessary dose reduction
Flu-like symptoms: In all treated patients, not significant
Alopecia: Not significant
Autoimmune thyroiditis: At least 15 %, significant, mostly reversible
Acute psychosis, depression: Very seldom before puberty (< 1 %), rare in adolescents, significant in cases with manifestation; should be under investigation in future trials
Growth delay: Clinically not significant, catch-up growth, but under investigation with relative high priority
Anorexia, weight loss: Mostly not significant with exceptions, normalisation after therapy stop
Ribavirin:
Anemia: Mostly clinically not significant with exceptions, reversible

Most side effects' intensity is decreasing after some weeks of treatment.

Baseline aminotransferases

It is remarkable that the level of aminotransferases or histological findings by liver biopsy do not significantly correlate with SVR. However, interestingly, there was a trend towards a slightly better SVR in patients with normal aminotransferases.

Mode of infection

There is no significant correlation between SVR and the mode of infection. Nevertheless, it seems that individuals with parenteral infection may have a slightly higher probability to obtain SVR. However, the overall response rate in vertically infected subjects was 55% and in genotype 1 patients 46%, which is comparable to the SVR in adults who are mainly parenterally infected (Table 1).

Standard of care

According to approval, in principle, treatment with interferon α-2b and ribavirin administering injections thrice per week can be performed. However, the majority of experts will prefer once weekly dosing using PEG-interferon. To date in America and Europe, only PEG-interferon α-2b (60 μg/m² per week) in combination with ribavirin (15 mg/kg per day) is approved by the FDA and EMA[1]. Patients with genotypes 1 and 4 should be treated for 48 wk, with treatment discontinued at 4-6 mo if there has been no viral response. Patients with genotypes 2 and 3 should be treated for 24 wk irrespective of pre-treatment viral load. In routine clinical practice, there is no need to perform liver biopsy before initiating treatment. In addition, pre-treatment levels of aminotransferases and mode of infection are not predictive for SVR. A five-year follow-up study of children with SVR treated with interferon α and ribavirin showed permanent viral elimination in 98% (Kelly D, personal communication).

Re-treatment

Response rates in patients retreated with a standard of care protocol are dependent on the primary treatment regimen. Individuals with previous interferon α monotherapy or recombinant α-interferon in combination with ribavirin may achieve a higher response rate. There are no studies specifically addressing re-treatment except for the trial by Gerner *et al*[34], which has been performed with a natural interferon α in combination with ribavirin. Previously published reports have only included small numbers of children with failed response, demonstrating a re-treatment response rate of 40%-50% in those with previous interferon α monotherapy. Gerner *et al*[34] reported SVR in only 2/18 patients. Thus, re-treatment, particularly in individuals who have been primarily treated with PEG-interferon and ribavirin, remains prognostically difficult and cannot be recommended until new combination treatment options including directly acting antivirals such as protease inhibitors become available.

ADVERSE EVENTS

The majority of treated children and adolescents will tolerate PEG-interferon and ribavirin well. Nevertheless, almost all patients will experience at least one side effect. The clinical significance of adverse events is summarized in Table 2. Most adverse events are mild to moderate, such as flu-like symptoms including fever, anorexia, fatigue, dry skin and moderate hair loss. In some patients, dose reduction of PEG-interferon may be necessary due to decreased white blood cell counts. Severe anemia is very rare; hence, the need for dose reduction of ribavirin is extremely infrequent. The rates of discontinuation of treatment due to adverse events were low in all trials published. Severe psychiatric side effects were rare in prepubertal individuals, but may be of significance in affected individuals. Appearance of thyroid autoantibodies and thyroid dysfunction during long-term treatment (> 24 wk) has to be considered and carefully monitored. Up to 20% of treated patients, particularly with genotype 1, may have abnormal thyroid stimulating hormone levels or other signs of thyroid dysfunction[31,35]. Another notable side effect is transient growth impairment. Inhibited growth can be observed in 50%-70% with decrease of growth velocity below the 3rd percentile. Shortly after the end of treatment, catch-up growth usually starts with an increased growth velocity followed by achievement of previous growth velocity levels, which can be observed during the follow-up period. Nevertheless, if possible, treatment during pubertal growth spurt should be avoided[36]. In addition, weight loss is very common during the treatment phase; however, most patients experience compensatory weight gain after treatment ends[32]. Regarding quality of life, and behavioral, emotional and cognitive outcomes during and after treatment, no significant impairment has been detected in the PEDS-C trial[37]. More follow-up studies are in progress to evaluate long-term sequelae.

NEW DEVELOPMENTS

There is no doubt that treatment response in patients with genotype 1 is not entirely satisfactory and improved treat-

Table 3 Indication for hepatitis C virus treatment in children-pros and cons

In favour of treatment	Deferral might be considered
High response rate, sustained viral response means cure of the disease	Before 3-4 years of age because of possible spontaneous viral elimination
Prevention of disease progression and social burden	Psychiatric disorder
Better tolerability and less side effects in younger patients (particularly before puberty)	Low response rate in subjects with genotype 1 and high viral load
More favourable factors for response in children (e.g., low viral load)	Pubertal growth spurt
Parents facilitate compliance	More effective treatments in future in genotype 1 non-responders

ment regimens are desirable. A number of directly acting antiviral agents, designed to target viral encoded proteins essential to the HCV life cycle, are currently under development. Phase Ⅲ trials in adults have been completed for two protease inhibitors (telaprevir and boceprevir) and have shown a significantly increased viral elimination rate in combination with PEG-interferon and ribavirin[38-40]. Brand new data indicate that in a considerable number of patients with rapid response, exposure to PEG-interferon and ribavirin may be shortened and response-guided therapy will become the treatment of choice[41]. Approval of telaprevir and boceprevir has been sanctioned by the FDA and EMA in 2011, and pediatric trials will follow in the near future. In adults, genotype 1 non-responders have also demonstrated SVR rates ranging between 59% and 66%, depending on the duration of boceprevir treatment, compared to 20% with standard of care[42]. Given that efficacy data could be extrapolated from adults to children, an approved triple therapy regimen should be expected for non-responders. Nevertheless, they should definitely be included in future pediatric trials[36].

CONCLUSION

In children and adolescents, PEG-interferon treatment in combination with ribavirin for 48 wk produces a sustained viral response rate in approximately 50% of adequately treated individuals. Thus, this option can be offered to all patients irrespective of the level of aminotransferases or mode of infection. There is evidence that subjects with low viral load may respond better than patients with high viral load. In patients infected with genotype 2 or 3, a 90% or even better SVR rate can be achieved. Thus, treatment for 24 wk should be administered in all patients with genotype 2 and 3. According to the approval of the drugs, treatment start is possible beyond three years of age. However, because spontaneous viral elimination may occur within the first 4-5 years of life in vertically infected individuals, watchful waiting for up to five years of age is a justified alternative to an early treatment start. Additionally, different individual and family variables may influence the appropriate time to initiate therapy. An experienced pediatric gastroenterologist should supervise the management of treating these patients. Mid-childhood age before pubertal growth spurt is preferable. Table 3 summarizes pros and cons to indicate or possibly to defer treatment. Adverse events are usually well tolerated, but severe side effects may occur in a small number of patients making dose adjustment necessary. Overall, the encouraging results, particularly in patients with relatively low viral load and/or favourable genotypes and in line with an appropriate consideration of early stopping rules, endorse application of treatment in eligible patients. Re-treatment in non-responding genotype 1 patients should be deferred until a combination of standard care with direct acting antivirals has become available.

Abstract

Considering epidemiological, genetic and immunological data, we can conclude that the inflammatory bowel diseases are heterogeneous disorders of multifactorial etiology in which hereditability and environment interact to produce the disease. It is probable that patients have a genetic predisposition for the development of the disease coupled with disturbances in immunoregulation. Several genes have been so far related to the diagnosis of Crohn's disease. Those genes are related to innate pattern recognition receptors, to epithelial barrier homeostasis and maintenance of epithelial barrier integrity, to autophagy and to lymphocyte differentiation. So far, the most strong and replicated associations with Crohn's disease have been done with *NOD2*, *IL23R* and *ATG16L1* genes. Many genes have so far been implicated in prognosis of Crohn's disease and many attempts have been made to classify genetic profiles in Crohn's disease. *CARD15* seems not only a susceptibility gene, but also a disease-modifier gene for Crohn's disease. Enriching our understanding on Crohn's disease genetics is important but when combining genetic data with functional data the outcome could be of major importance to clinicians.

Key words: Crohn's; Genetics; Polymorphism; Diagnosis; Prognosis; Genome wide scan; Genetic consortium

EVOLVING ROLE OF GENETICS IN CROHN'S DISEASE

Despite decades of research the etiology of inflammatory bowel diseases (IBD) remains largely unexplained, but considering together epidemiological, genetic and immunological data, we can conclude that IBD are heterogeneous disorders of multifactorial etiology in which hereditability (genetic) and environment (microbial, behavior) interact to produce the immunological background of the disease. It is probable that patients have a genetic predisposition for the development of the disease coupled with disturbances in immunoregulation. The disease can then be triggered by any of a number of different unknown environmental factors and sustained by an abnormal immune response to these factors. Rather, the intensive interaction between intestinal epithelial cells and immune competent cells is critical to maintain and perpetuate the chronic inflammatory process characteristic

for IBD[1].

Early epidemiologic evidence for the role of genetic factors in the pathogenesis of Crohn's disease (CD) came from studies demonstrating higher rates of CD among individuals of Caucasian and Jewish ethnicity, familial aggregation of CD and higher concordance rates of both twins developing CD in monozygotic compared with dizygotic twins. The search for specific CD susceptibility genes, however, has been difficult due to complex genetics, including factors such as the lack of simple Mendelian inheritance patterns, involvement of several genes, and the influence of environmental factors and intestinal microflora on disease development. More than 30 distinct genomic loci encode genes involved in a number of homeostatic mechanisms and have been suggested to be involved in CD etiopathogenesis and prognosis[2].

Until very recently, two main approaches could be undertaken to identify genes in complex diseases: the positional cloning approach, based on linkage analysis, and the candidate gene approach, based on association studies. Linkage analysis studies the co-segregation of the disease with a marker within families. The candidate gene approach uses case-control cohorts or trios of affected offspring with both parents. Here, a specific gene with known or potential interest for the disease is studied. The allelic frequencies (in the case of case-control study) or the transmission of a single nucleotide polymorphism (SNP) towards affected offspring (in the case of trios) are analyzed, and differences between patients and controls, or distortion of transmission towards affected children, will point towards implication of the gene in the pathogenesis of the disease under investigation.

Despite the large numbers of genome-wide association studies (GWAS) established to date, most diseases have only managed to explain some additional percentage of the hereditability estimates. In an attempt to explain some of this missing hereditability, researchers have adopted several complementary strategies. Larger cohorts of cases are being collected, through either further patient recruitment or collaborations. The meta-analysis data generated to date has demonstrated how increasing the cohort sample size generates additional statistical power to detect smaller and smaller odds ratios[3]. Advances in technology and particularly bioinformatics have now made it possible to perform GWAS using common copy number variation probes. Many groups are looking to high-throughput sequencing technology, with the aim of sequencing candidate gene regions identified by GWAS, to hopefully identify either the causal or rare variants[4,5]. Several GWAS have been published in the last decade and have identified many genes associated with Crohn's disease (Table 1). Among these there are recognition-related genes such as *NOD1* and *TLRs*, other susceptibility genes including *DLG5*, *OCTN* and *HLA* and the newest susceptibility genes in CD resulting from GWAS: *IL23R* gene, *ATG16L1* gene and *IRGM* gene[6].

Table 1 Genetic polymorphisms related to Crohn's disease

Genes and the diagnosis of Crohn's disease
Genes related to innate pattern recognition receptors
NOD2/CARD15
OCTN
TLR
Genes related to epithelial barrier homeostasis
IBD5
DLG5
Genes related to molecular mimicry and autophagy
ATG16L1
IRGM
LRRK2
Genes related to lymphocyte differentiation
IL23R
STAT3
Genes related to secondary immune response and apoptosis
MHC
HLA
Genes and the prognosis of Crohn's disease
Genes related to age of Crohn's disease onset
TNFRSF6B, CXCL9, IL23R, NOD2 , ATG16L1, CNR1, IL-10, MDR1, DLG5, IRGM
Genes related to Crohn's disease behaviour
Stenotic/structuring behaviour: *NOD2, TLR4, IL-12B, CX3CR1, IL-10, IL-6*
Penetrating/fistulizing behaviour: *NOD2, IRGM, TNF, HLADRB1, CDKAL1*
Inflammatory behaviour: *HLA*
Granulomatous disease: *TLR4/CARD15*
Genes related to Crohn's disease location
Upper gastrointestinal: *NOD2, MIF*
Ileal: *IL-10, CRP, NOD2, ZNF365, STAT3*
Ileocolonic: *ATG16L1, TCF-4 (TCF7L2)*
Colonic: *HLA, TLR4, TLR1, -2, -6*
Genes related to Crohn's disease activity
HSP70-2, NOD2, PAI-1, CNR1
Genes related to surgery
NOD2 , HLA-G
Genes related to dysplasia and cancer
FHIT
Genes related to extraintestinal manifestations
*CARD15, FcRL3, HLADRB*103, HLAB*27 HLA-B*44, HLA-B*35, TNFa-308A, TNF-1031C, STAT3*
Pharmacogenetics in Crohn's disease
CARD15, NAT, TPMT, MDR1, MIF, DLG5, TNF, LTA

ROLE OF GENES IN THE DIAGNOSIS OF CROHN'S DISEASE

Several genes have been related to the diagnosis of Crohn's disease so far. Those genes are related to innate pattern recognition receptors, to epithelial barrier homeostasis and maintenance of epithelial barrier integrity, to autophagy and to lymphocyte differentiation. So far, the strongest and replicated associations with CD have been done with *NOD2*, *IL23R* and *ATG16L1* genes.

Genes related to innate pattern recognition receptors

***NOD2/CARD15* gene:** *NOD2*/Caspase Recruitment Domain Family member 15 (*CARD15*) acts as a pattern recognition receptor (PRR); this locus has been characterized as the IBD1 locus on 16q12-13[7].

Fine mapping of the IBD1 locus identified the underlying gene on chromosome 16 as the *CARD15* (previous *NOD2)* gene. *CARD15* represents homology with the R genes in plants, genes that confer resistance to infection[8]. Thirty nonconservative polymorphisms have been identified within the gene, which are associated with CD, but only three are common (Arg702Trp, Gly908Arg and Leuc1007insC). The three common variants account for approximately 82% of the mutated alleles. CARD15 is associated with CD only and not with UC. CARD15 codes for a protein expressed in monocytes, macrophages, dentritic cells, epithelial cells and Paneth cells. CARD15 is involved in the recognition of bacterial peptidoglycan-derived muramyl dipeptide through the leucine-rich repeat (LRR) region. Of importance, the frameshift mutation 1007fsinsC that leads to a truncated protein lacking the 33 distal amino acids was associated with impaired activation of the transcription factor NF-κB after stimulation.

It has been shown that Paneth cells play an important role in innate host defense via their ability to secrete antimicrobial peptides and proteins. Although NODs are expressed at low levels in absorptive and secretory intestinal epithelial cells, Paneth cells in the small intestine have been recognized as the predominant site of expression of NOD2 in the epithelium. Furthermore, NOD2 mutations have been associated with decreased expression of antimicrobial peptides, the α-defensins, by Paneth cells. In addition, a distinct gene polymorphism resulting in low β-defensin 2-gene copy number has been associated with a predisposition to colonic Crohn's disease. In addition, NOD2 plays important roles in the promotion of antibacterial T-helper-17 (Th-17) cells in the IL-23-IL-1-IL-17 axis.

CARD15 variants are found in 35% to 45% of white CD patients, with the exception of Scandinavian, Irish and Scottish patients[9,10], in whom the prevalence is much lower. Genotype relative risks of 3 (simple mutation) and 10-44 (double mutations) have been reported in European Caucasians[9,10]. However, CARD15 mutation is not frequent or even absent in African-American populations, in Indians, Chinese and Japanese[11-13]. Other CARD related genetic loci that have been associated with CD diagnosis are the CARD4 (NOD1), CARD8 and CARD9 loci[14,15].

Organic cation transporter genes: Organic cation transporters (*OCTNs, 5q31-33*) are membrane transporters for drugs and positively charged endogenous metabolites. The novel OCTN subfamily may also transport carnitine, which is essential for metabolism of lipids and is involved in transport of light chain fatty acids into mitochondria for b-oxidation. The first study reported on two functional mutations in the carnitine/OCTN cluster on 5q31 (the IBD5 locus) that were associated with Crohn's disease. As membrane transporters of organic cations, OCTNs are therefore important in the maintenance of intracellular homeostasis. In humans OCTN1 and OCTN2 map to IBD5 on 5q31. An OCTN3 has recently been described in humans[16].

Toll-like receptor genes: Host response to microbial pathogens includes self-defense mechanisms such as defensins, PRRs, pathogen-associated molecular patterns and toll-like receptors (TLRs). TLRs recognize conserved motifs on pathogens that are not found in higher eukaryotes and initiate an "innate" (rapid and non-specific) immune response[17]. Subsequently, specific receptors recognizing chemo-attractant molecules mobilize phagocytic leukocytes and induce their migration to inflammatory sites. There, leukocytes encounter the invading microorganisms and ingest them through the activation of phagocytic receptors that mediate the uptake process. Innate immune responses are linked to the generation of corresponding adaptive immune responses and studies of genetically engineered or cellularly manipulated animal models have generated a great deal of new information[18].

Leucocyte-epithelial interactions are of special interest as exposure of epithelial TLRs to microbial ligands has been shown to result in transcriptional upregulation of inflammatory mediators whereas ligation of leucocyte TLRs modulate specific antimicrobial responses[19]. It has been shown that Paneth cells play an important role in innate host defense *via* their ability to secrete antimicrobial peptides and proteins. In addition, it has been shown that NOD2 mutations lead to loss of negative regulatory effects on TLR signaling while activation of the CARD domain results in activation of NF-κB[20].

TLRs are the most important receptors of the innate immune system. They are expressed by immune cells and by intestinal epithelial cells in IBD patients. In humans, at least 10 different TLRs are described and each recognizes a specific pathogen-associated molecular pattern. A transmission disequilibrium test on Belgian IBD trios with CD demonstrated preferential transmission of the TLR4 Asp299Gly polymorphism from heterozygous parents to affected children[21]. TLR9 modulates CD susceptibility and there is interaction between other polymorphisms such as NOD2, IL23R and DLG5[22,23].

Genes related to epithelial barrier homeostasis

The gastrointestinal tract uses a system of tolerance and controlled inflammation to limit the response to dietary or bacteria-derived antigens in the gut[24]. When this complex system breaks down, either by a chemical or pathogenic insult in a genetically predisposed individual the resulting immune response may lead to IBD[25]. Genes or loci involved in the maintenance of epithelial barrier integrity and associated with Crohn's disease are the *IBD5* and the Discs Large Homolog 5 (*DLG5*)[26].

The *DLG5* gene is a 180-kb protein containing 1900 amino acids. DLG5 protein harbours a CARD domain, is a further CD susceptibility gene of the CARD family and contributes to CARD-mediated mechanisms of host defense. In fact, the *DLG5* gene associated protein is a member of Membrane Associated Guanylate Kinase family of scaffolding proteins. Scaffolding proteins

organize protein complexes at cellular junctions to integrate the tethering of adhesion molecules, receptors and intracellular signaling enzymes. Of interest is a population variation in DLG5 variants. For example, DLG5 R30Q variant was not confirmed in other European studies[27,28]. Other genes of potential importance in the same panel are the *PTGER4, ITLN1, DMBT1, BPI* and *XBP1* genes[29].

Genes related to molecular mimicry and autophagy

The innate immune system is the first line of defense against infection. Of interest, virulence factors from bacteria and viruses have been identified that manipulate host innate immune signaling pathways through molecular mimicry. These microbial proteins contain signaling domains that bear sequence and structural similarity to their host targets, and thereby potentially sabotage host immunity by hijacking crucial signaling pathways and uncouple receptor activation from effector induction. Several protein families have evolved to function as receptors or sensors of pathogen invasion. There are two types of signaling domains for the above receptors: the TIR domain for the TLRs and the Pyrin domain or CARD for the NOD-like receptors (NLRs) and retinoic acid-inducible gene 1-like receptors or helicases (RLRs or RLHs).

Molecular mimicry has been invoked as one of the mechanisms responsible for the activation of autoreactive cells by microbial peptides that have structural similarities to self peptides but there is also evidence that antigenically unrelated infections or specific inflammatory signals can result in autoaggressiveness and induction of organ-specific autoimmunity including the gut. The extent and severity of this loss of tolerance is still being defined, as it has demonstrated that loss of tolerance in IBD patients is not exclusive for bacterial antigens and occurs also to orally administered soluble proteins[30]. This subversion of innate immune signaling through molecular mimicry is closely related to the phenomenon of autophagy. Autophagy is the tightly orchestrated cellular 'housekeeping' process responsible for the degradation of damaged and dysfunctional cellular organelles and protein aggregates and is well recognized as playing an important role in maintaining cellular homeostasis under physiological and pathophysiological conditions. Regulated degradation and turnover of subcellular components is essential for normal cellular function, growth, and development. The major catabolic pathway responsible for the disposal of obsolete or damaged organelles and protein aggregates is autophagy (i.e., "self-digestion"). During this process organelles and proteins are encircled in a double-membrane vesicle (the autophagosome), delivered to lysosomes, and the substrates for ATP generation that can be recycled to synthesize new proteins, high-energy phosphates, and other cellular components. Autophagy has evolved as a conserved mechanism for cell survival under conditions of starvation and stress. In addition to (macro)autophagy, characterized by the sequestration of organelles and proteins within an autophagosome, there are two additional subtypes of self-digestion, microautophagy which is protrusion of the lysosomal membrane per se around a region of cytoplasm and chaperone-mediated autophagy in which degradation is restricted only to those proteins with a consensus peptide sequence recognized by specific chaperone complexes[31]. Autophagy is now considered to be important for host defense against intracellular microorganisms. The associations of these autophagy-associated genes with Crohn's disease strongly support the hypothesis that abnormal innate immune responses to intracellular pathogens contribute to the pathogenesis of Crohn's disease. In fact, the pathological characteristics of human Crohn's disease represent "granuloma" formation. The mechanisms of granuloma formation remain unclear. Recent studies have demonstrated functional roles for IL-23 in the differentiation and promotion of Th-17 cells. Autophagy genes that have been related to CD diagnosis are the *ATG16L1*[32,33], *IRGM* and the *LRRK2* gene[34]. Unraveling the mechanisms of such molecular mimicry is crucial to our understanding and clinical intervention of infectious diseases and inflammatory disorders of unkown aetiopathogenesis including Crohn's disease.

Genes related to lymphocyte differentiation

***IL23R* gene:** Dysregulated cytokine production by mucosal lymphocytes and macrophages has been implicated in the pathogenesis of CD. In fact, an exclusive increase of $CD4^+$ T cells in inflammatory bowel disease and their recruitment as intraepithelial lymphocytes has been demonstrated[35]. $CD4^+$ T cells secreting interleukin-17 (T helper type 17) cells have emerged as a key effector population driving colitis in animal models previously associated with exaggerated T helper type 1 responses.

Of the genes involved in the differentiation of Th-17 lymphocytes the *IL23R* gene has been proved of great importance and has been related to Crohn's disease[36,37].

The IL23R, consisting of an IL-12β1 and an IL23R chain, is highly expressed on memory T cells. IL23 is a novel cytokine formed *via* the binding of IL12p40 to a p19 protein. After binding to the IL23 receptor, IL23 preferentially activates memory T cells. IL23 does exhibit some similar biological activities to IL-12; however, IL-12 is more involved in the differentiation of naïve T-cells into Th1 lymphocytes and subsequent interferon-gamma production. IL23, on the other hand, mediates proinflammatory activities in part by the production of IL17 through activation of Th17 lymphocytes[38].

Signal transducer and activator of transcription 3 gene: Signal transducer and activator of transcription 3 (STAT3) play an important role in various autoimmune disorders including IBD[39,40]. STAT3 was initially identified as an acute phase response factor, an inducible DNA binding protein that binds to the IL-6 responsive element within the promoters of hepatic acute phase protein genes and is involved in IL-6 dependent T-cell proliferation through prevention of apoptosis. Subsequent studies indicate that STAT3 becomes activated in response to

a wide variety of cytokines and growth factors. Recent studies have revealed that STAT3 activation plays distinctly different roles between innate immune responses and acquired immune responses in colitis. STAT-3 mediated activation of acquired immune responses plays a pathogenic role in colitis by enhancing the survival of pathogenic T-cells. In contrast, STAT3-mediated activation of innate responses contributes to the suppression of colitis. Emerging data indicate that STAT3 is one of the crucial targets for the treatment of IBD. However, as the receptors of these cytokines and growth factors are present in both innate and acquired cells, activation of STAT3 is likely to occur in both cell types. Therefore as the function of STAT3 is a double-edged sword, careful attention should be directed toward the cell population that is being targeted when one contemplates STAT3 inhibition or activation in human IBD[41]. Within the same panel, other than *STAT3* genes, and with probable importance are the *TNFSF15, JAK2, CCR6* and *ICOSLG* genes[42-44].

Genes related to secondary immune response, apoptosis and other pathways

Chemokines play a central role in the pathogenesis of IBD as they are able to trigger multiple inflammatory actions including leukocyte activation and chemoattraction, granule exocytosis, production of metalloproteinases for matrix degradation and upregulation of the oxidative burst[45]. Therefore, further support is given for genes that relates to secondary immune response, apoptosis and other pathways. For example, in the IBD4 locus 4 several interesting candidate genes, which may be relevant in the pathogenesis of CD, lie within this region (e.g., genes regulating apoptosis, signal transduction proteins, chemokine receptors, T cell receptor, metalloproteinases).

Gene expression profiles from colon lamina propria fibroblasts have demonstrated several functional changes in some proteins coded from the corresponding genes: collagen types Ⅰ, Ⅳ, XIV, matrix metalloproteinase 1, cathepsin K, stroma cell-derived factor-1, chitinase3-like-1 and many others[46]. The major histocompatability complex (MHC) has been extensively investigated. Human leucocyte antigen (HLA) class Ⅱ molecules present partially digested antigen to the T-cell receptor and play a central role in the immune response. In CD MHC and HLA studies have yielded conflicting and heterogenous results. HLADR1 has been implicated with CD[47].

Many other genes, loci and chromosomes involved in CD have also been advocated in several studies that however still require wide replication and association with clinical practice. These include *CNR1, MCP-1*[48], *PTPN2* (protein tyrosine phosphatase)[49], *PTPN22, NKX-3, IL-18 RAP /IL-18R1, IL12/IL23* pathway[50], *PTGER4, MST1/BSN/MST1R*[50,51,52], *IL-2/IL-21*[53], *TYK2, JUN, NAT2*[54], *IL-10, NELL1, NKX2-3*[55], *Cyclin Y, Hect domain, 1q24, 10q21, 5p13, RCC1-like domain, ICOSLG, CDKAL1*[56], *13q13.3, 1p35.2, 3p29, 5p13.1*[57,58], *X chromosome*[59], *NLRP3*[60], *Vitamin D receptor polymorphisms*[61] and many others as well.

Genes in family and ethnic group studies

Linkage studies performed in complex genetic disorders such as CD frequently use model-free analytic methods, which are non-parametric analyses that do not assume Mendelian recessive or dominant models of inheritance.

The strongest risk factor for IBD is having a relative with the same disease. First-degree relatives of patients with CD have a 12-to-15 times greater risk of developing CD than do people of comparable age in the general population[61]. Familial clustering can also result from exposure to common environmental risk factors. Twin studies are very useful to determine the degree of genetic versus nongenetic etiologies for a trait. Today, there is no evidence of a separate entity of familial IBD[62,63]. Based on the current literature, phenotypic differences between familial and sporadic cases of IBD are weak. Available data are to be accepted with caution, however, as they are mostly retrospective and may be biased. CARD15 explains around 20% of the genetic predisposition to Crohn's disease[64]. The relative risk of developing CD in the presence of one mutation is 2-4, but increases dramatically in the case of two mutations (compound heterozygous or homozygous).

Although NOD2 provides no clear familial predisposition, unaffected relatives carry an increased rate of CARD15 variants (37.1%) compared to controls, and it would be interesting to see if they will eventually develop symptoms[65-67]. In addition, maternal transmission of CARD15 variants seems protective with a lower ratio of affected/unaffected children when compared to fathers[68,69]. In the light of the foregoing data, it seems that genetic counselling should be done with caution. In addition, families should not receive genetic counseling/information about age at onset and disease severity. Ethnic group studies and ethnic variation were first demonstrated in the Jewish population, and those studies are of major importance in this context[70].

ROLE OF GENES IN PROGNOSIS OF CROHN'S DISEASE

This is a major issue that greatly concerns patients. Many genes have so far been implicated in the prognosis of CD and numerous attempts have been made to classify the genetic profiles in CD. Of interest, CARD15 seems not only a susceptibility gene, but also a disease-modifier gene for CD. Of the many studies published on the clinical relevance of CARD15 mutations, there are several providing data on disease location, and the majority of them support a significant association of CARD15 mutations with ileal disease site, while some demonstrate a connection with the absence of colonic location. Some studies also provide data supporting the relevance to CARD15 variants with stricturing disease behavior, and also penetrating behaviour. Other pertinent studies revealed an association with early onset of the disease. These investigations also support the thesis that pediatric Crohn's is like a "more genetic disease" consistent with other polygenic disease

models. Other reports provide data on an increased risk or need of surgery related to CD[71].

Differences among studies are difficult to explain, and we could argue about the low number of patients in some of the studies, the disease variability among Caucasians and finally differences regarding disease assessment and interobserver agreement. Whether the described relationship between the CARD15 variants and both stenosing phenotype and increased need for surgery in CD patients is a true association or only reflects the high proportion of ileal CD developing bowel stenosis and, therefore, requiring surgery, is still a matter of controversy.

Genes related to age of Crohn's disease onset

With respect to age of CD onset and more specially to childhood or early-onset Crohn's disease, many genes/loci have been implicated: *TNFRSF6B, CXCL9*[72], *IL23R*[73,74], *NOD2*[75], *ATG16L1 rs2241880*[76], *CNR1*[77], *IL-10*[78], *MDR1*[79]. Of interest DLG5 seems protective for female children[80] while there are also studies not supporting the relation of genes and early onset of CD[81] or supporting the relation of IL-10 and IRGM with adult onset[82].

Genes related to crohn's disease behaviour

Genes related to stenotic/structuring behaviour in CD are: *NOD2/CARD15*[83], *TLR4*[84], *IL-12B*[85], and *CX-3CR1*[86,87]. Of importance NOD2/CARD15 has been also related to acute intestinal obstruction[88]. IL-10 and IL-6 are also potentially related to stenotic/structuring behaviour in CD while genetic variants of several metalloproteinases and their inhibitors would be excellent candidate genes, since these molecules are considered to play a key role in the abnormal fibrogenesis that underlies the development of bowel stenosis in CD patients. Genes related to penetrating/fistulizing behaviour in CD are as follows: *NOD2, IRGM, TNF*[89], *HLADRB1*[90]; the C-allele in CDKAL1 rs6908425 SNP is associated with NOD2 (-) perianal fistula, whereas OCTN and the near *IL-12B* gene rs12704036 T-allele have a relationship with non perianal fistula[91]. Inflammatory CD behaviour has been related to HLA variation[92] while granulomatous disease has been related with TLR4/CARD15 variants[93].

Genes related to Crohn's disease location

Upper gastrointestinal Crohn's disease has been related to NOD2[94] and MIF variants[95]. Ileal CD has been related to the following genes: *IL-10*[96], *CRP* gene[97], *NOD2, ZNF365* and *STAT3*[98]. Genes/loci associated with ileocolonic CD are *3p21*, *ATG16L1*[98] and *TCF-4* (*TCF7L2*)[99]. No role for phenotype in IL23R gene has been demonstrated[100] while a detailed genotype-phenotype analysis revealed weak associations of the IL23R rs10024819 variant with ileal involvement and stenoses in carriers of the TT genotype. Finally, the HLADRB1*0701 has been associated with ileal CD, but only in patients that have no CARD15 variants[101]. Colonic CD has been related to the following genes: the HLA region was associated with inflammatory colonic phenotype and TLR4[102], TLR1, -2, -6[103]. *TNF* gene showed a negative association with stricturing behaviour or colonic location[104]. For IBD5 and OCTN1 and 2, results have not been consistent but associations with perianal and ileal disease have been reported.

Genes related to Crohn's disease activity

Genes implicated in disease activity are the following: *HSP70-2* heat shock protein gene[105], *NOD2*[106], *PAI-1* (type 1 plasminogen activator inhibitor[107]), while the combination of NOD2 and PAI-1 predicted complicated disease behavior[108]. Of importance, NOD2 predicted lower weight in children[109], and CNR1 low BMI[110].

Genes related to surgery

NOD2 gene has been related to early pediatric surgery[111], stenosis and need for surgery[112], previous surgeries[113], increased number of surgeries[107] and surgical costs[114]. NOD2 has no relation to the risk of re-operation[115]. Finally, HLA-G has been associated with higher risk for ileocolonic resection[116].

Genes related to dysplasia and cancer

The *FHIT* gene (fragile histidine triad gene) located at 3p14.2 has been identified as a candidate tumor-suppressor gene. The gene spans the t (3; 8) translocation breakpoint of familial renal-cell carcinoma and contains the FRA3B fragile site. It encodes the human diadenosine triphosphate hydrolase, which in vitro cleaves the diadenosine substrate into ADP and AMP. It has been suggested that *FHIT* gene plays a role in the pathogenesis of IBD and the development and progression of a subgroup of IBD-related carcinomas at an early phase[117-119].

Genes related to extraintestinal manifestations and concommitant diseases

Extraintestinal manifestations are common in CD. Genes related to CD extraintestinal manifestations have been reported, as follows. Peripheral arthritis was related with FcRL3[120], HLADRB*103, HLAB*27 HLA-B*44, HLA-B*35, TNFalpha-308A[121]. CARD15 has been related to spondyloarthropathy[122] and uveitis[123] but not with sacroileitis[124]. TNF-1031C was associated with erythema nodosum while certain HLA alleles (HLA-B27, HLA-B35, HLA-B44) were connected with different disease behaviour and extraintestinal manifestations such as arthropathy, eye and skin manifestations. Genes/loci related to other chronic diseases concomitant to CD are 10p12.2 (sarcoidosis and CD)[125], STAT3 (multiple sclerosis and CD)[126], and a parallel genetic fingerprint between leprosy and CD[127].

Pharmacogenetics in Crohn's disease

Pharmacogenetics is of major importance in CD therapeutics and prognosis. Genes have been implicated in influencing the efficacy and side effects of drugs and reflect a complex interplay regarding absorption, elimina-

tion and transport. Future studies need to be large and prospective with uniformly phenotyped patients and correlating genetic associations with functional data. In addition hypotheses such as whether observations about drug response in IBD lead us to IBD etiology or whether the genes that control the drug response are related to genes that control the disease still remain unanswered. Pharmacogenetic studies to date have found no association between CARD15 variants and prediction of response to various IBD therapies. In addition, responses to azathioprine, steroids and infliximab are not related to NOD2[128]. Of note, NOD2 was related to antibiotic failure[129].For mesalazine, variability in drug acetylation was demonstrated many years ago with patients divided in slow and rapid acetylators, because of polymorphisms in the N-acetyltransferase (*NAT*) genes. Two isoenzymes NAT1 and NAT2 have been identified in humans and more than 50% of Caucasians are NAT2 slow acetylators. Mesalazine is acetylated in the liver by NAT1 into N-acetyl-5 aminosalicylates and excreted in the urine[47].

The clinical usefulness of pharmacogenetics in CD is limited to AZA and TPMT at this moment. The human TPMT gene, consisting of 10 exons, is located on chromosome 6p22.3. The hereditary nature of the TPMT deficiency in humans was initially identified in a study of TPMT activity in red blood cells (RBC). This and subsequent studies determined the distribution of TPMT activity in RBC to be trimodal; 90% of persons have high activity, 10% have intermediate activity and 0.3% have low or no detectable enzyme activity. To date, numerous mutant TPMT alleles have been identified, including the three most frequent alleles (TPMT*2, TPMT*3A and TPMT*3C), which account for 80%-95% of intermediate or low TPMT enzyme activity cases. The prevalence of the most frequent SNPs in the TPMT gene has been reported to vary worldwide. However, it is of interest that studies on the prevalence of TPMT SNPs in large IBD cohorts are lacking. Although AZA is an effective drug for maintenance of remission in IBD, it is associated with side effects. Clinically sound pharmacogenetic studies over the last two decades have shown that polymorphisms in the *TPMT* gene locus play a significant role in the occurrence of various side effects of thiopurine drugs including life-threatening bone marrow toxicity (BMT), a serious dose-related toxicity[130-134].

The G2677T variant in the *MDR1* gene predicted gastrointestinal and unspecified intolerance to azathioprine and methotrexate in IBD patients. These findings suggest a role for MDR1/P-gp in the mechanism of action of azathioprine and methotrexate[135,136].

Twin studies have linked polymorhisms of the vitamin D receptor (*VDR*) gene with bone mineral density in healthy women and in addition VDR is an important regulator of calcium metabolism and bone cell function and influences calcium absorption from the intestine. VDR polymorphisms have also been implicated in susceptibility to CD[137].

The HLADR region has been associated with failure to budesonide[138] while DLG5R30Q predicted response to steroids[139]. Other genes such as MIF (macrophage migration inhibition)[140] and MDR have been also related to steroid therapy[136]. In addition, 1082 AA IL-10 genotype was associated with steroid dependency, whereas the allele 113A of the *DLG5* gene conferred resistance to steroids.

Regarding response to infliximab the data for TNF gene are conflicting. Specifically, there are conflicting data regarding the role of FcGR3A, which has been supported by some authors[141,142], but was not confirmed in patients of the ACCENT I study. Response to infliximab is not related to *TNFa-308*[143] or *TNFR1* and *TNFR2*[144] or *NOD*[145] or *CRP* gene[136]. The association between the Fas ligand-843 TT genotype and lack of response to infliximab seemed to be the most relevant observation[136]. The relationship of infliximab response and lymphotoxin alpha gene (*LTA*) is also conflicting[144].

WHAT LIES AHEAD

Gene-to-gene crosstalk and epistasis

With new methodologies like genome wide association studies, microarrays, and fine SNP analysis becoming available during the last decade, our investigative armamentarium has been considerably enriched. As many studies with complex statistics arise, we understand increasingly the real crosstalk present among genes and the need of a genetic panel for disease diagnosis and prognosis. It is now evident that gene-to-gene interaction and epistasis modulate disease activity and susceptibility[146]. Some data have come to light. A genome-wide scan in a Flemish population of IBD affected families supports the existence of *IBD4* on 14q11, and has shown additional evidence for the existence of other susceptibility loci (1p, 4q and 10p). This study has further demonstrated that epistasis and gene to gene interactions (CARD15-TLR4) are also present in IBD and that population heterogeneity is not to be underestimated[147]. Crosstalk has been demonstrated for TLR9 with NOD2, IL23R and DLG5, and epistasis has been shown between IL23R and DLG5. Also potential epistasis between IL23R variants and the three other previously described CD susceptibility genes CARD15, SLC22A4 and SLC22A5 (OCTN 1 and 2) has been shown[116].

Genetic consortium studies and genome wide scans

Over the past few years, a combination of progress in high throughput genotyping technology and growing knowledge about the human genome through the International HapMap project and the Human Genome Project have enabled genome-wide association studies (GWAS) for several complex diseases. To understand the approach to conducting GWAS in this setting it is important to expound on the concept of linkage disequilibrium, which refers to the nonrandom association of alleles at nearby loci. Specifically, linkage disequilibrium refers to adjacent alleles assorting together nonindepen-

dently from generation to generation because they are tightly linked and thus less likely to become separated by recombination. Genetic consortium studies are of major importance and homogeneity in methodology issues is of paramount value[148-151]. Appropriate study design[152], power analysis[153] and overall data analysis and meta-analysis[154] are mandatory. Accurate estimation of sample sizes required in a genetic association study is essential before commencing genotyping, to ensure that the study is sufficiently powered to detect the subtle genetic effects that contribute to most complex diseases. The extensive genetic variation and complex linkage disequilibrium across even a small genomic region will give rise to several alternative scenarios. Genetic variation across a region studied should be carefully evaluated and consideration should be given to possible linkage disequilibrium and allelic heterogeneity when evaluating power of an association study. As larger datasets are studied and combined, as genotyping platforms provide even greater depth of coverage of the genome and as modest hits are followed up in large independent panels so that the vast majority of true signals should be identified. These robust genetic data will truly provide a solid platform for functional studies to understand the mechanisms by which these genetic variants predispose to CD. Finally studies at post-transcriptional level become more and more urgent[155]. Enriching our understanding of CD genetics is important but when combining genetic data with functional data the outcome could be of major importance. In fact, improved understanding of immune mechanisms, on which manifold genetic and environmental traits might converge, and which ultimately mediate all phenomena in inflammatory bowel disease, holds promise (Table 2).

CONCLUSION

The recent advances in the understanding of CD genetics have been tremendous[156]. Starting with the susceptibility area, whole genome linkage and association scans have already led to the identification of a number of susceptibility genes (*NOD2/CARD15, DLG5, OCTN1* and *2, NOD1, IL23R, PTGER4, ATG16L1* and *IRGM*) of which the *NOD2/CARD15* gene is the most replicated and understood at present. Although it is clear that genetic research in IBD has advanced our understanding of the clinical heterogeneity of the disease, new efforts are required and point towards the complex combination of a panel of clinical, biochemical, serological and genetic factors, in order to achieve the optimal prediction of both clinical behaviour and response to therapy.

Genome-wide association studies have allowed an unprecedented rapid unraveling of the genetic basis of IBD; however there will be much more follow-up work needed in this field. First, ongoing work including meta-analysis of the Crohn's disease genome wide association studies will probably reveal additional Crohn's disease susceptibility genes. It will then be essential to investigate the functional consequences of polymorphisms in these genes so the molecular and cellular mechanisms leading to CD can be better characterized. Finally, genotype-phenotype correlation studies should help clinicians predict disease outcomes with more accuracy, including the risk for complications, need for surgery, and response to therapy, and finally lead to redesigning the methods of treatment of CD patients.

Abstract

As a chronic inflammatory disease of the liver, the pathogenic mechanisms of autoimmune hepatitis (AIH) have not yet been elucidated, with prognosis and diagnosis remaining unsatisfied. Currently the only viable treatments of AIH are immunosuppressant application and liver transplantation. It is considered that lack of good animal AIH models is the main reason for the shortage of a simple and efficient cure. The Concanavalin A (Con A) model is a typical and well established model for investigating T-cell and macrophage dependent liver injury in mice, which closely mimics the pathogenesis mechanisms and pathological changes of patients, and is regarded as the best experimental model for AIH research so far. In this paper we elucidated the pathogenic mechanisms of AIH and the evolution of relative animal models. We go on to further focus on Con A-induced liver injury from the point of immunological mechanisms and the change of cytokine levels. Finally, we manifested the clinical significance of the AIH animal models and the challenges they would meet during their future development.

Key words: Autoimmune hepatitis; Animal models; Concanavalin A

INTRODUCTION

Autoimmune hepatitis (AIH) is a chronic inflammatory disease of the liver, characterized by a loss of self-tolerance leading to the appearance of autoantibodies, pathological changes and dysfunctions (the detailed pathogenic mechanisms of which still remain vague). According to different antibodies profiles, AIH is classified into three categories: AIH type 1 is characterized by the presence of antibodies to nuclear antigens (ANA) and/or anti-smooth muscle antigen (SMA) antibodies; AIH type 2 is characterized by anti-liver kidney microsomal (LKM)-1 and low level of LKM-3 antibodies (with or without ANA or SMA antibodies); AIH type 3 is characterized by autoantibodies against soluble liver

antigen/liver pancreas (with or without ANA or SMA antibodies)[1].

Around the world, the incidence of AIH is 0.1-1.9 cases out of 100 000 persons per year, which is not very high[2]. However, the prevalence of autoimmune hepatitis in Europe is in the range of 11.6-16.9 cases per 100 000 persons[2], and in the United States, the proportion of hepatitis among patients with liver cancer is about 11%[3]. Incidence is also different between men and women. It was reported that women are more vulnerable to AIH[2,4,5].

Unfortunately, we do not have any better choice of medicines other than immunosuppressants, which can be classified into four generations[6,7]. In the 1950s, the first generation immunosuppressants were limited to azathioprine and steroids, which were enriched by polyclonal anti-lymphocyte and anti-thymocyte globulins in the 1960s[6]. For this generation, 70%-80% patients might relapse after withdrawal of treatment[8]. More seriously, they have many side effects[9]. Corticosteroids, Tacrolimus and Cyclosporine are typical of the second generation[6]. In the early 1990s a broad range of third-generation immunosuppressants emerged[6], most of which are monoclonal anti-lymphocyte and anti-thymocyte globulins followed by the fourth generation, such as the IL-2 monoclonal antibody with its highly specific sites of action[7,10]. The second and the third generation immunosuppressants are in most cases successfully used for treatment of AIH[11,12]. But long term applications of these immunosuppressive drugs carries serious risks[13] and sustained remission[9], even at low doses. Non-system steroids may be the best candidates[14]. Patients with liver failure or fulminant presentation who fail to improve under immunosuppressive therapy should be considered as candidates for liver transplantation. Without treatment, nearly 50% of patients with severe autoimmune hepatitis die in approximately 5 years[15]. Taking this into consideration, it is significantly important to develop new specific drugs. Animal models are the basis of drug discovery and development. Up to the time of writing, there are still no universal animal models of AIH which can be used as pathogenic models as well as therapeutic ones.

As the most important AIH research model, the Con A animal model plays a key role in AIH drug development. In this article we attempt to review the evolution of the Con A animal model of AIH, to sum up the mechanisms of Con A-induced liver injury, and to illustrate its statue in AIH drug development. Furthermore, the future challenges of the animal model are also discussed.

EVOLUTION OF AIH MODEL

AIH models have evolved from crude liver homogenates and adjuvants to the genetic engineering level, which can be classified into five phases[16]. The first phase was in 1972 when Buschenfelde *et al*[17] induced chronic active hepatitis in rabbits immunized with human liver proteins combined with complete Freund's adjuvant. This work built a solid foundation for AIH models. The second phase began in 1983, when Mihas *et al*[18] established transient hepatitis in mice by immunization with syngeneic liver proteins together with the polysaccharide of Klebsiella pneumoniae. In the third phase, taking place from 1987 to 1990, many scientists used inbred or neonatal thymectomy mice to establish the T-cell reactive AIH model. They induced transient hepatitis by immunizing C57BL/6 mice with the supernatant of liver syngeneic liver homogenates with complete Freund's adjuvant and used adoptive transfer technology to study the roles of T-cell, which allowed studies of the pathogenesis of AIH[19]. The fourth phase, from 1992 to 2003, had endotoxin and plant lectin-induced hepatitis models receive extensive attention. Three types of inducers were wildly used during this period: Con A[20], D-galactosamine (GalN) with low dosage of lipopolysaccharides (LPS)[21], and high dosage of LPS[22]. In the fifth phase, from 2002 to 2008, the application of genetic engineering technology accelerated the development of AIH model[23]. From one aspect, gene knockout and transgenic animals facilitated the study of the functions of certain genes[24]. From the other, production of designated antibodies using genetic engineering methods made it possible for scientists to get specific types of autoantibodies[25], and also made it possible for the Con A models to mimic a specific subtype of AIH. Significantly, the production of designated autoantibodies is based on known antigens. Scientists have now clarified the antigens to the following autoantibodies: the antigen to LKM-1 is cytochrome P450 2D6[26,27], the antigen to LKM-2 is cytochrome P450 2C9[1], the antigens to Liver Microsomal are cytochrome P450 1A2 and cytochrome P450 2A6[1]. The animal models of type 2 AIH[28] have been reported, but obviously type I animal models have more clinical significance than type Ⅱ[2]. As is widely known, it is difficult to find the antigen of autoantibodies, which is the limitation of the gene engineering AIH model. The features and parameters of the three models are listed in Table 1[29].

From the information in Table 1, it is obvious that the Con A-induced hepatitis model possesses more advantages than the other two. Firstly, the Con A model includes only one inducer, making it easier to be established compared with the GalN/LPS model. Secondly, there is no significant change of the level of transaminase, which is considered a valid index of the severity of liver injury, in the LPS model, while such change is remarkable in the Con A model. Thirdly, in the Con A model, the serum level of many cytokines relevant to inflammation change dramatically, which is favorable for the study of the pathogenic mechanisms of AIH[29]. Furthermore, besides AIH, Con A animal models with different parameters are adaptable to many clinical diseases, such as fulminant hepatitis[30], virus hepatitis[31], hepatotoxin[32,33] and alcoholic liver diseases[34]. In summary,

Table 1 The features of the autoimmune hepatitis model induced by endotoxins and plant lectins

	Con A[29]	GalN/LPS[29]	LPS[29]
Animal	BALB/c-mice (6-8 wk)	BALB/c-mice (6-8 wk)	BALB/c-mice (6-8 wk)
Inducer	Con A	GalN/LPS	LPS
Dosage	20 mg/kg	LPS: 5 μg/kg GalN: 700 mg/kg	10 mg/kg
Application method	Tail vein	Subcutaneous	Subcutaneous
Transaminase level (max)	8 h	8 h	No significant change

Con A: Concanavalin A; GalN: D-galactosamine; LPS: Lipopolysaccharides.

Con A AIH model is easy, convenient, inexpensive and repeatable, as well as a T-cell activated model and could greatly facilitate the study of the mechanisms of AIH-induced liver injury.

IMMUNOLOGICAL MECHANISMS OF CON A-INDUCED LIVER INJURY

Con A is one kind of lectin, which is purified from *Canavalia brasiliensis*[35]. Tiegs *et al*[20] injected Con A, Succinyl Con A with no agglutination activity, and *Vicia faba* lectin with strong agglutination activity to nuclear magnetic resonance imaging mice *via* tail vein, respectively. The results showed that only Con A could induce liver injury, which indicated that the *in vitro* agglutination activity of this lectin does not correlate with its hepatotoxic potential *in vivo*. They also studied the correlation between the hepatotoxic potential of Con A and its sugar-binding site[20]. Con A has specific sugar-binding sites, whose ligands are α-D-mannoside, methyl α-D-mannopyranoside, α-D-glucose, and methyl-α-D-glucose[36]. They co-administrated Con A with α-D-mannoside or methyl α-D-mannopyranoside to mice, which prevented the induction of hepatic injury by the lectin[20]. This suggested that free sugar-binding sites are indispensible for the induction of liver injury by lectin. Sato *et al*[37] also confirmed that Con A/glycogen multilayer films can be decomposed by exposing them to sugar solutions (D-glucose, D-mannose, methyl-alpha-D-glucose and methyl-alpha-D-mannose), as a result of the displacement of sugar residues of glycogen from the binding sites of Con A by the free sugar added in the solution. This suggested that sugar-binding sites are prerequisites of activated Con A. But among Con A, Succinyl Con A and *Vicia faba* lectin, which have the same sugar-binding site, only Con A can lead to high level of transaminase[20]. These two results indicated that the hepatotoxic potential of Con A is not determined by its agglutination activity or sugar-binding site. Other mechanisms may exist.

The mechanisms of the Con A model have interested many scientists. Previews papers describe that the aminotransferase of mice in thymus[38] and CD4[39] neutralized groups decreased significantly compared with the control group, while the CD8 neutralized group show no significant change. What is more, after injection of Con A, the blood level of interleukin 2 (IL-2), IL-4 and interferon gamma (IFN-γ) all increased dramatically[40]. This suggested that the $CD4^+$ T helper (Th) cell was involved in the liver injury[40]. It is reported that $CD4^+$-positive Th cells recognize the Con A-modified major histocompatibility complex (MHC) structures of macrophages and become activated, followed by an inflammation reaction and the release of IL-1 and IL-2 to the blood[41]. In the experiment of CD8 neutralization, there was a minor decrease of the transaminase level, which suggested that the target cell lysis by cytotoxic $CD8^+$ T lymphocyte (CTL) also contributes to liver injury, but not as the major factor. In conclusion, the main mechanism of the Con A model is that Th cell activation increases the relevant cytokine level, which leads to liver injury. Meanwhile, the CTL mediated target cell lysis may be the secondary mechanism.

In the liver, lymphocytes, sinusoid endothelial cells (SECs), Kupffer cells (KCs) and stellate cells are all involved in the immune response[42]. Lymphocytes can be classified into two groups, exogenous and endogenous[43]. Exogenous lymphocytes originate from the thymus[44], bone marrow[44,45], intestinal tract[46], spleen[47] and lymph gland[48], and enter the liver through circulation. Endogenous lymphocytes are enriched in the portal area of the liver, which count for 25% of non-parenchyma cells in the liver[49]. The endogenous lymphocytes are mainly T cells, while B cells only count for 5% of them. This is why lymphocyte infiltration is mainly focused in the portal area[50].

For a long time, there have been debates about whether KCs or SECs plays a major role in immunological liver injury[51-53]. Knolle *et al*[52] established the spontaneous and LPS activated cell model, and found that SECs and KCs both secreted IL-1 and IL-6, which suggested that SECs are also key cells in liver injury. It has been found that fifteen minutes after intravenous injection of Con A, Con A binds to SECs first; 4 h later, Con A begins to bind to the KCs[52]. Using Scanning Electron micrograph, it is clearly seen that 4 h after intravenous injection of Con A, blood cell endothelium attaches to the SECs first[52]. Then lymphocytes or neutrophils are trafficked into the hepatocytes, leading to inflammation[52]. We can conclude that SECs and KCs are both important, but they play their roles in the different phases. After injection, Con A binds to the mannose gland in the SECs surface first, leading to the breakdown of the SECs membrane, bleb formation and cytoplasm disappearance[30]. SECs detachment facilitates the binding of Con A to the KCs. $CD4^+$ Th cells recognize the MHC class Ⅱ and T cell receptor of KCs modified by Con A and are then activated[30]. Such liver injury is mainly mediated by T helper cells, including Th1 and Th2 cells. Figure 1 depicted the mechanisms of T cell activated liver injury.

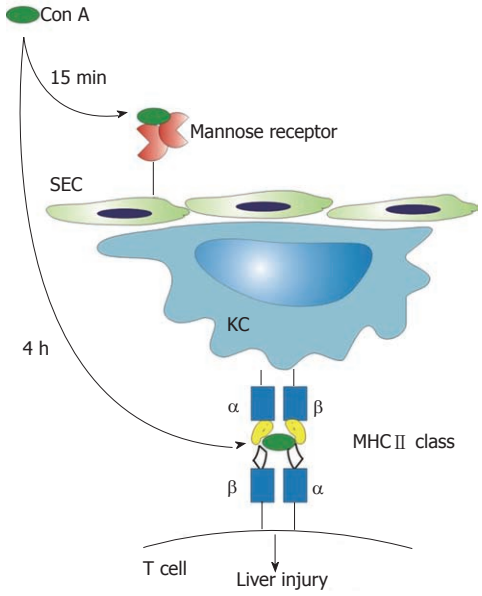

Figure 1 Mechanisms of Concanavalin A induced T cell activated liver injury. Con A: Concanavalin A; KC: Kupffer cell; SEC: Sinusoid endothelial cell; MHC: Major histocompatibility complex.

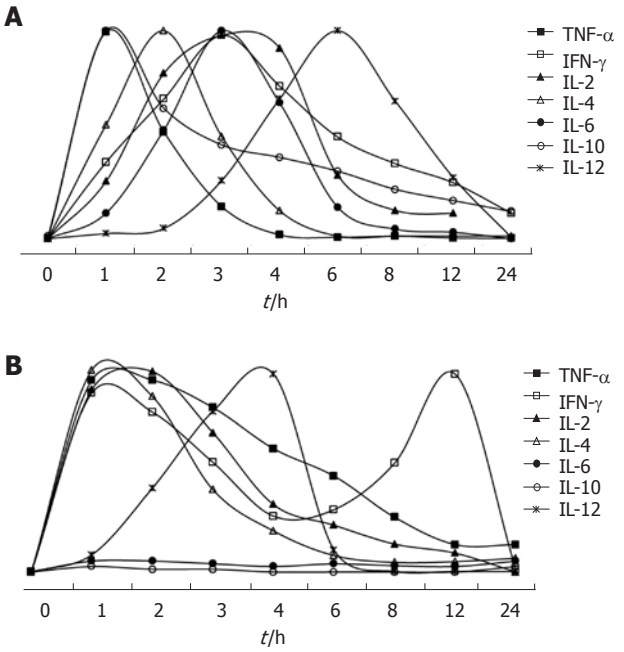

Figure 2 Different cytokines levels within 24 h. A: Plasma level; B: Liver level. TNF: Tumor necrosis factor; IFN: Interferon; IL: Interleukin.

CHANGES IN THE EXPRESSION LEVELS OF RELEVANT CYTOKINES

Some major cytokines involved in the Con A-induced liver injury are IFN-γ[54-55], IL-2[55], IL-4[56], IL-6[56] and tumor necrosis factor α (TNF-α)[56], of which TNF-α and IFN-γ are the major ones.

Figure 2 shows the time when different cytokines reach their peak level in the plasma and liver. In the plasma, TNF-α and IL-10[29,57] first reach their peak level after 1 h, followed by IL-4 after 2 h. IFN-γ, IL-2 and IL-6[29,57] reach their peak after 3 h, followed by IL-12. However, in the liver, TNF-α, IFN-γ, IL-4[29,57] reach their peak level in 1 h, followed by IL-2 and IL-12. There is no significant change for IL-6[57] and IL-10[29,57] in the liver. Especially, the level of IL-10[29] is very low in the liver compared with that in the plasma, which suggested that IL-10 might originate from other tissues, such as the spleen. But one previous paper reported that IL-10 expression in the liver is higher than that in the spleen[57]. As yet, where IL-10 originates remains unanswered.

Comparing the acute and chronic animal models, the expression profiles of IL-10 are quite different. For example, in the acute model induced by Con A, TNF-α, IFN-γ and IL-12 levels increased to 2.11, 1.92 and 8.30 times of their normal level, respectively, after neutralization of IL-10. Reversely, administration of recombinant IL-10 prior to injection of Con A decreased by 47%, 47% and 80% of TNF-α, IFN-γ and IL-12 expression levels respectively. IL-10 is considered to be an anti-inflammatory cytokine in a murine model of Con A[58]. Kato *et al*[59] described that the IL-10 level is increased at 12 h after the Con A injection. After neutralizing antibodies to IL-10, it was intraperitoneally injected into animals of the same model at 6 h before Con A treatment, with serum alanine aminotransferase level being significantly higher than in the control group. Histological studies showed spotty necrosis in the group treated with anti-IL-10 antibodies. These results suggest that IL-10 has an inhibitory effect on liver injury in a murine model of Con A-induced experimental liver injury mediated by cellular immunity[58]. These studies suggested that both endogenous and exogenous IL-10 can protect the liver from acute injury[59].

However, there is evidence indicating that IL-10 could accelerate liver injury in the chronic model[60]. When Con A was administrated intravenously to BALB/c mice once a week, the IL-10 expression level in plasma increased to 7 times higher 20 wk later. Accordingly, in this model, inflammatory infiltration also lasted for 20 wk and activated stellate cells also dramatically increased[60]. All these results suggested that IL-10 aggravated liver injury in the chronic Con A model.

Paradoxically, IL-10 does not play the same role in all chronic models. For example, in the CCl_4 chronic model, IL-10 slows down the process of fibrosis[61]. This may be due to the fact that the mechanisms of liver injury in these two models are different, and the latter does not involve T cell activation. In the acute Con A model, IL-10 may inhibit macrophages and Th1 cells from releasing inflammatory cytokines, which explains why it plays an anti-inflammation role in the acute model[58]. Though IL-10 can inhibit the secretion of anti-inflammation cytokines, secretion of IFN-γ is also inhibited[62]. Some previous studies reported that, to some extent, IFN-γ may relieve liver fibrosis. Therefore, a long duration of IFN-γ deficiency may aggravate fibrosis. As for the CCl_4 model, liver injury is mediated only by free

Table 2 New drugs developed based on the Concanavalin A model

	Classification	Target	Pathway
Hu 23C3[63]	Monoclonal antibody	Human osteopontin	NF-κB
Anti-his H1[64]	Polyclonal antibody	Histone H1	NF-κB
ApoA Ⅱ[65]	High density lipoprotein	Leukocytes and T cells	-
CpG ODN[66]	Oligodeoxynucleotides	DNA binding ability of NF-κB	NF-κB

CpG ODN: CpG-containing oligodeoxynucleotides; ApoA: Apolipoprotein A; Anti-his H1: Antibody against histone H1; NF-κB: Nuclear factor kappa B.

radicals, which is not relevant to the activation of the immune response and the release of inflammation cytokines. In conclusion, the expression profiles in different models, even with the same inducer, are not the same. The various mechanisms, cell types and micro-environments should be taken into consideration in experimental design and execution.

CON A MODEL AND NEW DRUG DEVELOPMENT

In recent years, based on the Con A animal model, many new therapeutic antibodies or proteins have been developed to attenuate liver injury in experimental models (Table 2)[63-66].

Fan *et al*[63] humanized a murine monoclonal antibody 23C3 against human osteopontin by a complementary-determining region grafting method based on computer-assisted molecular modeling, denoted as Hu23C3. They demonstrated that Hu23C3 could have the potential for attenuating Con A-induced liver injury through the nuclear factor kappa B (NF-κB) pathway.

Nakano *et al*[64] intraperitoneally injected a polyclonal antibody against histone H1 immediately after Con A injection; they found that injection of anti-histone H1 antibodies could reduce Con A-induced liver damage, also *via* the NF-κB pathway.

It is reported that Con A-induced hepatitis was attenuated by the administration of apolipoprotein A-Ⅱ, which is the second major apolipoprotein of high-density lipoprotein[65]; this inhibited leukocytes infiltration and the expression of T-cell related cytokines and chemokines.

The survival rate of mice was markedly enhanced by the administration of CpG-containing oligodeoxynucleotides (CpG ODN)[66]. This is because CpG ODN pretreatment inhibits the DNA binding ability of NF-κB, leading to the decrease of systemic/liver levels of TNF-α and IFN-γ. These results suggest that CpG ODN pretreatment protects the mice from Con A-induced liver injury, also *via* NF-κB pathway.

CONCLUSION

In this article we reviewed the evolution of the AIH model and emphasized the importance of the Con A AIH model. Based on the previous papers, we summarized the mechanisms of Con A-induced liver injury, its pathogenic changes and cytokines expression levels. The Con A animal model, which is a typical T cell dependent model, can mimic the mechanisms of clinical AIH diseases. Therefore, we think that it is a good and convenient model for studying the mechanisms of AIH and developing new therapeutic drugs.

Abstract

AIM: To determine the effects of curcumin, (-)-epigallocatechin-3-gallate (EGCG), lovastatin, and their combinations on inhibition of esophageal cancer.

METHODS: Esophageal cancer TE-8 and SKGT-4 cell lines were subjected to cell viability methyl thiazolyl tetrazolium and tumor cell invasion assays *in vitro* and tumor formation and growth in nude mouse xenografts with or without curcumin, EGCG and lovastatin treatment. Gene expression was detected using immunohistochemistry and Western blotting in tumor cell lines, tumor xenografts and human esophageal cancer tissues, respectively.

RESULTS: These drugs individually or in combinations significantly reduced the viability and invasion capacity of esophageal cancer cells *in vitro*. Molecularly, these three agents reduced the expression of phosphorylated extracellular-signal-regulated kinases (Erk1/2), c-Jun and cyclooxygenase-2 (COX-2), but activated caspase 3 in esophageal cancer cells. The nude mouse xenograft assay showed that EGCG and the combinations of curcumin, EGCG and lovastatin suppressed esophageal cancer cell growth and reduced the expression of Ki67, phosphorylated Erk1/2 and COX-2. The expression of phosphorylated Erk1/2 and COX-2 in esophageal cancer tissue specimens was also analyzed using immunohistochemistry. The data demonstrated that 77 of 156 (49.4%) tumors expressed phosphorylated Erk1/2 and that 121 of 156 (77.6%) esophageal cancers expressed COX-2 protein. In particular, phosphorylated Erk1/2 was expressed in 23 of 50 (46%) cases of esophageal squamous cell carcinoma (SCC) and in 54 of 106 (50.9%) cases of adenocarcinoma, while COX-2 was expressed in 39 of 50 (78%) esophageal SCC and in 82 of 106 (77.4%) esophageal adenocarcinoma.

CONCLUSION: The combinations of curcumin, EGCG and lovastatin were able to suppress esophageal cancer cell growth *in vitro* and in nude mouse xenografts, these drugs also inhibited phosphorylated Erk1/2, c-Jun and COX-2 expression.

INTRODUCTION

Esophageal cancer is one of the least studied and deadliest cancers. Tobacco smoke is the most firmly established risk factor for esophageal cancer and has been associated with the development of esophageal squamous cell carcinoma and adenocarcinoma; gastroesophageal reflux with bile acid is another important cause of adenocarcinoma[1-3]. Molecularly, the expression of retinoic acid receptor-β2 (RAR-β2) is frequently lost in premalignant and malignant esophageal tissues, and benzo[a]pyrene, a carcinogen present in tobacco and environmental pollution, and bile acid, a tumor promoter for gastrointestinal cancer, may be responsible for its loss. Restoration of RAR-β2 expression suppressed esophageal cancer cell growth and induced apoptosis *in vitro* and tumor formation *in vivo*; these effects were correlated with decreased expression of activator protein 1 and cyclooxygenase-2 (COX-2) and phosphorylated extracellular-signal-regulated kinases (Erk1/2)[4]. Moreover, the novel retinoid receptor-induced gene-1 (RRIG1), which is a downstream gene of RAR-β2, participates in regulating the effects of RAR-β2 on cell growth and gene expression[5,6]. RRIG1 protein binds to and inhibits a small GTPase RhoA activity. Restoration of RRIG1 expression inhibits RhoA activation and, consequently, reduces tumor cell colony formation, invasion, and proliferation, which are correlated with inhibition of Erk1/2 phosphorylation, COX-2, and cyclin D1 expression[5,6]. These genes together may form a novel molecular pathway that involves RAR-β2-induced RRIG1 expression and suppression of RhoA/Erk1/2/AP-1/COX2[4]. Therefore, targeting this molecular pathway should translate into better control of esophageal cancer.

Cancer chemoprevention was defined as the use of natural, synthetic, or biologic chemicals (such as drugs and food supplements) in the prevention, suppression, or delay of the carcinogenesis process[6]. Several clinical trials of different drugs have been conducted in an attempt to prevent esophageal cancer. The first class of agents tried was the retinoids[7]. The use of retinoids was based on the fact that vitamin A deficiency was found in esophageal cancer patients and the fact that this deficiency induced hyperkeratotic changes in the esophageal mucosa of experimental animals[8,9]. A clinical trial using N-4-(ethoxycarbophenyl) retinamide demonstrated that cancer incidence in the treatment group with severe esophageal dysplasia was reduced by 43.2% compared with that in the placebo group[10]. However, the results from two other trials conducted in Linxian, China, by the National Cancer Institute were inconclusive[11,12]. Our *in vitro* study demonstrated that esophageal cancer cells which do not express RAR-β2 are resistant to all-trans retinoic acid[13]. In animal experiments, dietary N-(4-hydroxyphenyl) retinamide enhanced tumorigenesis in response to N-nitrosomethylbenzylamine in the rat esophagus by increasing tumor initiation events[14]. Moreover, 13-*cis* RA did not reduce NBMA-induced esophageal tumor multiplicity in rats[15].

Non-steroidal anti-inflammatory drugs (NSAIDs) were also tested for the prevention of esophageal cancer[16]. Epidemiological and experimental studies indicated that NSAIDs decreased esophageal cancer incidence[17-21]. Our *in vitro* data showed that aspirin and NS398 induced apoptosis in esophageal cancer cells, which correlated with their ability to inhibit COX-2 enzymatic activity and upregulate the expression of 15-LOX-1 and -2[22-25]. However, during clinical trials of these agents in the chemoprevention of colorectal cancer, it was reported that Vioxx (rofecoxib) and Celebrex (celecoxib) induced cardiovascular events, which raised safety concerns about the high-dose and long-term use of these drugs in cancer prevention[26,27].

However, to date, most preclinical and clinical chemoprevention studies of human cancers have been focused on targeting a single gene, which showed limited activities *in vitro* and *in vivo*[3,16]. In this study, we aimed to target multiple genes in a molecular pathway using combinations of drugs to determine whether this approach is more effective than single-drug treatments in the inhibition of esophageal cancer.

MATERIALS AND METHODS

Cell culture and drug treatment

The human esophageal cancer cell lines SKGT-4 and TE-8 used in our previous studies[13,22] were grown in Dulbecco's modified Eagle's minimal essential medium (DMEM), supplemented with 10% fetal bovine serum (FCS), at 37 ℃ in a humidified atmosphere of 95% air and 5% CO_2. For drug treatment, these cells were grown in monolayer overnight and then treated with or without curcumin, (-)-epigallocatechin-3-gallate (EGCG), lovastatin, and combinations of these agents for up to 5 days. The drugs were dissolved in dimethyl sulfoxide (DMSO) and then diluted before use. The concentration of lovastatin was 2 or 4 μmol/L, curcumin was 20 or 40 μmol/L, and EGCG was 20 or 40 μmol/L (all from LKT Laboratories, Inc., St. Paul, MN, United States). The concentrations for the drug combinations were the same as those used individually. For the methyl thiazolyl tetrazolium (MTT) assay, 20 μL of MTT (5 mg/mL, Sigma, St Louis, MO, United States) was added to each well of the 96-well plates and incubated for an additional 4 h. After the growth medium was removed, 100 μL of DMSO was added to the wells to dissolve the MTT crystal, and the optical densities were measured with an automated spectrophotometric plate reader at a single wavelength of 540 nm. The percentage of cell growth was calcu-

lated using the formula: % control = ODt/ODc × 100, where ODt and ODc are the optical densities for treated and control cells, respectively. The data were then analyzed statistically using the Student's *t* test.

Tumor cell invasion assay

Boyden chambers coated with Matrigel were obtained from BD Biosciences (Bedford, MA, United States) for assaying tumor cell invasion ability[6]. Esophageal cancer cells SKGT-4 and TE-8 were first starved in medium without FCS overnight, and the cells (5×10^4) were re-suspended in the FCS-free medium and placed in the top chambers in triplicate. The medium in the top chambers contained lovastatin (4 μmol/L), curcumin (40 μmol/L), EGCG (40 μmol/L), or their combinations. The lower chamber was filled with DMEM and 10% FCS as the chemoattractant and incubated for 48 h. The upper surface was then wiped with a cotton swab to remove the remaining cells. The cells which invaded the Matrigel and attached to the lower surface of the filter were fixed and stained with 1% crystal violet solution. The cells in the reverse side were photographed (5 microscopic fields at 100 × magnification per chamber). The cells in the photographs were then counted, and the data were summarized as mean ± SD and presented as a percentage of the controls (mean ± SD). The data were then analyzed statistically using the Student's *t* test.

Protein extraction and Western blotting

The cells were grown and treated with or without the drugs for 2 d. After that, total cellular protein was extracted as described previously[5,6,13,22-25]. Samples containing 50 μg of protein from each treatment were then separated by 10%-14% on sodium dodecyl sulfate-polyacrylamide gel electrophoresis gels and transferred electrophoretically to a Hybond-C nitrocellulose membrane (GE-Healthcare, Arlington Heights, IL, United States) at 500 mA for 2 h at 4 ℃. The membrane was subsequently stained with 0.5% Ponceau S containing 1% acetic acid to confirm that the proteins were loaded equally and to verify transfer efficiency. Next, the membranes were subjected to Western blotting by overnight incubation in a blocking solution containing 5% bovine skimmed milk and 0.1% Tween 20 in phosphate-buffered saline (PBS) at 4 ℃. The next day, the membranes were first incubated with primary antibodies and then with horse anti-mouse or goat anti-rabbit secondary antibodies (GE Healthcare) for enhanced chemiluminescence detection of antibody signals. The antibodies used were anti-Ki67 (Vector Laboratories, Burlingame, CA, United States), anti-phosphorylated Erk1/2 (Cell Signaling Technology, Danvers, MA, United States), anti-COX-2 (BD Transduction Laboratories, Lexington, KY, United States), and anti-β-actin (Sigma-Aldrich, St. Louis, MO, United States).

Animal experiments

An animal usage procedure was approved by our Institutional Animal Care and Usage protocol. Esophageal cancer SKGT-4 cells were grown and treated with or without these drugs for 3 d before injection (the doses were the same as above). Nu/nu nude mice (6-8 wk of age) were treated with or without curcumin (50 μg/kg per day), EGCG (50 μg/kg per day), lovastatin (50 μg/kg per day), and their combinations (the same doses used individually) orally for two days and then subcutaneously injected in the right flank through a 22-gauge needle with 2×10^6 tumor cells mixed with 50% Matrigel (BD Biosciences) for a total volume of 200 μL per mouse. The animals were then continuously treated with or without these drugs orally 5 d/wk for an additional 30 dand monitored for tumor formation and growth daily. The tumor mass volumes, measured weekly with a vernier caliper, were calculated as follows: length × width^2/2. At the end of the experiments, the tumor xenografts were taken excised, weighed and the results summarized.

Esophageal cancer tissue samples

Our institutional review board (IRB) approved our protocol for the use of patient tissue samples in this study, which included 156 consecutive patients with available paraffin blocks who had undergone esophagectomy without preoperative chemotherapy or radiotherapy between the years 1986 and 1997 at The University of Texas M.D. Anderson Cancer Center.

Immunohistochemistry

Human esophageal cancer tissue specimens and tumor xenografts from the nude mice were resected and subjected to tissue processing, these samples were embedded in paraffin and 4-μmol/L-thick sections were prepared for immunohistochemical analyses of Ki67, phosphorylated Erk1/2, and COX-2 expression. Briefly, the sections were de-paraffinized twice in xylene for 10 min each and rehydrated in a series of ethanol (100%-50%) and were then subjected to antigen retrieval by cooking in a pressure cooker with 0.01 mol/L citric buffer for 10 min and H_2O_2 treatment to eliminate endogenous tissue peroxidase activity. The tissue sections were then incubated with 100 μL of 20% normal horse or goat serum in PBS and anti-Ki67 (1:50), phosphorylated Erk1/2 (1:50), or COX-2 (1:50) diluted in PBS overnight. The next day, the sections were washed with PBS three times and once with PBS containing 0.1% Tween 20 and further incubated with a second antibody (Horse anti-mouse IgG or Goat-anti rabbit IgG from Vector, Laboratories) for 30 min. After washing with PBS, the sections were then incubated with ABC solution (Vector) in the dark for 30 min and 9-ethylcarbazol-3-amine buffer for 15 min for color development. The sections were counterstained with hematoxylin for 30 s, covered with a cover slip and then reviewed and scored under a microscope as positive or negative staining (10% or more tumor cells with positive staining were counted as positive staining).

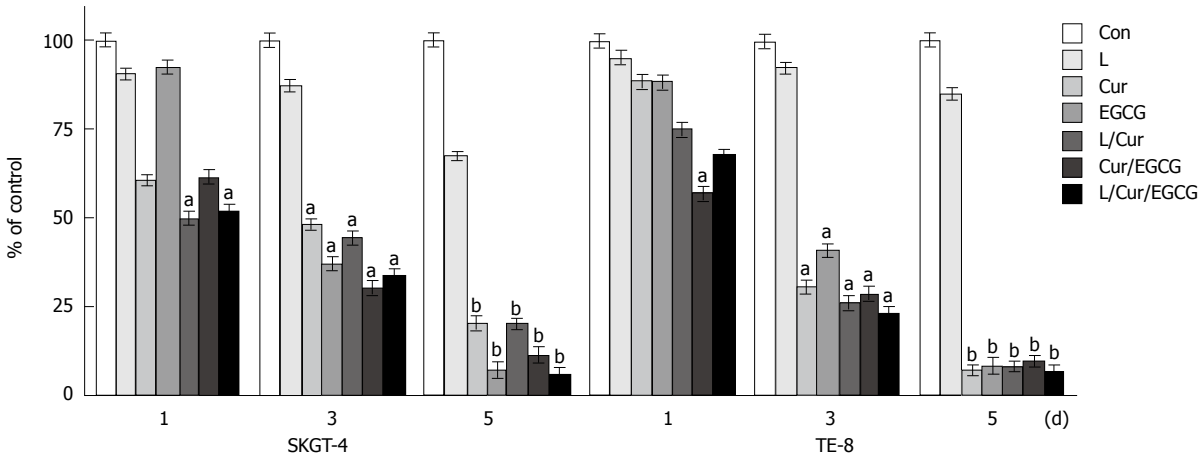

Figure 1 Suppression of esophageal cancer cell growth by curcumin, (-)-epigallocatechin-3-gallate, lovastatin and their combinations. Esophageal cancer SKGT-4 and TE-8 cells were grown in monolayer overnight and then treated with or without curcumin (Cur) (40 μmol/L), (-)-epigallocatechin-3-gallate (EGCG) (40 μmol/L), lovastatin (L) (4 μmol/L) and their combinations for up to 5 d. Methyl thiazolyl tetrazolium assays were then carried out to detect changes in cell viability (see Methods section). The experiments were repeated three times and the results are summarized as a % of the control (Con) (mean ± SD) and analyzed statistically using the Student's *t* test. $^{a}P < 0.05$, $^{b}P < 0.01$.

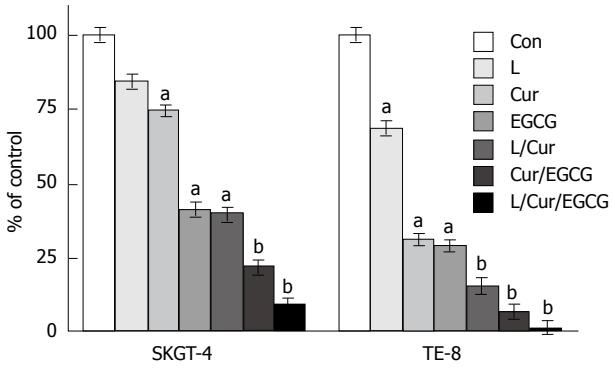

Figure 2 Suppression of tumor cell invasion by curcumin, (-)-epigallocatechin-3-gallate, lovastatin and their combinations. Esophageal cancer SKGT-4 and TE-8 cells were grown and treated with or without curcumin (Cur) (40 μmol/L), (-)-epigallocatechin-3-gallate (EGCG) (40 μmol/L), lovastatin (L) (4 μmol/L) and their combinations in monolayer for 3 d and then subjected to cell invasion assays in Boyden chambers containing Matrigel for 48 h. The invasive cells were stained with 1% crystal violet solution, counted and the results are summarized as a % of the control (Con) (mean ± SD). The data were then analyzed statistically using the Student's *t* test. $^{a}P < 0.05$, $^{b}P < 0.01$.

RESULTS

Reduction of tumor cell viability by curcumin, EGCG, lovastatin and their combinations

We first determined the effects of curcumin, EGCG and lovastatin individually and their combinations on the suppression of esophageal cancer cell growth by treating esophageal cancer TE-8 and SKGT-4 cell lines with two different doses (curcumin at 20 and 40 μmol/L, EGCG at 20 and 40 μmol/L, lovastatin at 2 and 4 μmol/L and these individual drug doses were used for combination treatments) for up to 5 d. The doses selected were based on previous studies[28-37]. Our data showed that lovastatin (4 μmol/L), curcumin (40 μmol/L), EGCG (40 μmol/L) and their combinations significantly reduced tumor cell viability (Figure 1).

Suppression of tumor cell invasion by curcumin, EGCG, lovastatin and their combinations

We next determined the effects of these three drugs on the regulation of esophageal cancer cell invasion capacity and found that lovastatin (4 μmol/L), curcumin (40 μmol/L), EGCG (40 μmol/L), and their combinations significantly reduced tumor cell invasion (Figure 2).

Modulation of gene expression by curcumin, EGCG, lovastatin and their combinations

We then assessed the regulation of gene expression by these three drugs and found that lovastatin (4 μmol/L), curcumin (40 μmol/L), EGCG (40 μmol/L) and their combinations downregulated the expression of p-Erk1/2, c-Jun and COX-2, but upregulated activated caspase 3 expression in esophageal cancer SKGT-4 and TE-8 cells (Figure 3).

Suppression of tumor growth in nude mouse xenografts by curcumin, EGCG, lovastatin and their combinations

We then performed nude mouse xenograft assays of SKGT-8 cells to determine the effects of the drugs individually and their combinations. We found that lovastatin (50 μg/kg per day), curcumin (50 μg/kg per day), EGCG (50 μg/kg per day) and their combinations at the same doses inhibited tumor growth differently (Figure 4). Treatment with a single drug such as curcumin or lovastatin did not have any effects on tumor formation and growth (Figure 4), although these drugs individually and in combination inhibited expression of Ki67, p-Erk1/2 and COX-2 expression in xenograft tissues (Figure 5).

Expression of phosphorylated Erk1/2 and COX-2 in esophageal cancer tissue specimens

To determine the relevance of p-Erk1/2 and COX-2 expression in human esophageal cancer, we analyzed their expression in esophageal cancer tissue specimens

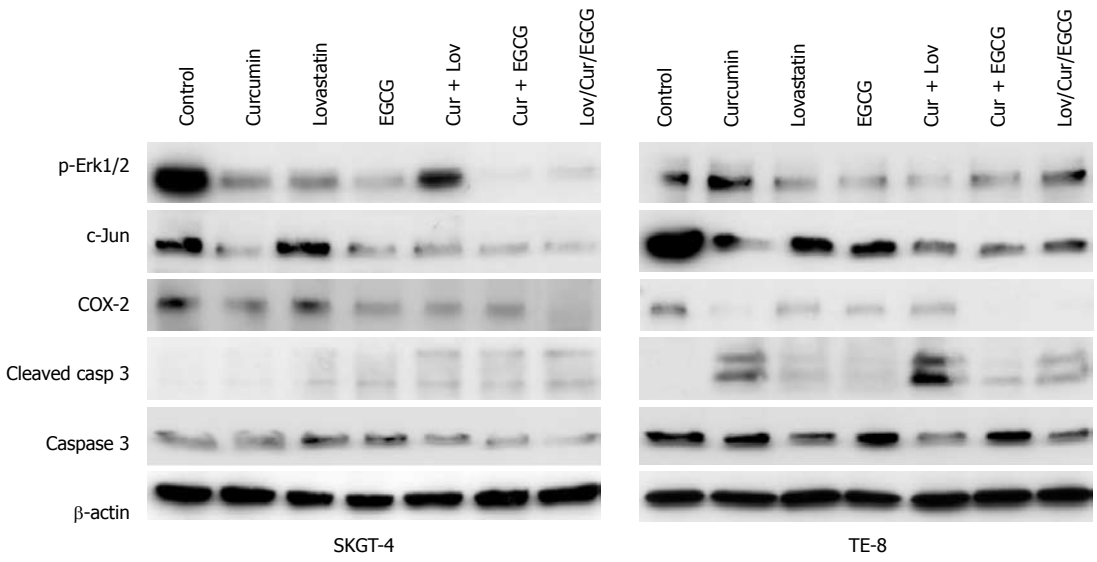

Figure 3 Modulation of gene expression by curcumin, (-)-epigallocatechin-3-gallate, lovastatin and their combinations. Esophageal cancer SKGT-4 and TE-8 cells were grown in monolayer overnight and treated with or without curcumin (Cur) (40 μmol/L), (-)-epigallocatechin-3-gallate (EGCG) (40 μmol/L), lovastatin (Lov) (4 μmol/L) and their combinations for 2 d and total cellular protein was extracted from the cells and subjected to Western blotting analysis of gene expression. Erk1/2: Extracellular-signal-regulated kinases; COX-2: Cyclooxygenase-2.

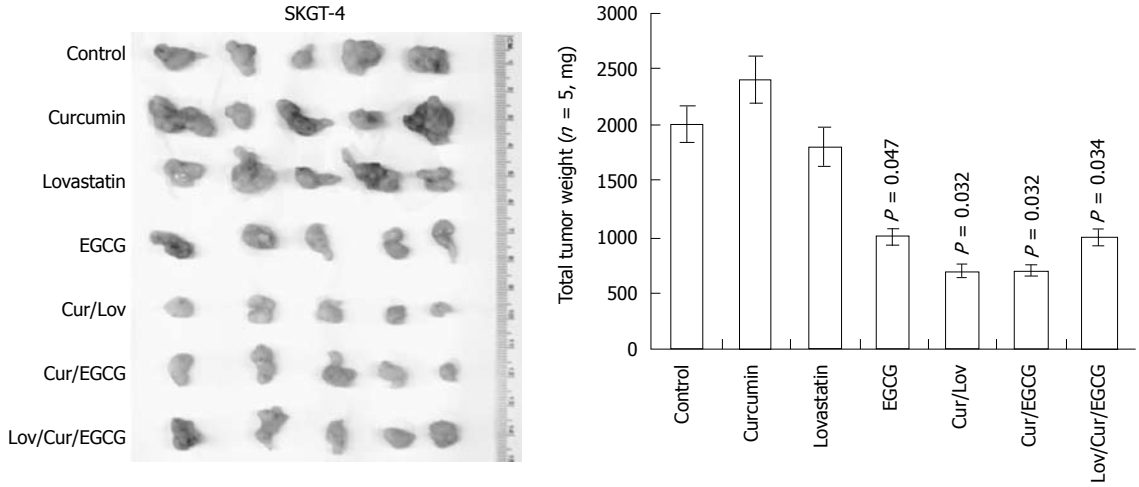

Figure 4 Inhibition of esophageal cancer cell growth by curcumin, (-)-epigallocatechin-3-gallate, lovastatin and their combinations in nude mouse xenografts. Esophageal adenocarcinoma SKGT-4 cells were inoculated subcutaneously into nude mice (5 per group). Two days before tumor cell injection, the mice started treatment with or without curcumin (Cur) (50 μg/kg per day), (-)-epigallocatechin-3-gallate (EGCG) (50 μg/kg per day), lovastatin (Lov) (50 μg/kg per day) and their combinations (the same doses as given individually) for 30 d (5 d/wk by oral gavage). At the end of the experiments, the xenograft tumor mass was isolated and weighed and summarized.

using immunohistochemistry. We found that 77 of 156 (49.4%) tumors expressed phosphorylated Erk1/2 and that 121 of 156 (77.6%) esophageal cancers expressed COX-2 protein. In particular, phosphorylated Erk1/2 was expressed in 23 of 50 (46%) esophageal squamous cell carcinoma (SCC) and in 54 of 106 (50.9%) adenocarcinoma, while COX-2 was expressed in 39 of 50 (78%) esophageal SCC and in 82 of 106 (77.4%) esophageal adenocarcinoma (Figure 6).

DISCUSSION

In the current study, we demonstrated that curcumin, EGCG, lovastatin, and their combinations can significantly reduce the viability and invasion capacity of esophageal cancer cells *in vitro*. Nevertheless, they were much less effective *in vivo* in nude mouse xenografts, especially curcumin and lovastatin individually. At the molecular level, these three agents individually or in combination inhibited the expression of phosphorylated Erk1/2, c-Jun, and COX-2 and induced caspase 3 expression in esophageal cancer cells *in vitro*. In nude mouse xenografts, the expression of p-Erk1/2 and COX-2 was downregulated by these three drugs, especially their combinations. We also analyzed the expression of phosphorylated Erk1/2 and COX-2 in tissue

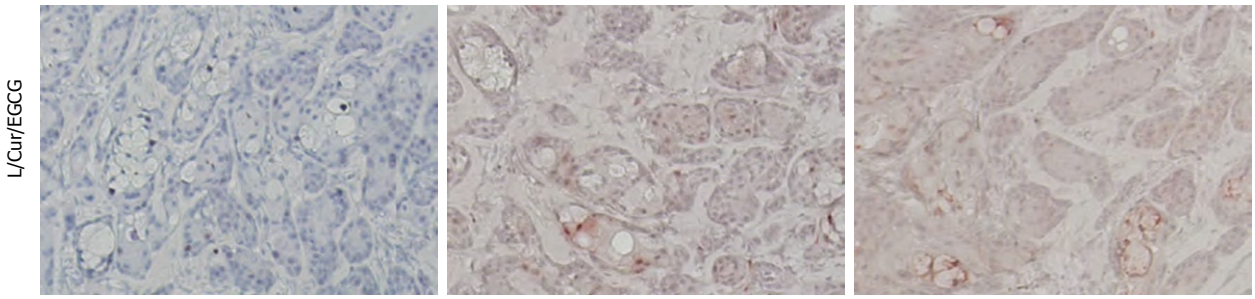

Figure 5 Reduced expression of Ki67, phosphorylated extracellular-signal-regulated kinases and cyclooxygenase-2 in xenografts following treatment of mice with or without curcumin, (-)-epigallocatechin-3-gallate, lovastatin and their combinations. Tumor cell xenografts obtained from the nude mouse experiments were processed and subjected to immunohistochemical analyses of Ki67, phosphorylated extracellular-signal-regulated kinases (Erk1/2) and cyclooxygenase-2 (COX-2) expression. Representative images were obtained in each treatment group. EGCG: (-)-epigallocatechin-3-gallate; L: Lovastatin; Cur: Curcumin.

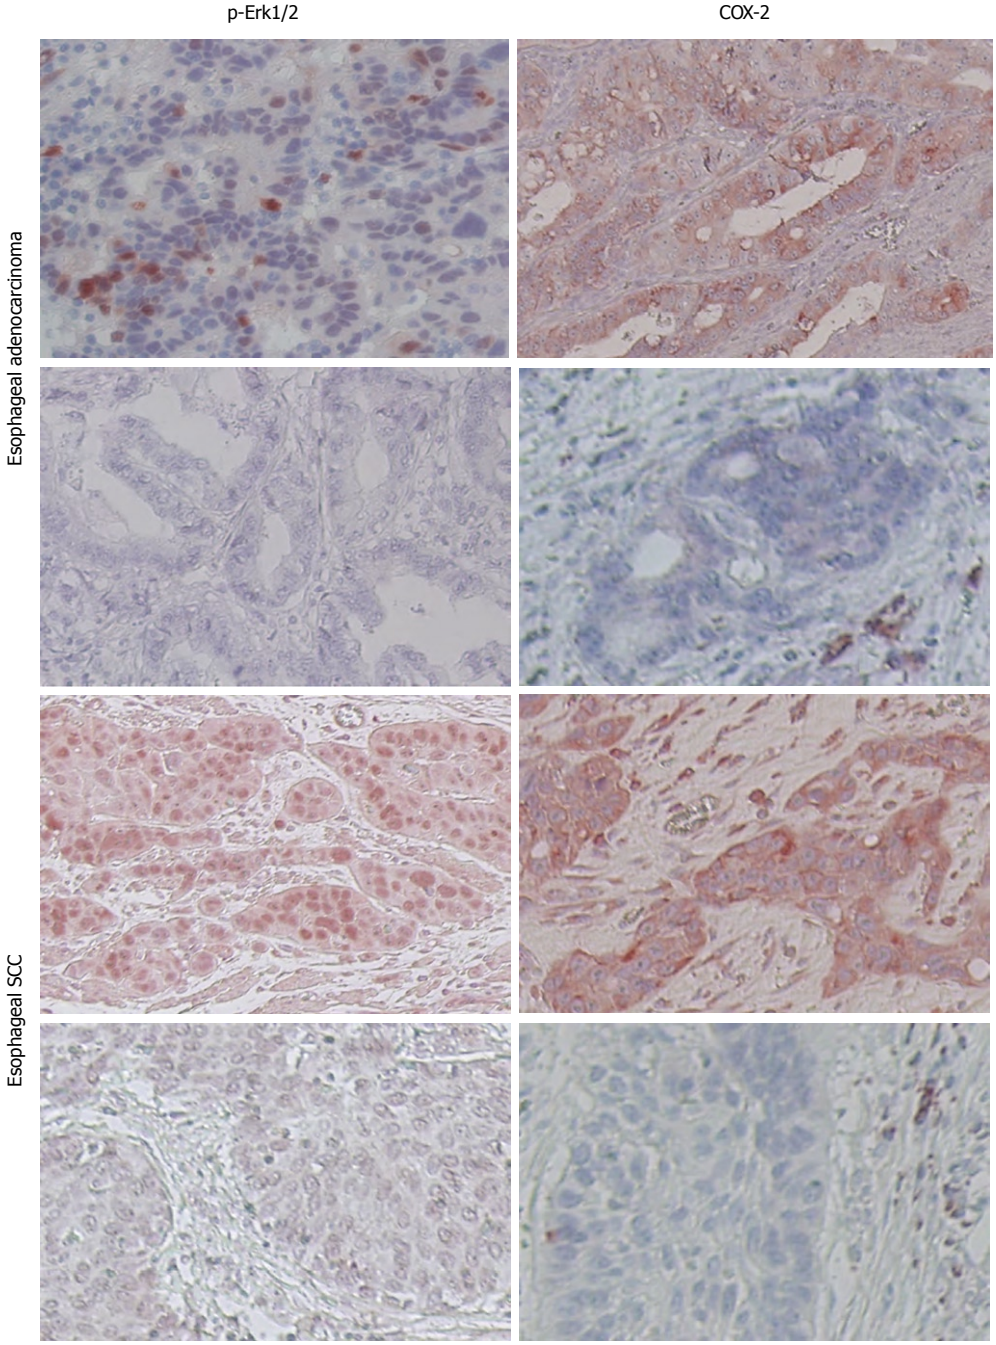

Figure 6 Expression of phosphorylated extracellular-signal-regulated kinases and cyclooxygenase-2 in esophageal cancer specimens. Paraffin sections of esophageal cancer tissues were immunostained with anti-phosphorylated extracellular-signal-regulated kinases (Erk1/2) or cyclooxygenase-2 (COX-2) antibody. Representative images were obtained from these tissue sections. SCC: Squamous cell carcinoma.

specimens from esophageal cancer patients. The data showed that 49.4% of esophageal cancers expressed phosphorylated Erk1/2 and that 77.6% of cancers expressed COX-2 protein. These data suggest that curcumin, EGCG, and lovastatin inhibit esophageal cancer cell growth *in vitro* and in nude mouse xenografts possibly through the suppression of phosphorylated Erk1/2, c-Jun and COX-2 expression.

Previous studies have shown the chemopreventive activity of EGCG in suppressing carcinogenesis in several organs, including the esophagus[29,34]. Molecularly, EGCG can suppress the mitotic signal transduction pathway, e.g., inhibit Erk1/2 phosphorylation and anti-AP-1 activity[38]. A recent study demonstrated that EGCG induced a concentration- and time-dependent reversal of hypermethylation of RAR-β2 in esophageal cancer cell lines, resulting in re-expression of RAR-β2[33]. Furthermore, curcumin has been shown to inhibit different cancers at the initiation, promotion, and progression stages in animal models[31,32,38]. Curcumin also suppressed growth and induced apoptosis in numerous types of cancer cells *in vitro*[38,39]. Although the defined mechanisms of its action require further study, its efficacy appears to be related to the induction of glutathione and glutathione-S-transferase activity, inhibition of lipid peroxidation and arachidonic acid metabolism, and suppression of oxidative DNA adduct formation[32,38,39]. Curcumin can inhibit the activation of NF-κB and the expression of c-Jun, c-Fos, c-Myc, Erk1/2, COX-2, PI3K, Akt, CDKs, and iNOS[31,35,38,39]. Curcumin was also able to suppress cigarette smoke-induced NF-κB activation and COX-2 expression in head and neck SCC and non-small-cell lung cancer cells[31,32]. In esophageal cancer, dietary curcumin can inhibit chemically-induced esophageal carcinogenesis in mice and rats[28,40]. In addition, the statin family of drugs has shown cancer chemopreventive effects[41]. Statins can trigger some tumor cells to undergo apoptosis *in vitro* and suppress tumor growth *in vivo*[30,37,41]. Statins also have an antimetastatic property, which is evident in their suppression of tumor cells invasiveness in Matrigel, as well as in animal experiments[42]. In addition, statins, especially at high concentrations, can inhibit capillary tube formation by endothelial cells *in vitro* and *in vivo*[35,44]. The effects of statins are thought to be mediated through inhibition of Ras and RhoA activity[41]. Based on these previous studies and reports, we determined the effects of their combinations on suppression of esophageal cancer cell growth *in vitro* and in nude mouse xenografts by targeting the RAR-β2/Erk1/2/AP1/COX-2 pathway[3]. Indeed, our current study has demonstrated the effects of their combinations *in vitro*. Molecularly, these three agents were able to regulate the expression of this gene pathway *in vitro* and *in vivo* in nude mice. Nevertheless, individually curcumin and lovastatin had no effect on tumor formation and growth in nude mice, even when the highest dose possible was used. This may be due to the bioavailability of curcumin and the induction of COX-2 expression by high dose lovastatin, reported previously[30,39]. However, the current study did not show the induction of COX-2 expression by high dose lovastatin in esophageal cancer *in vitro* and in nude mice, similar to that seen in prostate cancer[30].

However, there are some limitations in the current study. Firstly, we showed that these three drugs regulated gene expression of the RAR-β2/Erk1/2/AP1/COX-2 pathway, however, previous studies also showed that as chemoprevention agents, these drugs target multiple genes and their pathways in different cancers. Thus, further study is needed to determine the mechanisms of action of these drugs in human cancers. Furthermore, we used established esophageal cancer cell lines to determine the chemopreventive effects of these agents in this study, the results of which may be quite different in comparison to those in premalignant cells *in vivo*. The xenograft assay tested the effects of these agents in suppressing tumor initiation and growth, but not tumor development per se, although the xenograft assay did test the bioavailability of these agents *in vivo*. In addition, we did not test whether the doses of these three agents are clinically achievable, and to reduce costs, we utilized a single dose of each agent and their combinations. Thus, future studies are needed to test these agents in a clinical Phase I trial and in animal experiments where more doses and a time course study will be included.

COMMENTS

Background

Esophageal cancer remains a lethal disease, and is the least studied cancer in the United States. The overall 5-year survival rate for esophageal cancer is only 10%-15%, while the incidence of esophageal adenocarcinoma has significantly increased in the United States and other Western countries. These data indicate an urgent need for the development of novel strategies for prevention, early detection and management of esophageal cancer

Research frontiers

The authors found that the combination of curcumin, (-)-epigallocatechin-3-gallate and lovastatin was able to suppress esophageal cancer cell growth *in vitro* and in nude mouse xenografts.

Innovations and breakthroughs

These three agents inhibited phosphorylated Erk1/2, c-Jun and COX-2 expression.

Applications

Further clinical trials using these agents are warranted.

Peer review

This is the first report of the effects of combining these agents on esophageal cancer cells. The data suggest that these agents might be used individually or in combination for chemoprevention of esophageal cancer. Overall, the study is well designed and the data are convincing.

Abstract

AIM: To develop orthotopic gastric cancer mouse models from different cell lines and characterize the tumor features to assist further in preclinical trials and clinical treatment strategies.

METHODS: Human gastric cancer SGC-7901 and BGC-823 cell suspensions were injected subcutaneously into nude mice to develop solid tumors, and tumor tissue pieces were then implanted under the serous coat of the stomach. An autopsy was performed on all animals of the SGC-7901 and BGC-823 models to observe the primary tumor growth and metastases using pathological and immunohistochemical methods.

RESULTS: Both models showed large tumors *in situ* resulting in pressure and infiltration of the adjacent organs. The gastric cavity became smaller, along with stenosis of the cardia or pylorus. There were biological and statistical differences between the two models. The metastasis rate in involved organs (lymph nodes, kidney, spleen, testis) was significantly higher in the BGC-823 model compared to the SGC-7901 model ($P < 0.05$ or $P < 0.01$). The median survival of the BGC-823 model was shorter than that of SGC-7901 (23 d *vs* 84 d, $P < 0.05$). Histopathologically, the primary tumor and metastatic lesions of the two models showed obvious atypia and mucus in the cytoplasm. Compared with the SGC-7901 model, BGC-823 appeared more poorly differentiated (absence of adenoid structure), had a smaller volume, and richer capillary structure. Immunohistochemical staining revealed cytokeratin 20 and epithelial membrane antigen expression was positive in the SGC-7901 tumors, while negative in BGC-823 ones.

CONCLUSION: Models using the SGC-7901 and BGC-823 cell lines were established which could function in gastric cancer research on carcinogenesis mechanism and drug discovery. The two models showed different tumor behavior and the latter was more malignant than the former.

Key words: Gastric cancer; Orthotopic implantation; Mouse model; Metastasis; Cell line

INTRODUCTION

Gastric cancer is still the second most common malignant tumor in the world, and patients with gastric cancer generally have metastasis when clinically examined. There is a low five-year survival rate and poor quality of life even after tumor resection. We need to develop animal models of gastric cancer for exploring the mechanisms of carcinogenesis and clinical treatment strategy. Since the 1990s, orthotopic implantation techniques have gained popularity in establishing animal models of various tumors[1-4]. Many researchers have constructed orthotopic models of gastric cancer with different methods[5-11]. Of these methods, orthotopic transplantation using tumor pieces is useful because it not only simulates clinical cancer behavior but also promotes metastasis[12]. In the past, researchers mainly employed the "sewing" method to develop stomach cancer models[6,13]. However, there are disadvantages; such as a difficult operation, a time-consuming process, and low survival rates, and the sewing technique is not commonly used. In recent years, the procedure has been improved using tissue adhesive adhering to tumor pieces, which greatly facilitates surgical performance and decreases the mortality rate resulting from surgical operation[5,14]. Based on previous research, we intended to develop gastric cancer models from the SGC-7901 and BGC-823 cell lines and observe their biological characteristics to aid preclinical trials and therapy strategies. The human gastric cell line SGC-7901 was first established from the metastatic lymph node of a 56-year-old female patient suffering gastric adenocarcinoma. The BGC-823 cell line was derived from a specimen from a male patient who was 62 years of age, which was conserved in the Tumor Institute of Tianjin in China. The two gastric cell lines are poorly differentiated. This is the first time that a gastric cancer model of BGC-823 cell line was orthotopically constructed with histological tumor tissue *via* the "adhering" method.

MATERIALS AND METHODS

Cell lines

Human gastric cancer cell lines SGC-7901 and BGC-823 were used for this study. The cells were purchased from the Centre of Cell Cultures of Chinese Academy of Medical Sciences, Shanghai, China, and cultured at 37 ℃ in a humidified atmosphere with 5% CO_2, in RPMI-1640 medium (Gibco, Grand Island, NY) supplemented with 10% fetal calf serum (FCS; Gibco, Grand Island, NY), 100 U/mL penicillin, 100 μg/mL streptomycin, 2 mmol/L glutamine and 1 mmol/L sodium pyruvate. Cells were maintained by serial passaging after trypsinization with 0.1% trypsin.

Animals

Five- to six-week-old male Balb/c nu-nu mice (weight 18-20 g) were obtained from the Shanghai Experimental Animal Center of the Chinese Academy of Medical Sciences, China. They were kept in cages in a pathogen-free environment (temperature 25 ℃-27 ℃, humidity 45%-50%) and supplied with food and water *ad libitum*. All animal experiments were approved by the ethical committee of the Chongqing Medical University, and conformed to National and International Policies on Human Care and Use of Laboratory Animals.

Subcutaneous tumor specimens

Subcutaneous tumors were grown and then tumor tissue pieces used in surgical orthotopic implantation (SOI). Two cell lines were collected in the log phase and injected subcutaneously at 10^7/0.2 mL into the bilateral croup of Balb/c nu-nu mice. After 2 wk, the resulting tumors from the croup were harvested under strict aseptic conditions following removal of necrotic tissue from the central tumor areas, and cut into small pieces of approximately 1 mm^3.

Orthotopic implantation of tumor fragments

Nude mice were divided into 2 groups of 12 animals each, and were explanted with tumor fragments[5] from the SCG-7901 and BGC-823 cell lines, respectively. All procedures were performed under anesthesia with Sumianxin Ⅱ (0.02 mL per animal; China Academy of Military Medical Science) at the benchtop. After a left-side upper abdominal incision was made, the stomach of the nude mouse was gently exteriorized. One small tissue pocket was prepared in the middle wall of the greater curvature using an ophthalmic scissor, and then one tumor piece was placed into the pocket following fixation with a drop of medical tissue adhesive (gifts from Shunkang Corporation of Biological Adhesive, Beijing, China). To avoid adhesion to adjacent normal tissue, the quantity of the tissue adhesive was strictly measured. The stomach was then returned to the peritoneal cavity, and the abdominal wall was closed with 4-0 absorbable sutures. The mice were given special care and fed in cages as usual after surgery.

Evaluation of tumor growth and metastasis

All mice of the two groups were closely observed. At time of death, an autopsy was carried out to examine the tumor growth. The volume of primary tumor was calculated by the following formula: $V = 0.4 \times ab^2$ (a: maximum diameter; b: minimum diameter)[15]. Primary tumor, lymph nodes (gastroepiploic plexus, hilus pulmonis and mesenterium), and other organs (liver, lung, kidney, testis, spleen, *etc.*) involving infiltration or metastasis were sampled. The sampled tissues were fixed in 10%

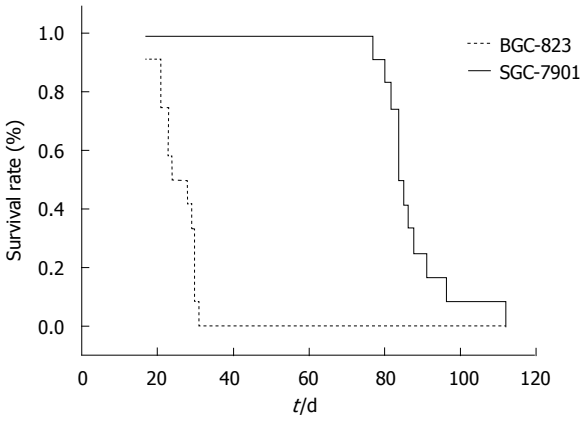

Figure 1 Survival curve of the SGC-7901 and BGC-823 gastric cancer models. The median survival in the BGC-823 model is significantly shorter than that in SGC-7901 (23 d *vs* 84 d, $P < 0.05$).

formalin, embedded in paraffin, sectioned to 3 μm thick, and stained with hematoxylin and eosin for microscopic examination. The ascitic fluid was centrifuged (1000 r, 5 min), and a cytologic smear was prepared for microscopic examination of malignant tumor cells.

Immunohistochemistry

The expression of cytokeratin (CK; High MW), cytokeratin 20 (CK-20) and epithelial membrane antigen (EMA) was studied by using mAbs 34βE12, KS20.8 and GP1.4 (MAB-0052, 0057, 0061; Maixin Inc., Fuzhou, China). An ultrasensitive SP kit (KIT-9710; Maixin Inc., Fuzhou, China) and a DAB kit (DAB-0031; Maixin Inc., Fuzhou, China) were employed according to the manufacturer's instructions. The expression of CK, CK-20 and EMA proteins was defined as positive if the stained area of tumor cells was predominant in their cytoplasm.

Statistical analysis

Data are presented as mean ± SD. The median survival was analyzed using the Wilcoxon Rank-Sum test. The volume of primary tumor was analyzed by the student *t* test. The incidence of metastasis in both groups was analyzed using Fisher exact test. Differences were judged statistically significant at a *P* value < 0.05.

RESULTS

The incidence of tumor growth and general condition

The tumor uptake rate after orthotopic implantation in both of the two groups was 100% (12/12). The median survival for the SGC-7901 and BGC-823 groups were 84 d and 23 d, respectively ($P < 0.05$, Figure 1). Mice of the SGC-7901 group had obvious cachexia (emaciation, retardation, ascites formation, *etc.*), whereas none of the BGC-823 group showed a decline in their general health.

Observation and evaluation of primary tumor growth

The average tumor volume of the BGC-823 group was 1.24 ± 0.73 cm^3, while it was 9.30 ± 3.62 cm^3 in the SGC-7901 group (Figure 2A and B). There was a statistical significance in the difference ($P < 0.05$, Figure 2C). In addition, observations of the primary tumor and related characteristics in the two groups are presented in Table 1 in detail.

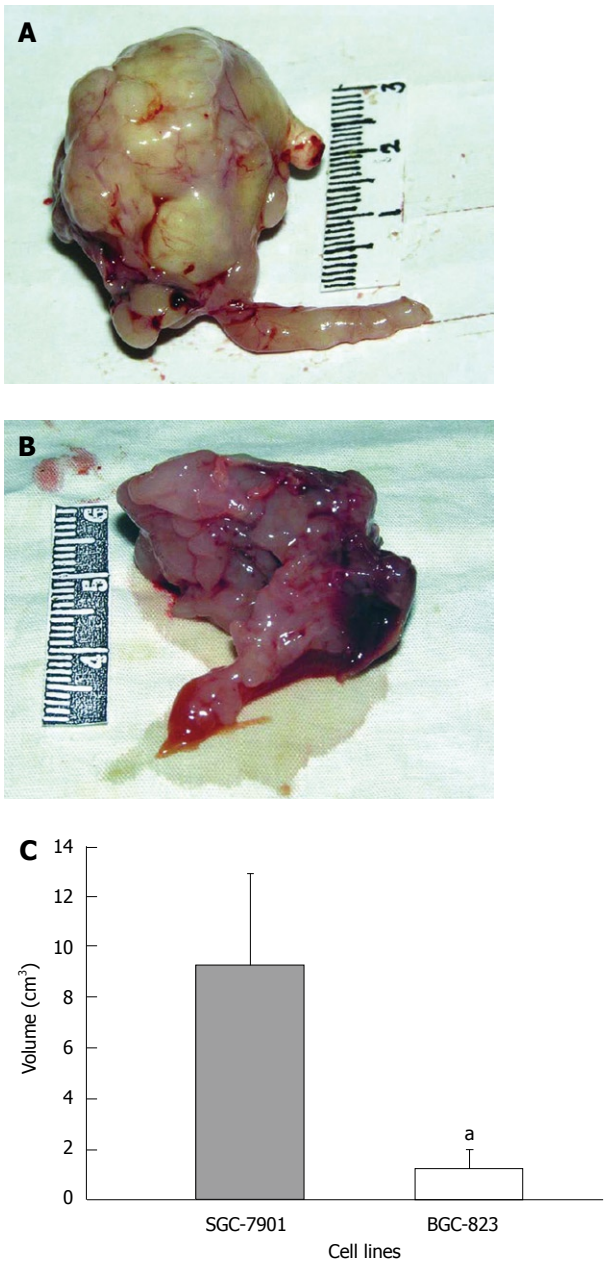

Figure 2 Macroscopic examination of the primary tumor in the two models. A: The tumor of SGC-7901 shows large volume (9.30 ± 3.62 cm^3), irregular lobular shape, and stenosis in the cardia or pylorus; B: The tumor volume of BGC-823 is 1.24 ± 0.73 cm^3, with irregular lobular appearance; C: Comparison of primary tumor volume in two models. The difference is statistically significant. $^aP < 0.05$, student *t* test.

Evaluation of metastases derived from orthotopic implantation tumors

Metastasis, which was always located in lymph nodes, liver, kidney, lung, peritoneum or diaphragm, occurred in both groups of gastric cancer models. Additionally, oth-

Table 1 Comparison of primary tumor and related characters in the two models

Items		SGC-7901 group	BGC-823 group
Primary tumor	Shape	Irregularly lobular	Irregularly lobular
	Color	Grayish yellow	Gray-white
	Texture	Stiffer	Softer
	Vascularity	Rich	Richer
Section of stomach tumor	Gastric cavity	Narrow or vanished	Narrow or vanished
	Greater and lesser curvature	Undistinguishable	Undistinguishable
	Pylorus	Partly or totally obstructed	Totally obstructed
Effects on adjacent organs	Abdominal cavity	Occupying whole abdomen	Occupying upper abdomen
	Adhering extent	Adhering to liver lobes	Adhering to many organs
	Compressed status	Severely compressed	Partly compressed
Ascites	Liquid quantity	Little	Much
	Property	Clear and yellowish	Bloody fluid

Table 2 Comparison of metastatic rates in models of SGC-7901 and BGC-823, *n*/*N* (%)

Groups	Site and incidence of metastasis						
	Lymph nodes[a]	Liver	Kidney[a]	Lung	Spleen[b]	Testicle[a]	Peritoneum or septum
SGC-7901	7/12 (58)	10/12 (83)	5/12 (42)	1/12 (8)	0	0	10/12 (83)
BGC-823	12/12 (100)	12/12 (100)	10/12 (83)	5/12 (42)	7/12 (58)	5/12 (42)	12/12 (100)

[a]$P < 0.05$, [b]$P < 0.01$.

er organs (spleen and testicle) were also found to have metastatic lesions in the BGC-823 group. The incidence of metastasis from various organs in the BGC-823 group was higher than that in the SGC-7901 group, and these differences (except for liver, lung, peritoneum or diaphragm) were considered statistically significant ($P < 0.05$ or $P < 0.01$, Table 2).

Histology

The two groups differed in histological appearance of subcutaneous tumor samples, though the cell lines forming tumors were both poorly differentiated adenocarcinomas. In the SGC-7901 group, tumor cells spread with nest-like structures, characterized by nuclear polymorphism, nuclear hyperchromatism, many red nucleoli, and rich pathological karyokinesis. Mucus was observed in the cytoplasm of part of the tumor cells which resulted in mucus lakes, and adenoid structures and rich blood vessels formed in tumor areas. In the BGC-823 group, histopathologic examination confirmed a different phenotype of the BGC-823 tumor compared to the SGC-7901 tumor. The tumor cells mostly showed medullary growth with characteristics of ample cells, fewer fibroblasts, and rich vascularity. The neoplasm revealed the signs of undifferentiated structure, small size, nuclear hyperchromatism, and rich pathological karyokinesis. Mucus was found in the cytoplasm of part of the neoplastic cells, but there was an absence of glandular differentiation.

Both primary tumors and metastases, whose tumor cells were microscopically identical to the subcutaneous tumor, of the two group models showed similarity in histopathologic characteristics. The stomach cancer of the two models infiltrated the various layers of gastric wall with disruption of the integrity of the mucous layer or muscularis mucosae (Figure 3A and B). Widespread infiltration of tumor cells was found in the subcapsular, the cortical and medullary areas of lymph nodes, while extension into the medullary parts the lymph sinus was diminished (Figure 3C). In some of the lymph nodes, the nodal parenchyma was even totally replaced by neoplastic tumor. Metastases were detected in the liver (Figure 3D) and the kidney (Figure 3E) with nest-like structures or a glandular appearance, occasionally in the adrenal gland or pancreas (not shown). Metastatic lesions were always separated from adjacent normal tissue by fibrous capsules, and lymphoid infiltration in peripheral tumor areas was also seen. Tumors metastasized to the lung and destroyed bronchi or bronchioles (Figure 3F). In addition, local invasion was observed within the abdominal muscle or diaphragmatic muscle. Organs such as the spleen and the testicle (Figure 3G and H) were not spared in the BGC-823 models. Histological examination revealed that the spleen parenchyma was infiltrated and the seminiferous tubules of the testis or ductus epididymidis, and the prostate, were invaded by the metastatic tumor.

Smears of cast-off cells from ascites in both groups confirmed that the malignant cells originated from the primary adenocarcinoma (not shown).

Immunohistochemistry analysis

The expression of CK-20 and EMA protein was positive within the primary tumor and metastases in the SGC-7901 group, whereas CK expression was negative in the same tissues (Figure 4). In the BGC-823 group, CK, CK-20 and EMA immunostaining were negative.

DISCUSSION

The purpose of our study was to develop gastric cancer models from different cell lines with intact tumor

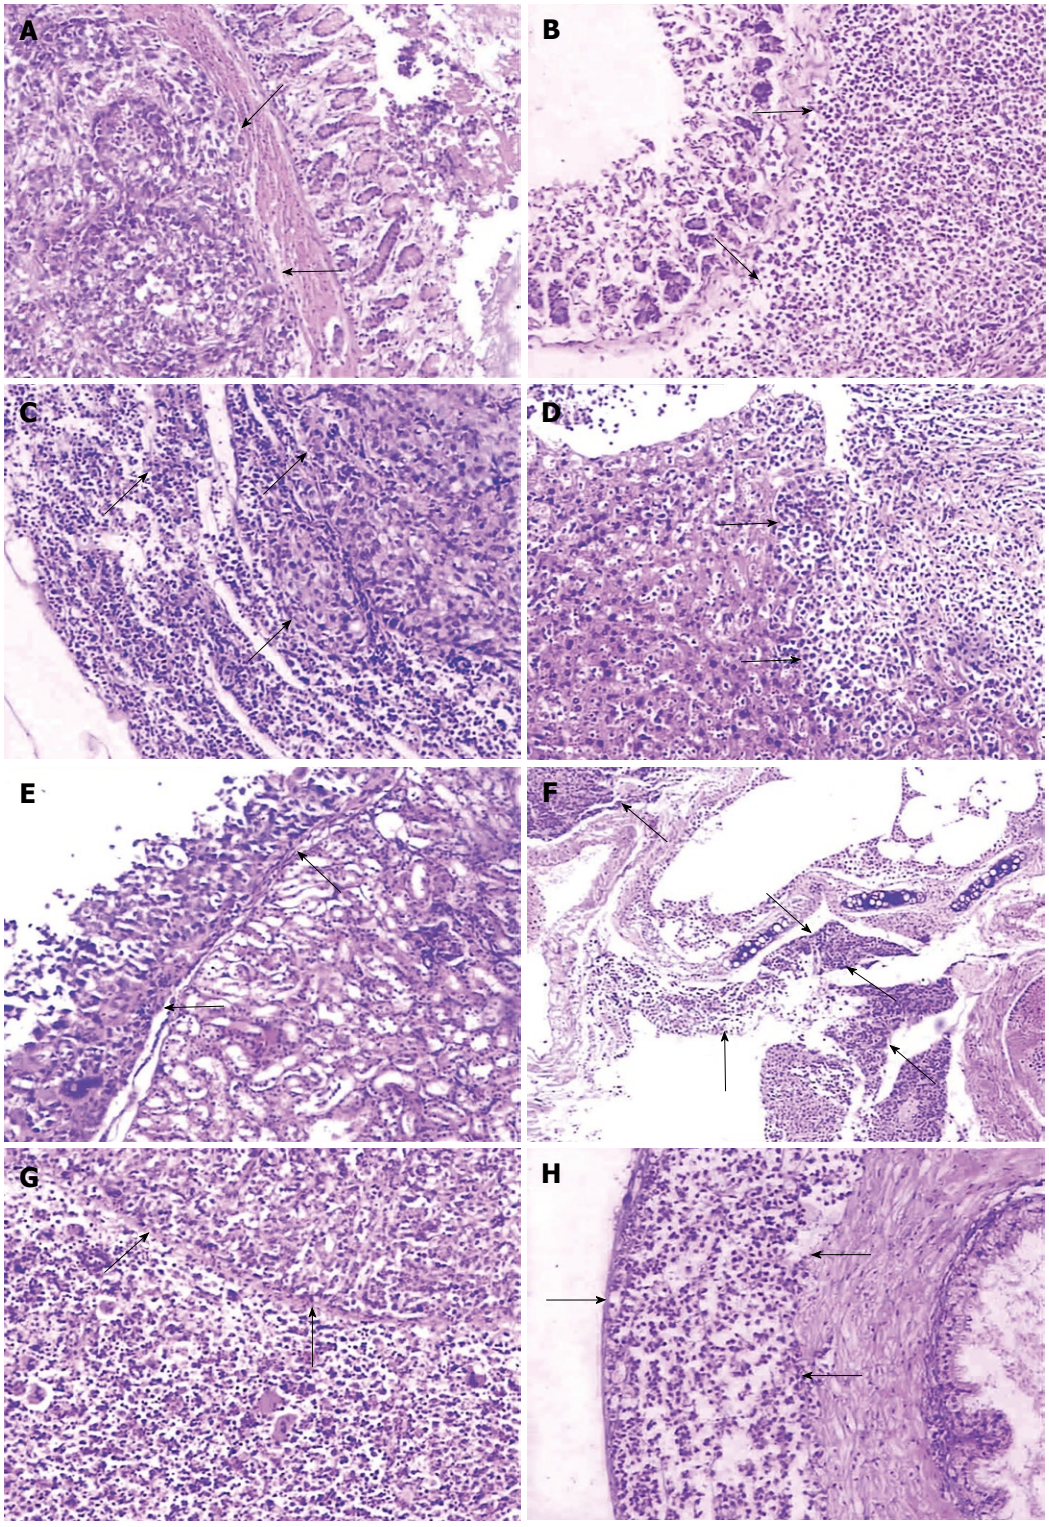

Figure 3 Histology of the primary tumor and metastasis in the two models by hematoxylin and eosin staining. The tumor cells of the SGC-7901 (A) and the BGC-823 (B) model infiltrate the submucosa of the stomach; C: Tumor cells (arrows) are found in the subcapsular and cortical areas of lymph node of the SGC-7901 model; D: Metastases (arrows) detected in the liver of the BGC-823 model; E: Tumor invades into the kidney of the SGC-7901 model, with a fibrous capsule surrounding relatively normal renal tissue (arrows); F: Tumor metastasizes to the lung and surrounds the bronchium in the BGC-823 model; Other organs (G: Spleen; H: Testicle) with metastasis involvement in the BGC-823 model. Tumors are marked with arrows. Hematoxylin and eosin stain; Magnification, × 100.

pieces orthotopically implanted into the stomach wall by tissue glue adhesion. In the present study, we could replicate similar results of the SCG-7901 orthotopic models which have been established by other researchers in China. This is the first time that an animal model has been created from the BGC-823 gastric cancer cell line with SOI of tumor tissue.

Interestingly, we find the two models reveal signifi-

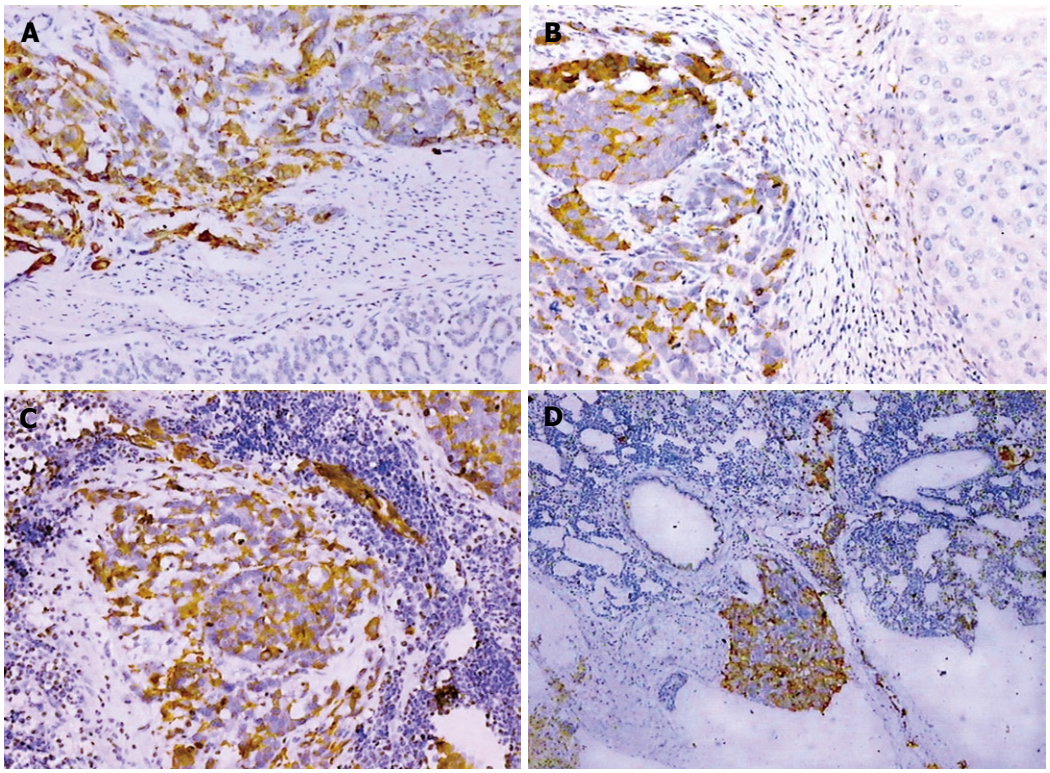

Figure 4 Immunohistochemistry of primary tumor and metastasis in the SGC-7901 model using the self-potential method. Cytokeratin 20 (A: Stomach; B: Liver) and epithelial membrane antigen expression (C: Lymph node; D: Lung) shows as positive, characterized by the brown-yellow stain in the cytoplasm. Visualized by using DAB reagent; Magnification, × 100.

cant differences in biological behavior. It has been reported that heterogeneity resulting from differences of histopathological type, grade, and individual factors reside in different tumor cell lines[5,16]. Thus, animal models derived from different tumor cell lines present different characteristics. Bhargava *et al*[5] orthotopically established gastric cancer models in two sites of the stomach using tumor fragments from three cell lines of differently differentiated extent. The findings showed that the tumor uptake rate and metastases were all different among the three cell lines, between two sites, and at various time points. Fujihara *et al*[13] developed a gastric cancer cell line subtype named OCUM-2M LN, characterized by high incidence of lymph node metastasis, which was obtained from the OCUM-2M cell line by serial passage selection in animals. The ability to metastasize to lymph nodes in subtype OCUM-2M LN was significantly higher than that in parental cell line OCUM-2M. In keeping with these authors above, we also found that heterogeneity among different cell lines contributed to differences of tumor behavior in both gastric cancer models.

Histopathological characteristics of malignant neoplasms were reflected in both cancer models, characterized by neoplastic atypia of varying degrees, and rich blood vessels promoting tumor growth and metastasis. However, the two types of tumor showed differences in pathologic phenotype. The SGC-7901 tumors showed nest-like structures and glandular differentiation, while the BGC-823 tumors presented medullary structures and no adenoid differentiation, which might be explained by the fact that the BGC-823 cell line develops variation and partly changed neoplastic properties during passage[9,13]. Microscopically, mucous secretion in both types of tumor cells, especially in the SGC-7901 tumor, was consistent with the characteristics of mucous adenocarcinoma. Meanwhile, the negative result of CK expression in the two models also excluded the differentiation of squamous carcinoma. The expression of CK-20 and EMA by immunohistochemical staining was positive in the SGC-7901 tumors, but negative in BGC-823. Histopathology and immunohistochemistry analysis all confirmed that the BGC-823 carcinoma had poorer differentiation than SGC-7901. In addition, all epithelial markers in BGC-823 tumors were negative which might suggest an epithelial-to-mesenchymal transition phase. We shall perform immunohistochemical staining with a mesenchymal marker, such as vimentin, to verify this presumption in our next experiments. It is reported that survival prognosis has close correlation with histopathologic grading of tumor[17-19]. The results in our study demonstrated that median survival course in the BGC-823 model was shorter than that in SGC-7901 ($P < 0.05$), which is compatible with histological examination.

Retrospective studies have suggested that there is correlation between tumor volume size and lymph node metastasis or five-year survival[19-22]. In our experimental results, the original tumor in both models presented a large-volume lesion invading adjacent organs and

destroying the stomach cavity. There is no theoretical significance regarding difference of the tumor volume in the SGC-7901 and BGC-823 groups, though the former is obviously larger than the latter ($P < 0.05$) mainly resulting from the different course of primary tumor growth. However, the SGC-7901 tumor texture was harder than that of BGC-823, which was possibly linked with rich stromal component in the former but ample tumor cells and rich blood vessels in the latter. Angiogenesis is a prerequisite for metastatic spread[15,23], which also explains why vascular metastasis is a frequent occurrence in the BGC-823 model.

Metastasis is not only linked with the prognosis of patients but also the dilemma of cancer therapy. In the field of experimental research, metastatic events are assumed to cover the factors of the anatomic site of implantation[12,13,24,25] or status (suspension or fragment) of tumor sample used in implantation[10,23]. Orthotopic transplantation in animal models of various cancers has played a key role in mimicking the clinical tumor behavior[5,23,24]. There has been variable success at achieving good tumor uptake rate and metastatic incidence with implantation procedures using suspension injections and tumor pieces[10,23]. Many studies indicate that the properties on the tumor cell surfaces are preserved by the implantation of tumor pieces, but destroyed after the cell suspensions have been treated by trypsinization resulting in changes of malignant character and further contributing to decline of tumor growth and metastatic rate[13,24]. In the present study, the models of orthotopic implantation into the gastric wall with intact tumor fragments showed not only high uptake rate but also metastasis through various pathways, which was consistent with the previous research. It is well known that the general metastasis in terminal patients with gastric cancer mainly involves direct infiltration, lymphatic metastasis, vascular spread, and implantation dissemination. The aggressive behavior in the two model groups resembles clinical patients suffering from gastric cancer. In the SGC-7901 group, direct infiltration and lymphatic metastasis were frequently observed. However, multiple steps were assumed to be involved in the metastases of the BGC-823 group. In BGC-823 models, we could not identify the accurate pathway of metastasis through local invasion in the liver, kidney, spleen and testicle. The total involvement of multiple steps facilitating metastases requires further studies.

Compared with the SGC-7901 group, metastasis occurrence is earlier ($P < 0.05$), metastasis incidence in different organs higher ($P < 0.05$), and the number of involved organs greater in the BGC-823 group. The deaths in the SGC-7901 group were considered as multi-organ failure caused by cachexia, while the BGC-823 mice mostly died of early metastases and high metastatic rates without visible cachexia. Taken together, the results in our study demonstrate that the BGC-823 gastric cancer model is more aggressive than the SGC-7901 one with the support of the comprehensive factors discussed above.

We have successfully developed two types of gastric cancer model with different tumor behavior by orthotopic implantation, which are characterized by advantages such as low cost and resemblance to clinical gastric cancer. The two models are both suitable for preclinical research on gastric cancer, and their different characteristics may aid with different needs of experimental research. Considering comprehensive factors, surgical orthotopic implantation is still a desirable technique compared with other methods of constructing gastric cancer models[26-29].

COMMENTS

Background

Gastric cancer is still the most common malignant tumor in the world, and detection is difficult before metastasis occurrence, so people need to develop animal models of gastric cancer for exploring the mechanisms of carcinogenesis and clinical treatment strategy. Gastric cancer models of orthotopic implantation with intact tumor tissue have been well established. Moreover, orthotopic implantation performance has been improved from the "sewing" method to the "adhering" one. SCG-7901 orthotopic models have been established by other researchers, whereas this is the first time that an animal model was created from the BGC-823 gastric cancer cell line with surgical orthotopic implantation of tumor tissue.

Research frontiers

Orthotopic implantation technique plays an important role in establishing an animal model of various tumors, including gastric cancer, which can not only simulate clinical cancer development but also facilitate metastasis occurrence. Moreover, the procedure of orthotopic implantation has been improved from the "sewing" method to the "adhering" one. The latter's performance has greatly simplified the surgical operation course. In addition, the BGC-823 gastric cancer model has not been constructed by others, and shows different tumor characteristics compares with the SCG-7901 model.

Innovations and breakthroughs

Orthotopic implantation with "glue paste technique" is a new, popular and convenient method used for the establishment of orthotopic animal models in recent years. The results regarding the BGC-823 gastric cancer model in this study are the first to be reported, and make it possible that researchers can learn the different biological characteristics of gastric cancer models from different cell lines.

Applications

Establishment of the BGC-823 gastric cancer model provides evidence for researchers to learn the biological differences between animal models from different gastric cancer cell lines, which can help them to choose an appropriate model to tailor their research.

Terminology

Surgical orthotopic implantation is defined as tumor cells in the form of suspension or fragments which are orthotopically implanted into the related organs.

Peer review

The study is aimed to develop gastric cancer models from different cell lines and analyze the difference of biological behavior in many aspects, in order to provide evidence for researchers to choose an appropriate experimental carrier and therapy target for clinical trials. The present research is valuable for clinical doctors and researchers.

Abstract

AIM: To assess B1a cell expression in the rectal mucosa of ulcerative colitis (UC) patients in comparison with healthy controls.

METHODS: Rectal mucosa biopsies were collected from 15 UC patients and 17 healthy controls. $CD5^+$ B cells were analysed by three colour flow cytometry from rectal mucosal samples after mechanical disaggregation by Medimachine®. Immunohistochemical analysis of B and T lymphocytes was also performed. Correlations between, on the one hand, rectal B1a cell concentrations and, on the other, erythrocyte sedimentation rate and C-reactive protein levels and clinical, endoscopic and histological disease activity indices were evaluated.

RESULTS: Rectal B-lymphocyte ($CD19^+/CD45^+$) rate and concentration were higher in UC patients compared with those in healthy controls (47.85% ± 3.12% *vs* 26.10% ± 3.40%, $P = 0.001$ and 501 ± 91 cells/mm^2 *vs* 117 ± 18 cells/mm^2, $P < 0.001$); Rectal B1a cell density ($CD5^+CD19^+$) was higher in UC patients than in healthy controls (85 ± 15 cells/mm^2 *vs* 31 ± 6.7 cells/mm^2, $P = 0.009$). Rectal B1a cell ($CD5/CD19^+$) rate correlated inversely with endoscopic classification (Rs = -0.637, $P < 0.05$).

CONCLUSION: B1a lymphocytes seem to be involved in the pathogenesis of UC, however, the role they play in its early phases and in disease activity, have yet to be defined.

Key words: B1 cell; CD5; Flow cytometry; Rectum; Ulcerative colitis

INTRODUCTION

The aetiology of ulcerative colitis (UC) is still unknown, but several studies have demonstrated that there is an abnormal immunologic response to gut antigens[1,2]. One

of the mechanisms which protects the body against intestinal luminal antigens before a specific aggressive inflammatory response is unleashed, is the production of natural antibodies, in particular immunoglobulin A (IgA)[3,4]. A large proportion of IgA is produced in a T-independent way by B cells and in particular, according to several studies, by the B1 sub-population. The majority of B1 cells, also called B1a, express CD5 on their surface. In a previous study[5] we reported that B1a cell ($CD5^+CD19^+$) blood concentrations were reduced in UC patients with respect to those in healthy controls, and that the B1a cell rate was inversely correlated with erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) levels in UC patients. The aim of the present study was to analyse the rate and concentration of B1a cells in the rectal mucosa of UC patients, to compare these values with those found in healthy controls, and to assess any possible correlation with disease activity.

MATERIALS AND METHODS

Patients

The study population consisted of 15 UC patients and 17 healthy controls. The study protocol was drafted in accordance with the Declaration of Helsinki and all of the patients and controls who participated signed informed consent statements. Patients taking immunosuppressive drugs or corticosteroids were excluded from the study.

The disease activity of the UC patients, undergoing ordinary follow-up colonoscopy, was classified in accordance with the Seo clinical score[6], the modified endoscopic Baron classification[7] and Geboes' histological scoring[8]. Subjects who underwent colonoscopy as a cancer screening procedure and whose result was negative, were enrolled as healthy controls.

Methods

Blood samples and 6 rectal mucosal biopsy specimens, taken 10-15 cm from the anal verge during colonoscopy, were collected from each patient.

Flow-cytometry

A cellular suspension, obtained by fragmentizing 4 rectal biopsies from each patient using a Medimachine (Consul TS, Rivalta di Torino, Italy), was used for flow cytometry. The method utilized was as follows: the collected rectal biopsies were placed in physiologic solution (Na 0.9%) and immediately processed. The biopsies were first washed twice with physiologic solution for 2 min each wash. Each biopsy was minced into < 1 mm^3 pieces which were placed in a sterile microblade-equipped polyethylene chamber (Medicons, BD Biosciences, San Jose, CA, United States) with 1 mL phosphate buffered saline (PBS) 0.01 mol/L. The Medicons contain an immobile stainless steel screen with 100 hexagonal holes, each surrounded by six microblades. When the Medicons are inserted into the Medimachine the tissue comes into contact with the blades by means of a rotating element

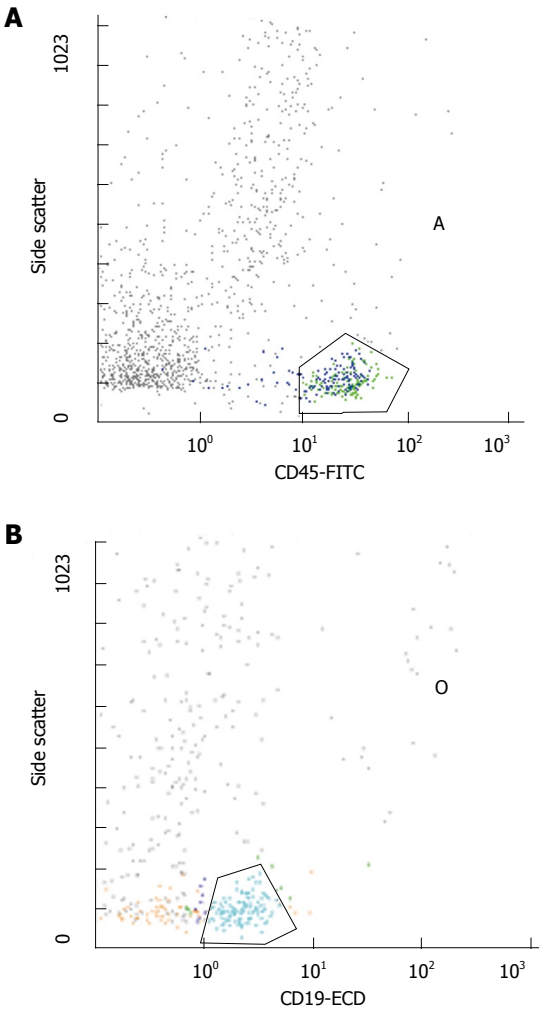

Figure 1 Flow cytometry. A: Immunologic gate for rectal $CD45^+$ cells; B: Immunologic gate for rectal $CD19^+$ cells.

and is disaggregated. A micropump positioned under the screen forces the liquid to pass through the bore-holes, ensuring that the bore-holes remain clean. Medicons with 35 μm separator screens were used.

Fragments were dissociated 4 times for 20 s at a constant speed of 100 r/min. The suspension was filtered using filters with 30 μm diameter holes (Flicons, BD Bioscences, San Jose, CA, United States) and then analysed by flow-cytometry (Figures 1 and 2).

A three-colour flow-cytometric analysis was performed using the following associations: CD45 fluorescein isothiocyanate (FITC), Isotype IgG1 (clone J.33, mouse) (Beckman Coulter Inc, Fullerton, CA, United States), CD5 RD-1 (phycoerythrin), Isotype IgG2a (clone SFCI24T6G12, mouse) (Beckman Coulter Inc.), CD19 ECD (Texas red), Isotype IgG1 (clone J4.119, mouse) (Beckman Coulter Inc.). Flow cytometry was performed as previously described[5].

All mAbs were used at optimal saturating concentrations as recommended by the manufacturers. The cells were washed in a FACS buffer containing PBS/5% FCS/0.05% and sodium azide, then incubated with 10 mg of human

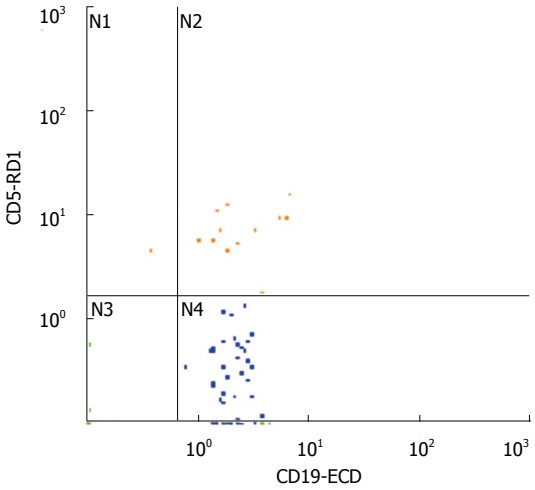

Figure 2 Flow cytometry. $CD5^+/CD19^+$ lymphocytes (B1a cells).

IgG (Sigma Chemical Co., St. Louis, MO, United States) for 30 min at 4 ℃-8 ℃ to block Fc receptors. Cells were washed to remove excess IgG and were triple-stained with either RD-1-conjugated mAb against CD5, or RD-1-control IgG mAb, ECD-conjugated mAb against CD19 or ECD-control IgG mAb and FITC-conjugated mAb against CD45 or FITC-control IgG mAb for 30 min at 4 ℃-8 ℃. Cells were washed twice, re-suspended in a FACS buffer and fixed with 1% paraformaldehyde. At that point, 2 mL of lysing solution (0.17 mol/L NH_4Cl) were added and following 15 min of incubation, samples were analyzed by flow cytometry using a Coulter EPICS XL-MCL (Beckman Coulter Inc). Mononuclear cells were gated depending on their CD45 expression characteristics. Different subsets of cells (CD19) were then gated on the basis of fluorescence 1 and fluorescence 2 staining. An immunologic gate was performed on $CD19^+$ cells to uncover CD5. Isotypic controls were used for all the samples. A two-colour flow cytometric analysis was similarly performed to study the T cells using anti-CD45 FITC mAb (Isotype IgG1, mouse, clone J.33, Beckman Coulter Inc.) and anti-CD3 Phycoerythrin-Cyanin 5 (Pc5) mAb (Isotype IgG1, mouse, clone UCHT 1, Beckman Coulter Inc.).

Immunohistochemistry

Two rectal biopsies from each patient studied underwent immunohistochemical analysis. Samples were fixed in 10% neutral buffered formalin, processed for embedding in paraffin wax, and cut into 5 μm-thick sections. Sections were dewaxed and rehydrated by routine protocols. For anti-CD3 immunohistochemistry, antigen unmasking was performed with 10 mmol/L sodium citrate buffer, pH 6.0, in a microwave oven at 96 ℃ for 30 min. Antigen unmasking was not necessary for anti-CD20 analysis. Sections were incubated in 0.3% hydrogen peroxide for 10 min at room temperature to remove endogenous peroxidase activity, and then in blocking serum for 30 min. Samples were incubated with primary antibodies at room temperature for 45 min. The primary antibodies used were: anti-CD3 (Polyclonal rabbit anti-Human, Dako, Milan, Italy) and anti-CD20 (Monoclonal mouse anti-human CD20cy, Dako) diluted 1:50 and 1:200, respectively. Sections were then washed three times in PBS for 5 min each wash, treated with secondary antibody (Envision System HRP, Dako) for 30 min at room temperature and developed in 3,3'-diaminobenzidine (DAB, Sigma-Aldrich, Milan, Italy). Finally, the sections were counterstained with hematoxylin.

Sections were examined using a Leica DM4500B microscope (Leica Microsystems, Wetzlar, Germany) connected to a Leica DFC320 high-resolution digital camera (Leica Microsystems) and a computer equipped with software for image acquisition and analysis (QWin, Leica Microsystems). The densities of CD3- and CD20-positive cells were evaluated at a magnification of 40 ×, and 10 fields per section were examined. The densities were calculated for each section by dividing the number of positive cells by the area of the rectal mucosa analysed.

Table 1 Comparison of rectal B and T lymphocyte populations and B1 subpopulations in ulcerative colitis patients and controls

	Ulcerative colitis	Controls
$CD19^+/CD45^+$ (%)	47.8 ± 3.1[b]	26.1 ± 3.4
$CD20^+$ (cells/mm^2)	501 ± 91[b]	117 ± 18
$CD3^+/CD45^+$ (%)	53.5 ± 4.2[a]	68.3 ± 3.5
$CD3^+$ (cells/mm^2)	485 ± 100	445 ± 95
$CD5^+/CD19^+$ (%)	15.5 ± 2.0	23.5 ± 4.9
$CD5^+CD19^+$ (cells/mm^2)	85 ± 15[b]	31 ± 6.7

[a]$P < 0.05$, [b]$P < 0.01$ *vs* controls.

Calculation of rectal mucosa B1a cell concentration

The rectal mucosa B1a cell concentration ($CD5^+CD19^+$) was calculated by multiplying the $CD5^+/CD19^+$ ratio, obtained by flow-cytometry, by the B lymphocyte concentration, obtained by immunohistochemistry.

ESR and CRP analysis from blood test

ESR and CRP were measured using the Westergren method and immuno-nephelometry, respectively.

Statistical analysis

Results are expressed as mean ± SE. Statistical analysis was performed using Mann-Whitney *U* test for the comparison between the UC patients and controls and by Spearman's Rank test for correlations. Statistical significance was set at $P < 0.05$.

RESULTS

Adequate material for flow-cytometry was obtained from 13/15 UC patients (8 males and 5 females, median age 54 years, range 19-71 years) and from 13/17 controls (8 males and 5 females, median age 61 years, range 37-88 years). Of the 13 UC patients included in the study, 5 were taking mesalazine and 8 were not.

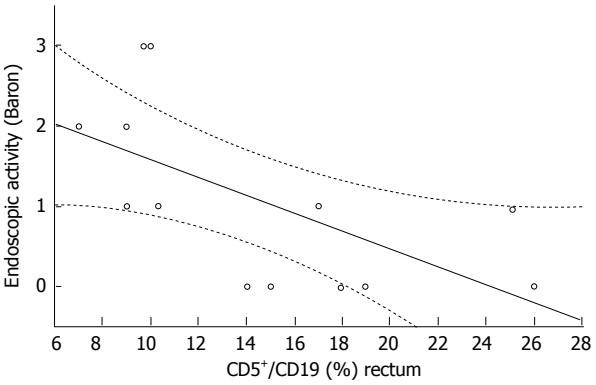

Figure 3 Correlation between B1a cells percentage in ulcerative colitis patients and endoscopic disease activity (*Rs* = -0.68, *P* = 0.01).

Ulcerative colitis was clinically active (Seo score > 150) in 5 patients and endoscopically active (Baron score > 1) in 4. The median histologic activity score was 3 (range 0-5).

Flow cytometry

The percentage of B lymphocytes ($CD19^+/CD45^+$) in the rectal mucosa was higher in UC patients with respect to healthy controls (47.8% ± 3.1% *vs* 26.1% ± 3.4%, *P* = 0.001); while the percentage of rectal T lymphocytes ($CD3^+/CD45^+$) was significantly lower in UC patients with respect to the controls (53.5% ± 4.2% *vs* 68.3% ± 3.5%, *P* = 0.02).

The rectal B1a cell rate ($CD5^+/CD19^+$) did not differ significantly in the two groups (Table 1), and was inversely correlated with endoscopic activity (Rs = -0.68, *P* = 0.01, Figure 3), but not with the clinical SEO disease activity index, ESR and CRP levels, or with age. The mean rectal B1a cell rate was higher, but not significantly different in patients with remission or mild histologic activity (score 0-1), with respect to patients with moderate-severe histologic activity (score 2-5) (22.0% ± 3.0% and 12.7% ± 2.5%, respectively, *P* = 0.1). The rectal B1a cell rate was not significantly different in the patient group taking mesalazine compared with those not taking mesalazine (11.0 ± 2.1 and 17.2 ± 3.0, respectively, *P* = 0.13).

Immunohistochemistry

Histological analysis confirmed that there was an increased concentration of B lymphocytes CD20+ in the rectal mucosa of ulcerative colitis patients with respect to that in controls (cell density 501 ± 91 cells/mm^2 *vs* 117 ± 18 cells/mm^2, *P* < 0.001). T cell density was not significantly different in the UC patients and controls (485 ± 100 *vs* 445 ± 95, *P* = 0.6).

Calculated rectal B1a cell concentration

The calculated B1a cell density was significantly increased in UC patients with respect to that in controls: 85 ± 15 cells/mm^2 *vs* 31 ± 6.7 cells/mm^2, *P* = 0.009.

DISCUSSION

More than 80% of the body's activated B cells are located in the gut, where a continuous interaction takes place between the immune system and the trillion bacteria that reside there[9].

IgA generation by B cells is an important mechanism that regulates this homeostasis, contributing to immune protection but without provoking inflammation. A large proportion of the intestinal IgA against cell wall antigens and proteins of commensal bacteria is specifically induced in response to their presence within the microflora, but is independent of T cells or germinal centre formation. This T cell-independent IgA production is derived from B1 lymphocytes which develop in the peritoneal compartment and are distributed diffusely in the intestinal lamina propria[10]. In mice, peritoneal B cells (B1 cells) do not differentiate during migration through the lymphoid organs and finally home to the gut lamina propria where they switch and differentiate to IgA+ plasma cells[11]. The physiological importance of B1 cells in the maintenance of homeostasis at the mucosal surface has been clearly demonstrated[12].

B cells in inflammatory bowel disease have not been as extensively studied as T cells[13], and data on the role of B1 cells in UC are particularly scanty. Except for a smaller sub-group called B1b, B1 cells are distinguishable from B2 cells by expressing CD5 on their surface[14]. Even in the absence of external antigen stimulation, B1 cells produce natural antibodies (Ab) that provide early, broad protection against pathogens[4]. B1 cells are also known to produce auto-reactive Ab, including Ab to cell membrane components, such as phosphorylcholine[15] and phosphatidylcholine[16] to immunoglobulins (rheumatoid factor) and to single-stranded DNA[17].

B1 cells were thus analysed for their role in autoimmunity and high circulating B1a lymphocyte levels have been reported in some autoimmune diseases, such as systemic lupus erythematosus, primary Sjogren's syndrome[18], rheumatoid arthritis[19], multiple sclerosis[20] and anti-phospholipid syndrome[21]. In the light of recent findings, these cells, and in particular the CD5 molecule on B cells, seem to play a role in preventing autoimmunity[22].

In a previous study we reported that B1a cell ($CD5^+/CD19^+$) concentrations are reduced in the blood of patients with UC even after restorative proctocolectomy[5]. Moreover, B1a cell rate was found to be inversely correlated with ESR and CRP levels in UC patients, indicating that these cells play a protective role against inflammation. Low $CD5^+/CD19^+$ blood percentages in UC and in Crohn's disease (CD) have also been reported by other authors[23,24].

The present study focused on the presence of B lymphocytes, and in particular the B1a sub-group, in the rectal mucosa of UC patients. An increased concentration of B lymphocytes was found in the rectal mucosa of these patients and their percentage within the leukocyte pool was also increased. B1a cell concentrations

in the rectal mucosa of UC patients were significantly higher than those in healthy controls, but not their percentage within the whole B lymphocyte pool ($CD5^+$/$CD19^+$). Senju *et al*[25], who analysed subsets of lamina propria lymphocytes using two-colour flow cytometry, also found no differences in the percentage of $CD5^+$ B lymphocytes in UC, CD patients and controls. They reported that the majority of B cells in the intestinal mucosa did not possess CD5 antigens on their cell surface. In the present study, performed using three colour flow cytometry, we found that the percentage of $CD5^+$ B cells in the rectum was small, but not negligible (between 15% and 23%). The use of anti-CD45 helps to restrict the flow cytometric analysis to leukocytes, excluding from the study the other types of cells homing in the rectal mucosa.

Finding an increased concentration of B1a cells, but not a higher percentage within the whole B lymphocyte population, means that other B lymphocyte subsets were increased in the rectal mucosa of these patients. In addition, finding an inverse correlation between $CD5^+$ B cells and endoscopic disease activity suggests that these cells are recruited to a relatively lower extent when the disease is more severe and possibly, at that point, a more specific immune reaction has already begun. As our findings seem to indicate that there is a loss of tolerance at this disease stage, further studies will clarify this point. The finding of an inverse correlation between rectal mucosa B1a cell rate and endoscopic disease activity is consistent with previous data concerning the inverse correlation of circulating B1a cell rate and blood ESR and CRP levels[5]. The former is a sign of local events, and the latter of a systemic imbalance.

Peterson *et al*[26] reported that the depletion of $CD5^+$ B1 cells has different effects on the induction phase with respect to the effector phase of experimental autoimmune encephalomyelitis. During the induction phase it increases disease incidence, while in the effector phase it reduces disease severity. The role of $CD5^+$ B cells in UC is not yet clear. It remains to be clarified if they play a protective role by producing polyspecific immunoglobulins, an unleashing role by producing autoreactive Ab, or if there is an even more complex modulating role that differs depending on the disease activity. The findings in this and other studies seem to indicate that their role in UC is not marginal, but more in-depth analyses are warranted to better define their function and to determine if and how their modulation has an impact on disease activity.

COMMENTS

Background

The aetiology of ulcerative colitis (UC) is still unknown, but several studies have demonstrated that there is an abnormal immunologic response to gut antigens.

Research frontiers

B1 lymphocytes are important in maintaining mucosal surfaces in a state of homeostasis, and it has been found that B1 cell concentrations are reduced in the blood of patients with UC even after restorative proctocolectomy. In the present study, B1a cell expression was assessed in the rectal mucosa of UC patients and compared with that in healthy controls using three color flow-cytometry.

Innovations and breakthroughs

Rectal B1a cell density ($CD5^+CD19^+$) was increased in ulcerative colitis patients compared with healthy controls, but its rate correlated inversely with endoscopic disease score.

Applications

The findings in this and other studies seem to indicate that B1a lymphocytes play a role in the pathogenesis of ulcerative colitis and their modulation could have an impact on the control of disease activity.

Terminology

B1 lymphocytes are distinguishable from B2 lymphocytes because they express CD5 on their surface. Even in the absence of external antigen stimulation, B1 cells produce natural antibodies that provide early, broad protection against pathogens. B1 cells are also known to produce auto-reactive antibodies. CD5 is a 67 kD trans-membrane glycoprotein that interacts in the B lymphocyte with the B cell receptor, negatively regulating growth signaling.

Peer review

This study assessed B1a cell concentration in rectal mucosa of 13 UC patients as compared to controls. A possible correlation between these cells and either endoscopic (modified Baron classification) or clinical (Seo clinical score) activity index was also investigated. Data found that B1a cell concentration is increased in UC, but its distribution (i.e., percentage within leucocytes) did not differ between patients and controls. Moreover, a significant, inverse correlation between B1a cell concentration in rectal mucosa and endoscopic activity index was found.

Abstract

AIM: To assess human epidermal growth factor receptor-2 (HER2)-status in gastric cancer and matched lymph node metastases by immunohistochemistry (IHC) and chromogenic *in situ* hybridization (CISH).

METHODS: 120 cases of primary gastric carcinomas and 45 matched lymph node metastases from patients with full clinicopathological features were mounted onto multiple-punch and single-punch tissue microarrays, respectively, and examined for HER2 overexpression and gene amplification by IHC and CISH.

RESULTS: Twenty-four tumors (20%) expressed HER2 immunohistochemically. An IHC score of $\geqslant$ 2+ was observed in 20 tumors (16.6%). HER2 amplification was detected by CISH in 19 tumors (15.8%) and in their matched lymph node metastases. A high concordance rate was found between HER2 positivity (as detected by IHC) and *HER2* gene amplification (as detected by CISH), since 19 of the 20 IHC positive cases were amplified (95%). All amplified cases had 2+ or 3+ IHC results. Amplification was associated with intestinal phenotype ($P < 0.05$). No association with grading, staging or survival was found.

CONCLUSION: In gastric cancer, HER2 amplification is the main mechanism for HER2 protein overexpression and is preserved in lymph node metastases.

Key words: Human epidermal growth factor receptor-2; Immunohistochemistry; Chromogenic *in situ* hybridization; Gastric cancer

INTRODUCTION

Alterations of the human epidermal growth factor receptor-2 (*HER2*) gene are implicated in the development and progression of many tumors[1-4]. In breast cancer, HER2 amplification has been found in about 20% of cases and was linked to poor prognosis[5,6]. Breast cancer patients with HER2 amplification have been effectively treated with the monoclonal antibody trastuzumab, a HER2 inhibitor[7-10]. Recently, a number of studies have suggested a response to trastuzumab therapy for other

cancers with HER2 amplification, including germ cell, endometrium and salivary duct carcinoma[11-13].

In gastric cancer, HER2 amplification has been found in 7% to 27% of tumors[14-19]. Reports of trastuzumab therapy in metastatic gastric cancer showed complete tumor regression and disappearance of the metastases in two cases[20,21]. A phase Ⅲ randomized study (Trastuzumab for HER2-positive metastatic gastric cancer) in patients with inoperable, metastasizing and/or recurring gastric cancer with HER2 overexpression or *HER2* gene amplification, documented that 47.3% of the patients who received trastuzumab, along with their chemotherapy, showed a significant regression of the primary tumor and/or the metastases. Moreover, trastuzumab caused a prolongation of the median survival time by 2.4 mo in all patients[22]. Based on these reports, gastric cancer patients with HER2 overexpression and/or amplification could be good candidates for trastuzumab therapy.

HER2 testing can be performed either by immunohistochemical evaluation of protein expression or by evaluating the gene copy number by *in situ* hybridization, most commonly using fluorescence *in situ* hybridization (FISH). However, while immunohistochemistry (IHC) is a relatively inexpensive, easy to perform method for most pathology laboratories, FISH is technically demanding, expensive and requires special equipment[23-25]. An alternative method, chromogenic *in situ* hybridization (CISH), is a combination of *in situ* hybridization with a detection system using a chromogen similar to IHC. Slides are visible under a light microscope and show correlation with morphology. A number of studies compared HER2 testing with IHC, FISH and CISH in breast carcinoma and have shown good correlation between CISH and FISH results[25-30].

We evaluated HER2 overexpression and gene amplification by IHC and CISH, respectively, in 120 cases of gastric carcinoma patients and 45 matched lymph node metastases mounted onto multiple-punch and single-punch tissue microarrays respectively. Our data suggests that, in gastric cancer, HER2 amplification is the main mechanism for HER2 protein overexpression and is preserved in lymph node metastases.

MATERIALS AND METHODS

Patients

The current study involved 120 non-consecutive patients with gastric carcinoma, surgically treated at the 3rd and 4th Departments of Surgery, University of Athens, between 2004 and 2007. Histomorphological data were reviewed from the corresponding hematoxylin and eosin stained slides. Clinical data were obtained from corresponding reports. Clinicopathological information included: gender, age, tumor diameter, histological subtype, tumor location, pT stage, pN stage, pM stage, vascular and lymphatic invasion, survival time, and information on post-operative therapy. Characteristics of patients are summarized in Table 1.

Table 1 Characteristics of patients with gastric cancer

Clinicopathological feature		Frequency *n* (%)
Patient age at diagnosis (yr)	Mean 69.6, min-max 27-96	
Tumor diameter (cm)	Mean 4.6, min-max 1.3-12	
Gender	Male	84 (70)
	Female	36 (30)
Histological type	Intestinal	80 (66.66)
	Diffuse	24 (20)
	Mixed	16 (13.33)
Tumor location	Cardia	37 (30.8)
	Corpus	39 (32.5)
	Antrum	44 (36.66)
pT stage	pT1	15 (12.5)
	pT2	65 (54.16)
	pT3-4	40 (33.33)
pN stage	pN0	36 (30)
	pN1	43 (35.8)
	pN2+3	41 (34.2)
pM stage	pM0	105 (87.5)
	pM1	15 (12.5)
Tumor grade	G1-2	42 (35)
	G3	78 (65)
Venous invasion	Present	37 (30.8)
	Absent	83 (69.2)
Lymphatic invasion	Present	84 (70)
	Absent	36 (30)
Adjuvant therapy	None	32 (26.6)
	Treated	88 (73.4)
	Chemotherapy	55 (62.5)
	Chemo/Radiotherapy	33 (37.5)
5-year survival (%)	(95% CI)	38.9 (25-52)

Specimen characteristics

Paraffin-embedded tissue blocks of primary tumors and matched positive lymph nodes were retrieved from the Department of Pathology, University of Athens. The use of this material was approved by the local Ethics committee. Two tissue microarrays (TMAs) were constructed. The first included punches from primary tumors. In order to exclude bias due to possible tumor heterogeneity, each patient had multiple tumor punches taken from formalin-fixed, paraffin-embedded blocks using a tissue cylinder with a diameter of 1 mm, which were subsequently transferred into one recipient paraffin block (3 cm × 2.5 cm) using a semiautomated tissue arrayer. Each patient had on average 5.1 tissue punches included on this array, including at least 4 tumor punches. The second TMA included single punches from matched metastatic lymph nodes in 45 patients.

Assay methods

IHC: Five μm TMA sections were dewaxed and rehydrated in distilled water. Endogenous peroxidase was blocked using 0.5% H_2O_2. To determine the HER2 expression immunohistochemically, the HercepTestTM (Dako, Glostrup, Denmark) was used according to the manufacturer`s protocol. Following pressure cooker-mediated antigen retrieval sections were incubated with the prediluted primary antibody. Control samples included normal gastric mucosa and breast cancer tissue. Immunostaining was scored by an experienced gastrointestinal pathologist following a 4-step

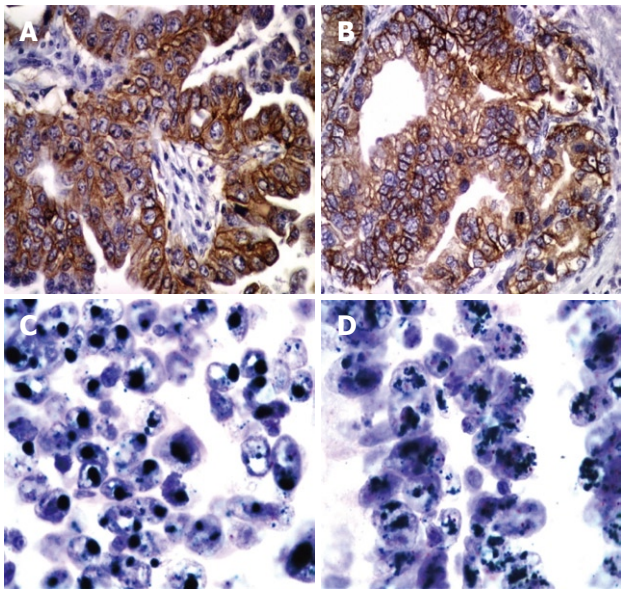

Figure 1 Examples of human epidermal growth factor receptor-2 immunohistochemical expression and amplification in primary and metastatic gastric cancer. Immunohistochemistry shows strong membranous staining of human epidermal growth factor receptor-2 (HER2) in intestinal type gastric cancer (A) and (B) (× 400). Chromogenic in situ hybridization assay shows amplification of HER2 in primary gastric cancer (C) and the corresponding lymph node metastasis (D). Clustered green signals represent the amplified *HER2* gene, while red signals represent centromere 17. Cell nuclei are counterstained with hematoxylin (× 1000).

score (0, 1+, 2+, 3+), according to the consensus panel recommendations on HER2 scoring for gastric cancer[31].

CISH: HER2 CISH was performed using a CISH HER2 probe and Immunodetection Kit (ZytoDot2C SPEC HER2/CEN 17 Probe Kit). TMA sections were deparaffinized and incubated for 5 min in 3% H_2O_2, followed by Heat Pretreatment Solution EDTA in a covered staining jar standing in a boiling water bath at 98 ℃ for 15 min. After washing in distilled water, Pepsin Solution (ES1) was applied and slides were incubated for 5 min at room temperature in a humidity chamber. Sections were then washed in distilled water, dehydrated in increasing ethanol, and air dried. ZytoDot2C SPEC HER2/CEN 17 Probe was applied and sections were covered with a coverslip sealed with a layer of hot glue. Samples were then denaturated at 80 ℃ for 5 min, transferred to a humidity chamber and left to hybridize overnight at 37 ℃. On day 2, immunodetection was performed according to the manufacturer's instructions and sections were counterstained with Hematoxylin and mounted.

Statistical analysis

χ^2 tests and contingency tables were used to analyze the relationship between IHC and CISH, and categorical parameters. Overall survival was estimated by the Kaplan-Meier method and evaluated by log-rank testing. All analysis were carried out using SAS (V9, The SAS Institute, NC, United States).

Table 2 Lauren phenotype, human epidermal growth factor receptor-2 immunohistochemistry and chromogenic *in situ* hybridization in gastric carcinoma

		Diffuse (n = 24)	Mixed (n = 16)	Intestinal (n = 80)
HER2 IHC	0	23	14	59
	1+	0	0	4
	2+	1	0	5
	3+	0	2	12
HER2 CISH	Non amplified	24	14	63
	Amplified	0	2	17

HER2: Human epidermal growth factor receptor-2; IHC: Immunohistochemistry; CISH: Chromogenic *in situ* hybridization.

RESULTS

HER2 immunohistochemistry

HER2 protein expression was observed in 24 of the 120 gastric carcinomas (20%). In more detail, one of the 24 diffuse type carcinomas (4.16%) and 23 of the 96 intestinal and mixed type carcinomas (23.95%) showed HER2 protein expression. Immunostaining was always membrane bound and showed basolateral predominance (Figure 1A and B). Immunostaining in mixed type carcinomas was restricted in the intestinal type component. Quantitative analysis of the immunostaining, according to the consensus panel recommendations on HER2 scoring for gastric cancer, resulted in fourteen 3+ cases (11.66%), six 2+ cases (5%) and four 1+ cases (3.33%)[31] (Table 2). IHC was interpretable in 652 of the 660 spots (98.8%). Reasons for non-interpretable results were missing tissue spots or absence of tumor tissue.

HER2 CISH

Tissue spots were scanned for possible intratumoral heterogeneity by using a 10× objective lens. CISH hybridization signals of the *HER2* gene appeared as dark green-colored dot-shaped signals. The chromosome 17 centromeric regions appeared as bright red-colored dot-shaped signals. Areas of necrosis and overlapping nuclei were avoided. Signal enumeration was performed using the 40× objective lens of a light microscope. HER2 amplification was observed in 19 of the 120 primary gastric carcinomas (15.8%). Amplified cases showed intratumoral heterogeneity with areas of low amplification where HER2 signals appeared as multiple dots or small clusters, and areas of high amplification with presence of large, green *HER2* gene signal clusters (Figure 1C and D). All amplified cases had 2+ or 3+ IHC results (Table 2). HER2 amplification showed significant association with histologic tumor type. Seventeen (21.25%) of the 80 intestinal and two (12.5%) of the 16 mixed type cancers, but 0 (0%) of the diffuse type cancers, were amplified ($P < 0.002$, Table 2). No association between *HER2* gene amplification and tumor grade, size, stage or localization was found.

Table 3 Comparison of human epidermal growth factor receptor-2 immunohistochemistry and chromogenic *in situ* hybridization in primary gastric carcinomas and matched lymph node metastases

	HER2 IHC			HER2 CISH		
	PT	LNM	Concordance	PT	LNM	Concordance
Positive	7	6	85.7%	6	6	100%
Negative	38	39	97.4%	39	39	100%

HER2: Human epidermal growth factor receptor-2; IHC: Immunohistochemistry; CISH: Chromogenic *in situ* hybridization; PT: Primary gastric cancer; LNM: Lymph node metastases.

HER2 alterations in lymph node metastases

Comparative analysis of primary tumors and corresponding lymph node metastases, performed in 45 cases, showed a high concordance in the presence of HER2 overexpression or amplification ($P < 0.0001$, Table 3).

Clinicopathological characteristics

Increasing tumor grade and stage were associated with reduced patient survival ($P < 0.0001$ each). No correlation was observed between patient survival and HER2 overexpression or amplification, even after including postoperative therapy of the patients and location of the tumors in the analysis (Figure 2).

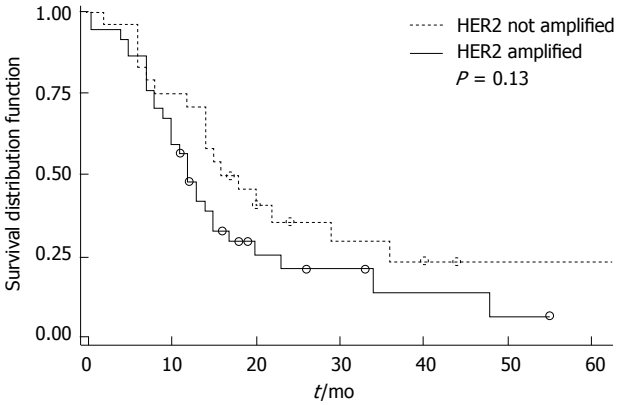

Figure 2 Kaplan-Meier curve for disease-specific survival and human epidermal growth factor receptor-2 amplification in gastric carcinomas. HER2: Human epidermal growth factor receptor-2.

DISCUSSION

The HER2 protein is a frequently analyzed gene product, especially in breast cancer. Recent studies have examined HER2 expression in other tumor types, including gastric cancer[18,32,33]. Immunohistochemical HER2 expression and protein positivity (≥ 2+) was observed in 20% and 14.58%, respectively, of the 120 gastric carcinomas in our study. These results are in keeping with previous reports demonstrating similar frequencies of HER2 overexpression in gastric cancer[18,32,33]. HER2 positivity was observed in 23% of the cases in the study by Yano *et al*[18] and in 22.6% of the cases in the study by Kim *et al*[33]. More recently, a TMA study of 166 gastric carcinomas by Marx *et al*[32] found a HER2 positivity rate of 17% and a strong correlation between IHC and *HER2* gene amplification detected by FISH. In our cases, comparable to others, HER2 overexpression and/or amplification were almost exclusively found in gastric cancers of the intestinal type. This finding supports the presence of different molecular characteristics between the main histologic tumor types that seem to develop through different molecular pathways.

No correlation between HER2 overexpression and/or amplification and tumor localization could be demonstrated in our study. This might be contradictory to previous studies where a high frequency of HER2 expression was reported in cardia carcinomas[34]. However, adenocarcinomas of the gastroesophageal junction, many of which are Barrett carcinomas, are known to have a high rate of HER2 amplification and cannot always be differentiated from cardia carcinomas. This may lead to an artificial increase in the rate of HER2 expression reported in cardia carcinomas.

A high concordance rate was found between HER2 positivity, as detected by IHC, and *HER2* gene amplification, as detected by CISH, since 19 of the 20 IHC positive cases (i.e., ≥ 2+) were amplified (95%). Many of them (73.6%) had high *HER2* gene amplification. However, one HER2 2+ case, detected in a diffuse carcinoma, was not found to be amplified, which may be attributed to a technical error of IHC associated with formalin fixation of the tissue. Alternatively, other mechanisms of HER2 protein overexpression can contribute to inconsistencies between IHC and ISH results.

In the present study we found a high concordance rate of HER2 status between primary tumors and their corresponding lymph node metastases. This finding is in keeping with previous published results, where HER2 amplification status was found to be almost identical in the primary gastric carcinomas and their corresponding lymph node metastases[32] and provides further evidence for the role of HER2 amplification in gastric cancer.

Our findings support gastric cancer HER2 amplification as being the main mechanism that leads to HER2 protein overexpression. Similar findings have previously been reported for esophageal cancer[35]. Moreover, Tapia *et al*[19], in a large-scale TMA study, examined more than 4000 samples from 120 different tumors and could not find any tumors with HER2 overexpression in the absence of gene amplification.

HER2 testing has developed over a number of years, and many retrospective studies using formalin-fixed, paraffin-embedded material and different methodologies have provided inconsistent results[36,37]. Correlation between technical methods can be used to obtain a high concordance rate and to better define the assays with the best ability to identify patient groups that would benefit from a targeted therapy. Although in breast cancer HER2 IHC is an acceptable method of predicting HER2 status, previous studies have shown marked variation in different diagnostic laboratories regarding the interpretation of positive staining[25]. On the other hand, FISH is

technically demanding, expensive and does not produce a permanent archival slide. In our study, CISH testing showed a good correlation to IHC, and therefore seems to represent a reliable methodology for HER2 testing. Moreover, the slides are visible under a light microscope and show good correlation with tumor morphology.

In this study, we used the tissue microarray technique using multiple tissue punches per case to account for possible heterogeneity in terms of protein expression or gene amplification in the primary tumor. Each patient had an average of 4 tumor punches taken. This is particularly important for HER2 testing in gastric cancer since considerable heterogeneity concerning gene amplification has been reported in many studies[38,39]. Such heterogeneity was also noted in our study, since in many amplified cases, areas with low and high amplification were found within the same tumor. Multiple sampling thus helped to minimize possible biases in evaluation, as suggested by Goethals *et al*[40], who recommended that at least four punches of primary tumor are required to account for possible heterogeneity. However, a single tissue punch was sampled in the case of lymph nodes since the issue of heterogeneity may be substantially less important. Our study also benefits from complete clinicopathological and follow-up characterization of patients. In contrast to previous studies[34,41] we could not demonstrate any association between HER2 positivity and clinical outcome.

Our study provides evidence supporting gastric cancer HER2 amplification as being the main mechanism for HER2 protein overexpression and that HER2 amplification is preserved in the lymph node metastases. Therefore, gastric cancer patients with HER2 overexpression and/or amplification seem to be good candidates for anti-HER2 therapy. Moreover, CISH is a reliable and inexpensive method that can be used for HER2 testing of gastric cancer.

COMMENTS

Background

Alterations of the human epidermal growth factor receptor-2 (*HER2*) gene are implicated in the development and progression of many tumors. Breast cancer patients with HER2 amplification have been effectively treated with the monoclonal antibody trastuzumab, a HER2 inhibitor. Recently, a number of studies have suggested a response to trastuzumab therapy for other cancers with HER2 amplification, including gastric cancer, where HER2 amplification has been found in 7% to 27% of the tumors. Reports of trastuzumab therapy in metastatic gastric cancer showed complete tumor regression and disappearance of the metastases in two cases. Based on these reports, gastric cancer patients with HER2 overexpression and/or amplification could be good candidates for trastuzumab therapy.

Research frontiers

The HER2 protein is a frequently analyzed gene product, especially in breast cancer. Recent studies have examined HER2 expression in other tumor types, including gastric cancer. The frequency and significance of HER-2/neu amplification in gastric carcinoma are investigated. In this study, immunohistochemical HER2 expression and protein positivity ($\geq$ 2+) was observed in 20% and 14.58%, respectively, of the 120 gastric carcinomas.

Innovations and breakthroughs

The authors evaluated HER2 overexpression and gene amplification by immunohistochemistry and chromogenic *in situ* hybridization (CISH) respectively, in 120 cases of gastric carcinoma patients and 45 matched lymph node metastases mounted onto multiple-punch and single-punch tissue microarrays respectively. The data suggest that, in gastric cancer, HER2 amplification is the main mechanism for HER2 protein overexpression and is preserved in the lymph node metastases.

Applications

This study provides evidence supporting gastric cancer HER2 amplification as being the main mechanism for HER2 protein overexpression and that HER2 amplification is preserved in the lymph node metastases. Therefore, gastric cancer patients with HER2 overexpression and/or amplification seem to be good candidates for anti-HER2 therapy. Moreover, CISH is a reliable and inexpensive method that can be used for HER2 testing of gastric cancer.

Peer review

The authors studied HER2/neu expression and gene amplification in a cohort of Greek patients with gastric cancer. The manuscript includes 2 aspects. Firstly, they describe the expression/amplification of HER2-neu in the study group. Secondly, they highlight the potential applicability of CISH as a routine method. Data are mostly well documented and conclusions drawn are appropriate.

Abstract

AIM: To investigate the effect of alcohol on the metabolic syndrome (MS) and fatty liver in Japanese men and women.

METHODS: A cross-sectional study was conducted in a medical health checkup program at a general hospital. This study involved 18 571 Japanese men and women, 18-88 years of age, with a mean body mass index of 22.6 kg/m^2. A standardized questionnaire was administered. The total amount of alcohol consumed per week was calculated, and categorized into four grades. Fatty liver was examined by ultrasound modified criteria of the revised National Cholesterol Education Program Adult Treatment Panel Ⅲ and the new International Diabetes Federation.

RESULTS: The prevalence of fatty liver decreased in men and women with light to moderate alcohol consumption, whereas the prevalence of MS was not so changed. The prevalence of fatty liver of any grade in men was lower than that in those with no or minimal alcohol consumption. In women with light to moderate alcohol consumption, prevalence of fatty liver was lower than that in women with no or minimal alcohol consumption. By logistic regression analysis, the odds ratio (OR) for MS in women with light alcohol consumption was decreased to < 1.0, but this change was not clear in men. The OR for fatty liver was clearly < 1.0 in men with any level of alcohol consumption and in women with light to moderate consumption.

CONCLUSION: Light to moderate alcohol consumption has a favorable effect for fatty liver, but not for MS in Japanese men and women.

Key words: Alcoholic hepatitis; Epidemiology; Fatty liver; Metabolic syndrome; Alcohol consumption

INTRODUCTION

The metabolic syndrome (MS) is defined by abdominal

obesity, hypertension, elevated fasting blood glucose, and dyslipidemia[1]. Importantly, MS is a risk factor for the development of type 2 diabetes mellitus and coronary artery disease, and is associated with an increased risk of cerebrovascular disease and all-cause mortality[2]. The favorable effect of alcohol intake enhances insulin sensitivity, increases high-density lipoprotein-cholesterol (HDL-C), and contributes to a lower risk of type 2 diabetes mellitus[3-6] and cardiovascular disease[7-10]. Some reports have shown that the prevalence of MS is associated with alcohol consumption, irrespective of the amount consumed[11-13]. However, several studies have reported beneficial effects of alcohol consumption on MS[14-16]. Moreover, a study in Korean adults has indicated that light alcohol consumption is associated with a reduced prevalence of MS, whereas substantial alcohol intake leads to a dose-dependent increase in the risk of MS[17]. The effect of alcohol on MS in the general population has been inconsistent in the literature.

Fatty liver is closely associated with MS, and is considered the hepatic manifestation of MS[18]. Findings on the relation between alcohol consumption and fatty liver have also been inconsistent in the literature. Although alcohol consumption certainly may be a cause of fatty liver in some cases[19,20], it potentially plays a protective role against fatty deposition in the liver[21-25].

Therefore recent studies have implied the possibility that the effect of alcohol is different between fatty liver and MS, although fatty liver is closely associated with MS. However, the discrepancy of alcohol effect among the previous studies may be due to differences in the following cofactors: ethnicity, age, body mass index (BMI), drug usage, and lifestyle, such as alcohol consumption, smoking, and exercise. However, no large epidemiological study has investigated the effect of alcohol on fatty liver and MS at the same time.

We performed a cross-sectional study to investigate the effect of alcohol on fatty liver and MS at the same time. In this study, we separated the subjects according to the grade of alcohol consumption and compared the prevalence of fatty liver and MS in each grade. We focused on the discrepancy in the association between alcohol and MS and between alcohol and fatty liver. Additionally, we checked the impact of prevalence of MS without fatty liver, or fatty liver without MS.

MATERIALS AND METHODS

Study design

We performed a cross-sectional study of participants of a medical health checkup program, including abdominal ultrasonography. The study was approved by the ethics committee of Murakami Memorial Hospital, Gifu, Japan. The program was conducted in the Medical Health Checkup Center at Murakami Memorial Hospital. The purpose of the medical health checkup program was to promote public health through early detection of chronic diseases and the evaluation of their underlying risk factors. Known as a "human dock", medical services of this kind are very popular in Japan.

Study population

All of the subjects participating in such health checkup programs at Murakami Memorial Hospital between January 2004 and December 2009 were invited to join this study. Participants who tested positive for hepatitis B antigen or hepatitis C antibody and those who reported a history of known liver disease, including viral, genetic, autoimmune, and drug-induced liver disease, were excluded from the study[26]. We invited 22 119 participants in the health checkup program to enroll in the study. Of these, a total of 19 016 Japanese participants (11 295 men and 7721 women) were enrolled after giving informed consent. We excluded 123 participants (92 men and 31 women) with hepatitis C virus, 312 (214 men and 98 women) with hepatitis B virus, and nine (7 men and 2 women) who were diagnosed with other liver diseases. As a result, this study consisted ultimately of 18 571 participants (10 982 men and 7589 women). The mean age was 46.5 years (SD: 9.9; range: 18-88 years), and the mean BMI was 22.6 kg/m^2 (SD: 3.3; range: 14.0-58.3 kg/m^2).

Data collection

The health checkup programs that were used for the collection of data included the following tests: eye examinations, urinalysis, blood-cell counts, blood chemistry, electrocardiography, chest radiography, barium examination of the upper gastrointestinal tract, and abdominal ultrasonography. The medical history and lifestyle factors of all participants, including physical activity and habits pertaining to smoking and alcohol consumption, were surveyed by a standardized self-administered questionnaire. When the participants had difficulty completing the questionnaire, trained nurses provided assistance. We undertook blood and urine examinations with MODULAR ANALYTICS (Hitachi High-Technologies Corp. Ltd., Tokyo, Japan).

Standardized questionnaire for lifestyle factors

A standardized questionnaire was administered to all participants by the same trained team of interviewers. Habits regarding alcohol consumption were evaluated by asking the participants about the amount and type of alcoholic beverages consumed per week during the past month, then estimating the mean ethanol intake per week. The validity of information related to alcohol consumption was confirmed previously[27]. The total amount of alcohol consumed per week was calculated in grams, and then categorized into the following four grades: non or minimal alcohol consumption, < 40 g/wk; light alcohol consumption, 40-140 g/wk; moderate alcohol consumption, 140-280 g/wk; and excess alcohol consumption, > 280 g/wk[22,24]. Smoking status was also categorized into three groups (never smoker, ex-smoker, and current smoker). On the questionnaire, participants reported the type, duration and frequency of their partici-

pation in sports or recreational activities[28]. When participants performed any kind of sports at least once a week regularly, we categorized them as regular exercisers[29].

Definition of fatty liver

The diagnosis of fatty liver was based on the results of abdominal ultrasonography, which was done by trained technicians with Aloka SSD-650CL (Aloka Co., Ltd., Tokyo, Japan). All ultrasonographic images were stored as photocopies. Gastroenterologists reviewed the photocopies and made the diagnosis of fatty liver without reference to any of the participant's other individual data. Of four known criteria (hepatorenal echo contrast, liver brightness, deep attenuation, and vascular blurring), the participants were required to have hepatorenal contrast and liver brightness to be given a diagnosis of fatty liver[30].

MS

There are several differing criteria for the MS worldwide[1,31-34]. In this study, we used the following two definitions: (1) the revised National Cholesterol Education Program Adult Treatment Panel Ⅲ (rATP Ⅲ) definition[34]; and (2) the new International Diabetes Federation (IDF) definition[32].

According to the rATP Ⅲ definition[1], subjects who had three or more of the following criteria were identified as having MS: (1) triglycerides ≥ 150 mg/100 mL; (2) HDL-C < 40 mg/100 mL for men, and < 50 mg/100 mL for women; (3) elevated blood pressure (systolic blood pressure ≥ 130 mmHg and/or diastolic blood pressure ≥ 85 mmHg); (4) fasting glucose ≥ 100 mg/100 mL instead of ≥ 110 mg/100 mL; or (5) abdominal-obesity-modified waist circumference cutoffs (≥ 90 cm for men and ≥ 80 cm for women) were used instead of the waist circumference cutoffs (≥ 102 cm for men and ≥ 88 cm for women) proposed in the existing definition.

According to the new IDF definition, Japanese people were defined as having MS if the subjects had abdominal obesity (waist circumference cutoffs ≥ 90 cm for men and ≥ 80 cm for women) plus two or more of the following risk factors: (1) elevated triglyceride level ≥ 150 mg/100 mL or on treatment; (2) low HDL–C < 40 mg/100 mL for men and < 50 mg/100 mL for women or on treatment; (3) elevated blood pressure (systolic blood pressure ≥ 130 mmHg and/or diastolic blood pressure ≥ 85 mmHg); and (4) high fasting glucose ≥ 100 mg/100 mL[32].

Sample size

Because preliminary studies indicated that the number in the excess alcohol consumption group was small (n = 22 and 24), we invited as many subjects as possible. Practically, we collected data for waist circumference from 2004. Then, we set the study period from 2004 to 2009.

Statistical analysis

The R version 2.4.1 (available from http://www.r-project.org/) was used for statistical analyses. Data was expressed as mean (SD). Two groups of subjects were compared by χ^2 test. The significance of differences between non or minimal alcohol consumption and the others was determined by two-tailed, multiple χ^2 tests with Bonferroni correction ($P < 0.016$ for three comparisons in four groups). The linear association of alcohol consumption with several parameters associated with MS was evaluated by Spearman's rank correlation, and a P value < 0.05 was accepted as significant. We assessed the odds ratio (OR) of the alcohol consumption grade for MS and fatty liver using a multivariate logistic model while controlling for potential covariates. In a multivariate logistic model, we selected age, use of drugs that potentially affect MS, and lifestyle, such as alcohol consumption, regular exercise, and smoking as the potential covariates. The adjusted OR and 95% CIs were calculated.

RESULTS

We investigated the OR of alcohol consumption for MS defined by rATP Ⅲ and fatty liver using a logistic regression model (Figure 1). The OR for MS was decreased to < 1.0 in women with light alcohol consumption, but it was not clear in men. The OR for fatty liver was clearly < 1.0 in men with any level of alcohol consumption and in women with light to moderate consumption. In men and women, the ORs for high blood pressure and high fasting plasma glucose were increased as the level of alcohol consumption increased. Conversely, the OR for low HDL-C was decreased to < 1.0 in men and women. However, the OR for high triglycerides was increased to > 1.0 in men with excess alcohol consumption, and decreased to < 1.0 in women with light consumption. Moreover, the OR for high waist circumference was not significant, and was the same as the OR for high BMI. The actual adjusted ORs are shown in Table 1.

Table 2 indicates the basic characteristics of men and women in the four grades. And liner association between alcohol consumption and several factors associated with MetS were evaluated by Spearman's rank correlation (Table 3). BMI and waist circumferences were lowest in light consumption (Table 2), but Spearman's rank correlation coefficients were not significant (Table 3). Systolic blood pressure, diastolic blood pressure, and fasting plasma glucose were increased as the alcohol consumption increased (Tables 2 and 3). On the other hand, the associations of consumption with diastolic blood pressure, and that with fasting plasma glucose were not statistically significant in women, while systolic blood pressure was also increased as the consumption increased in women. In men and women, low-density lipoprotein (LDL) cholesterol, non HDL cholesterol, and LDL cholesterol/HDL cholesterol ratio were decreased and HDL cholesterol were increased as the consumption increased (Tables 2 and 3). Triglycerides were lower in light consumption and were higher in moderate and excess than those in non or minimal (Table 2). Over all, the trend of the associations between alcohol consumption and MetS

were not so changed between men and women.

This observed inverse association between alcohol consumption and fatty liver might be due to changed habits of alcohol use after previous detection of fatty liver. We analyzed the study population according to previous data. Among 10 981 men, 6547 were new participants and 4434 were repeat participants. Among 7573 women, 5138 were new participants and 2435 were

Among 18 571 participants (10 982 men and 7589 women), we separate men and women into the following four grades: non or minimal alcohol consumption, < 40 g/wk; light alcohol consumption, 40-140 g/wk; moderate alcohol consumption, 140-280 g/wk; and excess alcohol consumption. Data was expressed as mean (SD). BMI: Body mass index; HDL-c: High density lipoprotein cholesterol; LDL-c: Low density lipoprotein cholesterol.

The liner association between alcohol consumption and several factors associated with the metabolic syndrome were evaluated by Spearman' s rank correlation in 10 982 men and 7589 women, respectively, and a *P* value of < 0.05 was accepted as a significant level. BMI: Body mass index; HDL-c: High density lipoprotein cholesterol; LDL-c: Low density lipoprotein cholesterol.

Table 4 Alcohol consumptions of new and repeat participants

	Men			Women		
	n	Alcohol consumption (g/wk)	*P* value	*n*	Alcohol consumption (g/wk)	*P* value
New participants without fatty liver	4417	113.02 (161.03)	< 0.001[2]	4662	21.37 (67.57)	0.092[2]
New participants with fatty liver	2130	96.14 (157.95)	0.7[1]	476	13.99 (68.47)	0.841[1]
Repeat participants without fatty liver	2986	125.79 (157.24)	< 0.001[3]	2154	21.48 (58.33)	0.853[3]
Repeat participants with fatty liver	1448	102.02 (155.3)		281	18.09 (75.15)	

[1]New participants with fatty liver *vs* repeat participants with fatty liver; [2]New participants with fatty liver *vs* new participants without fatty liver; [3]Repeat participants with fatty liver *vs* repeat participants without fatty liver.

repeat participants. The alcohol consumption of repeat participants with fatty liver was the same as that of new participants with fatty liver (Table 4). Next, we analyzed repeat participants and separated them into four groups according to previous and present fatty liver. We assessed the changed habit of alcohol consumption. At first, the change in alcohol consumption was small in each group (Table 5). Moreover, the level of change was no different among the four groups of men and women.

We calculated the number of subjects with both MS and fatty liver, those who had only MS, and those who had only fatty liver (Table 6). Unexpectedly, more than half of the participants with fatty liver were not diagnosed with MS, even if the definition was changed. 42.5% or 25.5% of men with fatty liver were diagnosed with MS defined by rATP Ⅲ or IDF, respectively. Conversely, 66.0% or 78.8% of men with MS defined by rATP Ⅲ or IDF were diagnosed with fatty liver. The result was similar in women: 43.7% or 38.6% of women with fatty liver were diagnosed with MS defined by rATP Ⅲ or IDF, respectively. Conversely, 49.1% or 55.9% of women with MS defined by rATP Ⅲ or IDF were diagnosed with fatty liver. The prevalence of fatty liver among men with MS decreased along with level of alcohol consumption and prevalence of fatty liver among women with MS decreased in those with light or moderate consumption (Table 6).

DISCUSSION

As far as we know, the present study is the first to investigate the association of alcohol with ultrasonography-

Table 5 Changed alcohol consumption habits among four groups

Previous fatty liver	Present fatty liver	Men		Women	
		n	Change of alcohol consumption (g/wk)	*n*	Change of alcohol consumption (g/wk)
Negative	Negative	2784	–1.69 (109.95)	2112	–5.38 (48.13)
Negative	Positive	269	4.07 (116.14)	75	–20.69 (142.71)
Positive	Negative	202	6.07 (104.09)	42	–20.9 (56.96)
Positive	Positive	1179	–4.45 (100.32)	206	–5.56 (31.87)

Change in alcohol consumption (g/wk) was calculated by present alcohol consumption minus previous alcohol consumption, and expressed as mean (SD). We performed a Tukey test to investigate the statistical significance of the difference between two groups. No significant difference was identified.

This table indicates the positive prevalence of parameters for four levels of alcohol consumption: non or minimal, < 40 g/wk; light, 40–140 g/wk; moderate, 140–280 g/wk; and excess, > 280 g/wk. Two groups of subjects were compared by using the unpaired *t* test and χ^2 test. The significance of differences between two side-by-side groups among the four groups was determined by two-tailed, multiple χ^2 tests with Bonferroni correction ($P < 0.016$ for three comparisons in four groups). Smoking status was also categorized into three groups; never smoker, ex smoker and current smoker. Regular exercisers were defined as participants who performed any kind of sports at least once a week. Usage of drugs was defined as participants who receive any drugs that potentially affected metabolic syndrome (MS). HDL-c: High-density lipoprotein-cholesterol; rATP Ⅲ: Revised National Cholesterol Education Program Adult Treatment Panel Ⅲ; IDF: International Diabetes Federation; BMI: Body mass index.

proven fatty liver and MS at the same time in a general population. Our study clearly indicated that the effect of alcohol was different between fatty liver and MS, although they are correlated closely. The effect of alcohol consumption on MS was not consistent, because it differed among components of MS. Alcohol consumption was associated with lower risk for HDL-C, but was associated with higher risk for high blood pressure and high fasting plasma glucose. Waist circumferences were not affected by level of alcohol consumption. Moreover, these results were similar when we used the Japan Society for The Study of Obesity definition for MS[33]. Our study clearly indicated that light to moderate alcohol consumption was associated with lower risk of fatty liver. Moreover, any level of alcohol consumption could have a protective effect on fatty liver in men. Our study was cross-sectional, therefore, the findings might be due to changed alcohol consumption after previous detection of fatty liver. However, our sub-analysis indicated that changes in alcohol consumption were small and were not due to previous detection of fatty liver.

Previous studies have indicated that the presence of fatty liver is a strong predictor of MS[36], and fatty liver correlates with all the components of MS[37]. Among populations with no or light alcohol consumption, liver fat content in participants with MS is significantly increased up to fourfold higher than those without MS[37], and the incidence of fatty liver has been shown to be increased fourfold in men and 11-fold in women with MS[27]. Although fatty liver is considered to be a hepatic manifestation of MS, more than half of Japanese men and women with fatty liver were not diagnosed with MS.

Interpretations

Alcohol consumption is a lifestyle factor, and its effects on health range from beneficial to detrimental. The dose-response relationship between alcohol and all-cause mortality follows a J- or U-shaped curve, which points to lower all-cause mortality among those with light to moderate alcohol consumption compared to excess consumption[38]. This effect is thought to be due mainly to a reduction in cardiovascular disease[7]. This reduction in cardiovascular disease has been attributed to the beneficial impact of alcohol on plasma lipid levels, hemostatic factors[8], and insulin sensitivity[3,6]. Some studies have suggested that as much as half of the cardiovascular benefit attributable to alcohol consumption may be because it increases HDL-C level[7-10]. We found that HDL-C was increased as the quantity of alcohol consumption increased, which was consistent with previous reports[7-10]. On the other hand, alcohol consumption contributes to elevated blood pressure[39,40]. Then, we also found that blood pressure was increased as the quantity of alcohol consumption increased.

In fact, studies about the association between alcohol consumption and obesity have not been consistent. Waist-to-hip ratio increases as the quantity of alcohol consumption increases[41,42], and waist circumference increases with excess alcohol consumption (> 40 g/d)[43]. Alcohol consumption of 30 g/d or more significantly increases BMI and the risk of weight gain[44]. In contrast, another study has reported that light-to-moderate alcohol consumption reduces waist circumference[16]. Moreover, some studies have found no significant association between alcohol consumption and obesity[45,46]. We also found no significant association between alcohol consumption and high waist circumference and BMI (BMI > 25 kg/m^2).

Alcohol consumption may increase triglyceride concentrations[8]. Triglycerides have been reported to be higher in individuals with excess alcohol consumption, but lower in those with light to moderate consumption[8]. Similar results were found in our study, which indicated that the OR for high triglyceride levels was increased to > 1.0 in men with excess alcohol consumption, and was decreased to < 1.0 in women with light consumption. The favorable effect of alcohol consumption contributing to enhance insulin sensitivity has been reported[3-6]. However, another study has provided different evidence that insulin resistance is related to alcohol consumption in a U-shaped manner[47]. In our study, the OR for high fasting plasma glucose was increased as the level of alcohol consumption increased.

Overall, the present study proved that the effect of alcohol consumption for MS was not significant in the Japanese general population. In fact, studies regarding the association between alcohol consumption and MS have not been consistent[11-17], because the relationship heavily depends on the individual components of MS. Moreover, previous studies have claimed that the type of alcohol is important for the association of alcohol consumption and MS[23,48,49]. Modest wine consumption has been reported to be associated with reduced all-cause mortality[48,49] and fatty liver[23]. In our study, however, the association between wine consumption and MS and fatty liver was not significant. Similarly, Djousse *et al*[15] have reported that the association between alcohol consumption and MS is unrelated to the type of alcoholic beverage.

Findings on the relation between alcohol consumption and fatty liver have also been inconsistent[19-25]. Fat deposition in the liver has been shown to be primarily due to an increased influx of fatty acids to the liver; most likely as a result of the increased lipolysis associated with obesity and insulin resistance, and as a result of increased hepatic *de novo* lipogenesis[50]. Reduced fatty acid oxidation and mitochondrial dysfunction and decreased export of fat further contribute to the accumulation of liver fat[51,52]. Alcohol-dehydrogenase-mediated ethanol metabolism generates a reduced form of nicotinamide adenine dinucleotide, which promotes steatosis by stimulating the synthesis of fatty acids and opposing their oxidation[53]. The hepatic lipogenic pathway is activated after the consumption of 24 g/d ethanol[53]. Sterol regulatory element binding protein 1c (SREBP1c)[54] and peroxisome proliferator activated receptor (PPAR)α[55], are altered with alcohol consumption. The involvement

of AMP-activated protein kinase activity in the action of ethanol on the liver has been demonstrated in experimental models of ethanol-induced steatosis[56].

SREBP1c is upregulated, which potentially results in increased conversion of glucose to fatty acids and triglycerides in experimental models of obesity[52]. PPARα is a nuclear receptor that is important in fatty acid uptake and oxidation, and has been shown to be underexpressed in experimental models of non-alcoholic steatosis[57]. In addition, the administration of adiponectin reverses non-alcoholic steatosis in experimental models[57,58].

Thus, several pivotal factors in the pathogenesis of fatty liver may be common in both alcoholic and non-alcoholic subjects. Therefore, the possible mechanism by which alcohol has a protective effect against fatty deposition in the liver remains unclear. Our study also provides clear evidence that light to moderate alcohol consumption has a favorable effect on fatty liver.

Some limitations of our study should be noted. First, although ultrasonography has been validated for detecting fatty liver, it may give an incorrect diagnosis compared to liver biopsy[30]. Second, self-reported information regarding alcohol intake is frequently subject to underreporting, and misreporting could be a source of bias. However, the self-reported information regarding alcohol intake in our study was validated previously[27]. Third, the generalizability of our study to non-Japanese populations is uncertain.

In conclusion, the effect of alcohol consumption was different between MS and fatty liver. The relationship between alcohol consumption and MS depends on the individual components of MS given the inconsistency of the association between alcohol consumption and MS. Light to moderate alcohol consumption has a favorable effect on fatty liver in Japanese men and women. Moreover, any level of alcohol consumption may have a protective effect against fatty liver in men. Unexpectedly, more than half of Japanese men and women with fatty liver were not diagnosed with MS, although fatty liver is considered to be a hepatic manifestation of MS. However, our previous studies have implied that the risk of fatty liver for cardiovascular disease is independent of MS[59]. Thus, fatty liver without MS is an important disease in the general population.

A future longitudinal study is needed to clarify that alcohol consumption has true hepatoprotective effects. Furthermore, the protective mechanism of alcohol against fatty deposition in the liver remains unclear. Thus, basic research is also needed to clarify the mechanisms that underlie modest alcohol consumption and fatty liver.

COMMENTS

Background

The effects of alcohol on the metabolic syndrome (MS) have been inconsistent in previous studies. Fatty liver is closely associated with MS, and is considered to be the hepatic manifestation of MS. Findings on the relation between alcohol consumption and fatty liver have also been inconsistent.

Research frontiers

The favorable effect of alcohol intake enhances insulin sensitivity, and increases high-density lipoprotein-cholesterol, which contributes to a lower risk of type 2 diabetes mellitus, and cardiovascular disease. Moreover, alcohol consumption plays a protective role against fatty deposition in the liver, although alcohol consumption certainly could be a cause of fatty liver in some cases.

Innovations and breakthroughs

The authors investigated the association of alcohol consumption with ultrasonography-proven fatty liver and the MS at the same time in a general population, and clearly indicated that light to moderate alcohol consumption has favorable and unfavorable effects for components of MS, but has a protective effect for fatty liver.

Applications

Light to moderate alcohol consumption has a favorable effect on fatty liver in Japanese men and women. Moreover, any level of alcohol consumption may have a protective effect in men. A future longitudinal study is needed to clarify that alcohol consumption has true hepatoprotective effects. Furthermore, the mechanism of alcohol protection against fatty deposition in the liver remains unclear. Thus, basic research is also needed to clarify the mechanisms that underlie the effect of modest alcohol consumption on fatty liver.

Peer review

The strengths of the study include its large sample size and validated questionnaire.

Abstract

AIM: To evaluate the correlation between the level of ^{18}F-fluoro-2-deoxyglucose (^{18}F-FDG) uptake and glucose transporter 1 (GLUT1) expression in colorectal adenocarcinoma (CRA).

METHODS: Forty four patients with resected CRA and preoperative ^{18}F-FDG positron emission tomography - computed tomography data were investigated in this study. Comparison of maximum standardized uptake value (SUVmax) of the lesion was made with GLUT1 expression by immunohistochemistry and various clinicopathologic factors including tumor volume, invasion depth, gross finding, and lymph node metastasis.

RESULTS: SUVmax was 14.45 ± 7.0 in negative GLUT1 expression cases, 15.51 ± 5.7 in weak GLUT1 expression cases, and 16.52 ± 6.8 in strong GLUT1 expression cases, and there was no correlation between between GLUT1 expression and SUVmax. SUVmax was significantly correlated with tumor volume ($P < 0.001$). However, there was no significant differences in SUVmax and GLUT1 expression among other clinicopathologic factors.

CONCLUSION: GLUT1 expression does not correlates significantly with ^{18}F-FDG uptake in CRA. ^{18}F-FDG uptake was increased with tumor volume, which is statistically significant.

Key words: ^{18}F-fluoro-2-deoxyglucose; Glucose transporter 1; Colorectal cancer

INTRODUCTION

Cancer cell growth is an energy-related process supported by increased glucose metabolism[1]. This uptake is mediated by glucose transporter (GLUT) proteins, which are membrane proteins responsible for the transport of glucose across cellular membranes. A family of seven glucose transporters have been cloned[2]. Among these, GLUT1 is the best-known basic, high-affinity glucose transporter, which is restricted to erythrocytes and blood-tissue barriers such as the blood-brain and blood-nerve barriers, in most normal tissues[3,4]. It has long been recognized that cancer cells have increased rates of glucose

metabolism compared with normal cells[5]. Increased GLUT1 expression has been described in many cancers, including breast, lung, kidney, urinary bladder, stomach, colorectum, endometrium, thyroid, head and neck, liver, ovary, salivary gland, and prostate cancer[6] due to a high metabolic rate and fast growth environment, but, generally absent in benign epithelial tissues. The expression of GLUT1 thus would appear to be a potential marker for malignant transformation, and the degree of tumor GLUT1 expression might correlate with biologic behavior in individual patients[7].

Positron emission tomography (PET) using ^{18}F-fluoro-2-deoxyglucose (FDG) is a rapidly developing functional-imaging modality that has shown great promise in the fields of primary, recurrent and metastatic tumor detection, planning and monitoring therapy[8-12]. The cellular mechanism underlying the increased ^{18}F-FDG accumulation in malignant tumors is associated with a higher rate of phosphorylation and diminished rate of dephosphorylation of intracellular phosphorylated glucose, a higher rate of glucose transport across the cell membrane, and higher activity of hexokinase[13]. There have been several studies about possible associations of GLUT1 expression with other clinicopathologic parameters and ^{18}F-FDG PET findings in several cancers, such as carcinoma of lung, pancreas, and breast[1]. However, to the best of our knowledge, it has not been elucidated in colorectal adenocarcinoma (CRA). Therefore, we conducted a prospective study to determine the association between GLUT1 expression and the maximum standardized uptake values (SUVmax) obtained from ^{18}F-FDG PET scans. The relationship between GLUT1 and SUVs with other clinicopathologic factors was also evaluated. Additionally, we evaluated a difference in GLUT1 expression between adenoma and carcinoma in the colorectum.

MATERIALS AND METHODS

Patients

Among patients who had FDG-PET examination and underwent curative surgery for CRA at Chosun University Hospital from January 2007 to December 2010, the present study was conducted on a non-consecutive series of 44 patients where paraffin embedded tissues were relatively well preserved and complete medical records were present. Patients who underwent preoperative chemoradiotherapy and emergency surgery, and patients who had evidence of hereditary non-polyposis colorectal cancer or familial adenomatous polyposis were excluded from the study. The various clinicopathological parameters of the patients were confirmed by reviewing the patient medical records and pathology files. The relationship between clinicopathological parameters for the patients and the immunohistochemical findings with survival was investigated for all 44 patients. Additionally, there were 27 adenomatous cases, including 15 cases of tubular adenoma (TA), 7 villous adenomas (VA), and 5 tubulo-villous adenomas (TVA).

Histopathological analysis

Microscopic examination: each tumor was re-evaluated by retrospective analysis of the medical records and the tissue slide files of the Department of Pathology. Age, gender, tumor size, histological subtypes and the degree of differentiation, the depth of tumor invasion, the status of lymph node metastases and the presence of a distant metastasis were assessed. Stage was defined according to the TNM staging system of the American Joint Committee on Cancer[17]. The examined tissues were fixed in 10% neutral formalin, and the prepared paraffin embedded tissues were sectioned 4-5 μm in thickness. Hematoxylin and eosin staining was performed, and the sections were examined under a light microscope. A representative area suitable for the study purpose was selected, and slides were prepared for immunohistochemical analysis.

Immunohistochemical staining

All of the specimens in this study were tested using a gout polyclonal antibody against GLUT1 (Abcam) according to the manufacturer's protocol. Immunolocalization was performed using the mouse ImmunoCruz Staining System: sc-2050 (Santa Cruz Biotechnology), according to the manufacturer's protocol. The staining process was performed according to a standard protocol. Briefly, the 4 μm sections that were obtained after formalin fixation and paraffin embedding were deparaffinized in xylene and were then rehydrated with distilled water through a graded series of ethanol solutions. The sections were then placed in a glass jar with 10 mmol/L citrate buffer (pH 6.0) and were irradiated in a microwave oven for 15 min. The sections were allowed to cool in the jar at room temperature for 20 min. The slides were then rinsed with Tris buffered saline (TBS). A blocking reagent was added for 10 min after quenching the endogenous peroxidase activity in 0.3% hydrogen peroxide for 10 min. The slides were then washed as described previously, and the slides were subsequently subjected to the primary antibody reaction. Immunohistochemistry was performed on the Nexes ES (Ventana, Tucson, AZ). Slides were incubated with the antibodies for 32 min. The Ventana basic DAB detection kit (catalog No. 760-001) was the secondary detection method. This includes biotinylated immunoglobulin secondary antibody, containing affinity purified goat-antimouse IgG and IgM (b200 lg/mL) and goat-antirabbit IgG (b200 lg/mL) in phosphate buffer with preservative. Incubation was for 8 min. This was followed by conjugated streptavidin horseradish peroxidase. Slides were counterstained with hematoxylin (Ventana catalog No. 760-2021).

Analysis and interpretation of staining

GLUT1 immunostaining was quantified by grading the proportion of cells that were GLUT1 positive. Cells showing strong and distinctive membranous immunoreactivity for GLUT1 were considered positive. Cyto-

plasmic staining, including a supra nuclear dot pattern or nuclear staining, was regarded as negative[6]. The degree of GLUT1 immunostaining of a specimen was graded according to the proportion of GLUT1-positive cells in it (weakly positive, < 10%; moderately positive, 10%-50%; strongly positive, > 50%)[7].

Statistical analysis

The mean with standard deviation (SD) was calculated for the longest tumor diameter and SUVmax. Mann-Whitney *U* or Kruskal-Wallis test was used to assess differences in the levels of SUVmax and in the staining scores of GLUT1 between the groups. Correlations between SUVmax and GLUT1 expressions and between SUVmax and tumor diameter were analyzed by Spearman's rank test. A value of $P < 0.05$ was considered as statistically significant. The SPSS statistics 17.0 program (SPSS, Korea) was used for statistical evaluation.

RESULTS

The clinical characteristics of the patients are summarized in Table 1. The average age at the time of surgery was 65.73 years and the ratio of male to female participants was 24:20 (54.5%:45.5%). Mean tumor size was 18.92 cm, and mean SUVmax value was 15.47. In normal epithelium, specific GLUT1 expression was not observed. As expected, erythrocyte membranes were strongly GLUT1 positive. In adenoma cases, GLUT1 expression was absent in 23 cases (85.1%) and weakly positive in 4 cases, which were one VA and 3 TVAs. The positive rate of GLUT1 expression was significantly different ($P = 0.008$) among the TA, VA, and TVA. Of 44 cases of CRA, 91% had specific GLUT1 immunostaining in the plasma membrane. The extent of expression varied greatly. Of immunopositive cases, 13 cases (29.5%) showed weak staining (< 10% of tumor cells), 12 cases (27.3%) moderate staining (10%-50% of tumor cells), and 15 cases (34.1%) strong expression (> 50% of tumor cells), which were significantly different from adenomatous cases ($P < 0.001$). In cancer tissue, GLUT1 is usually strongly positive in the center of the necrotic and infiltrative areas (Figure 1). Concerning correlation between GLUT1 expression and SUVmax in PET, the mean SUVmax was 14.45 ± 7.0 in negative GLUT1 expression cases, 15.51 ± 5.7 in weak GLUT1 expression cases, and 16.52 ± 6.8 in strong GLUT1 expression cases, and there was no significant correlation between GLUT1 expression and SUVmax. SUVmax was significantly correlated with tumor volume ($P = 0.002$). However, GLUT1 expression did not correlate with tumor size. There was no significant difference in SUVmax and GLUT1 expression among other clinicopathologic factors including invasion depth, lymph node metastasis and gross type (Table 2).

Table 2 Relation between glucose transporter 1 expression/maximum standardized uptake values and clinicopathologic parameters

Clinicopathologic factors	*n*	GLUT1 expression[1]				SUVmax	
		0	1	2	*P* value	Medium	*P* value

[1]GLUT1 expression; [2]Statistically significant, $P < 0.05$. 0: Negative or weak; 1: Moderate; 2: Strong expression. GLUT: Glucose transporter; SUVmax: Maximum standardized uptake values.

DISCUSSION

Among Gluts, Glut-1 and Glut-3 have been proven to show overexpression in both messenger RNA and protein in a variety of cancer cells[14-18]. Therefore, Glut-1 and Glut-3 may play an important role in glucose uptake by these cancers and could be useful biomarkers for malignant transformation[1]. We herein demonstrate that GLUT1 protein expression is a marker for malignant transformation in CRA. For CRA, an initial report showed increased expression of GLUT1 mRNA compared with normal colon[19], and GLUT1 immunostaining was subsequently demonstrated in seven of nine colorectal carci-

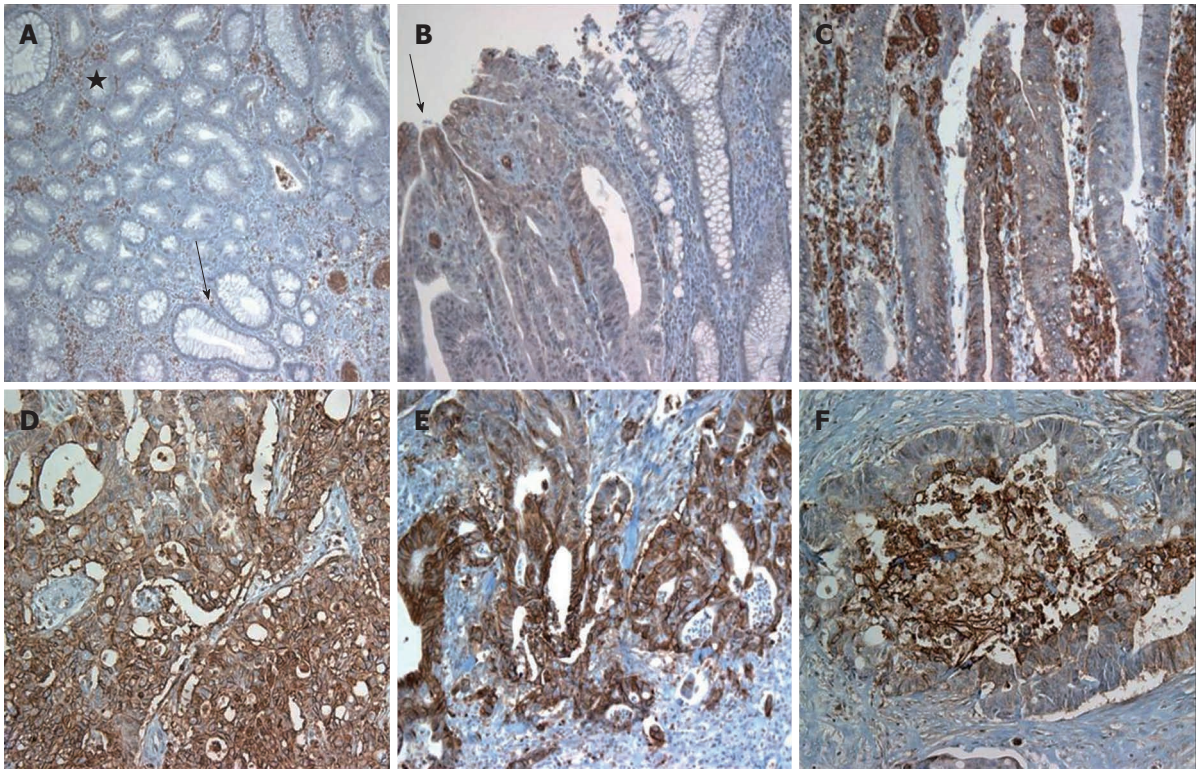

Figure 1 Glucose transporter 1 expression in normal colonic epithelium, adenomas and adenocarcinomas. A: No glucose transporter 1 (GLUT1) expression in tubular adenoma (star) and normal epithelium (arrow), while immunostaining in erythrocytes; B and C: GLUT1 immunostaining in the villous adenoma (B, arrow: Expression at the tip of villous frond); D: Colorectal adenocarcinoma with strong GLUT1 expression; E and F: More strong expression at the infiltrative border (E) and necrotic center (F).

nomas[20]. A recent study of 53 colon carcinomas demonstrated the presence of GLUT1 immunostaining in 83%, and a higher degree of GLUT1 expression correlated with the presence of lymph node metastases[21]. The greater degree of GLUT1 expression in these tumors most likely reflects a greater enhancement of glycolytic metabolism in the more malignant tumors. It has recently been reported that GLUT1 (and/or GLUT3 expression) correlates with poor prognosis and tumor aggressiveness in carcinomas of the lung and bladder, and in squamous cell carcinoma of the head and neck[22-24]. Although the present study did not show these results, these data suggest the possibility that tumors with absent GLUT1 staining might express another GLUT iso-form such as GLUT3, which also might be associated with poor prognosis[22].

In the present study, the normal and most adenomatous colorectal mucosa did not express GLUT1 protein. In benign colorectal neoplasms, GLUT1 expression was absent in TA, and in VA and TVA, there was only rare focal staining at the tips of villous fronds. These results are consistent with a recent report that some VAs have very limited focal GLUT1 expression[21]. GLUT1 expression in VA is consistent with the concept that GLUT1 is a marker of neoplastic progression in the colon, because it is this subtype of colonic adenoma that is believed to have the greatest potential for malignant transformation[7].

In cancer tissue, GLUT1 is usually strongly positive in the luminal border and center of the necrotic and infiltrative areas. Rapid proliferation relative to vascular support exposes tumor cells to persistent hypoxic conditions with potential necrotic or apoptotic effects[6]. Malignant cells, however, can undergo genetic and adaptive changes that allow them to avoid oxygen deprivation-induced death. One of these changes is an increased uptake of glucose and other sugars compared with normal cells[25]. In normal human small intestinal villi, the tips of villi may be a site of relative hypoxia[26]. Because hypoxia is known to stimulate glycolysis and GLUT1 expression[27], the localization of GLUT1 immunostaining to this site in VAs also might reflect an adaptation to enhanced local glycolytic demand[7].

Two possible mechanisms may explain the activation of *GLUT1* gene expression in CRA and other malignancies[7]. First, increased glycolysis and concomitant GLUT1 expression may be a constitutive feature of the malignant phenotype in many cancers. This is consistent with observations that transformation of cultured cells with ras or src oncogenes induces increased glucose uptake and GLUT1 expression[28,29]. Second, local hypoxia in the tumor microenvironment may result in an adaptive increase in glycolytic metabolism and GLUT1 expression[7]. The latter mechanism is also demonstrated in the present study; GLUT1 tended to be expressed stronger at the luminal border and center of tumor nests, increasing with distance from stromal blood vessels.

Higher levels of GLUT1 expression in neoplastic tis-

sue reflect an increased glycolytic metabolism[30]. In previous studies of CRA, a high level of GLUT1 expression was significantly associated with the presence of lymph node metastases[21] and poorer prognosis[7]. These studies suggested that the expression of GLUT1 could be a marker for malignant potential. In our study, the analysis of the association between GLUT1 expression and other clinicopathologic parameters did not show any significant correlation. These results differ from those of previously published data for other tumors[21,31,32], but they are compatible with the results of Avril *et al*[33] for breast cancer. In a study by Haber *et al*[7], the proportion of GLUT1 staining did not correlate with Dukes' stage of the CRA, but Sakashita *et al*[30] demonstrated that in T1 and T2 stage CRA, GLUT1 expression correlated with Duke stage. The discrepancy between the two studies could have been caused by differences in the clinical characteristics of the subjects enrolled. Haber's study included only 6 Dukes' A cases and all other cases were more advanced, while Sakashita's study analysed only T1 and T2 stage cases. So, Sakashita *et al*[30] speculated as follows: in early-stage carcinomas GLUT1 positivity is low, but correlates with the depth of the lesion. In contrast, in the more advanced stages, the tumor cells already show high GLUT expression, and no further increase of GLUT1 expression occurs, even when the cancer invades more deeply.

Cancer cells have higher rates of glucose metabolism than normal cells. Malignant tissues typically demonstrated higher ^{18}F-FDG uptake than benign lesions and normal tissue[34]. PET-CT using ^{18}F-FDG has been known to be a useful tool for several malignant tumors. Several immunohistochemical studies have demonstrated overexpression of GLUT1 in human malignancy and a correlation between GLUT1 expression and neoplastic progression[22]. The overexpression of GLUT1 in human cancers has been reported to be closely related to ^{18}F-FDG uptake on PET-CT[18]. Another report, however, showed no relation between GLUT1 expression and ^{18}F-FDG uptake on PET[33], and there is a controversial report that did not demonstrate a statistically significant correlation between GLUT1 expression and FDG uptake[35].

In present study ^{18}F-FDG uptake related to tumor size, whereas GLUT1 frequency did not. Brown *et al*[36] had mentioned that ^{18}F-FDG uptake and GLUT1 expression appeared to be associated with tumor size, but our data did not support their findings. Tumor size is one of the most important factors affecting the SUVmax[37]. The ^{18}F-FDG uptake might be influenced by the total amount of glucose uptake into the tumor. Therefore, the larger a carcinoma is, the higher is the ^{18}F-FDG uptake by the carcinoma shown on the PET scan. It is well known that SUVmax has a lower than "real" value when the tumor size is < 20 mm because of the limited resolution of current PET scanners[37,38]. In contrast, GLUT1 staining is examined through a microscope, and GLUT1 frequency is determined microscopically. Therefore, GLUT1 frequency shows microscopic activity of glucose uptake into the tumor and is influenced by cell type, cellularity, and pathological structure[39]. At the result, GLUT1 frequency would not be related to tumor size. GLUT1 expression could become strongly positive even in small carcinomas with high cellular density or metabolic activity.

In conclusion, in contrast to other malignant tumor such as lung cancer[39], squamous cell carcinoma of the cervix[1] and head and neck cancer[40], and cholangiocarcinoma[41], GLUT1 expression did not correlate significantly with ^{18}F-FDG uptake and other clinicopathologic parameters in CRA, which suggests that overexpression of GLUT1 cannot fully explain the biologic behavior of CRA. The ^{18}F-FDG uptake was significantly correlated with tumor size only. We identified that GLUT1 is usually strongly positive in the center of the necrotic and infiltrative areas in colorectal cancer. Although overexpression of GLUT1 is very important for ^{18}F-FDG uptake in cancer cells, further investigations should evaluate the contributions of other factors concerning tumor hypoxia and glucose metabolism.

COMMENTS

Background

Cancer cell growth is an energy-related process supported by increased glucose metabolism. This uptake is mediated by glucose transporter (GLUT) proteins, which are membrane proteins responsible for the transport of glucose across cellular membranes. Positron emission tomography (PET) using ^{18}F-fluoro-2-deoxyglucose (FDG) is a rapidly developing functional-imaging modality that has shown great promise in the fields of primary, recurrent and metastatic tumor detection, planning and monitoring therapy. Therefore, the authors conducted a prospective study to determine the association between GLUT1 expression and the maximum standardized uptake values (SUVmax) obtained from ^{18}F-FDG PET scans. The relationship between GLUT1 and SUVs with other clinicopathologic factors was also evaluated. Additionally, the authors evaluated the difference in GLUT1 expression between adenoma and carcinoma in the colorectum.

Research frontiers

This article may present information to the colorectal oncologist for further study about glucose metabolism of colorectal adenocarcinoma (CRA), and to the colorectal oncologist the usefulness of PET CT in evaluating colorectal cancer patients.

Innovations and breakthroughs

In contrast to other malignant tumors such as lung cancer, squamous cell carcinoma of cervix and head and neck, and cholangiocarcinoma, GLUT1 expression did not correlate significantly with ^{18}F-FDG uptake and other clinocopathologic parameters in CRA, which suggests that overexpression of GLUT1 cannot fully explain the biologic behavior of CRA. The ^{18}F-FDG uptake was significantly correlated with tumor size only. The authors identified that GLUT1 is usually strongly positive in the center of the necrotic and infiltrative areas in colorectal cancer. Although overexpression of GLUT1 is very important for ^{18}F-FDG uptake in cancer cells, further investigations should evaluate the contributions of other factors concerning tumor hypoxia and glucose metabolism.

Peer review

Overall the manuscript is reasonably well written and provides additional information on GLUT1 expression and FDG uptake.

Abstract

AIM: To determine the role of circulating tumor cells (CTCs) in prediction of the overall survival of patients with advanced malignant biliary tract obstruction.

METHODS: We investigated the prognostic value of CTCs by examining two markers, cytokeratin (CK) 19 and human telomerase reverse transcriptase (hTERT) mRNA, in 40 patients diagnosed with advanced malignant biliary tract diseases. Quantitative real-time reverse transcription polymerase chain reaction was used to detect CK19 and hTERT mRNA in the peripheral blood of these patients. Overall survival was analyzed using the Kaplan-Meier method and Cox regression modeling.

RESULTS: Positive CK19 and hTERT mRNA expression was detected in 45% and 60%, respectively, of the 40 patients. Univariable analysis indicated that positive CK19 mRNA expression was significantly associated with worse overall survival (P = 0.009). Multivariable analysis determined that positive CK19 mRNA expression, patient's age and serum bilirubin were each independently associated with overall survival.

CONCLUSION: CK19 mRNA expression levels in peripheral blood appear to provide a valuable marker to predict the overall survival of patients with advanced malignant biliary tract obstruction.

Prognostic relevance of circulating CK19 mRNA in advanced malignant biliary tract diseases. *World J Gastroenterol* 2012; 18(2): 175-181 Available from: URL: http://www.wjgnet.com/1007-9327/full/v18/i2/175.htm DOI: http://dx.doi.org/10.3748/wjg.v18.i2.175

INTRODUCTION

Malignant biliary tract obstruction is a condition that can

result from tumors of the biliary tract, ampulla of vater, duodenum or head of the pancreas. In Thailand, cholangiocarcinoma (CCA) is the most common cause of malignant biliary tract obstruction[1]. Despite recent advances in the diagnosis and treatment of this disease, patient outcome remains poor. The high mortality rate arising from malignant biliary tract obstruction is due to the aggressiveness of tumors that are often discovered at a late stage of disease progression[2]. Palliative therapeutic approaches to endoscopic biliary drainage, such as the use of endoprosthesis stents, are generally recommended for these patients. The two major types of endoprosthesis stents are plastic or polyethylene (PE) stents and self-expanding metal stents (SEMS). Previous studies have demonstrated that partial or total occlusion of PE stents usually occurs 3-4 mo after insertion[3]. Four randomized controlled studies demonstrated that SEMS exhibited a significantly higher patency rate as compared with the PE stents (9 mo *vs* 1.5 mo)[4-7]; however, SEMS is much more expensive than PE stents (1500 USD *vs* 80 USD, in Thailand). A recent study indicated that patients who have a predicted survival duration of more than 4.5 mo should use SEMs for their palliative biliary drainage[8]. In this instance, the higher cost of the SEMs is balanced by a decreased need for repeat intervention that is often necessary in patients who have received PE stents. Therefore, identification of reliable prognostic factors that allow for an accurate prediction of survival duration in patients with advanced malignant biliary tract obstruction is extremely important.

One of the major mechanisms for tumor metastasis is the dissemination of tumor cells from the primary tumor into circulating blood[9]. Previous studies have indicated that detection of circulating tumor cells (CTCs) in the peripheral blood can be used in staging and prognosis stratification for breast and colon cancer patients[10-12]. Until now, however, there has been no study concerning the role of the detection of CTCs as a prognostic factor in patients with malignant biliary tract diseases.

To date, the most common CTCs detection method is quantitative real-time reverse transcription polymerase chain reaction (RT-PCR), a process that can detect mRNA expression levels of the genes coding for these tumor antigens[13]. A high-quality detection marker is required for efficient quantitative real-time RT-PCR-mediated detection of CTCs. Therefore, identification of a good target marker is of the utmost importance for CTC detection. Several gene markers, such as cytokeratin (CK) 19 and human telomerase reverse transcriptase (hTERT), have been evaluated as tumor-specific markers for the detection of CTCs in gastrointestinal cancers[14,15].

hTERT mRNA can be detected in 85% of all cancer cells, including cholangiocarcinoma cells[16]. This is in contrast to most normal cells, which exhibit little or no expression. Our previous study demonstrated that high levels of hTERT mRNA can be detected in the blood circulation of cholangiocarcinoma patients, and it has also been suggested that hTERT mRNA is a promising marker for the detection of cancer cells[17].

CK19 is generally expressed in ductal epithelium (bile ducts, pancreas, and renal collecting tubules) and in the mucosa of the gastrointestinal tract. CK19 immunohistochemistry is used in diagnostic pathology mainly to confirm epithelial immunophenotype in undifferentiated tumors or to establish biliary, pancreatic or renal ductular origin[18]. Most adenocarcinomas arising from the gastrointestinal tract are CK19 positive, including cholangiocarcinoma and pancreatic cancer[18]. Many investigators have used the detection of CK19 mRNA in peripheral blood as a target gene to investigate CTCs[14,19,20]; however, until now there has been no study focusing on the detection of hTERT and CK19 in the peripheral blood of patients with malignant biliary tract diseases.

This study was aimed to evaluate if the levels of CTCs could be used to predict the overall survival of patients with advanced malignant biliary tract obstruction. *CK-19* and *hTERT* were selected as the target genes for CTCs. In addition, this study was performed in accordance with the REporting recommendations for tumor MARKer prognostic studies[21] to ensure the standardization and transparency of the study.

MATERIALS AND METHODS

Patients and samples

We prospectively included the patients with advanced malignant biliary tract diseases who underwent palliative endoscopic retrograde cholangiopancreatography or percutaneous transhepatic biliary drainage at Department of Surgery, Rajavithi Hospital from January 2008 to December 2009. The cutoff date for data analysis was December 31, 2010. The inclusion requirements included patients present with malignant bile duct obstruction that was not amenable to curative resection and patients who were followed up for at least one month after biliary tract drainage. All blood and clinical information was obtained with patient informed consent after approval by the Rajavithi Hospital Ethics Committee.

Pre-treatment fasting blood samples were collected from the peripheral vein into ethylenediaminetetraacetic acid-containing tubes. The first 3 mL blood was discarded to prevent epidermal contamination (2-syringe technique). Sample processing was performed within 1 h of blood withdrawal. Blood was transferred into a 30-mL falcon tube and centrifuged at 1800 r/min at room temperature for 20 min. Plasma was removed, and the peripheral blood mononuclear cell (PBMC) fraction was stored at -80 ℃ until use.

RNA extraction and cDNA synthesis

The total RNA of PBMC fraction samples was extracted using the RNeasy mini kit (Qiagen, GmbH, Germany) following the protocol provided by the manufacturer. RNA integrity was checked by electrophoresis and quantified by absorption at 260 and 280 nm using a spectrophotometer (Beckman Coulter Du® 800, Fullerton, CA). Total RNA was reversely transcribed using random primers and

Table 1 Primer sequences

Primer	Forward	Reverse
hTERT	GCGGAAGACAGTGGTGAACT	AGC TGGAGTAGT CGCTCT GC
CK19	CCCGCGACTACAGCCACTA	GCTCATGCGCAGAGCCT
β-Actin	GTGGGGCGCCCCAGGCACCA	GTCCTTAATGTCACGCACGATTTC

hTERT: Human telomerase reverse transcriptase; CK19: Cytokeratin 19.

the IscriptTM cDNA synthesis kit (Bio-Rad, Hercules, CA, United States) following the protocol provided by the manufacturer. cDNA was stored at -80 ℃ until use.

Detection of CK-19 and hTERT mRNA by quantitative real-time PCR

Expression of *CK19* and *hTERT* genes was analyzed using specific primers (Table 1). In this assay, the housekeeping gene *β-actin* was used as an internal control to normalize variations in integrity and the total amount of cDNA. Quantitative real-time PCR assays were performed in triplicate using SYBR Green master mix (Superarray, Frederick, MD, United States) on the Chromo 4™ System (MJ Opticon Monitor ver. 3.1) (Bio-Rad, United States) for 20 min at 50 ℃. After this, 42 cycling steps for amplification of PCR products were performed (15 s, 94 ℃ for denaturation; 30 s, 60 ℃ for annealing; and 30 s, 72 ℃ for extension). Melting curve analysis was used to assess the specificity of the amplified products. The expression levels of *CK19* and *hTERT* genes from the cDNA were measured by quantitative real-time PCR using the relative quantification method ($2^{-\Delta\Delta Ct}$ method)[22]. The fold-change in gene expression was normalized to a housekeeping gene (*β-actin*) and relative to a calibrator sample. A pool of cDNA derived from the PBMCs of 30 cases of benign (common bile duct stone and gall stone) biliary tract diseases was used as the calibrator source[23]. Evaluation of the $2^{-\Delta\Delta Ct}$ indicates the fold change in gene expression relative to the calibrator. In this study, we set the positive value as a fold change in gene expression that was greater than 1.5 times relative to the calibrator and the negative value was set as a fold change in gene expression that was lesser than or equal to 1.5 times relative to the calibrator.

Determination of blood chemistries in serum samples

Biochemical studies of serum samples, including aspartate aminotransferase (AST), alanine aminotransferase (ALT), total and direct bilirubin, alkaline phosphatase, carcinoembryonic antigen (CEA) and cancer antigen (CA)19-9, were measured using routine automated methods in the Pathological Laboratory at Rajavithi Hospital.

Cell lines and cell spiking experiments

The human cholangiocarcinoma cell line RMCCA1[24] was incubated in Ham's F12 medium (Invitrogen-Gibco, Carlsbad, CA, United States) containing 10% fetal calf serum (Euroclone-Celbio, Pero, MI) at 37 ℃ in 5% CO_2. To determine the sensitivity of quantitative real-time PCR for detecting cancer cells in PBMCs, cell spiking experiments was performed. The PBMCs obtained from healthy volunteers were counted and diluted in Ham's F12 medium. RMCCA1 cells were serially diluted from 1 × 10^6 cells/mL to 1 cell/mL and added to the PBMCs. Quantitative real-time PCR was then performed to detect CK19 and hTERT mRNA.

Statistical analysis

The primary endpoint of this study was the overall survival of the patients. Survival curves were estimated using the Kaplan-Meyer method, and univariable survival comparisons were calculated according to the log rank test. Multivariable survival analysis was performed using the Cox proportional hazards regression model. The quantitative variables were compared using Mann-Whitney *U* or Student's *t* test, as appropriate. Qualitative variables were reported as counts, and comparisons between independent groups were performed using the Pearson χ^2 test. All tests of significance were two sided and $P < 0.05$ was considered statistically significant.

RESULTS

Patient characteristics

Forty-two patients with malignant biliary tract disease were included in this study. Two patients were excluded because of the poor quality of the RNA extracted from their peripheral blood. The average age of these patients was 62 years (range, 41-82 years). With regard to cancer type, 6 (15.0%) were pancreatic head cancer, 2 (5.0%) were ampullary cancer, 2 (5.0%) were gall bladder cancer, 2 (5.0%) were middle and distal common bile duct cancer and 28 (70.0%) were hilar cholangiocarcinoma. The clinical characteristics of the patients are shown in Table 2.

Cell spiking assay

CK19 and hTERT mRNA levels were elevated in the RMCCA1 cell line (Figure 1); therefore, we decided to use this cell line as a positive control for our study. Detection sensitivity of the quantitative real-time PCR assay was determined by serial 10-fold dilutions of RMCCA1 cells in PBMCs. The results demonstrated that CK19 and hTERT mRNA could be detected at levels up to 1000 cells per 10^{10} PBMC dilutions.

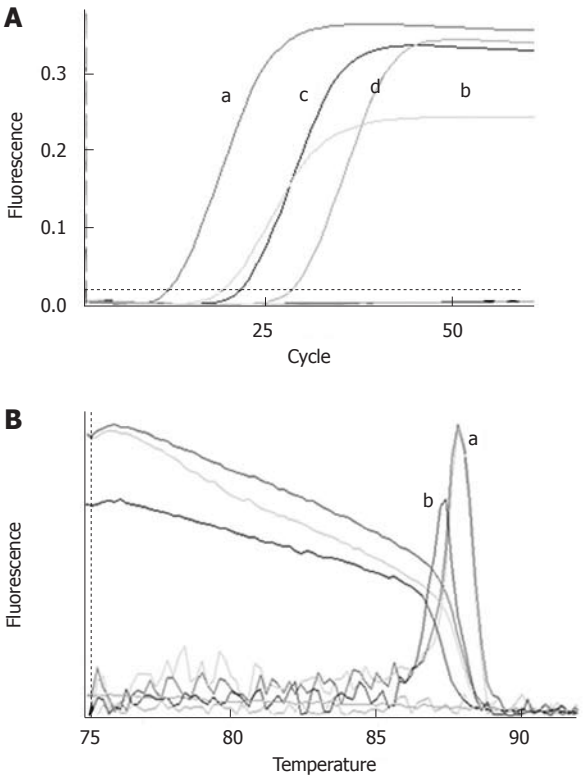

Figure 1 Gene expression levels of cytokeratin 19 and human telomerase reverse transcriptase in RMCCA1 cells (as measured by quantitative real time polymerase chain reaction). A: Amplification plot of cytokeratin (CK)19 mRNA from 10 000 RMCCA1 cells. (a) 1000 RMCCA1 cells; (b) amplification plot of human telomerase reverse transcriptase (hTERT) mRNA from 10 000 RMCCA1 cells; (c) 1000 RMCCA1 cells; and (d) are demonstrated; B: SYBR Green melting curve for quantitative real time reverse transcription polymerase chain reaction (RT-PCR). The melting curves from quantitative real time PCR for CK19 (a) and hTERT (b) consistently gave a single peak with no evidence of non-specific amplification or primer-dimerisation.

Detection of hTERT and CK19 mRNA in PBMCs of malignant biliary tract disease patients

PBMC samples from 40 patients were evaluated for the expression of hTERT and CK19 mRNA. The expression was positive (gene expression more than 1.5 times relative to the calibrator) in 45% (18/40) of samples for CK19 mRNA and 60% (24/40) of samples for hTERT. Figure 2 illustrates the distribution of CK19 mRNA and hTERT mRNA expression in the peripheral blood of these patients.

Relationship between CK19 and hTERT mRNA expression in peripheral blood and clinic pathological features of patients

No statistically significant difference was found among the data obtained from the patients considered as negative or those who were positive for hTERT or CK19 mRNA expression in PBMCs. Factors evaluated included gender, age, serum albumin, globulin bilirubin AST and ALT and alkaline phosphatase levels (Table 3).

Survival analysis

At the time of data analysis, only 1 patient was alive and 39 patients had died. The median overall survival for these patients was 4.0 mo (95% CI: 2.56-4.56). The median survival time was 1.7 mo in patients with positive CK19 mRNA expression, whereas the survival time was 5.3 mo in patients with negative CK19 mRNA expression (Log Rank, $P = 0.009$). We found that the median survival time in patients with a negative hTERT mRNA expression was not significantly different from patients with positive hTERT mRNA expression (5.9 mo *vs* 3.2 mo, Log Rank, $P = 0.183$) (Figure 3).

To identify variables that could be of potential prognostic significance in patients with advanced malignant biliary tract disease, univariable and multivariable analyses were performed using the Cox proportional hazard model to compare the impact of the mRNA expression levels of CK19 and hTERT. Other clinical parameters such as positive or negative hTERT expression, CK19 expression (positive or negative), CEA (cut-off value = 5 ng/mL), CA19-9 (cut-off value = 500 U/mL), total bilirubin (cut-off value = 15 mg/dL) and albumin (cut-off value = 3 g/dL) were also examined. Univariable analysis indicated that only CK19 mRNA expression showed significance as a prognostic factor. Multivariable analysis demonstrated that CK19 mRNA expression ($P = 0.024$), age ($P = 0.026$) and serum bilirubin ($P = 0.002$) were all independent risk factors for survival. The relative risk for CK19 mRNA positive patients was 3.2 times greater than that for CK19 mRNA negative patients (Table 4).

Table 3 Clinical characteristics of patients with negative and positive cytokeratin 19 and human telomerase reverse transcriptase gene expression

	CK19 gene		*p*	*hTERT* gene		*p*
	Negative	Positive	value	Negative	Positive	value
Age (yr)	63.80	61.38	0.42	65.26	60.88	0.16
Sex (male: female)	11:11	12:6	0.35[1]	8:8	15:9	0.52[1]
Total bilirubin (mg/dL)	16.21	16.42	0.95	17.73	15.47	0.53
Albumin (g/dL)	2.88	2.97	0.62	2.83	2.99	0.36
Globulin (g/dL)	3.98	3.76	0.42	3.92	3.84	0.79
AST (U/L)	84.57	112.80	0.23	69.27	117.48	0.12
ALT (U/L)	42.47	65.85	0.12	34.87	66.68	0.28
ALP (IU/L)	449.68	528.85	0.56	436.88	421.91	0.98
BUN (mg/dL)	13.77	26.58	0.13	12.25	23.52	0.18
Creatinine (mg/dL)	0.75	1.30	0.20	0.61	1.19	0.22
CA19-9 (U/mL)	570.20	594.30	0.62[2]	1818.00	259.15	0.11[2]
CEA (ng/mL)	7.47	5.68	0.50[2]	7.21	5.82	0.23[2]

Quantitative variables are presented as the mean value, with the exception of cancer antigen (CA)19-9 and carcinoembryonic antigen (CEA), which are presented as median values. [1]Pearson χ^2 was used to compare two groups; [2]Mann-Whitney *U* test was used to compare groups. CK19: Cytokeratin 19; hTERT: Human telomerase reverse transcriptase; AST: Aspartate aminotransferase; ALT: Alanine aminotransferase; ALP: Alkaline phosphatase; BUN: Blood urea nitrogen.

DISCUSSION

The highest incidence of cholangiocarcinoma occurs in Thailand, and the majority of patients included in this study were diagnosed with this disease[1]. In this study,

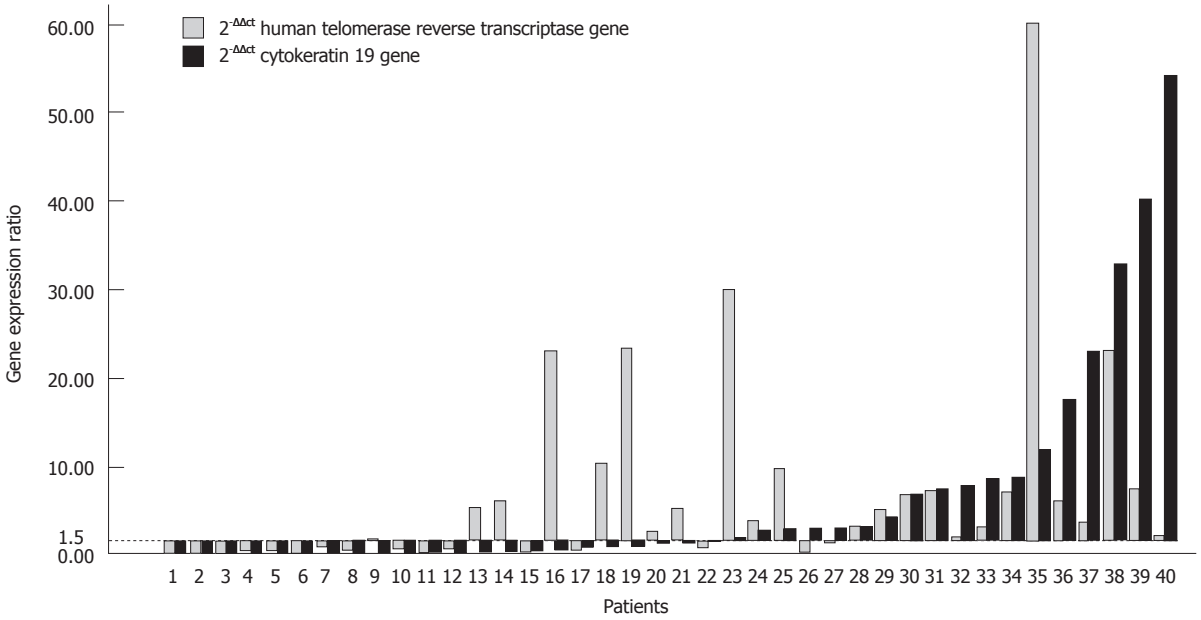

Figure 2 The distribution levels of cytokeratin 19 and human telomerase reverse transcriptase genes in the peripheral blood of 40 patients. The positive value is determined as a fold change in gene expression of more than 1.5 times relative to the calibrator.

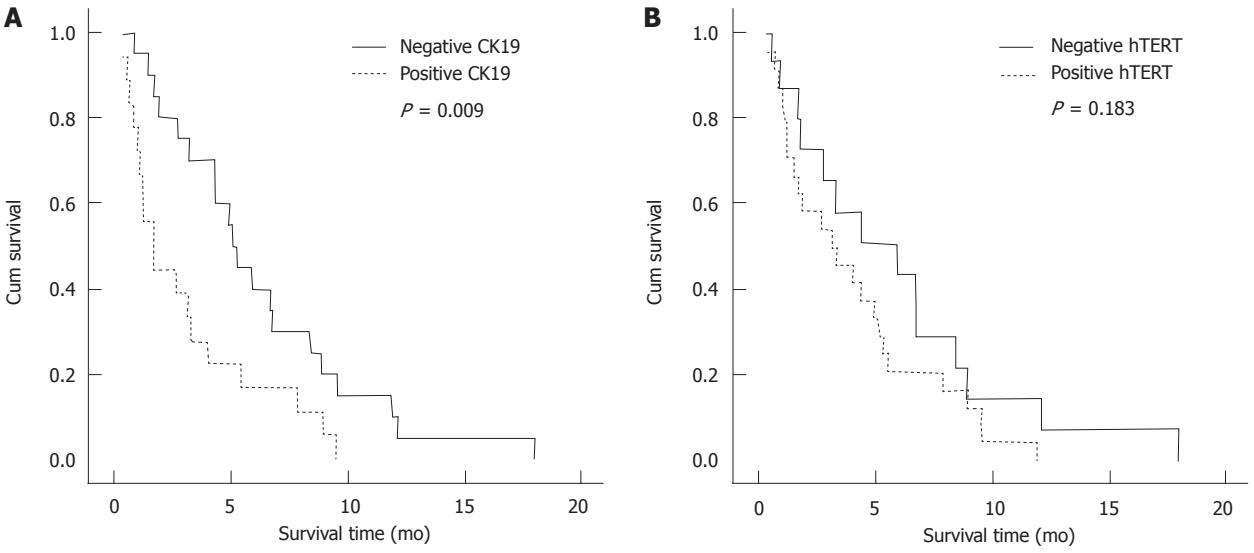

Figure 3 Kaplan-Meier survival curves of patients with positive or negative expression of cytokeratin 19 (A) and human telomerase reverse transcriptase (B) genes measured in the peripheral blood. CK19: Cytokeratin 19; hTERT: Human telomerase reverse transcriptase.

the median survival was 4.0 mo, a finding that is not significantly different from the survival time (3.6-5.0 mo) observed in previous studies of advanced malignant biliary tract disease where the majority of patients were diagnosed with pancreatic cancer[7,8,25]. These results indicate that all cancers that lead to malignant biliary tract obstruction are highly lethal. Most advanced malignant biliary tract disease patients can only be treated with palliative biliary tract drainage.

The choice of stents (PE or SEMs) for endoscopic palliation of jaundice due to malignant biliary tract obstruction is dependent upon the estimation of patient survival[8]. Therefore, there is a need for more accurate tests to predict the survival of patients with advanced malignant biliary tract diseases, as this could significantly improve the treatment outcome for these patients. This is the first cohort paper that studies the level of CTCs as a prognostic factor for overall survival of patients with advanced malignant biliary tract obstruction.

We used quantitative real-time RT-PCR to detect CTCs. As a result of the PCR-based methods, we cannot identify exactly the cell source of the measured markers. Quantitative real-time RT-PCR assesses the expression of target genes from mRNA extracted from the lysates of cells harvested from the peripheral blood of patients. As such, these samples contain not only CTC but

Table 4 Survival analysis using clinical parameters measured by univariable and multivariable analysis

Variables	Univariable analysis		Multivariate analysis	
	P value	Hazard ratio (95% CI)	*P* value	Hazard ratio (95% CI)
CK19 expression	0.011[1]	2.42 (1.22-4.78)	0.024[1]	3.20 (1.17-8.75)
hTERT expression	0.188	1.60 (0.80-3.22)	0.580	1.34 (0.47-3.82)
Age	0.541	0.82 (0.42-1.57)	0.026[1]	0.38 (0.16-0.89)
Total bilirubin	0.106	1.72 (0.89-3.31)	0.002[1]	3.97 (1.69-9.36)
Albumin	0.360	0.73 (0.37-1.35)	0.213	0.59 (0.26-1.35)
CA19-9	0.374	0.73 (0.37-1.43)	0.478	0.74 (0.32-1.70)
CEA	0.381	1.39 (0.68-2.88)	0.124	1.86 (0.84-4.12)

[1]Statistically significant. CI: Confidence interval; CK19: Cytokeratin 19; hTERT: Human telomerase reverse transcriptase; CA: Cancer antigen; CEA: Carcinoembryonic antigen.

also PBMC, circulating endothelial cells and skin cells (e.g., keratinocytes, fibroblasts and melanocytes) that contaminate the sample during blood withdrawal and provide alternate potential sources for the PCR-detected genes[13,26]. Therefore, strict selection of target genes for detection of CTCs is very important. In this study, we used *CK19* and *hTERT* genes as targets for the detection of CTCs. Previous studies have suggested that CTCs are likely to be the principal cell source for *CK19* gene expression, as CK19 expression is mainly restricted to epithelial cells and is limited in normal peripheral blood cells[20,27]. Additionally, we used the 2-syringe technique during blood collection to avoid epithelium contamination from injected site.

In our study, the patients with positive CK19 expression exhibited significantly shorter overall survival compared with the patients with negative CK19 expression (5.3 mo *vs* 1.7 mo; $P = 0.009$). Additionally, multivariable analysis using the Cox regression model also demonstrated that the levels of CK19 expression in peripheral blood, the levels of serum total bilirubin and the age of the patients can all function as independent prognostic factors in patients with advanced malignant biliary tract disease. This is consistent with previously published studies that reported that positive CK19 mRNA expression in peripheral blood was independently associated with a reduction in disease-free survival in patients with breast cancer[20]. In addition, positive CK19 mRNA expression in peripheral blood following chemoradiation was an independent, unfavorable prognostic factor for both overall survival and progression-free survival in patients diagnosed with non-small cell lung cancer[19].

In this study, there were more patients with positive hTERT mRNA expression in peripheral blood than the patients with positive CK19 mRNA expression (60% *vs* 45%); however, detection of hTERT mRNA in the peripheral blood was not identified as an independent prognostic factor in this study. We suggested that the detection of hTERT mRNA expression levels was not a good candidate as a prognostic factor for patients with advanced malignant biliary tract disease. It may be suitable for the distinction between malignant and benign biliary tract diseases in combination with other tumor specific markers.

In this study, neither univariable nor multivariable analysis indicated that serum levels of CA19-9 could be used as a prognostic factor for patients with advanced malignant biliary tract disease. This finding is inconsistent with a previous study that indicated that the levels of serum CA19-9 are of prognostic relevance in patients with biliary tract cancer[28,29]. We suggested that differences among the patients should be considered. Overall survival in a previous study was 16.1 mo[29], whereas the overall survival in our study was 4.0 mo. In addition, the majority of patients in the previous study received chemotherapy, while only two patients in our study received this treatment. This finding reflects a higher disease severity in the patients examined in our study.

Our study demonstrated that the expression of CK19 mRNA in PBMCs prior to palliative procedures was significantly associated with overall survival of the patients with advanced malignant biliary tract disease. We therefore recommend PE stents for patients with positive CK19 mRNA expression in their peripheral blood. The more expensive SEMS should be reserved for patients with negative peripheral blood expression of CK19 mRNA. Further cost-effectiveness studies should be conducted to evaluate the benefit of using CK19 mRNA in helping the physician make decisions regarding the selection of stent-type and the need for endoscopic repeat intervention in patients with advanced malignant biliary tract disease.

COMMENTS

Background

In Thailand, cholangiocarcinoma is the most common cause of malignant biliary tract obstruction. Despite recent advances in the diagnosis and treatment of this disease, patient outcome remains poor. Palliative therapeutic approaches to endoscopic biliary drainage, such as the use of endoprosthesis stents, are generally recommended for these patients. Identification of reliable prognostic factors that allow for an accurate prediction of survival duration in patients suffering from advanced malignant biliary tract obstruction is extremely important.

Research frontiers

This study demonstrated that the levels of circulating tumor cells (CTCs) could be used to predict the overall survival of patients with advanced malignant biliary tract obstruction.

Innovations and breakthroughs

The expression of cytokeratin (CK)19 mRNA in peripheral blood mononuclear cells prior to palliative procedures was significantly associated with overall survival of patients with advanced malignant biliary tract disease.

Applications

This study recommends polyethylene stents for patients with positive CK19 mRNA expression in their peripheral blood. The more expensive self-expanding metal stents should be reserved for patients with negative peripheral blood expression of CK19 mRNA.

Terminology

CTCs is the dissemination of tumor cells from the primary tumor into circulating blood. The detection of CTCs can be used in staging and prognosis stratification for cancer patients.

Peer review

This study provides evidences that high levels of CTCs in advanced malignant biliary tract obstruction patients might be used as a prognostic factor. This is a well performed and clearly presented study.

Abstract

AIM: To investigate the health related quality of life (HRQoL) and psychological outcome of donors after living donor liver transplantation.

METHODS: Participants were 92 consecutive liver transplant donors who underwent hepatectomy without middle hepatic vein at West China Hospital of Sichuan University between January 2007 and September 2010. HRQoL was measured using the Chinese version of the Medical Outcomes Study Short Form-36 (SF-36), and psychological symptoms were measured using the Symptom Checklist-90-Revised (SCL-90-R). Data collected from donors were compared to previously published data from the general population. Clinical and demographic data were collected from medical records and questionnaires.

RESULTS: The general health score of the SF-36 was significantly lower in females (59.78 ± 12.25) than in males (75.83 ± 22.09). Donors more than 40 years old scored higher in social functioning (85.71 ± 14.59) and mental health (82.61 ± 20.00) than those younger than 40 (75.00 ± 12.13, 68.89 ± 12.98; social functioning and mental health, respectively). Donors who had surgery more than two years prior to the study scored highest in physical functioning (P = 0.001) and bodily pain (P = 0.042) while those less than one year from surgery scored lowest. The health of the liver recipient significantly influenced the general health (P = 0.042), social functioning (P = 0.010), and role-emotional (P = 0.028) of donors. Donors with full-time employment scored highest in role-physical (P = 0.005), vitality (P = 0.001), social functioning (P = 0.016), mental health (P < 0.001), the physical component summary scale (P < 0.001), and the mental component summary scale (MCS) (P < 0.001). Psychological measures indicated that donors were healthier than the general population in obsessive-compulsive behavior, interpersonal sensitivity, phobic anxiety, and paranoid ideation. The MCS of the SF-36 was significantly correlated with most symptom scores of the SCL-90-R.

CONCLUSION: HRQoL and psychological outcome were favorable in living liver transplant donors after donation. Specifically, gender, age, time since operation, recipient health condition, and employment after donation, influenced postoperative quality of life.

INTRODUCTION

The rapid growth of living donor liver transplantation (LDLT) is attributable to the continual improvement in recipient survival and the shortage of deceased donor liver grafts[1,2]. Evidence supports a significant reduction in mortality of recipients listed for liver transplantation[3,4]. However, the donor of LDLT is exposed to risks inherent to a surgical procedure, and may suffer a considerable psychological burden[5]. Therefore, the safety of the donor operation and the health related quality of life (HRQoL) of the donor after surgery is critical while maintaining graft viability.

In the transplant center at West China Hospital of Sichuan University, liver recipient survival rates at one, three, and five years were 87.4%, 80.5% and 72.7%[6], respectively, which are similar to that reported elsewhere. Since 2001[7] over 250 cases of LDLT have been performed in our center, accounting for 30% of total transplant volume and this ratio is expected to increase in the future. However, the HRQoL and psychological outcome of donors remain unclear. The aim of the current cross-sectional study was to explore the HRQoL and the psychological outcome of donors after LDLT. To our knowledge, this is the first study of HRQoL and psychological outcome for the living liver transplant donor in mainland China. The results of the study may better guide adult-to-adult LDLT practice.

MATERIALS AND METHODS

Patients

From January 2007 to September 2010, 92 consecutive liver donors at West China Hospital of Sichuan University were approached for participation. The investigation extended from September 2010 to March 2011. Inclusion criteria were: age ⩾ 18 years, an understanding of Chinese, and greater than 6 mo recovery from surgery. Exclusion criteria were: severe medical complications and limited ability to self-express. Clinical and demographic data were collected from medical records and self-report questionnaires (completed by interview or mail).

Instruments

HRQoL was assessed using the Chinese version (2002)[8] of the Medical Outcomes Study Short Form-36 (SF-36)[9,10]. The SF-36 is a valid, self-administered questionnaire used internationally to measure 8 domains of health: physical functioning, role-physical, bodily pain, general health, vitality, social functioning, role-emotional, and mental health during the last 12 mo. The raw scores of each subscale were transformed into scores that ranged from 0 to 100, with higher scores indicating higher levels of functioning or well-being. The level of HRQoL was assessed by comparing the mean value for the study sample with the mean value for a representative sample of the general population of Sichuan province in China[11]. Scores representing overall physical functioning and mental functioning were calculated from the subscales and presented as the physical component summary scale (PCS) and mental component summary scale (MCS).

The Symptom Checklist-90-Revised (SCL-90-R)[12] is a 90-item self-report symptom inventory used to measure the psychological symptoms patterns of community, medical, and psychiatric respondents. It is a simple questionnaire that has been validated in a number of languages. The Chinese version was adapted by Wang[13]. Each of the items is rated on a five-point scale of distress ranging from "not at all" (1) to "extremely" (5). The nine primary symptom dimensions were labeled as: somatization, obsessive-compulsive behavior, interpersonal sensitivity, depression, anxiety, hostility, phobic anxiety, paranoid ideation, and psychoticism. We assessed the level of psychological health of our sample and compared it with the Chinese norm[14].

Ethical considerations

The study protocol conformed to the ethical guidelines of the 1975 Declaration of Helsinki and was approved by the West China Hospital of Sichuan University Ethics Committee. All participants were asked to sign an informed consent form.

Statistical analysis

Statistical analysis was performed using SPSS statistical software, version 13.0. Between-group differences in HRQoL and psychological health were examined with independent sample *t* tests, analysis of variance, or nonparametric tests, as appropriate. Multiple comparisons for observed means were tested using the Student-Newman-Keuls procedure when equal variances could be assumed, and by the Games-Howell procedure when equal variances could not be assumed. Pearson correlation analysis were used to analyze the relationships between HRQoL and psychological symptoms. Statistical significance was set at $P < 0.05$.

RESULTS

Donor characteristics

Informed consents for participation were obtained from 92 donors. In the end, 71 (77.2%) validated questionnaires were returned. The results of SF-36 and SCL-90-R completed by interview or mail were not statistically different. All donors received a right hepatectomy without middle hepatic vein, and the vast majority of them reported that they would donate again. All donor relationships with liver recipient and recipient families

Table 1 Donor characteristics

Factors	Frequency	mean ± SD/percent (%)
Age (yr)		38.94 ± 10.44
≤ 40	42	59.2
> 40	29	40.8

were improved after donation. The demographics and clinical characteristics of the study population are shown in Table 1. The mean age of participants was 38.94 ± 10.44. Most donors were married (87.3%). More than half of the donors were male (56.3%), peasants (50.7%), and had achieved a secondary education level (64.8%). A total of 7.0% of donors experienced early or late complications including slight biliary leakage, pulmonary infection, and bodily pain. Many (47.9%) donor operations occurred 1-2 years before completing the questionnaires. Most donors worked full- or part-time after donation (87.3%). All donors were related to recipients, and most of them were close relatives (77.6%). The majority of recipients (78.9%) were in good health at the time of investigation.

HRQoL and psychological outcomes

The majority of scores on SF-36 domains did not significantly differ between donors and a representative sample (n = 1603) from the general population of Sichuan province in China (Table 2). Only scores in bodily pain (t = -2.387, P < 0.05) and social functioning (t = -2.246, P < 0.05) were significantly lower in donors compared to the general population, while the average donor physical functioning score was significantly higher than the general population (t = 2.230, P < 0.05).

Table 2 Health related quality of life after donation

SF-36 domains	Donors (71) mean ± SD	General population mean ± SD	t value	P value
Physical functioning	93.66 ± 7.26	90.80 ± 15.07	2.230	0.033
Role-physical	80.88 ± 33.18	79.51 ± 34.70	0.241	0.811

Mental health	74.13 ± 17.12	73.52 ± 15.68	0.196	0.846

SF-36: Short Form-36.

Table 3 Psychological symptoms after donation

SCL-90-R dimensions	Donors (71) mean ± SD	Chinese norm mean ± SD	t value	P value
Somatization	1.41 ± 0.39	1.37 ± 0.48	0.600	0.553
Obsessive-compulsive behavior	1.50 ± 0.30	1.62 ± 0.58	-2.119	0.042
Interpersonal sensitivity	1.42 ± 0.32	1.65 ± 0.51	-4.183	< 0.001
Depression	1.39 ± 0.35	1.50 ± 0.59	-1.741	0.092
Anxiety	1.35 ± 0.37	1.39 ± 0.43	-0.708	0.485
Hostility	1.54 ± 0.44	1.48 ± 0.56	0.797	0.432
Phobic anxiety	1.11 ± 0.13	1.23 ± 0.41	-5.312	< 0.001
Paranoid ideation	1.25 ± 0.29	1.43 ± 0.57	-3.472	0.002
Psychoticism	1.25 ± 0.34	1.29 ± 0.42	-0.660	0.514

SCL-90-R: Symptom Checklist-90-Revised.

The average SCL-90-R scores of the general population were significantly greater than average donor scores in the areas of obsessive-compulsive behavior (t = -2.119, P < 0.05), interpersonal sensitivity (t = -4.183, P < 0.001), phobic anxiety (t = -5.312, P < 0.001), and paranoid ideation (t = -3.472, P < 0.01) (Table 3). These results indicate that the psychological well-being of liver transplant donors was higher than the general population in these dimensions.

Analysis of HRQoL

The general health domain of the SF-36, was significantly lower for female donors compared to male donors (t = 2.661, P < 0.05). Donors more than 40 years old scored higher in social functioning (t = 2.269, P < 0.05) and mental health (t = 2.184, P < 0.05). Donors who underwent surgery more than two years before the current study scored highest in physical functioning (F = 9.394, P = 0.001) and bodily pain (F = 3.513, P < 0.05), while those undergoing surgery less than one year prior to the study scored lowest. Quality of life differed significantly depending on donor employment status. Donors with full-time employment scored highest in role-physical (F = 5.790, P = 0.005), vitality (F = 9.018, P = 0.001), social functioning (F = 4.786, P < 0.05) and mental health (F = 11.051, P < 0.001). Interestingly, recipient health condi-

Table 5 Correlation analysis between health related quality of life and psychological symptoms

SCL-90-R dimensions	SF-36			
	PCS		MCS	
	r value	*P* value	*r* value	*P* value
Somatization	0.200	0.290	-0.246	0.190
Obsessive-compulsive behavior	0.173	0.362	-0.421	0.020
Interpersonal sensitivity	-0.067	0.726	-0.545	0.002
Depression	-0.306	0.114	-0.557	0.002
Anxiety	-0.222	0.238	-0.393	0.032
Hostility	-0.335	0.071	-0.456	0.011
Phobic anxiety	0.118	0.535	-0.201	0.266
Paranoid ideation	0.035	0.853	-0.157	0.407
Psychoticism	0.028	0.881	-0.209	0.267

SCL-90-R: Symptom Checklist-90-Revised; SF-36: Short Form-36; PCS: Physical component summary scale; MCS: Mental component summary scale.

tion also influenced donor general health (t = 2.121, P < 0.05), social functioning (t = 2.763, P = 0.010), and role-emotional (t = 2.603, P < 0.05) (Table 4). Marital status, educational status, categories of occupation, complications, or donor-recipient relationship did not significantly affect quality of life.

To reduce the number of outcome variables regarding HRQoL, outcomes among donors were also compared using the PCS and the MCS of the SF-36. PCS (F = 11.051, P < 0.001) and MCS (F = 32.748, P < 0.001) scores were highest in donors with full-time employment and lowest in unemployed donors (Table 4). Other demographic and clinical factors did not affect PCS or MCS scores.

Table 5 presents the correlation coefficients between PCS and MCS scores of the SF-36 and the scores on the SCL-90-R subscales. MCS scores were significantly (all P < 0.05) correlated with obsessive-compulsive behavior (r = -0.421), interpersonal sensitivity (r = -0.545), depression (r = -0.557), anxiety (r = -0.393), and hostility (r = -0.456). There were no significant correlations between PCS scores and SCL-90-R scores.

DISCUSSION

Overall, donors reported a positive experience. The vast majority of donors stated that they would donate again, and almost all believed they had benefited from the donation. All donors were able to return to their (pre-donation) job a few months after donation (while some donors chose to quit their previous job). There were few significant differences in quality of life domains between the donors in the current study and the general population. Interestingly, donors reported a higher level of physical functioning than the general population. This observation has been previously described[15-17].

Female donors scored lower than male donors in the general health domain of the SF-36. This difference may be due to social and psychological factors[18,19]. The rates of psychological distress and physical illness are higher in women probably due to gender roles. Gove[20] points out that the highly structured roles of men tend to be causally linked to good mental health and low rates of morbidity, while the typical nurturing roles of women tend to be associated with a high level of social demand and lack of privacy. Furthermore, occupying a nurturing role impairs one's ability to effectively adopt a patient role[20].

Employment status, a measurement indicative of the

donor's ability to resume societal roles, was significantly related to quality of life. Previous research[21,22] has found that employed liver recipients reported better HRQoL than those unemployed after liver transplantation. However, the relationship between employment and HRQoL of donors remains elusive. While previous research[23,24] reported that most donors are able to return to pre-donation employment status within a few months, the direct relationship between employment status and HRQoL was not detailed until the current study.

Other factors impacting the quality of life included age of donor and time since operation. Older donors reported a significantly higher quality of life in domains such as social functioning and mental health. In addition, quality of life of donors more than one year after surgery was greater than that of donors who had undergone surgery during the previous time. These results suggest that HRQoL recovers with time post operation. In agreement, a study by Chan *et al*[25] found that donor quality of life, particularly the physical component, was most significantly affected during the first three postoperative months while physical and mental quality of life returned to pre-operation levels by a 6 to 12 mo period.

Despite previous reports[15,17] showing no relationship between recipient outcome and donor quality of life, the current study found that recipient well-being was an important factor influencing donor quality of life. The donors in the present study were all genetically and emotionally related to recipients. Throughout the donation process, donors were strongly concerned about the recipients. These emotional ties resulted in a strengthening of the relationships between donors and recipients and their families.

The resection of the right hepatic lobe is a safe operation and resulted in a good psychological outcome for most donors, irrespective of donation-related potential risks. The majority of donors were not anxious, did not feel coerced, and did not consider donation dangerous prior to the operation. Some donors reported excitement in facing a new experience and some said they could handle any consequences of the surgery. Only a few donors reported being anxious, being unsure about the operation, and experiencing increased stress prior to the operation. Some donors verbalized feelings of gratefulness and increased maturity post surgery. Most aspects of donor mental quality of life were significantly related to psychological symptoms. These results indicate the necessity of providing support to donors who experience negative feelings.

In conclusion, LDLT donors were healthy and the overall quality of life and psychological outcome were favorable. Employment after donation is an important factor significantly related to quality of life. Gender, age of donor, time since operation, and recipient health were all found to influence aspects of the quality of life of donors. Right hepatectomy is an acceptable procedure, with encouraging donor outcomes. Donor HRQoL and psychological status should continue to be monitored.

The current study has limitations that should be addressed. The data were collected at a single transplant center and the study design was a cross-sectional analysis which can be less informative than a longitudinal analysis. Nevertheless, the present study yielded important preliminary findings in mainland China. Longer follow-up periods and prospective studies will be necessary to identify long-term quality of life and psychosocial consequences of adult LDLT donors.

COMMENTS

Background

Living-donor liver transplantation (LDLT) is an effective treatment for end-stage liver disease in selected recipients, especially in Asian countries where the cadaveric graft supply is markedly limited. The graft and recipient survival rates are excellent and equivalent to those after deceased-donor liver transplantation. However, the donor of LDLT is exposed to risks inherent to a surgical procedure, and may suffer a considerable psychological burden. Therefore, the safety of the donor operation and the health related quality of life (HRQoL) of the donor after surgery is critical while maintaining graft viability.

Research frontiers

Currently, Not much researches about HRQoL and psychological well-being of the living liver donors have been reported after LDLT. There is a lack of comprehensive and systemic assessment data on donors' HRQoL and psychological well-being after LDLT. So the present study evaluated the HRQoL and psychological well-being on the LDLT donors and identified some potential factors affecting their HRQoL.

Innovations and breakthroughs

This article is one of the few literatures on the quality of life and psychological well-being of the living liver donors after LDLT. The study is well constructed and well planned, and is a comprehensive and systemic assessment data on donors' HRQoL and psychological well-being after LDLT.

Applications

The present study yielded important preliminary findings on reseaches of the donors' quality of life and psychological well-being. The findings will have a significant impact on future clinical strategies.

Terminology

LDLT is a procedure in which a living person donates a portion of his or her liver to another. HRQoL is a multi-dimensional concept that includes domains related to physical, mental, emotional and social functioning.

Peer review

This is a good study contributing to this important area of liver transplantation. The authors have shown that the right donor hepatectomy is an acceptable procedure.

Abstract

Sensory or motor peripheral neuropathy may be observed in a significant proportion of hepatitis C virus (HCV)-infected patients. However, central nervous system (CNS) involvement is uncommon, especially in cryoglobulin-negative subjects. We describe a case of peripheral neuropathy combined with an ischemic CNS event as primary manifestations of chronic HCV infection without cryoglobulinemia. Significant improvement was observed after antiviral therapy. We discuss the spectrum of neurological manifestations of HCV infection and review the literature.

INTRODUCTION

Hepatitis C virus (HCV) infection has become a major cause of liver disease with approximately 170 million people infected worldwide[1]. The severity of the disease varies widely, ranging from asymptomatic carrier state to cirrhosis and hepatocellular carcinoma. HCV chronic infection is often associated with abnormal immunological responses that can result in several extrahepatic conditions such as membranoproliferative glomerulonephritis, Sjögren's syndrome, idiopathic thrombocytopenic purpura, lichen planus, porphyria cutanea tarda, and mixed cryoglobulinemia[2]. Even though these conditions occur relatively infrequently, they significantly increase morbidity and mortality among HCV patients. Although sensory or motor peripheral neuropathy may be observed in a significant proportion of HCV-infected patients, central nervous system (CNS) involvement is uncommon, especially in cryoglobulin-negative subjects[3]. Here, we describe a patient with peripheral neuropathy combined with CNS vasculitis as primary manifestations of chronic HCV infection.

CASE REPORT

A previously healthy 37-year-old Caucasian woman presented to the emergency department in May 2003, with a 9-mo history of malaise, loss of appetite, and substantial weight loss (19.96 kg). Over the previous month, she had developed fatigue and muscle weakness, and become

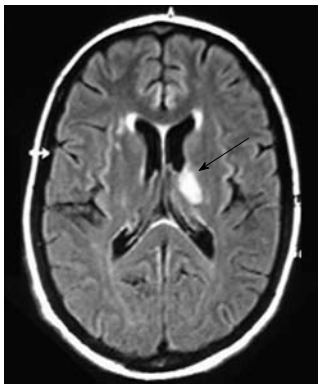

Figure 1 Magnetic resonance imaging of the head showing a 1.5-cm, high-signal lesion in the left thalamus, suggestive of ischemic injury (arrow).

Figure 2 Necrotic lesions on the right forefoot due to severe vasculitis.

unable to perform several activities of daily living, such as hair brushing, climbing stairs and doing household chores. There was no history of blood transfusions or intravenous drug abuse. The patient was conscious and oriented to time and place. On examination, atrophy of the dorsal interosseous muscles, flaccid quadriparesis with hyporeflexia, and symmetrical distal sensory loss were noted. An electroneuromyographic study revealed sensorimotor polyneuropathy.

Over the next 24 h, she became increasingly disoriented. Magnetic resonance imaging of the head showed a T1 low, T2 and fluid-attenuated inversion recovery (FLAIR) high-signal lesion in the left thalamus, approximately 1.5 cm in diameter (Figure 1), which probably represented ischemic injury. In addition, small foci of increased signal intensity at the semioval center and subcortical white matter were identified on T2 and FLAIR sequences. A rheumatologic panel including antinuclear antibody, rheumatoid factor, anti-DNA and cardiolipin antibodies was negative. Thyroid-stimulating hormone, vitamin B12, and aminotransferases levels were within normal limits. Further testing showed negative serology for hepatitis B virus, HIV, syphilis, cytomegalovirus, and human T-lymphotropic virus 1/2. Enzyme immunoassay to detect HCV antibody was positive, as well as serum HCV-RNA by polymerase chain reaction (PCR). A liver biopsy confirmed chronic hepatitis with mild necroinflammatory activity and no fibrosis. We then considered that the diagnosis of CNS vasculitis and peripheral polyneuropathy was probably related to chronic HCV infection. Serum cryoglobulins were persistently negative after seven determinations. The patient was initially treated with intravenous methylprednisolone followed by oral prednisone, with resolution of her symptoms. Subsequently, standard interferon-α (3 mU three times per week) plus ribavirin (1 g/d) were added to steroid maintenance therapy. During HCV treatment, an attempt to reduce prednisone dose resulted in the development of necrotic lesions on the right forefoot (Figure 2), which led to its amputation. In spite of permanent discontinuation of antiviral drugs and the need for increasing corticosteroid dosage, the patient showed sustained virological response, with HCV RNA persistently undetectable in serum by sensitive PCR-based assay. She remains asymptomatic, until last seen, under low dose prednisone.

DISCUSSION

Although the precise frequency of peripheral neuropathy in HCV-infected patients is unknown, it is considered the most common neurological complication in this setting. In a French cohort of 321 subjects with chronic hepatitis C, symptomatic peripheral neuropathy was observed in 9% of the cases[4]. Even though the neurological findings were more frequent among cryoglobulin-positive patients, in this study, a significant proportion of cryoglobulin-negative individuals presented with peripheral nervous system involvement (17% *vs* 8%). Other reports of peripheral neuropathy in HCV-infected patients without detectable cryoglobulins[5-7] indicate that, although the presence of cryoglobulins seems to be an important feature in these cases, there are possibly other factors contributing to the development of peripheral neuropathy. In a study including 51 patients with HCV infection and neuropathy, Nemni *et al*[7] showed that 22% of the subjects had undetectable serum cryoglobulins. Cryoglobulin-negative individuals were more likely to have mono- or multiple neuropathy. Interestingly, the morphological findings in the sural nerve from cryoglobulin-negative and -positive patients are consistent with an ischemic mechanism of nerve damage. The authors stated that the vasculitic process in cryoglobulin-negative HCV subjects was probably secondary to complement pathway activation by HCV itself, or by an interaction between the virus and the host immune system. A direct role of HCV in the pathogenesis of peripheral neuropathy was also proposed, based on the finding of HCV RNA in nerve biopsy specimens[8]; however, this association remains to be confirmed.

Specific CNS involvement is more rarely reported in HCV-infected patients. CNS involvement, however, may present different facets, such as fatigue, depression, cognitive impairment and vasculitis. Although it may be the initial extrahepatic manifestation of HCV infection, well-documented reports on CNS involvement in patients with HCV-associated vasculitis are rare and include mostly cryoglobulin-positive patients[9-11]. Stroke

episodes, transient ischemic attacks, progressive reversible ischemic neurological deficits, lacunar infarctions, or encephalopathic syndrome, commonly attributed to ischemia or rarely to hemorrhage, may occur[12]. Similar to HCV-related peripheral neuropathy, the mechanism behind the CNS vasculitic process in HCV infection is poorly understood, but it has been postulated that recurrent cryoglobulin precipitation with complement fixation and/or HCV-related induction of the innate mechanism of complement activation might be involved in ischemic and inflammatory tissue damage[7]. Although the exact pathway is not known, HCV-induced vasculitis without cryoglobulinemia by the other mechanisms previously discussed for peripheral neuropathy may be responsible for the CNS findings in this case.

The treatment of HCV-associated peripheral neuropathy in cryoglobulin-positive individuals is based on anti-HCV drugs. Combination therapy with interferon (pegylated or not) plus ribavirin may induce a complete clinical response in a significant proportion of patients with HCV-related systemic vasculitis, and consequently, in those with cryoglobulin-related peripheral neuropathy[13,14]. The role of HCV therapy in subjects with cryoglobulin-negative peripheral neuropathy is unclear. Lidove *et al*[5] have reported significant neurological improvement in two cryoglobulin-negative patients treated with interferon monotherapy. However, long-term follow-up was not reported and the possibility of development or worsening of peripheral neuropathy in interferon-based treatments is a major concern in this setting[15]. Data about the safety and efficacy of interferon-based regimens in the treatment of HCV-associated CNS vasculitis are even scarcer. There are a few case reports showing favorable outcomes in cryoglobulinemic subjects treated with corticosteroids or interferon for CNS involvement[12,16,17]. However, such reports cannot support a solid recommendation, especially for those patients with cryoglobulin-negative CNS vasculitis. In addition, it should be emphasized that for cases of severe cryoglobulinemia-associated vasculitis (as those with rapidly progressive renal failure or neurological involvement), it is recommended that antiviral therapy should be delayed for 2-4 mo, while they are submitted to aggressive therapy with plasmapheresis, corticosteroids (intravenous methylprednisolone followed by oral prednisone), and either cyclophosphamide or rituximab[18].

In this report, we describe a patient with peripheral neuropathy combined with an ischemic CNS event as primary manifestations of chronic HCV infection. The absence of other classical risk factors for ischemic stroke, the association with peripheral vasculitis and the improvement observed after steroid therapy suggests a vasculitic origin for the neurological findings. Although this report cannot prove a definite cause-and-effect of HCV infection and the neurological manifestations observed, an important role of HCV is suggested by the significant improvement observed after the HCV sustained virological response. Another interesting finding in the present case was the achievement of sustained viral clearance in spite of the prolonged use of steroids. Although we have not been able to evaluate viral load during therapy sequentially, previous studies have shown that exposure to steroids increases HCV viral load, both in liver transplant patients and in the non-transplant setting[19,20].

In conclusion, our case highlights the need for clinicians to broaden consideration of differential diagnoses, with particular attention to atypical features of common diseases. Testing for HCV should be performed in all cases of neurological signs of uncertain origin, even in the absence of usual risk factors for hepatitis C. Successful antiviral therapy may lead to a significant improvement of neurological manifestations and should be considered in these cases.

Abstract

Chronic hepatobiliary inflammatory diseases are not widely acknowledged as underlying disorders of systemic AA amyloidosis, except epidemic schistosomiasis. Among them, primary sclerosing cholangitis (PSC) might initiate amyloid A protein deposition in diverse tissues, giving rise to systemic amyloidosis, due to a progressive and unresolved inflammatory process, and its possible association with inflammatory bowel diseases. Nevertheless, only one such case has been reported in the literature to date. We report a 69-year-old Japanese woman with cirrhosis who was diagnosed with PSC complicated with systemic AA amyloidosis, without any evidence of other inflammatory disorders. As a result of cholestasis in conjunction with biliary strictures and increased serum IgG4, the presence of $IgG4^+$ plasma cells was examined systemically, resulting in unexpected documentation of Congo-red-positive amyloid deposits, but not $IgG4^+$ plasma cells, in the liver, stomach and salivary glands. Elevated serum IgG4 is the hallmark of IgG4-related disease, including IgG4-associated cholangitis, but it has also been demonstrated in certain patients with PSC. Amyloid A deposits in multiple organs associated with an indolent clinical course that progresses over many years might have a diagnostic value in discriminating PSC from IgG4-associated cholangitis.

INTRODUCTION

Primary sclerosing cholangitis (PSC) is an intractable fi-

bro-inflammatory disease of the bile ducts that is characterized by biliary strictures without any underlying insults, e.g., immunodeficiency, ischemia, and biliary toxins[1]. PSC usually follows an indolent but progressive course, which results in eventual death or liver transplantation in the majority of patients. A single center study in Germany demonstrated that the estimated median survival from the time of diagnosis to death or time of liver transplantation was 9.6 years; 39.6% of patients underwent liver transplantation, while 14.3% of them developed hepatobiliary malignancies[2]. Definite diagnosis is thus required in cases with suspected lesions, especially to discriminate PSC from IgG4-associated cholangitis (IAC); a recently defined disorder with better prognosis[3-5].

IAC consists of a biliary stricture that responds to or improves with corticosteroid therapy[6], and is recognized as one of a variety of IgG4-related disease that exhibits a wide range of clinical manifestations. The clinical diagnostic criteria for IgG4-related disease consists of three parts: namely, enlarged/thickened lesions in one or more organs; elevated serum IgG4 levels (≥ 135 mg/dL); and histopathological findings[5]. Although IgG4 levels are usually higher in patients with IAC than in those with PSC, raised serum IgG4 levels have been recently reported in 9%-36% of patients with PSC[7,8]. Therefore, the identification of $IgG4^+$ plasma cell infiltrates in the bile duct as well as in other organs[5,9] is important in making a diagnosis.

In this report, we describe a patient with cirrhotic PSC who had elevated levels of serum IgG4. Multiple organ biopsies were performed to obtain a definitive diagnosis and rule out IAC. Unexpectedly, Congo-red-positive amyloid deposits, but not $IgG4^+$ plasma cells, were demonstrated in the liver, stomach and salivary glands. Subsequently, raised levels of serum amyloid A protein (SAA) were confirmed, resulting in a diagnosis of PSC complicated with systemic AA amyloidosis, despite the absence of known genetic susceptibility[10]. This is the second report describing the concurrence of systemic AA amyloidosis in PSC. A sustained acute phase response involving the overproduction of SAA over a period of many years is likely to characterize indolent hepatobiliary inflammation in PSC, but not in IAC.

CASE REPORT

A 69-year-old Japanese woman was referred to our hospital with progressive elevation of cholestatic liver enzymes in October 2009. She had a history of endoscopic sphincteropapillotomy for choledocholithiasis at age 47 years, at which time, PSC was also suspected due to the irregularity of the extra- and intrahepatic bile duct walls, as revealed by endoscopic retrograde cholangiopancreatography (ERCP). Her cholestatic liver tests subsequently remained abnormal despite removal of all gallstones, indicating the presence of PSC. She had never been immunocompromised. Fatigue, pruritis, and abdominal fullness had worsened even after administration of ursodeoxycholic acid (600 mg/d; 13.2 mg/kg body weight) and she was therefore admitted to our hospital in October 2010. On admission, mild jaundice was apparent, and blood tests revealed elevated liver enzymes along with increased acute phase proteins, i.e., aspartate aminotransferase 109 IU/L (normal < 37 IU/L), alanine aminotransferase 80 IU/L (normal < 39 IU/L), alkaline phosphatase 871 IU/L (normal < 359 IU/L), γ-glutamyltranspeptidase 72 IU/L (normal < 75 IU/L), total bilirubin 3.2 mg/dL (normal < 1.2 mg/dL), C-reactive protein 2.66 mg/dL (normal < 0.3 mg/dL), and SAA protein 303.9 mg/L (normal < 8.0 mg/L). With a Child-Pugh score of 10, her functional hepatic reserve was reduced and she had moderate ascites. Anti-nuclear, anti-smooth muscle, anti-mitochondrial, and perinuclear anti-neutrophil cytoplasmic antibodies were negative. Serum IgG was 2890 mg/dL (normal < 1700 mg/dL), including elevated IgG4 level of 251 mg/dL (normal < 105 mg/dL). Although serum IgE was 15 400 IU/mL (normal < 361 IU/mL), antibodies against parasites, including liver flukes, were negative. Viral markers for hepatitis B and C were both negative. Abdominal contrast-enhanced computed tomography showed biliary strictures from common hepatic duct to the second to third branches, accompanied by dilatation of the distal bile ducts. Atrophy of the right hepatic lobe in conjunction with collateral vessel formation around the lower esophagus confirmed cirrhosis. The size and contours of the pancreas were normal. ERCP revealed irregularities of the walls of the lower common, hilar and intrahepatic bile ducts, which were accompanied by multiple strictures and a "pruned-tree" appearance in the intrahepatic bile ducts (Figure 1). Deterioration of liver function likely resulted from progression of PSC, but given the equivocal ERCP results and elevated IgG4 levels, we elected to rule out IgG4-related disease, particularly IAC. The biopsied specimen from the distal common bile duct contained only erosive duct mucosa, preventing the visualization of $IgG4^+$ lymphoplasmacytic infiltration. We therefore performed biopsies of the major duodenal papilla[9], the salivary glands, and the gastric mucosa in order to investigate the possibility of multiple organ infiltration of $IgG4^+$ plasma cells.

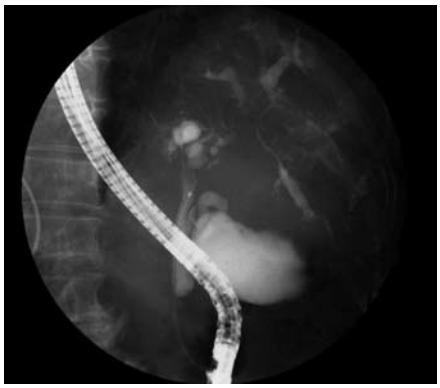

Figure 1 Endoscopic retrograde cholangiopancreatography revealed multiple strictures of the hilar and intrahepatic bile ducts, with a "pruned-tree" appearance, accompanied by dilatation of the distal bile ducts.

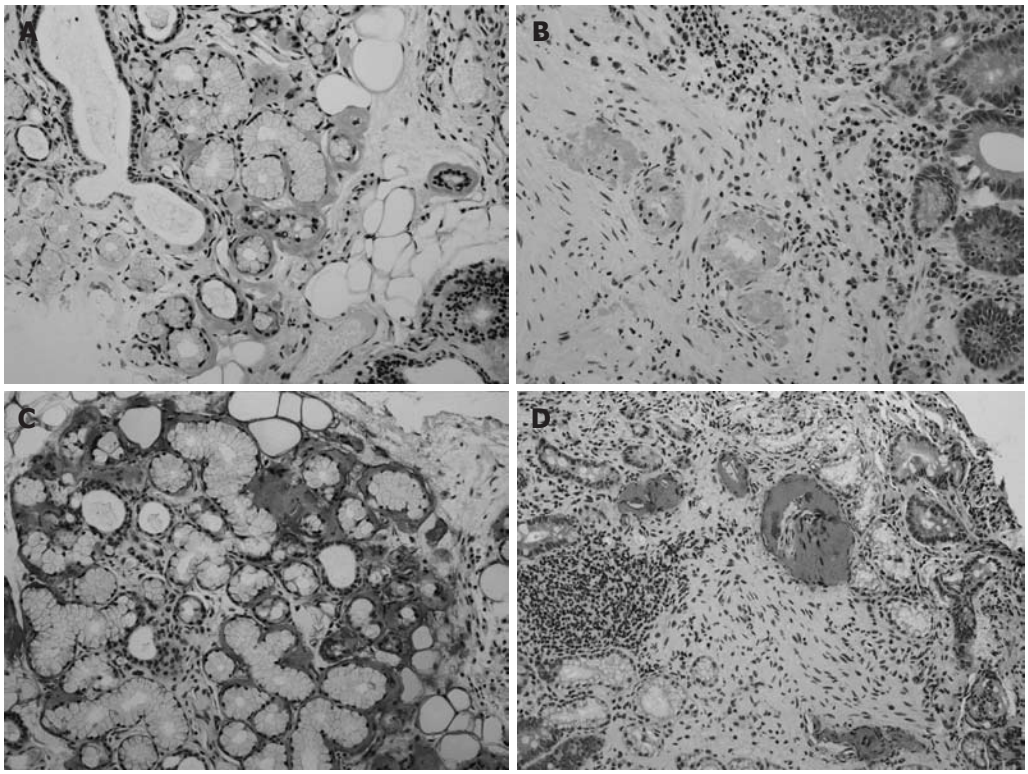

Figure 2 Histology of the salivary glands and the stomach by hematoxylin and eosin stain (200 ×). Amorphous eosinophilic materials in the subglandular and stroma of the salivary glands (A) and submucosal stroma of the stomach (B) were demonstrated. They were found to be Congo-red-positive. Immunohistochemical staining with anti-human amyloid A antibody (200 ×) confirmed a positive AA stain in the salivary glands (C) and stomach (D).

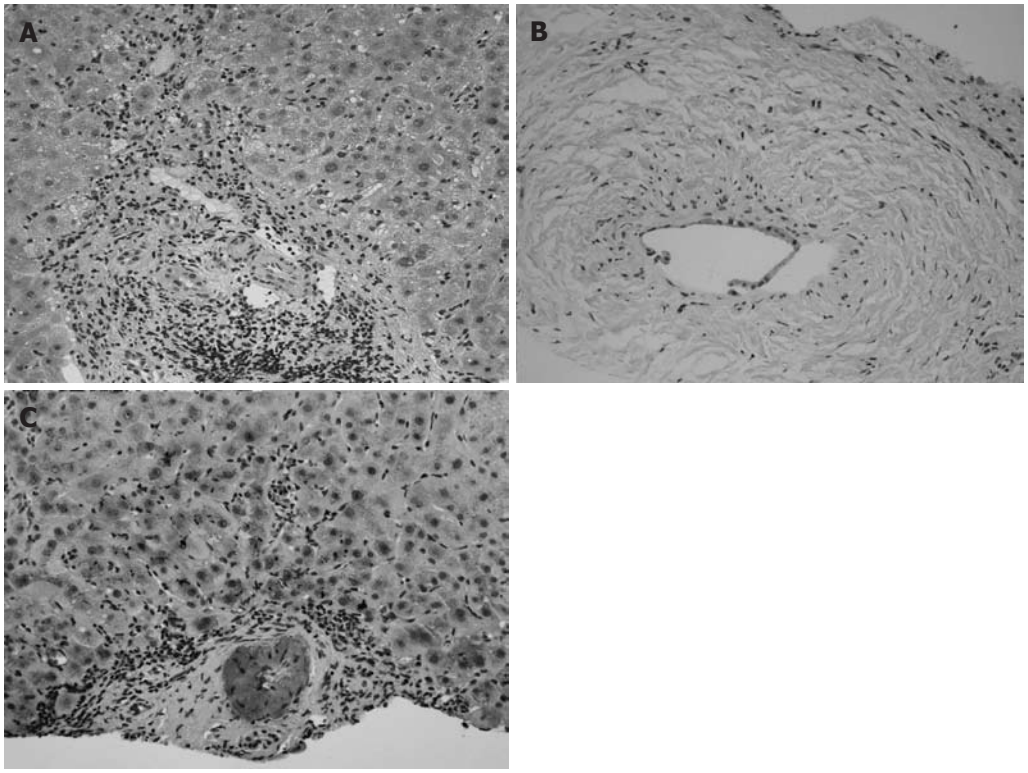

Figure 3 Histology of the liver by hematoxylin and eosin stain. An increase in lymphoneutrophilic infiltrates in the portal tracts, interface hepatitis with ductular proliferation, cholate stasis (400 ×, A), and damaged interlobular bile ducts with collagenous periductal thickening (200 ×, B) were revealed. Amyloid deposition in the vessel walls of the portal tracts was also apparent in immunohistochemical staining (200 ×, C).

Unexpectedly, IgG4$^+$ plasma cells were scarcely found by immunohistochemistry, while Congo-red-positive, amorphous eosinophilic materials were demonstrated in the subglandular and stroma of the salivary glands and in the submucosal stroma of the stomach (Figure 2A and B). Potassium permanganate sensitivity and positive AA immunohistochemical staining confirmed that these materials were AA amyloid deposits (Figure 2C and D). Subsequent liver histology revealed an increase in lymphoneutrophilic infiltrates with some eosinophils in the portal tracts, interface hepatitis and bridging fibrosis, damaged interlobular bile ducts with collagenous periductal thickening, marked ductular proliferation, and cholate stasis (Figure 3A and B). Amyloid deposition in the vessel

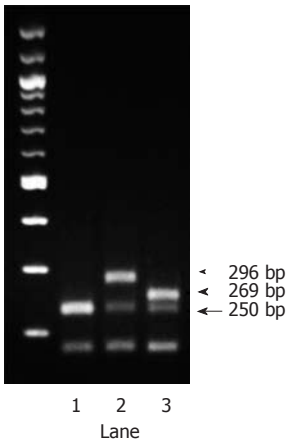

Figure 4 Serum amyloid A1 genotyping by polymerase chain reaction-restriction fragment length polymorphism analysis (2% agarose gel electrophoresis). Arrow (250 bp), arrow head (269 bp) and small arrow head (296 bp) correspond to serum amyloid A1 allele 1.5, 1.3 and 1.1, respectively. Lane 1: 1.5/1.5 homozygosity (our patient); Lane 2: 1.1/1.5 heterozygosity (control patient); Lane 3: 1.3/1.5 heterozygosity (another control patient).

walls of the portal tracts was also apparent (Figure 3C). Oral administration of 30 mg/d prednisolone for 1 wk failed to show any beneficial effect on cholestasis, therefore, a diagnosis of IAC turned out to be implausible. Abnormal uptake was not found in positron emission tomography; again, excluding underlying IgG4$^+$-related lymphoproliferative disease, as well as IgE myeloma. The normal colonoscopic appearance of the colonic mucosa, as well as the histology that only indicated nonspecific inflammation of the intestine, excluded a concurrent diagnosis of inflammatory bowel disease. Currently known patterns of genetic susceptibility to systemic AA amyloidosis were found to be absent[10,11]. SAA1 genotyping by polymerase chain reaction-restriction fragment length polymorphism analysis[12] revealed homozygosity of SAA1.5/1.5 (Figure 4), and sequencing of whole Mediterranean fever (MEFV) exons demonstrated no amino acid substitution mutations (data not shown). Based on all of the above data, we diagnosed the patient with PSC complicated by systemic AA amyloidosis.

DISCUSSION

In this study, we presented a patient with PSC complicated by systemic AA amyloidosis. To the best of our knowledge, this is the second reported case of concurrent PSC and systemic AA amyloidosis, and it included detailed information on pathology as well as on genetic susceptibility to AA amyloidosis.

Sustained overproduction of SAA in association with chronic unresolved inflammation, as demonstrated in our case, is essential for the development of amyloidosis[13]. Nevertheless, susceptibility to AA amyloidosis differs among various diseases. According to Lachmann et al, the most prevailing underlying inflammatory disorder is chronic inflammatory arthritis, followed in descending order by chronic sepsis, periodic fever syndromes, and Crohn's disease[13]. Although PSC is indolent, progressive inflammatory hepatobiliary disease results in cholestatic cirrhosis. Nonetheless, only one other case of PSC has been reported as a cause of AA amyloidosis[14]. Even assuming that about 6% of AA amyloidosis patients do not have underlying inflammatory disorders[13], AA amyloidosis in our case was likely to be secondary to PSC, as coexisting inflammatory bowel disease was excluded. The patient had neither the SAA locus conferring susceptibility to AA amyloidosis in Japanese rheumatoid arthritis, namely SAA1.3, nor MEFV amino acid substitution mutations that are responsible for familial Mediterranean fever, an autoinflammatory disease. Multiple factors affecting amyloid deposition in tissues, such as amyloid P and apolipoprotein E, might have cooperatively contributed to the pathogenesis of AA amyloidosis in this case.

Regarding the diagnosis of PSC, discrimination of IAC is of primary importance owing to better prognosis of the latter with corticosteroid therapy. Serum IgG4 levels in conjunction with cholangiographic features have clinical relevance in this process. In our case, while the elevated serum IgG4 level favored diagnosis of IAC, the "pruned-tree" appearance of the intrahepatic bile ducts coupled with stenosis of the lower common bile duct were equivocal. Moreover, the fact that 9%-36% of patients with PSC also show mildly elevated IgG4[7,8] indicates the need for additional parameters to facilitate differential diagnosis. The presence of IgG4$^+$ plasma cells in the bile ducts and in other organs is suggestive of IgG4-related disease and thus has more diagnostic specificity[5]. In our case, PSC was confirmed by the absence of IgG4$^+$ plasma cells in the examined organs. On the other hand, unexpected demonstration of Congo-red-positive amyloid deposition in the salivary glands, stomach and liver prompted us to consider the distinct implications of these findings on the differential diagnosis, because AA amyloid found in various organs might have diagnostic specificity for PSC. To the best of our knowledge, there have been no case reports describing coexistence of AA amyloid deposits with IgG4$^+$ plasma cells in IgG4-related diseases. A sustained acute phase response in PSC might be a sufficient cause for AA amyloid deposition. Alternatively, mechanistically distinct and/or mutually exclusive inflammatory processes occurring in PSC and IAC, in the latter case reportedly Th-2-dependent[5], might be responsible for the phenomenon. At any rate, estimation of the incidence of AA amyloidosis in PSC[15], as well as in IAC, in a large cohort is necessary to verify our hypothesis.

The proper treatment of PSC complicated by systemic AA amyloidosis remains to be determined. The aim of treatment of AA amyloidosis is generally considered to be the suppression of underlying inflammatory conditions, thereby reducing SAA concentrations[13]. Immunosuppressive agents including anti-tumor necrosis factor therapies are often administered for this purpose, with the exclusion of conditions involving chronic sep-

sis, such as bronchiectasis. Renal dysfunction has been reported as a predominant disease manifestation, and progression to end-stage renal failure has been linked to increased mortality of systemic AA amyloidosis[13]. Regression of AA amyloid deposits (as evaluated by serum amyloid P scintigraphy), that is associated with median SAA concentration during anti-inflammatory therapy, is inversely correlated to the outcomes of renal dysfunction[13]. Although the first case of coexisting PSC and systemic AA amyloidosis reported in the literature experienced relief of symptoms and biochemical improvement as a result of the combination of corticosteroid and azathioprine, the patient experienced progression of amyloidosis-induced nephrotic syndrome followed by its reversal after liver transplantation[14]. Maintaining SAA in a low-normal range through use of anti-inflammatory agents was also difficult in our case; short-term use of prednisolone showed no benefit and colchicine did not decrease serum SAA (data not shown). Administration of tocilizumab, a humanized anti-interleukin 6 receptor antibody that strongly suppresses SAA levels, might be promising for patients with secondary AA amyloidosis who are not responding adequately to treatment for underlying inflammation[16].

In summary, we presented a female PSC patient who had concurrent systemic AA amyloidosis. Is AA amyloidogenesis more specific to PSC than IAC? Could AA amyloid deposition discriminate PSC from IAC? Reexamination of AA amyloid deposition in PSC cases in a large cohort will help answer these and other relevant questions.

ACKNOWLEDGMENTS

We would like to thank following colleagues for their help: Yuka Jiuchi and Yumi Maeda for technical assistance; Yuki Naruke and Yumi Mihara for pathological diagnosis; Satoru Hashimoto, Shinya Nagaoka and Hiroshi Yatsuhashi for the diagnostic decision.

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1361 experts in gastroenterology and hepatology from 64 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article *via* online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systemically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensuses and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

Baishideng Publishing Group Co., Limited

SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing
Statistical review is performed after peer review. We invite an expert in Biomedical Statistics from to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Ridit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc*. The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

Conflict-of-interest statement
In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent
Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights
When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www.clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://www.wjgnet.com/1007-9327office. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no less than 256 words) and structured abstracts (no less than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no less than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections.

AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/…"; MATERIALS AND METHODS (no less than 140 words); RESULTS (no less than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 *vs* 3.61 ± 1.67, $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: …*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of *P* values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of *P* values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that...".

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed and http://www.crossref.org/SimpleTextQuery/, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in boldfaced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in boldfaced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*

Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*

Biology: *H. pylori*, *E coli*, *etc.*

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be re-submitted online (http://www.wjgnet.com/1007-9327office/). The author should send the copyright transfer letter, responses to the reviewers, English language Grade B certificate (for non-native speakers of English) and final manuscript checklist to wjg@wjgnet.com.

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

WJG is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1300 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.

Abstract

There have been increasing concerns regarding the safety of perioperative anti-tumour necrosis factor (anti-TNF) α agents. We performed a literature review to evaluate the post-operative complications associated with perioperative anti-TNF use in patients with inflammatory bowel disease. A comprehensive review was performed with a literature search utilizing Pub Med, Cochrane, OVID and EMBASE databases according to published guidelines. To date, there are only data for infliximab. There are three published studies which have assessed post-operative complications with perioperative infliximab use in patients with Crohn's disease (CD), four studies in ulcerative colitis (UC) patients, and one study on both CD and UC patients. Two out of the three studies in CD patients showed no increased post-operative complications associated with perioperative infliximab. Two out of four studies in UC patients also did not show an increase in post-operative complications, and the combined study with CD and UC patients did not show an increased risk as well. Study results could not be combined secondary to significant differences in study designs, patient population and definition of their endpoints. There appears to be a risk of post-operative complications associated with TNF therapy in some patients. Based on these data, careful patient selection and prospective data collection should be performed.

Key words: Crohn's disease; Ulcerative colitis; Colectomy; Post-operative complications

INTRODUCTION

Therapeutic options for the management of inflammatory bowel disease include aminosalicylates, antibiotics, corticosteroids, antimetabolite immunomodulators (e.g., 6-mercaptopurine, azathioprine and methotrexate), and biologic therapies such as anti-tumour necrosis factor (anti-TNF) agents (e.g., infliximab, adalimumab, certolizumab pegol) and natalizumab[1-3]. The anti-TNF therapies are associated with adverse events including serious infections. In large controlled clinical trials of infliximab (IFX), the percentage of patients with serious infections ranged from 4.0% to 4.6%, and the mortality rate was 0.7% to 1.3%[4,5]. IFX-related adverse events, including serious

opportunistic infections such as tuberculosis, listeriosis and histoplasmosis, have also been documented in reports of open-label or retrospective trials[6-9]. However, the TREAT (Crohn's therapy, resource, evaluation, and assessment tool) Registry, a large-scale, ongoing, observational registry designed to examine the safety of Crohn's disease (CD) therapies, found prednisone use (OR: 2.21, 95% CI: 1.46-3.34, $P < 0.001$), narcotic analgesic use (OR: 2.38, 95% CI: 1.56-3.63, $P < 0.001$), and moderate-to-severe disease activity (OR: 2.11, 95% CI: 1.10-4.05, $P = 0.024$) were significantly associated with serious infections. Although the unadjusted analysis showed an increased risk for infection with IFX use, multivariate logistic regression analysis show that IFX was not an independent predictor of serious infections (OR: 0.99, 95% CI: 0.64-1.54)[10].

Despite optimal medical therapy, about two-thirds of patients with CD and one-third of those with ulcerative colitis (UC) eventually require surgery for disease control[11]. Factors increasing the risk of post-operative complications include: preoperative sepsis[12,13] (such as abdominal abscess or systemic infection), impaired nutritional status and intestinal obstruction[14-17]. Common early post-operative complications include abdominal wound infection, anastomotic leakage, pelvic sepsis and small bowel obstruction. Late complications include: anastomotic leak with pelvic sepsis or fistula, anastomotic stricture and pouchitis, and ileo-anal pouch dysfunction[18].

While anti-TNF use has been shown to induce and maintain steroid-free disease remission, improve quality of life and decrease the rate of hospitalizations and surgeries[4,19], concerns have risen regarding the potential harm of these medications. Most recently attention has also been focused on perioperative outcomes for patients who have received anti-TNF therapy and require surgery. The purpose of this review is to analyze the evidence regarding post-operative complications associated with anti-TNF in patients with inflammatory bowel disease.

LITERATURE SEARCH

Separate literature searches were conducted in the Pub Med, Ovid, EMBASE and Cochrane library databases (1950-2010) in accordance with published recommendations[20,21]. Databases were used to search English language literature using search terms such as "post-operative complications", "post-operative sepsis" and "surgical outcomes" in combination with words such as "anti-TNF therapy", "infliximab", "adalimumab", "certolizumab pegol", "natalizumab", "inflammatory bowel disease", "Crohn's disease" and "ulcerative colitis". Exploded terms were reviewed and included or excluded as per their relevance. A comprehensive review of the reference lists of all selected articles was also performed. Two investigators separately performed the literature search. Studies with patients having a diagnosis of ulcerative colitis, Crohn's disease and indeterminate colitis who had received anti-TNF therapy prior to surgical intervention were included. The initial search yielded one hundred and eight articles. Studies published as full articles were included in our systematic review. Only studies involving adult patients (18 years and older) and including control groups were included for the review. Odd ratios were calculated by 2 × 2 tables where the studies failed to include them, with the help of an online calculating system accessed *via* a website (http://faculty.vassar.edu/lowry/odds2x2.html).

No randomized prospective trial was identified. After applying the above mentioned selection criteria, only three retrospective studies assessing IFX associated complications in CD were selected for review[22-24] . Similarly, four retrospective studies involving patients with UC and infliximab were identified[25-28]. One additional study that included patients with both UC and CD was also included in the review and discussed separately[29]. A recently published meta-analysis examining the relationship between IFX and short term complications in patients with UC was also reviewed[30].

AVAILABLE STUDIES IN LITERATURE

Studies with Crohn's disease

No prospective randomized control trial has been published to determine the post-operative complication risks associated with anti-TNF therapy. Three retrospective studies were identified in the literature addressing risk of post-operative complications with IFX[22-24]. Individual study characters (including study design, use of concomitant medications use and dosing of IFX in relation to surgery) are presented in Table 1. Study endpoints and various complications assessed in each study are presented in Table 2, and the results of the risks of complications are presented in Table 3.

Marchal *et al*[22] retrospectively studied a cohort of three hundred and thirteen consecutive patients with CD who received infliximab between 1998 and 2002. A trend towards an increased early infection rate was found in IFX pre-treated patients (6 patients *vs* 1 patient $P = 0.10$), but the authors concluded this was probably due to the increased use of corticosteroids and/or immunosuppressive agents in this group[22]. However, the limited number of patients suggests the possibility of a type Ⅱ error.

In a study by Colombel *et al*[23], a group of investigators identified two hundred and seventy patients who underwent abdominal surgery for CD between 1998 and 2001. This retrospective analysis suggested that perioperative use of IFX use was not associated with an increased risk of post-operative complications. A multiple variable model including both steroid and IFX use was also performed and there was no independent association with either septic or total complications. However, these data were not presented in the published manuscript. Odds ratios were calculated from univariate regression analysis and additional multiple regression analysis was not performed secondary to the limited number of patients.

The investigators of the Appau *et al*[24] study evaluated

Kunitake[29] (combined study)	Post-operative cumulative complications	16.80	15.70	1.1 (0.6-2.0)

IFX: Infliximab; OR: Odd ratio; CI: Confidence interval.

30 d post-operative outcomes for CD patients treated with IFX (60 patients) within 3 mo *vs* infliximab-naïve patients (329 patients) prior to ileocolonic resection from 1998 to 2007. In an effort to reduce selection bias, the IFX group was also compared with pre-IFX patients (69 patients) undergoing ileocolonic surgery before 1998. Using multivariate analysis, the IFX group appeared to have an increased risk of 30 d post-operative readmission, sepsis, and intra-abdominal abscess. IFX patients who had a stoma (n = 17) above their anastomosis had a lower incidence of sepsis when compared with those without a stoma. While the sample size for the IFX group was larger than any published data, the sample size of 60 patients is still low; thus, differences in postsurgical outcomes that were found in this study might be further underestimated.

Studies with ulcerative colitis

There have not been any reported differences in the incidence and type of side effects attributed to IFX in patients with CD *vs* UC in general, but one area that has been getting more attention recently is post-operative complications. Four studies evaluating IFX and post-operative complications in UC patients were identified[25-28]. Individual study characters, including study design, use of concomitant medications and dosing of IFX in relation to surgery, are presented in Table 4. Study endpoints and various complications assessed in each study are presented in Table 5, and the results of the risks of complications are presented in Table 6.

The primary aim of the Selvasekar *et al*[25] study was to assess short-term post-operative infectious complications in UC patients who received preoperative IFX and underwent colectomy with ileal pouch anal anastomosis (IPAA) from 2002-2005. The overall post-operative complications in both groups were similar (P = 0.1). This was the first published study addressing post-operative complications and preoperative IFX use in UC. However, this was a single center study with a retrospective design and small sample size. This study was primarily before its approval by the Food and Drug Administration (FDA) in September 2005 and thus it represents off-label use, so ideal dosing was not defined and one might speculate that these were more severely ill patients. Therefore, the use of IFX may simply be a surrogate marker for more severe disease and sicker patients.

The Schluender *et al*[26] study was conducted to assess the 30-d post-operative medical and surgical complications of medically refractory UC patients who received preoperative IFX and underwent colectomy (subtotal or total proctocolectomy with IPAA) from October 2000-October 2005. There was a difference in concomitant 6-mercaptopurine (6-MP)/6-thioguanine (6-TG) use, with 94% in the IFX group also on 6-MP/6-TG *vs* 44% in the non-infliximab group (P = 0.03). However, that there was no significant difference in medical, surgical or infectious complications in patients receiving both IFX and 6-MP compared to patients receiving 6-MP alone was determined. This study was also limited by its single-center single surgeon retrospective design, and small sample size of seventeen patients who received IFX, and therefore lacks the statistical power to detect significant differences related to the two groups. Potential confounders, such as disease severity, were not assessed. However, the article highlighted the significantly increased risks of complications, including infectious complications, in patients exposed to cyclosporine and IFX which has also been reported in another study in steroid refractory UC[31].

The primary aim of a case-matched retrospective study by Mor *et al*[27] was to evaluate post-operative complications after restorative proctocolectomy in UC patients who received IFX preoperatively from January 2000-December 2006. Overall, the prevalence of early post-operative complications (35% *vs* 15%, P = 0.027) was significantly different, and the difference was mostly due to pelvic sepsis (22% *vs* 2%, P = 0.016) in the IFX and non-IFX groups, respectively. On further examination of the patients with pelvic sepsis, an ileo-anal pouch anastomotic leak was identified in eight of ten patients treated with IFX. There was no difference in overall late post-operative complications (52% *vs* 37%, P = 0.23), but pouchitis was more common (39% *vs* 15%, P = 0.037) in IFX *vs* non-IFX groups, respectively. In addition, the rate of three stage procedures was higher in those treated with IFX preoperatively (OR: 2.07, 95% CI: 1.18-3.63) even when adjusting for extent and severity of colitis, as well as steroid and immunomodulators use. The limitations of this study include its retrospective nature and single-center location. Disease severity was assessed in this study, but the retrospective use of hemoglobin and platelet counts are limited markers for severity assessment. Although the study found an increased rate of pouchitis in patients who had received preoperative IFX, risk factors for pouchitis were not controlled, and the diagnosis was not confirmed by endoscopy and histology. In addition, the finding of more frequent three stage procedures in the IFX group must be taken with caution, as the surgeons were not blinded to IFX use and thus may have influenced their decision.

The Ferrante *et al*[28] study evaluated the impact of IFX on post-operative infectious complications in UC or indeterminate colitis patients undergoing restorative proctocolectomy between 1998 and 2008. Short-term post-operative pouch-specific surgical and non-surgical site infectious complications were not significantly different in those who received IFX preoperatively. In multivariate analysis, a moderate-to-high dose of corticosteroids was associated with short-term post-operative pouch-specific complications (P = 0.001), surgical site complications (P = 0.002) and infectious complications overall (P = 0.003). This study, like its predecessors, was a single-center retrospective study with only 22 patients who received IFX within 12 wk of surgery and was too underpowered to detect significant differences between the two groups.

Recently, a meta-analysis was performed by Yang *et al*[30] examined the relationship between preoperative IFX treatment and short term post-operative complications in patients with UC. A total of 5 studies and 706 patients

Table 5 Complications defined in ulcerative colitis studies

Study	Study Endpoints	Infectious	Medical	Surgical	Pouch
Selvasekar[25]	Post-operative pouch specific and infectious complications	Pouch complications plus; wound infections			Anastomotic leak; pelvic abscess
Schluender[26]	30 d post-operative surgical and medical complications	Not defined	Major: pneumonia, DVT, pancreatitis, ARF, CVA; minor: dehydration, thrombophlebitis, pyoderma gangrenosum, urinary retention	Major: SBO, abscess, bleeding, leak; minor: wound infection, ileus, bleeding	
Mor[27]	Early (30 d) and late post-operative complications	Early: pelvic sepsis, bleeding, thrombosis, ileus; Late: pouchitis, SBO, stricture			
Ferrante[28]	30 d post-operative complications	Surgical infections: pouch complications plus wound infection; non surgical: UTI and respiratory infections			Anastomotic leak; pelvic abscess
Kunitake[29] (combined study)	Post-operative cumulative complications	Infections, hypomotility, thrombotic, cardiac complications, hepato-renal complications, anastomotic leak, bleeding and death			

DVT: Deep vein thrombosis; ARF: Acute renal failure; CVA: Cerebrovascular accident; SBO: Small bowel obstruction; UTI: Urinary tract infections.

were included in their meta-analysis. The analysis failed to find a strong association between preoperative treatment of IFX and short term infectious (OR: 2.24, 95% CI: 0.63-7.95) or non-infectious (OR: 0.85, 95% CI: 0.5-1.45) post-operative complications. However, preoperative IFX use increased short term total post-operative complications (OR: 1.80, 95% CI: 1.12-2.87). These results need to be interpreted with caution. There are significant differences in patient population, characteristics, and study end points in the studies included in the meta- analysis. For

Table 6 Post-operative risks of complications with ulcerative colitis

Authors	Complications	Cases (%)	Controls (%)	Risks of complications, OR (95% CI)
Selvasekar[25]	Pouch specific	19	7	2.6 (0.9-7.5)
	Infectious	28	10	2.7 (1.1-6.7)

OR: Odd ratio; CI: Confidence interval.

example, only one study[29] included patients who received their last dose of IFX within 12 wk prior to surgery and the remaining studies included patients where such characteristics and important distinctions were not accounted for. Even the definitions of infectious and non-infectious complications were different in the various studies[25-29]. In the presence of such confounders, it is hard to draw any meaningful results from this meta-analysis.

Combined Crohn's disease and ulcerative colitis study

Kunitake *et al*[29] retrospectively studied 413 patients (45% with CD, 38% with UC and 17% with IC) who underwent abdominal surgery between 1993 and 2007, evaluating the association of preoperative IFX use with post-operative complications. There were trends for higher rates of post-operative death, anastomotic leak, thrombotic complications, hypomotility, hepatorenal complications, and post-operative bleeding in the IFX group, but this did not reach statistical significance. Given its retrospective design, this study shared the same weaknesses as its predecessors. A sample size of approximately 250 patients in each arm to identify a 5% difference in post-operative outcomes was required. This study, while the largest to date in the literature, could only identify 101 patients who underwent IFX treatment within the 12 wk preceding their abdominal surgery. While no statistical significance was observed between the groups, some of the trends seen in the IFX group, such as the higher death rate, were indeed worrisome, especially as the deaths in both groups were because of failure of multiple organ systems due to intra-abdominal sepsis.

RISK OF POST-OPERATIVE COMPLICATIONS

Surgery plays an integral role in the treatment of inflammatory bowel disease, both to control symptoms and to treat complications. The rate of surgery within 3 years of diagnosis of CD varies from 25 percent to 45 percent. Twenty-five percent to 38 percent of patients require a second surgery by 5 years after the first, and about one third of patients who need a second surgery eventually require a third[32]. Indications for surgery include complications such as intra-abdominal abscess, medically intractable fistula, fibrotic stricture with obstructive symptoms, toxic megacolon, hemorrhage, and cancer[33]. Approximately 25 percent of UC patients ultimately require colectomy for the management of their disease[34]. Common indications for surgical therapy of UC are medically refractory disease, intractable disease with an impaired quality of life, and unacceptable side effects from medical therapy. Other indications for surgery include uncontrolled hemorrhage, toxic megacolon, perforation, dysplasia or carcinoma, systemic complications, and growth retardation.

Surgery in inflammatory bowel disease (IBD) patients is associated with morbidity and mortality. The common early post-operative complications include abdominal wound infection, anastomotic leakage, pelvic sepsis and small bowel obstruction. Late complications include anastomotic leak with pelvic sepsis or fistula, anastomotic stricture and, with IPAA, pouchitis and pouch dysfunction[18]. Post-operative infections increase length of hospital stay, cost, mortality and morbidity rates[35]. In one study, the post-operative infections in colectomy patients resulted in an approximately 2 wk longer hospital stay, with an increase of more than 300 percent in the total direct cost[36].

Patients receiving immunosuppressant medications, including biologic therapies, are at increased risk of bacterial, fungal and protozoal infections due to multiple effects on the immune system[7,37,38]. TNF α functions to stimulate angiogenesis and fibroblast proliferation, as well as to increase collagenase and prostaglandin synthesis[39]. In addition, the TNF α receptor has been shown to be necessary for an effective immune response to mycobacteria in animal models[7,39,40]. In addition to the above, reports of histoplasmosis, coccidiomycosis, listeriosis, pneumocystosis, and other fungal, bacterial and mycobacterial infections have been observed in patients receiving IFX.

The perioperative management of a patient with IBD requires a multifaceted approach involving both tradi-

tional and disease-specific considerations. As with any surgical candidate, preoperative risk assessment is crucial. Whether to suspend immunomodulating therapy during the perioperative period has been a challenging question. The difficulty lay in striking a balancing between that of maintaining disease control and that of optimizing wound healing, along with minimizing the post-operative risk of infection and other morbidity. As the use of biologic therapy in IBD continues to grow, we are faced with the additional task of providing recommendations for their use as well, and there is little information on which to base any definitive guidelines[41].

There have been several studies now published evaluating IFX use and perioperative complications. However, as described above, they suffer from similar weaknesses such as their retrospective design, small sample size (most studies included only 40-60 patients receiving IFX), dissimilar study populations (different IBD phenotypes, surgical procedures, and time periods on infliximab), single referral center populations, and use of the medication prior to FDA approval and thus generating selection bias with more ill patients receiving IFX and non-standardized usage of IFX. Potential confounders are generally not well addressed, especially severity and duration of disease, malnutrition, comorbidities, race and type of surgical procedure. Studies evaluating effect of IFX in CD are not adjusted for disease severity. Disease severity determined retrospectively is often inaccurate and surrogate covariates may be inadequate substitutions for validated methods of assessing disease activity. However it is interesting to note that in the studies of UC, those that were adjusted for disease activity showed a relationship between IFX and complications, while the converse was true for those studies that did not. Inappropriate use of anti-TNF therapy among some patients may also confound existing studies owing to their retrospective nature. Studies of the pharmacokinetics of IFX in IBD suggest that the elimination half-life is between 7 and 18.5 d[42,43]. By 12 wk (84 d, or 4.5 half-lives), most IBD patients should have undetectable levels of IFX. A window of 12 wk used by several of these studies may not reflect outcomes associated with the presence of drug at the time of surgery. Ideally, the duration between last infusion and surgery should be included as a continuous variable, but it is difficult to do this in retrospective analyses. Referral practice patterns also may account for the heterogeneous findings of these studies, as these may differ substantially in various regions of the world. Using anti-TNF therapy late in the course of disease in patients less likely to benefit from it (e.g., fixed stricture in CD) may introduce risk without clear benefit. Also, continuing to use anti-TNF therapy after it is clear that it has failed may send a higher risk patient to the operating room. These factors are difficult to measure and could be better addressed in a prospective, randomized study.

CONCLUSION

To date, all of the studies of anti-TNF therapy are of infliximab and are mixed in their reports of the risk of post-operative complications associated with it. The studies are limited by small numbers of patients, disparate comparison groups, different definitions of measured outcomes and varying timeframes of drug exposure and follow-up. Larger controlled studies, with well-defined standardized criteria, are needed to clarify this issue. In the meantime, physicians must be aware of these potential risks so that prudent decisions about patient selection and timing of interventions can be made.

Abstract

In recent years the advent of programs for enhanced recovery after major surgery (ERAS) has led to modifications of long-standing and well-established perioperative treatments. These programs are used to target factors that have been shown to delay postoperative recovery (pain, gut dysfunction, immobility) and combine a series of interventions to reduce perioperative stress and organ dysfunction. With due differences, the programs of enhanced recovery are generally based on the preoperative amelioration of the patient's clinical conditions with whom they present for the operation, on the intraoperative and postoperative avoidance of medications that could slow the resumption of physiological activities, and on the promotion of positive habits in the early postoperative period. Most of the studies were conducted on elective patients undergoing colorectal procedures (either laparotomic or laparoscopic surgery). Results showed that ERAS protocols significantly improved the lung function and reduced the time to resumption of oral diet, mobilization and passage of stool, hospital stay and return to normal activities. ERAS' acceptance is spreading quickly among major centers, as well as district hospitals. With this in mind, is there also a role for ERAS in non-colorectal operations?

INTRODUCTION

In recent years the advent of programs for enhanced recovery after major surgery (ERAS) has led to modifications of long-standing and well-established perioperative treatments. These programs are used to target factors that have been shown to delay postoperative recovery (pain, gut dysfunction, immobility) and combine a series of interventions to reduce the perioperative stress and organ dysfunction[1]. With due differences, the programs of enhanced recovery are generally based on the preoperative amelioration of the patient's clinical conditions with whom they presents for the operation, on the intraoperative and postoperative avoidance of medications that could slow the resumption of physiological activities, and on the promotion of positive habits in the early postoperative period (Table 1)[2]. Common factors are postoperative pain control through continuous mid-thoracic epidural anaesthesia and avoidance of regular opioids drugs, stimulation of gut motility, no mechanical bowel preparation, early physical reactivation, and limited use of catheters, tubes and drains[1].

Most of the studies were conducted on elective patients undergoing colorectal procedures (either laparotomic or laparoscopic surgery) and a growing number of articles and reviews have analysed the data produced (Figure 1). Results showed that ERAS protocols significantly

improved the lung function and reduced the time to resumption of oral diet, mobilization and passage of stool, hospital stay and return to normal activities[3]. Any delay in hospital discharge or early readmission was due to the development of major complications[4,5]. Higher American Society of Anesthesiologists (ASA) score, advanced age, and rectal surgery were associated with delayed mobilization, morbidity and prolonged stay[6]. ERAS' acceptance is spreading quickly among major centers as well as district hospitals. With this in mind, is there also a role for ERAS in non-colorectal operations?

NON-COLORECTAL SURGERY

Compared to colorectal surgery, fewer studies have investigated ERAS in other operations (Table 1)[3-24].

Radical cystectomy

Radical cystectomy is one of the urological procedures which has the highest rate of complications and longest hospital stay[25]. Overall complication rate is 21%-34%, early reoperation rate 6%-7%, mortality rate 0.4%-2.7%, and the hospital stay is 17.4 ± 4.7 d. The most frequent complications are pelvic lymphoceles (8.1%), wound dehiscence (6%-9%), deep venous thrombosis (4.7%), ileus (3.9%), and pulmonary embolism (2%-4%)[26-28]. Over the years, improvements in the surgical technique, anaesthesia and perioperative care have already resulted in reduced morbidity and shorter hospital stays[28]. Age is not a contraindication, and the operation can be administered even to elderly patients with similar complications rates to younger patients[26,29,30]. More important for the prediction of postoperative complications are the preoperative cardiac history, ASA score and the number of intraoperative blood transfusions. For preoperative mortality, the ASA score, blood transfusions and preoperative nutritional deficiency are important[28,31,32].

Arumainayagam *et al*[25] developed the only ERAS protocol available for radical cystectomies. The protocol consisted of stopping the use of mechanical bowel preparation before the cystectomy, implementation of early enteral feeding (with nutritional supplements) and mobilization as tolerated. Patients with ileal conduits after radical cystectomy were encouraged self management of the stoma and catheter care on postoperative day 2. The application of the ERAS protocol produced a significant reduction in the length of stay (13 d *vs* 17 d) but had no effect on the time to first defecation (6 d), morbidity, mortality and readmission rates[25]. Obviously the ERAS protocol does not affect these rates, as it has no influence on risk factors for morbidity, mortality and readmission rates. It would be interesting to evaluate if preoperative nutritional improvement, and not only for early enteral feeding, might decrease the postoperative complications rates in order to better prepare the body for surgical stress.

Liver resections

Liver resections have morbidity rates of 25%-48% and mortality of 1%-7%[33-35]. The length of stay with a traditional perioperative pathway ranges from between 8 and 14 d. The length of stays and intensive therapy unit stays are shorter if resections are conducted with laparoscopic surgery[36,37]. Factors associated with postoperative morbidity are neoadjuvant chemotherapy, vascular clamping, intraoperative blood loss with transfusion[35,38], comorbid conditions, pre-existent liver disease and small remnant liver volume[39]. Factors associated with postoperative mortality are the presence of blood transfusions and extended resections[40]. Age is not associated with an increase of morbidity or mortality[41].

The application of an ERAS protocol to liver surgery was evaluated by van Dam *et al*[1]. Their protocol was similar to those of colorectal surgery, including: nutritional supplements up to two hours before surgery, thoracic epidural analgesia, short acting anesthetics, avoidance of excessive IV fluids, warm fluids, and one night in the recovery ward before being admitted to the normal surgical ward. Among the criteria for discharge was the normalization or decreasing of serum bilirubin. Results achieved confirmed hospital stays shorter than 2 d and with no significant differences in the rates of morbidity, mortality and readmissions. In fact, as for radical cystectomies, the ERAS protocol did not alter any of the risk factors for these outcomes. A different study performed on liver resections undergoing ERAS evaluated the addition of laxatives to the protocol[42]. Although routing postoperative laxatives resulted in an earlier first passage of stool, the overall rate of recovery remained unaltered[42].

Upper gastrointestinal surgery

Gastric and oesophageal resections are operations associated with long hospital stays and postoperative morbidities. The average length of hospital stay after oesophagectomy ranges from 11 to 26 d following open surgery, and 7 to 13 d following laparoscopic surgery[43]. Postoperative pulmonary complications have been reported in 15%-30% of cases and are the most common cause of major morbidity and mortality[44]. Risk factors include impairment in lung function, cardiac reserve, preoperative physical activity and body composition[44]. Furthermore, a history of pulmonary disease, age, and preoperative physical activity also significantly predicts postoperative death[45]. For gastric resections, old age does not seem to affect morbidity rates (25%-29%)[46,47] but still influences mortality, which is higher amongst elderly patients (3% *vs* 10%)[29]. Advanced age, low albumin, ASA score, palliative resections and resection of two or more additional organs were independent risk factors for mortality[47].

ERAS protocols have been applied on both transthoracic oesophagectomies (Ivor-Lewis procedure) and laparoscopic gastric resections[43,48]. The ERAS protocol for oesophagectomies involved extubation in the operating theatre or immediately on arrival in the intensive care unit, early mobilization, negative fluid balance, intense respiratory physiotherapy and epidural analgesia. Patients remained in intensive care for three days, most drains

Table 1 Types of Enhanced Recovery protocols adopted

	Preoperative	Intraoperative	Postop (first 24 h)	Day 1	Day 2	Day 3	Day 4	Additional comments
Kahokehr *et al*[7,8]	Routine nutritional assessment; nutrition supplementation; NBM 2 h preinduction; carbohydrate loading; no bowel preparation; functional assessment and goal setting	Thoracic epidural; short acting anesthetics; intraoperative fluids: 1000 mL of crystalloid and 500 mL of colloid; prophylactic antiemetics at induction (dexamethasone); no drains or NG tubes	All Ⅳ fluid stopped before patient discharged to ward; prophylactic antiemetics; early oral feeding; nutritional supplementation; no opioids	Removal of urinary catheter	Removal of epidural			Early mobilization and physiotherapy
King *et al*[9-11], Blazeby *et al*[12], Faiz *et al*[13]	Optimized premorbid health status; functional assessment and goal setting; Meeting with stoma nurse. Nutrition supplementation; bowel preparation (for left colonic, sigmoid and rectal tumours)	Thoracic epidural; intraoperative fluids: 2000 mL of crystalloid; minimal-access surgery; local anaesthetic infiltration to the largest wound; no drains or NG tubes	Free fluid; 1 high-protein/high-calorie drink; patient sat out in chair	All Ⅳ fluid stopped; regular paracetamol; 3 high-protein/high-calorie drink; normal diet offered; patient sat out in chair; start walking; removal of urinary catheter for colonic resections; laxatives	Removal of epidural; regular NSAIDS; Morphine for breakthrough	Removal of urinary catheter for rectal resections		Aim for discharge on day 3 for colonic or day 5 for rectal resection; Provision of hospital contact numbers, review on ward if problems within 2 wk; review in outpatient clinic on day 12
Jottard *et al*[14]	Functional assessment and goal setting; nutrition supplementation; no bowel preparation	Thoracic epidural; anti-thrombotic and infection prophylaxis; standard anesthetic protocol; prevention of intraoperative hypothermia; no drains or NG tubes	Free fluid	All Ⅳ fluid stopped; normal diet offered				Use of anti-emetics; early mobilization; postoperative nutritional care
Maessen *et al*[4,5], Nygren *et al*[3], Hendry *et al*[6]	Functional assessment and goal setting; nutrition supplementation; no bowel preparation	Thoracic epidural; prevention of intraoperative hypothermia; Transverse/curved incision	Oral analgesia; Patient sat out in chair; nutritional supplements; free fluid > 800 mL	All Ⅳ fluid stopped; nutritional supplements > 400 mL; normal diet offered; patient sat out in chair > 6 h	Removal of epidural; removal of urinary catheter			
Soop *et al*[15]	Nutrition supplementation	Thoracic epidural	Prophylactic antiemetics	Regular paracetamol and NSAIDS; patient sat out in chair for 2 h	Patient sat out in chair for 4 h	Patient sat out in chair for 3 h	Epidural removed (at least)	
Raymond *et al*[16]	Functional assessment and goal setting; nutrition supplementation	Thoracice epidural; Intra-operative targeted fluid management; No NG tube						Early mobilization/resumption of diet
Turunen *et al*[17]	Functional assessment and goal setting; preoperative feeding; bowel preparation	Thoracic epidural; high-oxygen P; prevention of hypothermia; no drains or NG tubes		Removal of urinary catheter				Early mobilization/resumption of diet; no routine opioids, regular; paracetamol and NSAIDS; fluid restriction
Senagore *et al*[18]		No NG tube	PCA; free fluids	Removal of urinary catheter; normal diet offered; regular NSAIDs, gabapentin, hydroxycodone if needed; no drains				
Wennstrom *et al*[19]	Functional assessment and goal setting; no bowel preparation; preoperative oral hydration	Thoracic epidural; short acting anaesthetics; no opioids	Free fluid; patient sat out in chair		Epidural removed; urinary catheter removal			

Mohn *et al*[20]	Functional assessment and goal setting; nutrition supplementation; bowel preparation.	Thoracic epidural; total intravenous anesthesia; intra-operative targeted fluid management; restricted postoperative intravenous fluids; routing antiemetics postoperatively; short midline incisions; No drains or NG tubes	Patient sat out in chair	Removal of urinary catheter; patient sat out in chair; normal diet offered; regular paracetamol and nsaids, opioids for breakthrough	Epidural removed		Regular laxatives twice daily; antithrombotic prophylaxis
Teeuwen *et al*[21]	Nutritional supplements; bowel preparation in left-sided resections; thrombotic prophylaxis	Thoracic epidural; transverse incisions except in Crohn's disease and rectal surgery; intra-operative targeted fluid management (hypotension treated with vasopressors); no drains except in rectal surgery; no NG tubes; prophylactic antiemetics	Free fluids; nutritional supplements; patient sat out in chair	Normal diet offered; intravenous fluid administration; start walking	Epidural removed; urinary catheter removal; regular paracetamol; NSAIDs opioids for breakthrough		
Ahmed *et al*[22,23]	Functional assessment and goal setting; nutritional supplements; no bowel preparation	High inspired oxygen; concentration; transverse incisions; no drains or NG tubes	Free fluids; soft diet offered; patient sat out in chair	Start walking			Regular paracetamol NSAIDs, opioids for breakthrough
Kirdak *et al*[24]	Thrombotic prophylaxis; bowel preparation; nutritional supplements	Thoracic epidural; pelvic drains with rectal dissections; urinary, central venous, and nasogastric catheters were routinely used	Start walking	NG tubes and urinary catheters removed (except pelvic dissection); soft diet offered; start walking; patient sat out in chair	Removal of urinary catheter (low pelvic operations) and drains	Epidural removed; regular paracetamol; central venous catheters removed; normal diet	

NBM: Neuronal basal medium; NG: Nasogastric; NSAIDS: Nonsteroidal antiinflammatory drugs; PCA: Pyrrolidone carboxylic acid.

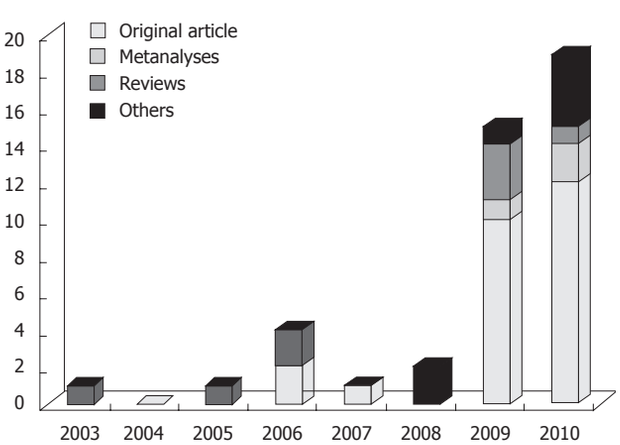

Figure 1 Number and types of articles published on Enhanced Recovery.

and tubes were removed on day 4, oesophageal radiology studies were performed on day 5 and the nasogastric tube consequently removed. Particular attention was dedicated to early signs of potential complications (pulmonary infections or anastomotic leaks). With this protocol the authors achieved a significant reduction of pulmonary complications (31% *vs* 38%), mortality (1% *vs* 5%) and hospital stay (9 d *vs* 13 d)[43]. Even in this case, as well as for radical cystectomy, no evaluation aimed for an improvement of the preoperative nutritional status, which might decrease the postoperative complications rates in order to better prepare the body for surgical stress.

Patients receiving an ERAS protocol for laparoscopic gastric surgery had their anastomosis tested on the first postoperative day with a water soluble swallow study. If the anastomosis was intact, free fluids were started and an early diet on day 2 consisting of small, frequent low-sugar meals[48]. The urinary catheter was removed on day 1. No epidural analgesia was used for pain relief, nor any abdominal drains or nasogastric tubes. Discharge was planned for day 3. Results showed a short length of stay (4 d, range 2-30) and reduced readmission rate (6.2%). Only two patients developed postoperative complications, namely a wound abscess and an urinary infection[48].

Gynecological surgery

Hysterectomy is a common gynecological procedure that is performed through various routes. Overall morbidity is present in 16% of cases, but their frequency depends on the route adopted to remove the uterus; they are usually rare after open abdominal hysterectomies (hemorrhages: 2.4%, genitourinary disorders: 1.9%, infection: 1.6% and urinary tract infections: 1.6%), even lower with the vaginal route but higher for laparoscopic abdominal hysterectomy[49]. The major causes of morbidity in patients who undergo abdominal hysterectomies are medical rather than surgical and the most important factor associated with them is the presence of comorbidities[50,51]. Readmissions are confined to 5.4%-7.2% of cases.

One article focused on ERAS protocol in gynecological operations. The protocol consisted of intensified information on pre-hospitalization consultations and admission. Intravenous lines, urinary catheters and tampons were removed before the patient left the recovery unit. Mobilization and normal food intake, including per oral analgesics, started a few hours after the operation. Routine postoperative enemas were discontinued[52]. A significant reduction of the length of stay was also confirmed in this study, but no mention was made about the rate of postoperative complications or readmission[52].

Post-bariatric body contouring surgery

Patients undergoing post-bariatric body contouring surgery have a higher risk for postoperative complications (28%)[53,54] and among these the most common are those involving the wound healing process (infections, seromas, hematomas and delayed healing)[55-58]. The causes are multifactorial and include the percentage excess weight loss[53], total tissue resection weight[59], preoperative body mass index[60] and the recently discovered "high-calorie malnutrition"[61]. This syndrome involves the preoperative deficiency of vitamins and minerals that are important for the healing process. Differently from the other risk factors, high-calorie malnutrition syndrome is common to the overweight, obese and post-obese patients, and its perioperative corrective could improve the wound healing in all these subcategories. This is shown in the study by Agha-Mohammadi where the rate of complications in post-bariatric and obese patients was similar to normal-weight patients after perioperative nutritional supplementation of many primary ingredients necessary for wound healing and immune system competency[61]. In this case the length of stay was not evaluated because most plastic surgery procedures can be conducted during short admissions or even day surgery.

CONCLUSION

The application of ERAS protocols to non-colorectal surgery is more complex due to the paucity of literature available and to the outcomes that might be different according to the peculiarities posed by each discipline and its specific problems. Generally, a principle of ERAS is that the reduction of hospital stay should be balanced against the possibility of increased readmission rates. To achieve this objective, the rate of postoperative complications should be reduced so that patients can be safely sent home earlier with no risk to their health and no need for readmission. These two principles, reduction of the length of stay and of the postoperative morbidity, should both be targeted in a comprehensive ERAS program. However, most of the studies analyzing ERAS protocols in non colorectal-surgery focused mainly on only one factor, the length of hospital stay, which is the most evident in terms of hospital costs and productivity. The analysis conducted on non-colorectal studies showed that most protocols tried to optimize the perioperative administration of drugs, fluids and tubes following the path traced by colorectal studies. These factors obviously impacted on the overall length of stay but did not act on risk factors for postoperative morbidity, with an exception made for the post-bariatric study. Not surprisingly, the incidence of postoperative complications remained the same in most articles except for the post-bariatric study. To further improve the already positive results achieved by most ERAS programs it is advisable to focus more on the clinical conditions with which the patient arrives to the operation, redefining the situation by which the body faces the surgical stress and improving its ability to deal with it. This could not only reduce the length of stay, but also the complication and readmission rates.

Abstract

Hepatitis C virus (HCV) infection is an important risk factor for insulin resistance (IR). The latter is the pathogenic foundation underlying metabolic syndrome, steatosis and cirrhosis, and possibly hepatocellular carcinoma (HCC). The interplay between genetic and environmental risk factors ultimately leads to the development of IR. Obesity is considered a major risk factor, with dysregulation of levels of secreted adipokines from distended adipose tissue playing a major role in IR. HCV-induced IR may be due to the HCV core protein inducing proteasomal degradation of insulin receptor substrates 1 and 2, blocking intracellular insulin signaling. The latter is mediated by increased levels of both tumour necrosis factor-α (TNF-α) and suppressor of cytokine signaling 3 (SOC-3). IR, through different mechanisms, plays a role in the development of steatosis and its progression to steatohepatitis, cirrhosis and even HCC. In addition, IR has a role in impairing TNF signaling cascade, which in turn blocks STAT-1 translocation and interferon stimulated genes production avoiding the antiviral effect of interferon.

INTRODUCTION

Infection with hepatitis C virus (HCV) is a common problem worldwide, affecting millions of people across all populations. Most acutely infected patients develop chronic hepatitis and become a potential source of virus transmission, and as many as 1 in 5 will develop cirrhosis and its complications[1]. Besides, HCV is an increasingly recognized important cause of extrahepatic manifestations, including insulin resistance (IR)[2].

IR is a complex pathophysiological condition where higher-than-normal concentrations of insulin are needed to maintain a normal glycemia and adequate glucose utilization in insulin target tissues[3]. IR is of global importance since is closely linked to the epidemic condition of obesity and it precedes and predicts the development of type 2 diabetes mellitus (T_2DM) and increases the risk of life-threatening complications such as cardiovascular diseases, renal failure, and infections. However, these complications are not major causes of death in cirrhotic patients with IR[4]. In contrast, the development of in-

trahepatic complications, including HCC, is known to be associated with IR[5].

IR is extremely common in patients with chronic HCV infection and has been associated with increased disease severity, extrahepatic manifestations and decreased response to antiviral therapy[6]. Understanding the basis of such associations is of paramount importance to inform treatment strategies for patients with HCV. This review summarizes recent information on the different issues of HCV infection and IR.

CAUSES OF INSULIN RESISTANCE

It represents interplay between genetics (inherited) and environmental (acquired) factors. Genetic factor include abnormal insulin, abnormal insulin receptor and abnormal signaling proteins. The main acquired factors of IR include: abdominal obesity, aging, hyperglycemia, medications and recently HCV infection.

Abdominal obesity

Obesity is associated with IR, hepatic steatosis and over expression of tumor necrosis factor-α (TNF-α). All of these factors increase the risk of fibrosis and decreased antiviral efficacy. Also, obesity decreases interferon bioavailability and impairs immune stimulating properties of interferon. Hepatic steatosis, nonalcoholic steatohepatitis and fibrosis are associated with release of reactive oxygen species (ROS), which contribute to decreased HCV response to interferon (IFN)[7,8].

Moreover, obesity is associated with decreased number and downregulation of insulin receptors and impairment of postreceptor signaling. Overflow of free fatty acids (FFAs) from adipose tissue interferes with intrahepatic insulin signaling pathway *via* increased levels of proinflammatory cytokines such as TNF-α[9,10], and proteasomal degradation of the insulin receptor substrates (IRS) 1 and 2 (Figure 1)[11].

Aging

Aging is associated with increased levels of FFAs and triglycerides, in addition to glucose transporter-4 (GLUT4) decrease and mutation.

Hyperglycemia

Overflow of FFAs from adipose tissue to systemic circulation impairs insulin-mediated glucose uptake by the muscles resulting in hyperglycemia and peripheral IR.

Medications

Some medications can induce IR as glucocorticoids, cyclosporine, growth hormones, thyroid hormones, sex hormones, analogues, thiazides, β-blockers, protease inhibitors for HCV and nucleoside analogues for hepatitis B virus.

Hepatitis C virus infection

Recently has evolved as a significant risk factor for the development of IR.

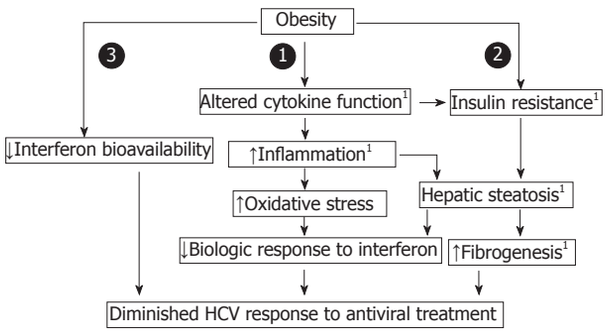

Figure 1 Obesity is associated with insulin resistance and decreased antiviral efficacy. [1]Indicates potential for coexistent viral potentiation. HCV: Hepatitis C virus.

ROLE OF ADIPOKINES IN INSULIN RESISTANCE

Adipokines

Adipokines are polypeptides secreted in the adipose tissue in a regulated manner and they include adiponectin, leptin, resistin, retinol-binding protein 4, visfatin, omentin, vaspin, chemerin, apelin, TNF-α, interleukin 6 (IL-6), and monocyte chemoattractant protein-1[12].Chronic HCV infection is associated with changes in the serum level of some adipokines[13].

Adiponectin

Decreased serum levels of adiponectin have been reported in chronic hepatitis C (CHC), especially in patients with steatosis. Deficiency of adiponectin is associated with obesity, IR, glucose intolerance, triglyceride (TG) accumulation and steatosis, and metabolic syndrome[13].

Leptin

Leptin insufficiency is associated with increased body weight, increased FA synthesis, decreased FA oxidation, decreased TG excretion, increased steatosis, and impaired insulin sensitivity and secretion[13]. In a recent controlled study of HCV-infected nondiabetic males compared to matched uninfected controls, circulating levels of the adipokines leptin and adiponectin were independently associated with IR, but not with the presence of HCV, and it was concluded that HCV-associated IR does not seem to be mediated by adipokines or proinflammatory cytokines[14].

Tumor necrosis factor-α

TNF-α is also considered one of the adipokines secreted in adipose tissue. HCV may also induce IR by triggering the production of proinflammatory cytokines, because in hepatitis C, circulating TNF-α levels are increased[15,16]. TNF-α can induce IR by several mechanisms, both direct and indirect. TNF-α interferes with the insulin signaling pathway, *via* induction of the suppressor of cytokines 3 (SOCS-3) that inactivates phosphatidylinositol-3-kinase (PI3K). The latter inhibits GLUT-4 translocation to cell membrane and intracellular glucose entry[13]. Increased

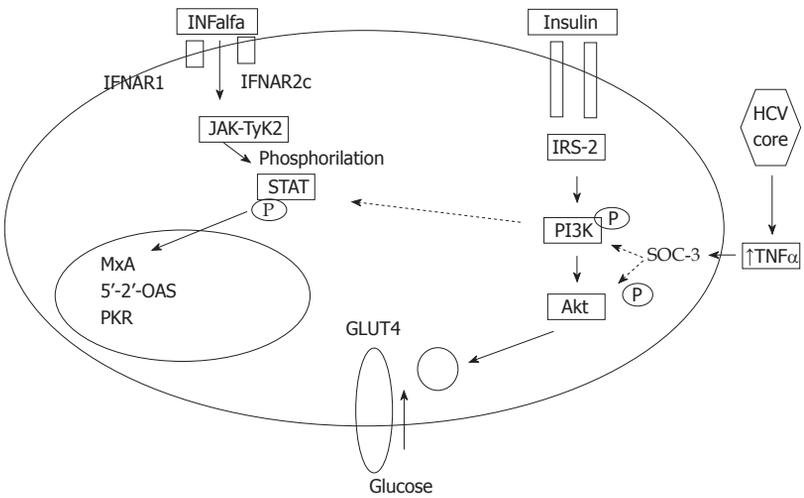

Figure 2 Interaction between hepatitis C virus core, insulin- and interferon-α signaling pathways continuous lines represent activation. Dotted lines represent inhibition. Hepatitis C virus core protein induces expression of tumour necrosis α (TNF-α), which in turn activates suppressor of cytokines-3 (SOCS-3). Activation of SOCs-3 leads to proteasomal degradation of insulin receptor substrate and inactivates phosphatidyl-inositol-3-kinase (PI3K), leading to inhibition of translocation of glucose transferase (GLUT-4) to cell membrane, blocking intracellular glucose entry, with subsequent hyperglycemia, hyperinsulinemia and peripheral insulin resistance. Activation of SOCS-3 also leads leading to inhibition of Tyr-phosphorylation of signal transducers and activators of transcription 1 leading to impaired TNF-α signaling. HCV: Hepatitis C virus; IFNAR2c: Interferon receptor chain 2; IRS2: Insulin receptor substrate 2; JAK: Janus kinase; TYK2: Tyrosine kinase 2; STAT: Signal transducer and activator of transcription.

TNF-α-mediated expression of SOCS-3 has been identified in obese, genotype 1 patients with chronic HCV infection[17].

In addition, TNF-α triggers lipolysis of FFAs from adipose tissue, leading to increased serum levels of free fatty acids and it has also a direct inhibitory effect on insulin action in the liver. These effects lead to reduced glucose uptake in muscle, and to increased hepatic glucose production[18,19]. TNF-α is also suggested to regulate expression of several adipocyte genes known to modulate insulin sensitivity/resistance[20], therefore, it is suggested that TNF-α acts as a possible link between HCV and diabetes[21].

Apeline

Apeline, an adipocytokine derived from adipose tissue, has been recently suggested to be associated with fibrosis progression and development of cirrhosis in HCV infection. In addition, apeline levels are more elevated in IR subjects than in non-IR. Both TNF-α and apeline may rather express complementary effect in fibrosis progression as well as impaired response to IFN therapy.

HEPATITIS C VIRUS AND INSULIN RESISTANCE

Hepatitis C virus induces insulin resistance

The causal relationship of HCV infection and IR development has been demonstrated by the increased prevalence of IR in chronic HCV infection. Whereas the overall prevalence of IR is 10%-25% of the population[22], the prevalence IR in HCV infection reaches figures ranging between 30% to 70%[23,24]. Moreover, IR with HCV infection is increased at early stages of liver disease without liver fibrosis, and is on average significantly higher than that found in patients with chronic hepatitis B, matched for age and body mass index[25].

The causal relationship of HCV infection and IR development has also been demonstrated by improvement of IR after successful therapy in CHC patients, whereas no improvement is observed in nonresponders[26-28].

Mechanism

HCV virus, through both direct and indirect pathways, affects the insulin signaling pathways, promoting IR at a cellular level. Insulin effects are elicited after binding of insulin to its receptor that is linked to a complex signaling pathway that involves sequential activation of IRS, PI3K, Akt, a protein kinase which is a downstream of PI3K activation, and protein kinase C. This cascade of events eventually results in stimulation of glucose uptake after translocation of the GLUT4 to the plasma membrane. IR results from defects at any level of the insulin receptor-related signaling pathway[29] (Figure 2).

Following inflammatory response in the liver to HCV infection, a profound impairment of insulin signaling occurs at the level of IRS tyrosine phosphorylation and PI3K activation[30]. HCV core protein induces expression of TNF-α, which activates SOCS-3, leading to subsequent proteasomal degradation of IRS1 and IRS2, resulting in the development of IR. Meanwhile, SOCS-3 inactivates PI3K, which in turn inhibits translocation of GLUT-4 to cell membrane, thus blocking intracellular glucose uptake[10,11,31] (Figure 3).

It has been also suggested that increased levels of pro-inflammatory cytokines such as interleukin 1, TNF-α, IL-6 and leptin, and reduced levels of adiponectin may directly contribute to the occurrence of HCV-related IR[23].

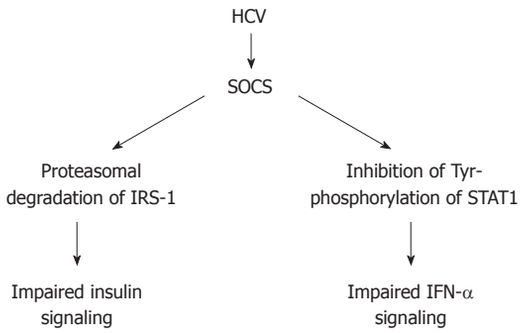

Figure 3 Proposed dual role of the upregulation of members of the suppressor of cytokines family by hepatitis C virus: simultaneous impairment of the insulin and IFN-a signaling systems. HCV: Hepatitis C virus; SOC: Suppressor of cytokines; IRS-1: Insulin receptor substrate 1; STAT1: Signal transducers and activators of transcription1; IFN-α: Interferon-α.

Viral load and insulin resistance

The relationship between the severity of IR and HCV replicative levels has been very difficult to prove. However, recent work seems to suggest so[32]. In addition, it has been shown that IR is modified by treatment and that the incidence of T2DM in patients achieving sustained virological response (SVR), defined as undetectable HCV RNA 24 wk after completing treatment, is significantly lower than that seen in nonresponders[26-28]. However, it is still not clear whether HCV replication directly increases IR, or whether hyperinsulinemia stimulates viral replication, as suggested by in vitro data[33]. It is to be noted that the global level of IR is likely to depend on the contribution from the adipose tissue and the muscle, two extrahepatic compartments that are not infected by HCV.

Viral genotype and insulin resistance

Although the interference with the insulin effects shows some HCV genotype-specificity, IR has been reported to occur in all HCV genotypes, but to a different extent[34]. HCV genotype 3a, in addition, may alter the intrahepatic insulin signaling through a downregulation of peroxisome proliferator-activated receptor[35]. In HCV genotype 1b infections, substitutions of amino acids 70 and/or 91 in HCV-1b core were found to be significant determinants of severe IR, in patients without cirrhosis and diabetes mellitus, which suggests a real connection between HCV-1b infection and IR at early stages of liver disease[36].

Hepatitis C virus, iron overload, oxidative stress and insulin resistance

Hepatic iron overload has been repeatedly reported in patients with chronic HCV infection[37-39]. Although the mechanisms of hepatic iron overload remains unclear, recent studies showed a decreased hepatic expression of hepcidin, a negative regulator of duodenal iron absorption, in patients with HCV infection[40-42], in addition to increased hepatic expression of transferring receptor 2, a mediator of iron uptake, which is responsible for the hepatic iron overload[43].

The mechanisms through which iron causes IR are not clear. Hepatic iron overload produces oxidative stress and is a factor responsible for the development of HCV-associated IR[44-47]. Oxidative stress, itself, is an independent factor in the development of IR in patients with signaling[47], and has been associated with altered IFN-α signaling *via* decreased phosphorylation of the Janus kinase-signal transducer and activator of transcription (JAK-STAT) pathway[48]. In addition, a cross-talk between iron metabolism and insulin-glucose metabolism has recently been documented[49]. Iron has been found to reduce hepatic extraction/metabolism of insulin and to interfere with insulin action on the liver, leading to peripheral hyperinsulinemia[50,51]. In contrast, hyperinsulinemia may cause rapid stimulation of iron uptake into the liver, because insulin is known to redistribute transferrin receptors from an intracellular membrane compartment to the cell surface[52].

EFFECTS OF HEPATITIS C VIRUS-INDUCED INSULIN RESISTANCE

Increased incidence of type 2 diabetes mellitus

An important clinical implication of IR in chronic HCV infection is the strong relationship of IR and T2DM development[53]. One recent meta-analysis has confirmed that chronic HCV is associated with an increased risk of developing T2DM compared with both non-infected controls and patients with chronic HBV infection, which is independent of the presence of cirrhosis[54]. Nearly 30%-70% of patients with CHC display some form of IR[23]. accordingly worldwide, 47 million patients may have HCV-associated DM[21].

On the other hand, IFN therapy is often implicated in the literature as having a role in the development of diabetes in HCV patients. However, this association is rare, and the few cases of DM developing during IFN therapy had T1DM, in line with other autoimmune manifestations induced by IFN[55,56].

Insulin resistance-induced hepatic steatosis, fibrosis and hepatocellular carcinoma

HCV, IR and steatosis: The overall prevalence of steatosis in patients with HCV infection is approximately 55% ranging from 35% to 81% in various studies, which is approximately 2-3 folds higher than the prevalence of steatosis in other liver disease[57]. One-to two-thirds of liver biopsies from CHC patients have histological evidence of steatosis, which has been associated with being overweight, hepatic fibrosis and increased TG levels[58,59].

The relationship between IR and HCV infection is complex and bidirectional; HCV induces steatosis[57], and the latter could also cause IR[60]. In addition to inflammation, HCV proteins also play a role in the development of IR and oxidative stress, the two key pathways in the pathogenesis of non alcoholic fatty liver disease (NAFLD)[61]. On the other hand, insulin is an anabolic

hormone and promotes hepatic lipogenesis[62], and inhibits lipolysis[63]. Therefore, the initial step in HCV-related metabolic disorders remains unclear.

The current evidence suggests that HCV-associated hepatic steatosis is mainly virus-induced in genotype-3a infected patients[64]. which seem to be mediated by an impaired very low-density lipoprotein (VLDL) secretion, most likely *via* an impaired activity of the liver microsomal triglyceride transfer protein (MTP)[65]. On the contrary, the host-factors (mainly IR) play a major role in steatosis in non-3 genotypes[64]. In addition to inflammation, HCV proteins also play a role in the development of IR and oxidative stress, the two key pathways in the pathogenesis of NAFLD[65]. It is well known that IR causes impaired metabolic clearance of glucose and hyperglycemia. In addition, peripheral IR also increases adipose tissue lipolysis, leading to increased plasma and hepatic uptake of FFAs. Increased hepatic uptake of FFAs impairs β-oxidation in mitochondria, together with decreased excretion of VLDL, resulting in TG retention with subsequent development of hepatic steatosis[66,67].

A direct relationship between HCV replication and steatosis has been extensively documented by both clinical and experimental data[68,69]. HCV core protein also regulates secretion of VLDL, TG, and apoliprotein B through regulation of MTP peroxisome proliferator-activated receptor γ (PPAR-γ), and sterol regulatory element binding protein-1c (SREBP-1c)[70-72]. The latter is a protein central to insulin signaling, also involved in up-regulation of de novo lipogenesis and inhibition of fatty acid β-oxidation; two events that can favour intracellular accumulation of triglycerides.

Recently, there has been considerable interest in the role of micro-RNAs (miRNA) in the genesis of both fatty liver and HCV replication, in particular, mir122, the most abundant liver miRNA, has been shown to affect the development of steatosis by increasing lipogenesis and by enhancing HCV virus replication[73].

HCV, IR and fibrosis: Both IR and hepatic steatosis have been closely associated with progression of hepatic fibrosis in patients with HCV infection[57]. A recent meta-analysis using 3068 patients recruited at 10 centers in 5 countries suggests that steatosis and diabetes are both independent factors of fibrogenesis in patients with genotype 1 infection[74]. Significant fibrosis has also been associated with IR independent of steatosis in CHC genotype 1 and 4 infections.

Recently, several reports have suggested that IR may contribute to the progression of fibrosis[75-77]. IR may directly stimulate the proliferation of hepatic stellate cells (HSCs) promoting collagen I synthesis[78] or IR-induced hepatic lipid accumulation and generation of ROS can activate HSCs, initiating progression of fibrosis to cirrhosis[79].

HCV, IR and HCC: Subjects with HCV and diabetes have a higher risk of developing HCC[80]. In a very large, general population-based, cohort study comprising a total of 23 820 residents in Taiwan and followed up for 14 years[81], diabetes was associated with HCC especially among individuals with HCV infection, with lower risk values among carriers of the hepatitis B virus or uninfected individuals. Recent evidence strongly suggests that steatosis and diabetes may also significantly enhance the risk of HCC[82,83].

HCV core protein was reported to induce HCC in transgenic mice, providing a direct experimental evidence for the contribution of HCV core protein in the development of HCC in human HCV infection[84]. More recent reports support the oncogenic potential of HCV and linked clinically the substitutions of amino acid 70 and/or 91 in HCV-1b core region to HCC[85,86]. This may suggest the presence of IR-dependent pathway as a mechanism of HCV-1b core region-associated hepatocarcinogenesis, and the importance of eradicating such mutant HCV in reducing the development of HCC[36].

IR is recognized as an independent risk factor for the development of HCC worldwide[87-89], and the development of diabetes-related HCC suggests that IR has direct effects on hepatocarcinogenesis, although precise mechanisms for this effect remain unclear. IR causes lipid accumulation, which results in changes in serum adipocytokine levels, including reduction of adiponectin, which has suppressive effects for hepatocarcinogenesis[90] Hepatic lipid accumulation also increases oxidative stress, which may be responsible for the development of HCC[88,89]. Hyperinsulinaemia and increased levels of insulin growth factors have been shown to promote cell proliferation[90,91], and IL-6. Another possibility is that insulin has a mitogenic effect, through activation of a mitogen-activated protein kinase pathway, suggesting that insulin may be directly linked to hepatocarcinogenesis[92]. However, the specific cytokines and mechanisms that promote neoplasia during IR have not yet been fully defined.

Insulin resistance-induced interferon resistance

IR is associated with a poor response to anti-viral treatment in patients with HCV infections, both for initial virological response[93,94] and SVR[76,95]. This negative association has been reported to occur both in patients infected with the genotype 1[76,96] and in those with genotypes 2 and 3[97].

Although the reason for such association is largely unknown, several possibilities have been suggested. In one study, obese HCV patients have approximately an 80% lower chance of achieving SVR compared with non-obese patients[98]. Obese HCV patients with steatosis are thought to have increased lipid droplets in hepatocytes, which can act as a functional barrier for the interaction between antiviral drugs and hepatocytes[8,99]. Alternatively, lipids are important for HCV replication[100],and accumulation of hepatic lipid droplets may increase HCV replication and results in poor responses to anti-viral treatment[100]. Obese people are known to have a poor lymphatic circulation[101], this could result in suboptimal

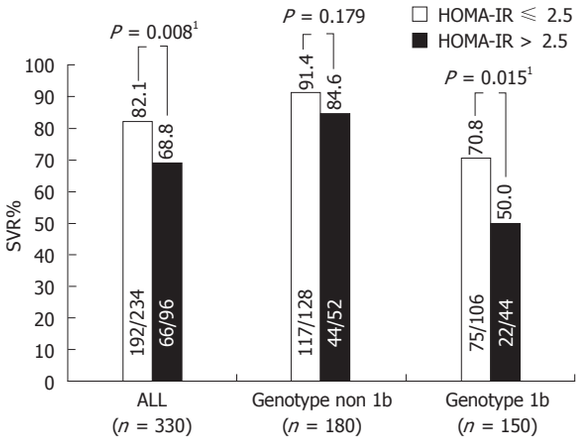

Figure 4 Insulin resistance predicts response to peginterferon-α/ribavirin combination therapy in chronic hepatitis C patients[106]. [1]Statistical significance. SVR: Sustained virological response; HOMA-IR: Homeostasis model assessment-insulin resistance.

serum levels of pegylated interferons (PEG-IFNs) and a reduced response to antivirals, as certain PEG-IFNs may be preferentially absorbed through blood capillaries or the lymphatic circulation. Obesity may also affect the antiviral response by modulating the IFN signaling pathway, as a recent study showed that obese HCV genotype 1 patients had increased mRNA expression of SOCS-3 compared with normal controls[102] (Figure 2).

However, in a recent large-scale study, IR but not steatosis or fibrosis was the most important predictor for response to PEG-IFN and ribavirin therapy[103]. Moreover, the molecular link between insulin signaling and reduced response to IFN-α has been demonstrated in several studies[104-106]. HCV core protein stimulates the SOCS-3, which is a negative regulator of IFN-α signaling. SOCS-3 upregulation inhibits expression of interferon stimulated genes as 2',5'-oligoadenylate synthetase and protein kinase receptor (PKR), through inactivation of the JAK-STAT pathway[105].

Downregulation of PPAR-γ and an upregulation of SOCS-7 were also observed upon expression of the HCV genotype 3 core protein[107], and it was suggested that the activation of SOCS family members may be a mechanism common to all major HCV genotypes[108]. However, activation of SOCS family members is not the only mechanism suggested to account for HCV-induced IR, as it has been shown that HCV core protein also suppresses insulin signaling through a proteasomal activator 28 γ-dependent pathway[109]. This is worthy of note, because this activator plays a role also in the development of steatosis and HCC[110].

Insulin resistance-associated extrahepatic manifestations

In patients with extrahepatic manifestations of HCV, fasting insulin levels and homeostasis model assessment (HOMA) for IR are significantly higher than for patients without extrahepatic manifestations[111]. Among various extrahepatic manifestations, IR is associated with oral lichen planus[112], oral squamous cell carcinoma and multiple primary cancers including gastric cancer[113]. Although reasons for this association remain unclear, a high prevalence of precancerous lesions and cancers are seen in patients with T_2 DM[114,115], suggesting that IR or hyperinsulinemia may enhance carcinogenic activities.

THERAPEUTIC IMPLICATIONS

The clinical implications of the presence of IR in patients with CHC have become evident in many studies that consistently showed that these cofactors are related to both disease progression and a poorer response to antiviral therapy.

Effect of insulin resistance on sustained virologicresponse

The negative impact of IR on response to antiviral therapy has been demonstrated in several studies[93-97]. Romero-Gómez *et al*[76], showed marked differences in the rates of SVR in HCV infected patients with and without IR, assessed by HOMA-IR. In this study, 23 of 70 (32.8%) patients with genotype 1 CHC and IR (HOMA-IR > 2) achieved a SVR *vs* 26 of 43 (60.5%) genotype 1 CHC patients without IR. These findings were independently confirmed[65], and extended to genotypes 2 and 3[103].

In a recent large-scale study in CHC patients, pretreatment HOMA-IR was associated with SVR to combination therapy with (PEG-IFN)/ribavirin, in particular among "difficult-to-treat" patients (genotype 1b and high baseline viral loads). These findings suggest that pretreatment measurement of HOMA-IR, in combination with tests of HCV genotypes and viral load, may be used as the determinants for selecting regimens in CHC patients (Figure 4)[103].

Effect of improving insulin resistance on sustained virologicresponse

Since IR is considered a factor that can be modified and improved by various interventions, it would be valuable to evaluate by prospective studies whether the improvement of IR before initiation of the combination therapy for CHC can significantly increase the SVR rate. It has been shown that weight reduction may have an impact on both liver histology and biochemistry in patients with CHC[116,117]. Moreover, a strict low calorie diet for three months, aiming to achieve a 10% reduction in body mass index before starting treatment has determined higher rates of response to Peg-IFN plus ribavirin therapy[118].

Amelioration of IR may improve the response to antiviral treatment. However, the impact of insulin-sensitizing agents, biguanides and thiazolidinediones, on SVR rates has not yet been established.

Recently, metformin, a biguanide agent that decreases the production of glucose in hepatocytes and increases the utilization of glucose within skeletal muscle, has been reported to ameliorate HCV-associated IR, and increase the SVR rate in HCV genotype 1- infected patients with normalization of HOMA-IR at week 24 of therapy[119].

Thiazolidinediones improve insulin sensitivity through

activation of the peroxisome proliferator-activated receptor-γ (PPAR-γ) in adipocytes and skeletal muscle[120]. Pioglitazone, a thiazolidinedione agent, has been found to decrease SOCS-3 expression in diabetic patients[121], and has been also reported to ameliorate IR and increase SVR rates in Egyptian patients with HCV genotype 4 infections[122]. In a recent randomized, double-blind, placebo-controlled study, adding pioglitazone 30 mg once daily simultaneously to the standard of care clearly increased the on-treatment virological response, but failed to increase the sustained virological response after the end of treatment[123]. A recent prospective, multicenter study aimed to investigate the efficacy and safety of pioglitazone, 15 mg once daily, added to the Peg-IFN-α2a, 180 μg once weekly/ribavirin and 1200 mg once daily combination therapy in chronic hepatitis C patients who were previously nonresponders to a Peg-IFN-α/ribavirin combination without the insulin sensitizer. All patients had a baseline HOMA > 2 as additional inclusion criterion and diabetic patients were however excluded. Unfortunately, none of the first five patients enrolled into the trial had a satisfactory virological response after 12 wk of retreatment, despite the fact that in at least three of them the IR score improved, and thus the study was prematurely terminated[124].

Because both metformin and thiazolidinedione agents have severe adverse effects, neither is recommended for patients with liver cirrhosis. Biguanides predispose cirrhotic patients to lactic acidosis[125], while thiazolidinediones may cause significant hepatotoxicity[126]. Therefore further validation for safety is required.

It is still unclear whether one should start the antiviral retreatment together with the insulin sensitizer or only once the HOMA-IR score has decreased to a level predicting a sufficient SVR rate[76]. Also, insulin sensitizing therapy might need to be tailored according to HCV genotype, and PPARs agonists should probably be considered only in insulin-resistant patients with HCV genotype 3a[127]. This approach, however, should also take into consideration the known effects of PPAR agonists on serum lipid profile and their potential consequences on the HCV life cycle. HCV circulates bound to lipoproteins in complexes known as lipoviroparticles[128]. As a result, HCV entry into hepatocytes appears to be mediated and facilitated, among others, by the low density lipoprotein (LDL) receptor[129]. In keeping with this, at least two recent studies have suggested that baseline LDL-associated cholesterol levels may affect response to antiviral therapy[130,131]. In fact, higher levels of cholesterol-and ApoB-rich lipoproteins could facilitate viral clearance by impeding HCV interaction with cell surface receptors. Thus, drugs like thiazolidinediones that modify the circulating lipoprotein profile may have unexpected and potentially unwanted effects on the HCV life cycle. Although highly speculative, these hypotheses deserve being appropriately evaluated in clinical trials.

Finally, dipeptidyl peptidase (DPPIV) inhibitor is a new therapeutic agent[132] that has shown its clinical efficacy in T_2DM[133]. It may be suited for ameliorating HCV-associated IR, as activation of DPPIV was considered a factor responsible for HCV-associated IR[134].

Effect of sustained virologicresponse on insulin resistance

Evidence that effective antiviral treatment will result in improved glucose homeostasis in patients with T_2DM is at best preliminary. It has been shown that IR is modified by treatment and that the incidence of T_2DM in patients achieving SVR is significantly lower than that seen in non-responders[25,26]. Kawaguchi *et al*[28], reported a significant decrease in HOMA-IR values in patients who attained a SVR, while no changes occurred in HOMA-IR non-responders and relapsers.

Effect of sustained virologicresponse on steatosis

In HCV genotype 3 infections, the severity of steatosis is directly related to the HCV RNA viral load, and steatosis often resolves with the loss of viremia after antiviral treatment[8,135,136], and reappears after the end of therapy in relapsers[7].

On the contrary, in genotype 1 infection, the severity of steatosis is independent of the HCV viral load and antiviral therapy alone does not improve steatosis in these patients[7,137]. Similar data have been obtained for genotype 4 infections, while little data are available for genotype 2[138].

Therapeutic effects of phlebotomy

In order to reduce hepatic iron deposition, both dietary iron restriction and phlebotomy are effective. It has been shown that dietary iron restriction (less than 7 mg/d) decreases serum alanine aminotransferase levels in patients with HCV infection[138], and phlebotomy reduces oxidative stress as well as IR in patients with HCV infection[47,138-140].

A number of studies have shown that phlebotomy to induce iron depletion may lead to regression of fibrosis. In the three trials in which paired liver biopsies before and after treatment with IFN or phlebotomy plus IFN were evaluated, all reported histological improvements in the phlebotomy group[141-144]. Di Bisceglie *et al*[145] compared treatment with phlebotomy alone to phlebotomy plus IFN, and found that, after 1 year, the phlebotomy-only group demonstrated mild histological improvement that did not reach statistical significance.A recent meta-analysis of six prospective randomized controlled trials found that phlebotomy also improves therapeutic response to interferon in patients with CHC[146].

Additionally, it has been reported that hepatic iron concentration is correlated with the risk of developing HCC[147]. Moreover, a long-term combination treatment with phlebotomy and dietary iron restriction has been found to reduce the risk of development of HCC in patients with HCV infection[143]. If these observations are correct, it is possible that therapeutic phlebotomy in patients with CHC may provide a benefit to patients even in the absence of an SVR to current therapy[147].

Effect of anti-diabetic agents

Anti-diabetic agents such as exogenous insulin and sulfonylurea agents, are effective for decreasing plasma glucose leading to prevention of diabetes mellitus-associated complications including cardiovascular diseases[148-150]. However, the use of exogenous insulin or sulfonylurea agents may worsen hyperinsulinemia. Recently, an association has been reported between exogenous sulphonylurea or insulin treatment and the development of HCC in patients with HCV infection[151,152]. The use of exogenous insulin has also been reported to be associated with the development of colon cancer[153], and other malignancies[154,155]. Although a causal relationship between exogenous insulin and the development of HCC remains controversial[122], the reduction of serum insulin levels is a first line therapeutic strategy for IR[156].

CONCLUSION

IR is one of the pathological features in patients with HCV infection. IR plays a crucial role in the development of various complications and events associated with HCV infection. Mounting evidence indicates that HCV-associated IR may cause hepatic steatosis, hepatic fibrosis, resistance to anti-viral treatment, hepatocarcinogenesis and proliferation of hepatocellular carcinoma; and extrahepatic manifestations.

Thus, HCV-associated IR is a therapeutic target at any stage of HCV infection. However, therapeutic guidelines for preventing the distinctive complications of HCV-associated insulin resistance have not yet been established. Insulin-sensitizing agents are reported to improve sustained virologic response rates, but further validation for safety is required. Little is known regarding the effect of anti-diabetic agents on HCV infection, and a possible association between use of exogenous insulin or a sulfonylurea agent and the development of HCC has recently been reported.

Abstract

AIM: To investigate the influence of repeated water avoidance stress (rWAS) on the visceromotor response (VMR) to colorectal distension (CRD) and the modulation of the response by a prebiotic diet in rats using a novel surgery-free method of solid-state manometry.

METHODS: Male Wistar rats fed a standard diet with or without 4% enzyme-treated rice fiber (ERF) for 5 wk were subjected to rWAS (1 h daily x 10 d) or no stress. The VMR to graded phasic CRD was assessed by intraluminal colonic pressure recording on days 0 (baseline), 1 and 10 (45 min) and 11 (24 h) after rWAS and expressed as percentage change from baseline. Cecal content of short chain fatty acids and distal colonic histology were assessed on day 11.

RESULTS: WAS on day 1 reduced the VMR to CRD at 40 and 60 mmHg similarly by 28.9% ± 6.6% in both diet groups. On day 10, rWAS-induced reduction of VMR occurred only at 40 mmHg in the standard diet group (36.2% ± 17.8%) while in the ERF group VMR was lowered at 20, 40 and 60 mmHg by 64.9% ± 20.9%, 49.3% ± 11.6% and 38.9% ± 7.3% respectively. The visceral analgesia was still observed on day 11 in ERF- but not in standard diet-fed rats. By contrast the non-stressed groups (standard or ERF diet) exhibited no changes in VMR to CRD. In standard diet-fed rats, rWAS induced mild colonic histological changes that were absent in ERF-fed rats exposed to stress compared to non-stressed rats. The reduction of cecal content of isobutyrate and total butyrate, but not butyrate alone, was correlated with lower visceral pain response. Additionally, ERF diet increased rWAS-induced defecation by 26% and 75% during the first 0-15 min and last 15-60 min, respectively, compared to standard diet, and reduced rats' body weight gain by 1.3 fold independently of their stress status.

CONCLUSION: These data provide the first evidence of psychological stress-related visceral analgesia in rats that was enhanced by chronic intake of ERF prebiotic.

Key words: Stress-related visceral analgesia; Water avoidance stress; Colorectal distension; Enzyme-treated rice fiber prebiotic; Short chain fatty acids; Defecation; Rat; Solid-state manometry

INTRODUCTION

Irritable bowel syndrome (IBS) is a common functional bowel disorder of unclear etiology, characterized by recurrent abdominal pain and altered bowel habits without structural abnormalities affecting 10%-15% of the US[1,2] and 5%-10% of the Asian adult population[3,4]. Stress is an important factor in the onset, maintenance and exacerbation of IBS symptoms[5-7]. Recently, interactions between intestinal microbiota, mucosal barrier function, and immune system have been identified to play a role in IBS pathogenesis[8,9]. An imbalance in the gastrointestinal microbial population induced by infection, dietary changes or antibiotics can produce low grade inflammation as observed in a subset of IBS patients[10]. Alterations in gut transit, which can be related to dietary factors, stress or antibiotics, may also contribute to the abnormalities observed in enteric microbiota metabolic activity including fermentation processes[11]. Prebiotics as indigestible food constituents provide specific substrates ready to be metabolized by the beneficial gut microbiota thereby stimulating their growth or activity[8,12]. Prebiotics are also a source of short chain fatty acids (SCFAs) that provide energy to the epithelium and exhibit anti-inflammatory properties[13].

Visceral hypersensitivity, a key feature of IBS[14], can be associated with a low grade colonic mucosal inflammation in a subset of patients[15]. Therefore, the concept that anti-inflammatory action of probiotics and prebiotics could be beneficial in visceral pain has emerged[16]. In fact, there are reports that *Escherichia coli Nissle 1917* inhibits the visceral hypersensitivity associated with trinitrobenzene sulphonic acid colitis[17]. Similarly, *Lactobacillus paracasei* prevents the visceral hypersensitivity associated with inflammation in mice with gut microbiota altered by antibiotics[18]. Recently, a new prebiotic, enzyme-treated rice fiber (ERF) made from rice bran containing dietary fiber and fat soluble fraction has been shown to reduce inflammation and clinical symptoms in the murine dextran sodium sulfate colitis model by modulating the colonic microbiota environment and regulating immune cell differentiation[12] and to prevent 3-d intermittent restraint stress-induced IBS-like symptoms in rats[19].

Existing evidence from several groups including ours indicates that stress induces alterations of colonic functions (increased permeability, mucus secretion, motility, myenteric nerves activation and serotonin release) and the development of visceral hypersensitivity in rats[20-22]. In particular, we previously developed a psychological stress model of intermittent water avoidance stress (WAS)[23] which upon repeated exposure (rWAS) in rats induces sustained visceral hyperalgesia when monitored by electromyography (EMG)[24,25]. In rats, rWAS also induces colonic epithelial alterations associated with cytokines increase, mast cell activation and antigen sensitization[24,26-28], which may all contribute to greater visceral sensitivity[29]. Administration of probiotics chronically throughout the 10 d of rWAS prevents the stress-related colonic epithelial alterations and antigen load in the mucosa[30]. By contrast, we have recently shown in mice that exposure to rWAS can induce stress-related visceral analgesia in response to colorectal distension (CRD) when monitored non-invasively using a novel method of solid-state manometry, which avoids prior surgery to implant recording electrodes and subsequent single housing which are required in commonly used EMG monitoring of visceral pain[31].

Therefore in the present study, we first examined whether exposure to rWAS induced visceral analgesia in rats using the non-invasive monitoring of the visceromotor response (VMR) to graded phasic CRD. Second, we tested whether the chronic feeding of 4% ERF prebiotic would affect rWAS-related alterations of visceral sensitivity and colonic motor functions and potential underlying mechanisms by monitoring histological changes in the colonic mucosa and cecal content of SCFAs.

MATERIALS AND METHODS

Animals

Male Wistar rats (Harlan Laboratories, Indianapolis, IN) were fed *ad libitum* a standard diet (composition detailed in Table 1) with or without 4% ERF (formulated in pellets for 4 wk, then in powder form) (Kirin Holdings Company, Laboratory, Japan) starting from weaning (~ 21 d old, weight ~ 50-74 g) and throughout the 48 experimental days. Rats were housed in pairs, under standard conditions of temperature and humidity, on bedding with enrichment. At the end of the experiment, animals were euthanized by an intraperitoneal overdose of anesthesia (urethane 25%) and thoracotomy. Experimental protocols were performed in accordance with animal protocol No. 12049-09 approved by the Greater Los Angeles Institutional Animal Care and Use Committee.

Preparation and chemical composition of enzyme-treated rice fiber

The ERF diet was prepared as detailed previously[12] and composed roughly of 70% dietary fiber by weight[19,32] formulated to have 4% of ERF in standard food (Table 1). In the standard diet, 4% ERF was replaced by cellulose (30 g/kg) (Table 1).

Repeated water avoidance stress

The procedure of rWAS was performed as described before[23]. Each adult Wistar rat (232-311 g) was placed on a pedestal (10 cm × 8 cm × 8 cm) affixed to the center of a Plexiglas® standard rat cage floor (45 cm length × 25 cm width × 25 cm height) for 1 h daily for 10 consecutive days between 8 and 10 am. The Plexiglas® rat cage

[1]Enzyme-treated rice fiber (protein, 14.9%; dietary fiber, 74.5%); [2]According to AIN 93G formula, protein and dietary fiber contents in two diets were adjusted to the same value using casein and cellulose, respectively. ERF: Enzyme-treated rice fiber.

was filled with room temperature water (25 ℃) up to 1 cm from the top of the pedestal. Non-stressed rats were kept in their home cage and handled daily (5 min).

Measurement of colonic motor function and visceral pain

Fecal pellet output: In rats subjected to rWAS protocol, fecal output was monitored as the total number of pellets expelled for the 1-h period of rWAS exposure on each of the 10 d with a time course response monitored every 15 min.

Assessment of visceral pain response to CRD: Visceral sensitivity to CRD was assessed using the non-invasive manometric method that we recently developed and validated for use in mice and rats[31,33]. Briefly, a PE50 catheter was taped 3.5 cm below the pressure sensor of a miniaturized pressure transducer catheter (SPR-524 Mikro-Tip catheter; Millar Instruments, Houston, TX). A custom-made balloon (2 cm wide × 5 cm long)[33,34], prepared from an infinitely compliant high-density polyethylene 16 micron gauge plastic bag (STOUT, C4348N16, Wichita, KS), was tied over the catheter at 1 cm below the pressure sensor with silk 4.0 (Henry Schein Inc., Melville, NY).

On experimental day, rats were briefly anesthetized with isoflurane (3% in O_2) and the lubricated "balloon-pressure sensor" catheter was introduced into the rectum and distal colon such that the distal end of the balloon was positioned at 1 cm from the anus and the catheter secured to the tail with tape. Each animal was placed in a Bollman cage covered with a light tissue blanket and left to rest for 30 min before the CRD procedure. Each balloon was connected to the barostat and the miniaturized pressure transducer to a preamplifier (model 600; Millar Instruments, Houston, TX). The intracolonic pressure (ICP) signal was acquired using CED Micro1401/SPIKE2 program. The CRD protocol consisted of two CRDs at 60 mmHg to unfold the balloon immediately followed by two series of graded phasic distensions to constant pressures of 10, 20, 40 and 60 mmHg. Each CRD lasted 20 s and was applied at a 4 min inter-stimulus interval (Figure 1). A similar CRD paradigm has been used previously to assess visceral pain-related responses in rats[35].

Data analysis

The phasic component of the intracolonic pressure (pICP) was extracted from the ICP signal recorded[31,33]. The VMR was defined as the increase in area under the curve (AUC) of pICP during CRD over the mean value of pre- and post-distension 20 s periods. To examine the pressure-response relationship and adjust for inter-individual variations of the signal[35], ICP amplitudes were normalized for each rat to the highest pressure (60 mmHg) in the 1st set of CRD. This value served as 100% response (control) in the baseline period of data collection before exposure to WAS (day 0) and represented the baseline VMR. The VMR to the subsequent CRDs was expressed either as % from their baseline values or mean change from the baseline response (Δ VMR in %) at different pressures of distension as validated in our previous studies[25,31,33]. In some cases, to determine correlations between visceral pain responses and inflammatory scores or cecal organic acid content, the non-normalized cumulative AUC response during the CRD procedure on day 11 (for all pressures of distensions) was used[36]. For subgrouping analysis, each rat exhibiting VMR to CRD at 60 mmHg with a value higher than that obtained at baseline (> 10%) was categorized as hyperalgesic, while each rat presenting value lower than that obtained at baseline (< 10%) was categorized as analgesic.

Experimental protocol

Rats were fed 4% ERF diet (2 groups) or standard control diet (2 groups) starting at the weaning period for 37 d until they reached the age of 6-6.5 wk (weight ~ 232-311 g) and handled every 3-4 d (petting, 5 min). All experimental protocols were performed in the morning and conducted in conscious non-fasted rats. All groups were habituated to the experimental conditions for VMR monitoring (training to Bollman cages, 90 min per day for 3 consecutive days before day 0), then tested for baseline CRD response (day 0). Thereafter rats were exposed daily to 1 h WAS for 10 consecutive days or no stress (days 1-10), while still maintained under standard or 4% ERF diet. Non-stressed animals were kept in their home cages and handled daily. Body weight was monitored in the morning, every 2-4 d for 37 d and daily during the stress period before each stress session as well as in non-stressed groups. Body weight gain was expressed as % of initial body weight. Fecal pellet output (FPO) was monitored during each rWAS session. On days 1 (acute WAS) and 10 (rWAS), 45-50 min after the end of the stress session, and on day 11, 24 h after the last rWAS session, rats were subjected to CRD protocol and VMR was monitored in all groups (Figure 1). Immediately after the last CRD, animals were euthanized and cecum and distal colon, at a level caudal to the balloon placement, were collected.

Colonic histological assessment

The distal colonic segment was rinsed with cold phosphate buffer saline, fixed in 4% paraformaldehyde and kept at 4 ℃ until processed. After fixation, paraffin-embedded specimens were sectioned at 5 μm (whole thickness) and stained with HE. Inflammatory scores were

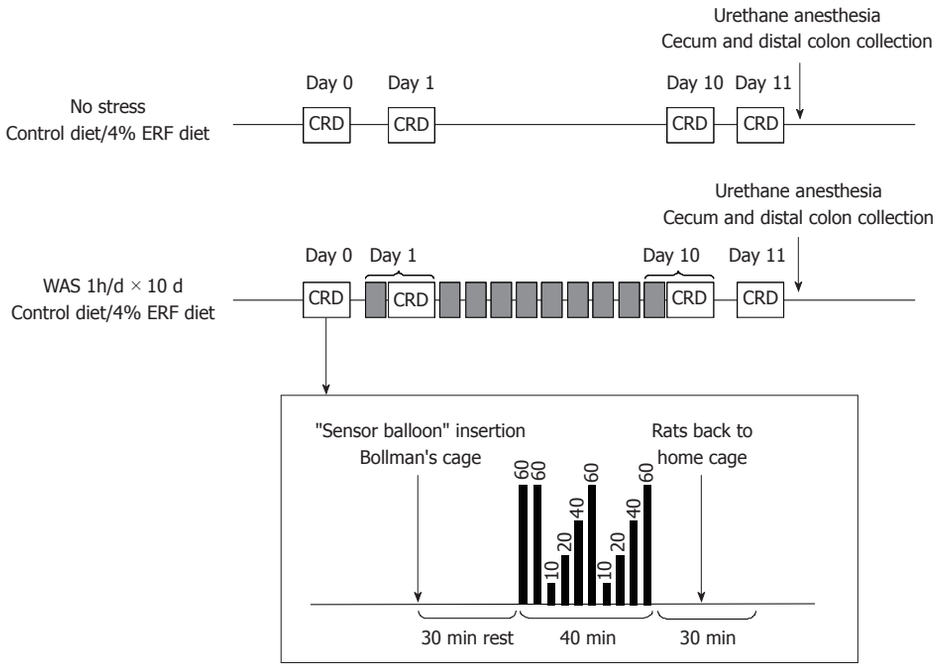

Figure 1 Treatment and colorectal distension (black column with number in mmHg) protocol for the assessment of visceral pain in Wistar rats exposed to daily intermittent water avoidance stress. Grey boxes represent the daily sessions of water avoidance stress (1 h). ERF: Enzyme-treated rice fiber; CRD: Colorectal distension.

Table 2 Baseline visceromotor response to colorectal distension at day 0

60	100 ± 0	100 ± 0	100 ± 0	100 ± 0

[1]Rats were fed standard or 4% enzyme-treated rice fiber (ERF) diet (2 groups each before to be assigned to no stress or water avoidance stress, WAS) starting at the weaning period for 37 d before performing the baseline visceromotor response (VMR) to colorectal distension (CRD); [2]Each value represents the mean ± SE of n as indicated in parenthesis; [a]$P < 0.05$ *vs* all other groups at 20 mmHg - 2-way ANOVA, Bonferroni post test.

established following a scale of 0 to 3: 0: normal, 1: mild, 2: moderate, 3: severe based on the occurrence of inflammatory cell infiltration and mucosa microscopic aspect (submucosal edema, vascular dilation, mucosal erosion, atrophy).

Cecal content of organic acids

The cecum was cut open and its content flash frozen less than 15 min post collection and kept at -80 ℃ until assayed for SCFAs levels as previously described[12]. Briefly, 0.3 g of the cecal content was weighed and 1 mL of Milli-Q water added. The mixture was incubated at 4 ℃ for 60 min. After centrifugation at 12 000 r/min at 4 ℃ for 10 min, the obtained supernatant was filtered using a 0.22 μm filter. Organic acids were separated with the Shimpack SPR-H 250 L (Shimadzu Co. Ltd., Kyoto, Japan). The mobile phase was 4 mmol/L of p-toluene sulfonic acid, and the detector was electric conductivity (Shimadzu CDD-6A, Kyoto Japan).

Statistical analysis

Each experimental group included 5-10 rats. Data were analyzed using one-way ANOVA or 2-way ANOVA followed by Bonferroni *post hoc* test or by paired or unpaired Student *t* test as specified to assess the difference between treatment groups. Contingency statistical analyses for correlation between visceral sensitivity and cecal organic acid content were performed using two-tailed Fisher's exact test. Based on the Grubb's test results, three out of the total number of 34 rats on two different days of CRD were found to be outliers and excluded from VMR data analysis. Due to technical issues (i.e., expulsion of the balloon before CRD or probe failure during CRD), 5 rats were excluded from some parts of the analysis immediately after stress (day 1: 2 rats) or 24 h later (day 11: 3 rats). A P value < 0.05 was considered significant.

RESULTS

Visceral pain

Rats were fed a standard diet or 4% ERF diet for 48 d and CRD was performed on days 37 (baseline, day 0), 38 (day 1), 47 (day 10) and 48 (day 11) with or without (no stress) 1-h daily WAS from days 38 to 47. At day 0, the VMR to baseline CRD in each of the four groups of rats was similar at all pressures of distensions, except at 20 mmHg in rats fed standard diet to be assigned to no stress which presented a lower VMR [$F(3.108)=184.7$, $P < 0.001$] compared to the groups fed ERF diet ($P < 0.05$) (Table 2).

[1]Rats were fed 4% enzyme-treated rice fiber (ERF) diet or standard control diet starting at the weaning period for 37 d, then tested for baseline visceromotor response (VMR) to colorectal distention (CRD) response (day 0) and thereafter exposed daily to 1 h water avoidance stress (WAS) for 10 consecutive d or no stress (days 1-10), while still maintained under standard or 4% ERF diet. Non-stressed animals were kept in their home cages. On days 1 (acute WAS) and 10 [repeated water avoidance stress (rWAS)], 45-50 min after the end of the stress session, and on day 11, 24 h after the last rWAS session, rats were subjected to CRD protocol and VMR was monitored in all groups; [2]Each value represents the mean ± SE of % VMR changes from baseline (day 0) in number of animal indicated by n in columns). Minus values represent analgesia. [a]$P < 0.05$, [b]$P < 0.01$ *vs* baseline; [c]$P < 0.05$ *vs* respective diet non stressed group, 2-way ANOVA, Bonferroni post hoc test.

Repeated water avoidance stress induces an immediate analgesia compared to baseline in standard diet fed rats

Non-stressed rats on standard diet exhibited no statistically significant changes in VMR compared to baseline at all pressures of CRD when tested on days 1 ($n = 7$), 10 ($n = 7$) and 11 ($n = 5$) after baseline recording [$F(3.99) = 1.248$, $P = 0.28$] (Table 3 and Figure 2). By contrast, acute WAS (day 1) decreased the VMR to CRD (analgesia) at 40 mmHg and 60 mmHg by 32.4% ± 15.2% and 30.0% ± 10.8% respectively compared to baseline ($n = 7$, $P < 0.05$, Bonferroni post hoc test) (Table 3 and Figure 2A). After 10 consecutive days of rWAS, rats tested within 45-50 min after the last session of stress exhibited a decreased VMR to CRD (analgesia) at 40 mmHg by 36.2% ± 17.8% compared to baseline ($n = 7$, $P < 0.01$) but not at 60 mmHg ($n = 7$, $P > 0.05$) (Table 3 and Figure 2B). The VMR to CRD was not significantly different from baseline values on day 11, 24 h after the last stress session ($n = 7$, $P > 0.05$) (Table 3 and Figure 2C). Two-way ANOVA showed a significant influence of rWAS treatment [$F(3.88) = 2.761$, $P = 0.0468$] and time [$F(3.88) = 77.56$, $P < 0.0001$]. However, there was no interaction between treatment and time. In rats fed standard diet, 85.7%, 66.7% and 85.7% of animals developed visceral analgesia in response to rWAS when tested at day 1, 10 or 11, respectively, while 100% exhibited visceral analgesia in rats fed ERF diet consistently over the 3 d of testing.

ERF diet potentiates the immediate and induces delayed visceral analgesia to rWAS compared to baseline in rats

In non-stressed rats fed 4% ERF diet tested on days 1 ($n = 8$), 10 ($n = 8$) and 11 ($n = 6$) after baseline recording, the VMR was not significantly different to the baseline at all pressures of CRD [$F(3.104) = 0.6390$, $P = 0.59$]; $P > 0.05$) (Table 3 and Figure 2). By contrast, one session of WAS decreased the VMR to CRD compared to baseline at 40 and 60 mmHg by 29.5% ± 12.3% and 28.7% ± 6.0% respectively ($n = 8$, $P < 0.01$ each) (Table 3 and Figure 2A). Likewise when rats were exposed daily to rWAS and tested on day 10 (Figure 2B) the VMR to CRD was decreased significantly at 20, 40 and 60 mmHg by 25% ± 7.8%, 49.3% ± 11.6% and 38.9% ± 7.3%, respectively compared to baseline ($n = 9$, $P < 0.05$, $P < 0.001$ and $P < 0.001$, respectively) and the decreased VMR was maintained on day 11 (Table 3 and Figure 2C).

ERF diet compared with control diet decreases the percentage of rats developing hyperalgesia in response to rWAS at 60 mmHg CRD over the 10 d of stress

We further performed subgrouping analysis of VMR in animals developing hyperalgesia vs analgesia compared to their basal VMR at 60 mmHg and combined this number over the 10 d of stress (three testing days) for each group. In the non-stressed rats fed either standard or ERF diet, there was no statistical difference ($P > 0.05$, Fisher's exact test) in the percentage of rats that exhibited hyperalgesia throughout the whole 10 d of stress (40%, 28.6% and 80% of rats fed the standard diet, $n = 7$/group *vs* 57%, 57% and 60% fed ERF diet, $n = 7$/group, at days 1, 10 and 11, respectively). By contrast in rWAS groups, while 14.3%, 33.3% and 14.3% fed standard diet developed hyperalgesia at day 1, 10 and 11 ($n = 6$-8/group) respectively, none did in the ERF diet fed group ($n = 8$-9/group) ($P = 0.0478$, Fisher's exact test).

Cecal organic acids analysis

Cecum content was collected on day 48 immediately after the last CRD. In non-stressed rats, 4% ERF diet significantly increased cecal butyrate content compared with standard diet (9.2 ± 0.8 mmol/L per g *vs* 6.1 ± 0.8 mmol/L per g, $P < 0.05$; Figure 3A). In rWAS exposed rats fed ERF diet, cecal butyrate content values were still maintained at similar levels (9.5 ± 1.1 mmol/L per g), however the values did not reach significance when compared with rWAS + standard diet group (7.3 ± 1.4 mmol/L per g) due to a trend to increased butyrate in the rWAS + standard diet group. No statistical differences were detected for the other cecal organic acids even though there was a tendency for isobutyrate to be lower in rats fed ERF diet and exposed or not to rWAS compared to standard diet

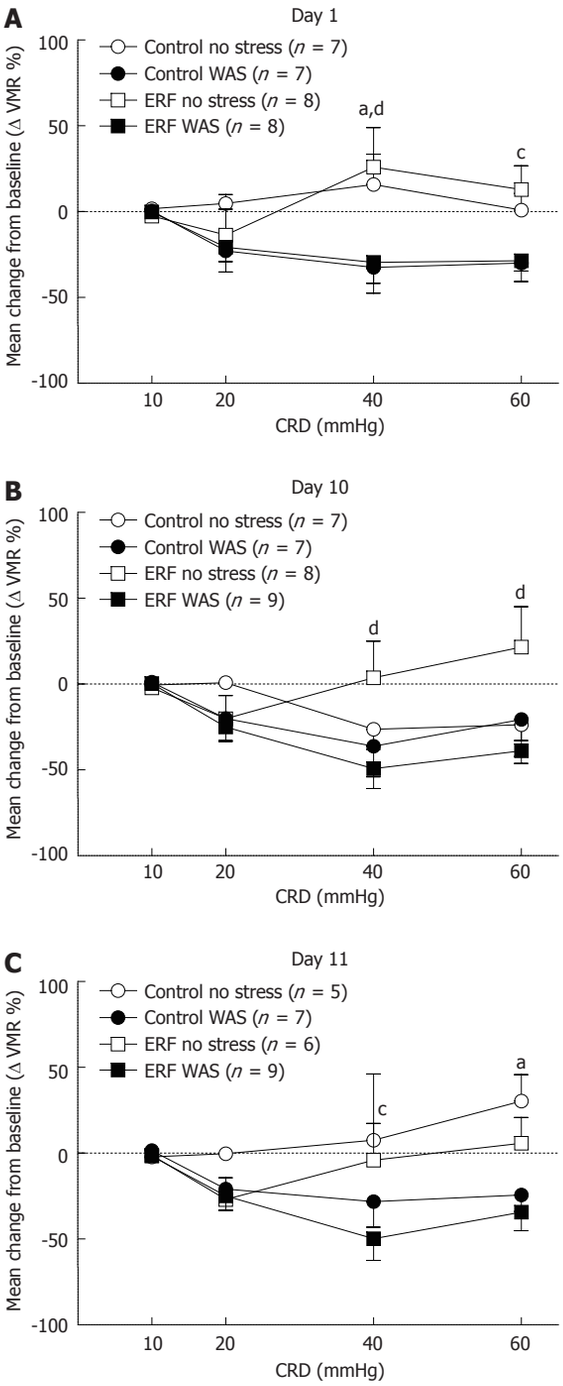

Figure 2 Influence of water avoidance stress or no stress on visceral sensitivity to colorectal distension in rats fed standard or prebiotic (4% enzyme-treated rice fiber) diet ad libitum. A: Immediate visceral motor response (VMR) at day 1; B: Immediate VMR at day 10; C: VMR 24 h at day 11. Data are expressed as mean ± SE of number of animals indicated in parenthesis for each group. [a]$P < 0.05$ standard diet no stress *vs* standard diet water avoidance stress (WAS); [c]$P < 0.05$, [d]$P < 0.01$ enzyme-treated rice fiber (ERF) no stress *vs* ERF WAS; 2-way ANOVA followed by Bonferroni post hoc test. CRD: Colorectal distention.

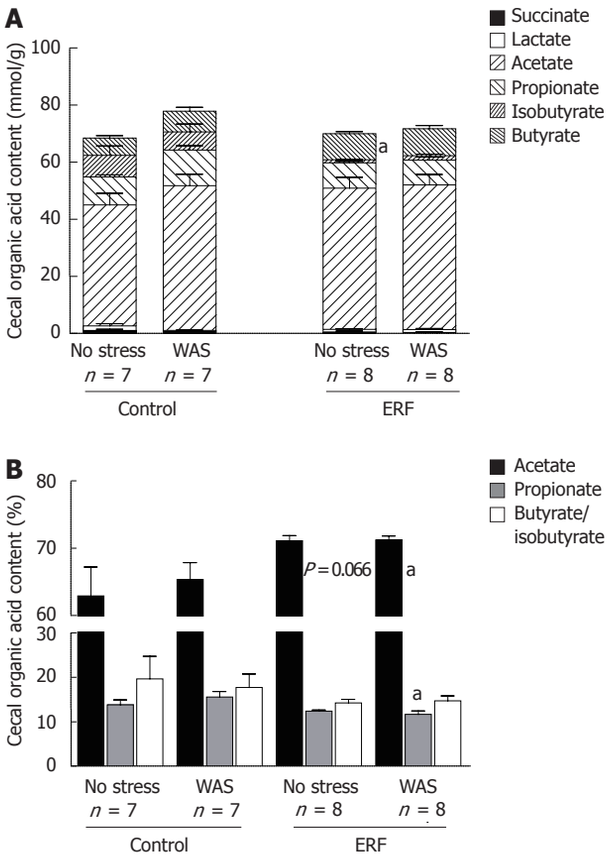

Figure 3 Cecal organic acid content in mmol/L per g (A) or % (B) in rats fed either standard or 4% enzyme-treated rice fiber prebiotic diet and exposed or not to repeated water avoidance stress in rats. Data are expressed as mean ± SE, of number of rats indicated as *n* below columns. [a]$P < 0.05$ *vs* control diet same stress status group; unpaired student *t* test. WAS: Water avoidance stress; CRD: Colorectal distention.

fed rats (1.51 ± 0.64 mmol/L per g *vs* 6.30 ± 2.79 mmol/L per g, $P = 0.10$; 1.04 ± 0.11 mmol/L per g *vs* 7.52 ± 3.37 mmol/L per g, respectively, $P = 0.06$).

The ratio of SCFAs, acetate:propionate:butyrate/isobutyrate, in the cecal content of rats fed ERF diet compared to standard diet, stressed or not, showed that ERF diet increased the percentage of acetate in stressed rats (71.2% ± 0.6% *vs* 65.4% ± 2.5%, $P < 0.05$) as well as in non-stressed rats, although not significantly (71.2% ± 0.7% *vs* 63.0% ± 4.3%, $P = 0.07$) (Figure 3B). ERF diet also decreased the percentage of propionate in stressed animals (11.7% ± 0.8% *vs* 15.6% ± 1.2%, $P < 0.05$; Figure 3B).

Interestingly, lower concentrations in cecal content of isobutyrate and total butyrate (isobutyrate + butyrate), but not butyrate alone, were correlated with lower visceral pain response (overall AUC during CRD on day 11) ($R_p = 0.41$, $P = 0.0368$ and $R_p = 0.42$, $P = 0.0335$, respectively) in stressed and non-stressed animals fed either ERF or standard diet.

Colonic histological assessment

In animals fed standard diet, rWAS evoked slight colonic inflammation with mild invasion of inflammatory cells and submucosal edema that was rarely observed in non-stressed animals. The inflammatory score was statistically different between these groups (1.3 ± 0.3 *vs* 0.3 ± 0.2 arbitrary units, $P < 0.05$, unpaired *t* test) (Figure 4A, B and E) and statistical analysis confirmed that positive inflammatory scores occurred less frequently than expected by chance in stressed animals ($P < 0.05$, two-tailed Fisher's exact test). The inflammatory score of 4% in ERF-fed

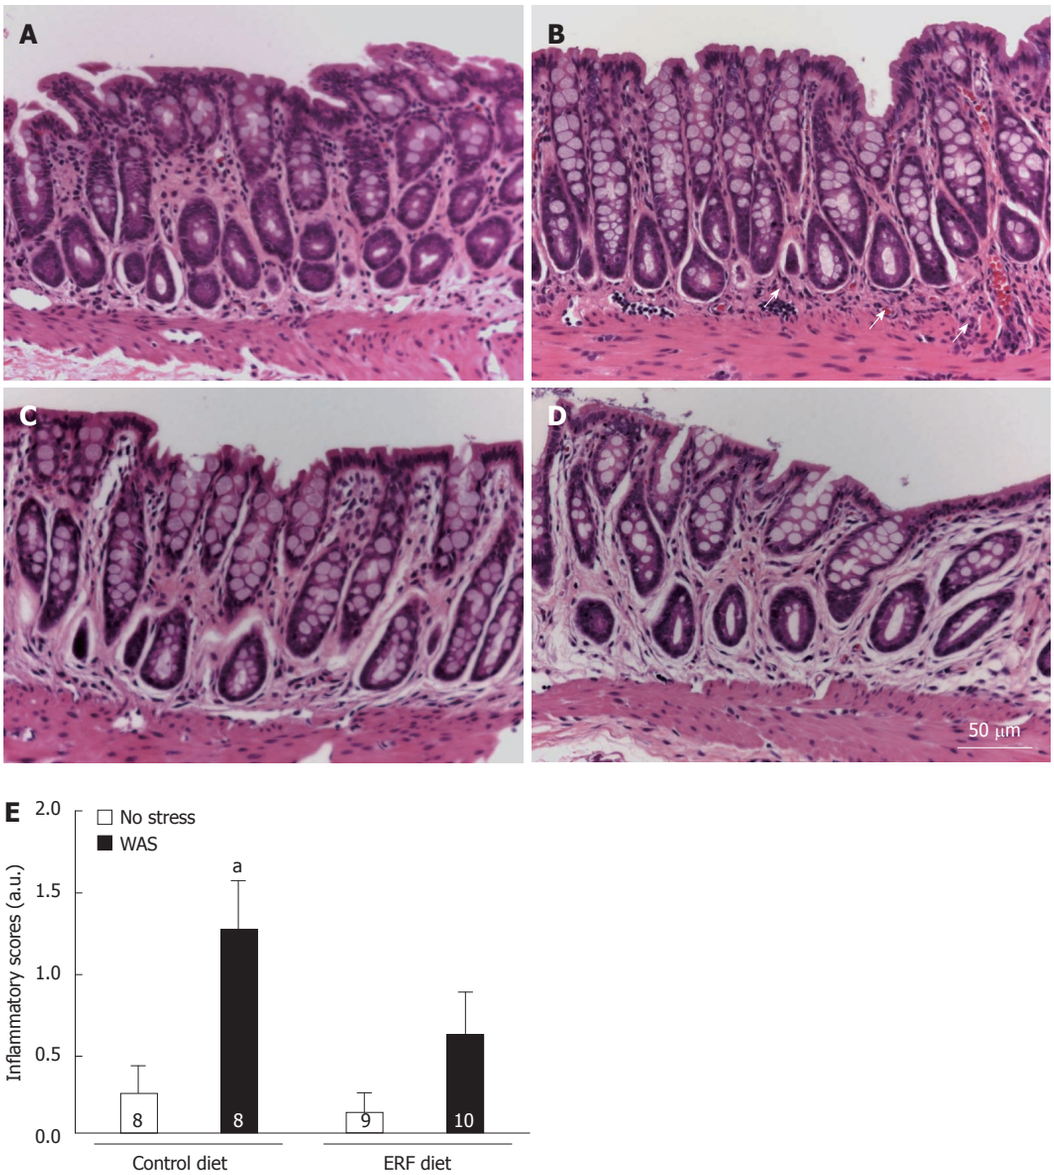

Figure 4 Inflammatory scores in distal colon of rats fed either standard or 4% enzyme-treated rice fiber diet and exposed or not (no stress) to repeated water avoidance stress. A-D: Representative histological sections of the rat distal colon stained with hematoxylin and eosin. The arrows point to an area in the lamina propria with inflammatory cell infiltration in stressed rats fed with standard diet (B) that was not observed in non-stressed rats fed with standard (A) or 4% enzyme-treated rice fiber (ERF) (C) diet and stressed rats fed with 4% ERF diet (D). E: Inflammatory scores. Data are expressed as mean ± SE, of number of rats indicated as n in each column. [a]$P < 0.05$ *vs* opposite diet same stress status group; unpaired student *t* test. WAS: Water avoidance stress; a.u.: Arbitrary unit.

animals exposed to stress was similar to that of non-stressed animals (fed ERF or standard diet, $P > 0.05$ paired and unpaired *t* test, respectively) (Figure 4C-E). Of the animals exposed to rWAS, 4 out of 10 in the ERF-fed group (40%) and 7 out of 8 in the standard diet-fed group (87.5%) exhibited positive inflammatory scores ($P = 0.07$, two-tailed Fisher's exact test).

There was no correlation between inflammatory scores and visceral pain responses ($R_p = 0.17$, $P > 0.05$).

Influence of ERF diet on rWAS-induced defecation

No diarrhea was observed in either group and all the feces expelled during the stress period were formed. Time course study showed that in the standard diet, the average defecation response to WAS took place during the first 0-15 min (1.05 ± 0.12 FPO/15 min per 100 g body weight) followed by little to no defecation during the remaining 15-60 min of exposure (0.22 ± 0.02 FPO/15 min per 100 g body weight). This response was significantly increased in ERF compared with the standard diet group (1.42 ± 0.07 and 0.31 ± 0.03 FPO/15 min per 100 g of body weight, respectively) [$F(3.320) = 85.73$, $P < 0.0001$] (Figure 5A and B). Even though for both diet groups, over the 10 d of WAS, most of the defecation occurred in the first 15 min of exposure to stress, the average defecation in both the 0-15 min and 15-60 min periods were significantly higher in the ERF diet than the standard diet group (1.42 ± 0.07 *vs* 1.05 ± 0.12 and 0.31 ± 0.03 *vs* 0.22 ± 0.02 FPO/15 min per 100 g body weight, respectively; $P < 0.05$; Figure 5A and B).

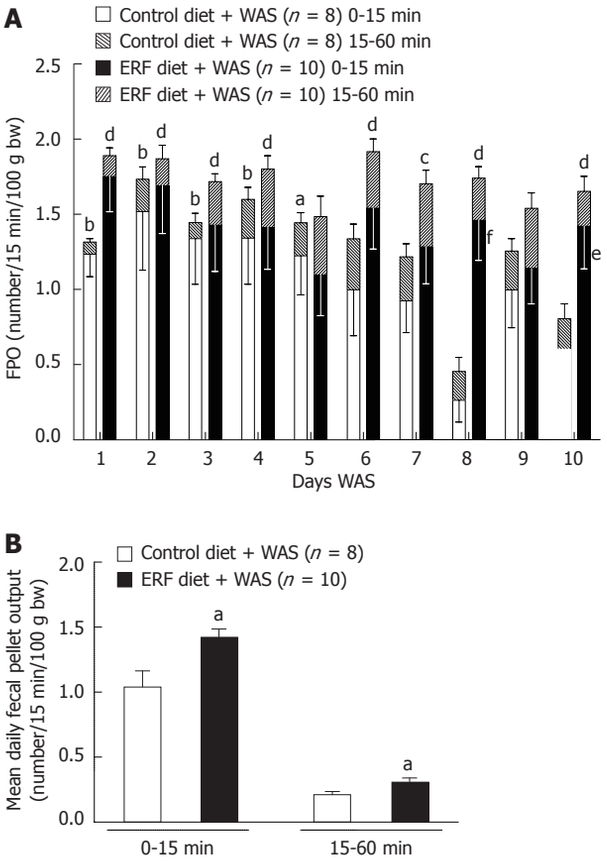

Figure 5 Defecation induced by repeated water avoidance stress in rats fed either standard or 4% enzyme-treated rice fiber prebiotic diet. A: Time-course of hourly defecation expressed as number/15 min per 100 g of body weight for 0-15 min and 15-60 min time periods over the 10 d of 1-h water avoidance stress (WAS). [a]*P* < 0.05, [b]*P* < 0.01 *vs* standard diet interval 0-15 min; [c]*P* < 0.05, [d]*P* < 0.01 *vs* enzyme-treated rice fiber (ERF) diet interval 0-15 min; [e]*P* < 0.05, [f]*P* < 0.01 *vs* standard diet interval 0-15 min; 2-way ANOVA followed by Bonferroni post hoc test; B: Mean daily defecation expressed as number/15 min/100 g of body weight for 0-15 min and 15-60 min intervals. [a]*P* < 0.05 *vs* control diet same time interval; unpaired student *t* test. Data are expressed as mean ± SE, *n* as indicated in parenthesis for each group. FPO: Fecal pellet output.

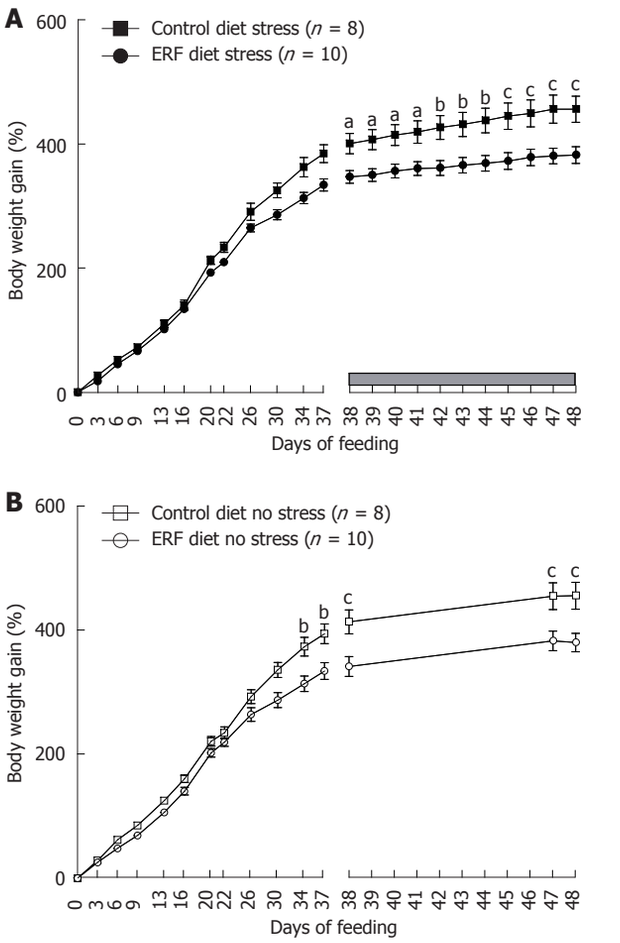

Figure 6 Body weight gain in rats fed either standard or 4% enzyme-treated rice fiber prebiotic diet: influence of repeated water avoidance stress. Rat body weight gain from weaning age (day 21) and during 37 d followed by 10 d of water avoidance stress (WAS) (A) or not (B). Data are expressed as mean ± SE, *n* as indicated in parenthesis for each group. [a]*P* < 0.05, [b]*P* < 0.01, [c]*P* < 0.001 *vs* enzyme-treated rice fiber (ERF) diet group; 2-way ANOVA followed by Bonferroni post hoc test.

ERF diet slows rat body weight gain independently of stress status

The body weights of rats at postnatal day 21 were similar in the four assigned groups before the start of treatments: standard diet + rWAS: 53.4 ± 2.4 g, standard diet + no stress: 58.0 ± 1.2 g, ERF diet + rWAS: 58.2 ± 1.2 g and ERF diet + no stress: 58.3 ± 1.1 g [$F(3.30) = 2.223$, $P = 0.10$]. During the whole experimental period (day 0-48), body weight gain expressed in % from initial body weight showed a significant interaction between diet and time in rats assigned to rWAS [$F(22.368) = 2.455$, $P = 0.0003$] (Figure 6A) or not [$F(14.210) = 2.808$, $P = 0.0007$] (Figure 6B). The percentage of body weight gain started to be significantly higher in standard diet *vs* 4% ERF diet group assigned to rWAS on day 38 (400.9% ± 16.5% *vs* 347.3% ± 10.2%, respectively, $P < 0.05$) or no stress on day 34 (373.3% ± 15.1% *vs* 313.7% ± 12.5%, respectively, $P < 0.01$). Animals on standard diet still maintained a 1.3-fold higher body weight gain than rats on ERF diet over the 10 d of rWAS or no stress (Figure 6A and B). No significant differences were detected in body weight gain between stressed and non-stressed rats in either standard [$F(14.210) = 0.1426$, $P = 0.99$] or ERF [$F(14.240) = 0.1252$, $P = 1.00$] diet groups.

DISCUSSION

In the present study, we demonstrated that exposure to a psychological stressor in the form of WAS 1 h per day once or repeated for 10 d in rats induced stress-related visceral analgesia in as much as 87.3% of the animals tested using a novel non-invasive solid-state manometric method. Additionally, we showed that chronic feeding with a prebiotic diet containing 4% ERF hemi-cellulose-rich dietary fibers, enhanced the expression of stress-induced visceral analgesia at all periods of testing, reduced by 2.2-fold the number of animals displaying stress-induced colonic microscopic alterations, decreased by 76% the isobutyrate cecal content, and slowed rats body weight gain independently of stress exposure and facilitated colonic fecal expulsion.

Over the years, a number of acute and chronic stress paradigms have been developed to mimic the alterations of visceral sensitivity seen in IBS patients[37,38]. Acute exposure to WAS is a well-characterized psychological stressor that induces the transcription of *corticotropin-releasing factor* (*CRF*) gene in the paraventricular nucleus of the hypothalamus[23,39] and consequently activates the pituitary-adrenal axis along with inducing a brain CRF receptor subtype 1-mediated stimulation of colonic motor function assessed at the end of the first hour of WAS[23,40]. In animals surgically equipped for EMG monitoring of the VMR to CRD as classically performed[24,35,41], this combined stress paradigm (surgery, post-surgical housing and rWAS 1 h daily for 10 d) induces visceral hypersensitivity in 82%-86% of the animals starting 24 h after the first exposure[41] which is maintained up to 40 d after the last stress session[24,25,42]. In the present experiment however, using a novel non-invasive solid-state manometric method of visceral sensitivity monitoring to CRD that bypassed the surgery and subsequent single housing[31,33], the majority of rats (66.7% to 85.7%) fed a normal diet exposed to rWAS exhibited a consistent visceral analgesic response. This was observed when CRD was performed within 45-50 min after either one or 10 sessions of WAS. Likewise, we recently demonstrated that rWAS for 10 d resulted in the development of visceral analgesia in up to 72.2% of mice tested non-invasively for the VMR to CRD[31]. Taken together these data provide evidence of visceral stress-induced analgesia in rodents as previously established in the somatic pain field[43].

Moreover, previous and present findings point to the possibility that underlying mechanisms of visceral hypersensitivity may involve both disturbances in descending inhibitory pathways along with sensitization of pain pathways in response to stress as demonstrated in somatic pain studies[44]. Indeed, we recently delineated that 69.2% of single housed mice equipped with EMG electrode to record VMR to CRD developed visceral hypersensitivity in response to a similar regimen of rWAS exposure when monitored 24 h after the last stress session[31]. Therefore VMR alterations reflects not only the effect of the stressor *per se* but also the basal state of the animal and conditions associated with visceral pain monitoring, namely the chronic implantation of abdominal wall electrodes, post surgery medications including antibiotics and single housing thereafter[31]. Other studies showed that skin incision correlates with the development of long-lasting visceral hyperalgesia in rats[45], and that stress becomes proalgesic in rats previously exposed to surgery[46]. To date, there is only one report using another minimally-invasive method, the abdominal withdrawal reflex (AWR), which suggests that rWAS in male Wistar rats decreases their threshold to visceral pain[47]. However, AWR monitoring requires observation of abdominal wall musculature contractions and this semi-quantitative score is subjective. Using this non-invasive ICP monitoring, we have previously demonstrated a hyperalgesic response in Wistar rats following a peripheral injection of the selective CRF_1 receptor agonist, cortagine, known to act directly on CRF_1 receptor subtype expressed in the colon[33], further indicating that the analgesia observed in response to an acute psychological stress in the present study is likely to recruit stress-related brain inhibitory mechanisms. Taken together the previous and present data indicate that this new method of VMR monitoring is valuable to unravel both analgesia and hyperalgesia without confounding factors in rats. In the field of somatic pain, the underlying mechanisms of stress-induced analgesia can be mediated by opioid or non-opioid dependent inhibitory systems[43]. Our preliminary results suggest that WAS-induced visceral analgesia in male rats is naloxone-independent[48]. Further studies are warranted to delineate the underlying components of the visceral analgesic response to rWAS in particular, the role of endocannabinoid tone recently reported to be increased by this stressor[42].

Interestingly, chronic feeding of rats with 4% ERF prebiotic diet potentiated the acute or repeated WAS-induced visceral analgesia. This was shown by the prolongation of the analgesic response to 24 h after the last rWAS session and expansion to all CRD pressure levels (20, 40 and 60 mmHg) compared to normal diet in which the visceral analgesia was mainly observed at 40 mmHg within the 45 min post WAS exposure. Additionally, ERF completely prevented the development of hyperalgesia seen in 14.3%-33% of rats fed a standard diet and undergoing CRD at 60 mmHg after WAS on day 1 or rWAS on day 10. These observations support the analgesic potential of ERF prebiotic diet on visceral sensitivity. In a previous report, 4% ERF diet reduced restraint stress-induced visceral hypersensitivity as monitored with AWR[19]. Collectively, these findings indicate that ERF prebiotic diet may be beneficial to strengthen the stress-related visceral analgesia as well as to curtail the development of visceral hypersensitivity.

Prebiotics as dietary carbohydrates are a source of carbon and energy for colonic bacteria which ferment SCFAs primarily to acetate, propionate and butyrate[13,49]. Based on the local site of action of prebiotics, we investigated the potential peripheral colonic mechanisms through which ERF diet enhances the stress-related analgesic response by first assessing changes in organic acid cecal content. The molar ratio among the three major SCFAs (constituting roughly 90% of the SCFAs in the lumen) was ~ 64:15:19 for acetate:propionate:butyrate/isobutyrate in the animals fed standard diet (stressed or non-stressed), which is close to the average ratio of ~ 60:20:20 described in mammals[49] while that of rats fed ERF diet was ~ 71:12:15. The change in butyrate/isobutyrate molar ratio observed in ERF fed rats was linked to an increase in butyrate consistent with our previous study[19] and a concomitant reduction in isobutyrate. Isobutyrate is derived from valine microbial degradation obtained by proteolysis of endogenous and dietary proteins and not from carbohydrates as are propionate and acetate[50]. As both standard and ERF diets contain identical levels of protein (Table 1), differences in diet protein content are unlikely to account for the reduction observed. Despite the observed increase in butyrate in ERF-fed animals, we

found no correlation between the visceral pain response and butyrate cecal concentration which does not support an underlying role in ERF modulatory effect on visceral sensitivity. In addition, while butyrate enemas have been shown to dose-dependently decrease visceral sensitivity in healthy volunteers[51], other reports indicate that they promotes visceral hypersensitivity in rats[52,53] and clinical studies showed that colonic butyrate levels are increased in IBS patients[54]. Interestingly however, we found a positive correlation between isobutyrate and total butyrate (isobutyrate + butyrate) cecal concentrations and visceral pain responses. Reduction in isobutyrate cecal levels associated with a concomitant increase in acetate and decrease in propionate as observed in ERF-fed rats, may have contributed to lowering the pH in the colon of those animals possibly participating to the modulation of the colonic microflora[55,56] and the reduction in visceral pain observed. Indeed, prebiotics alter the composition and balance of microflora, both in the colonic lumen and at the mucosal surface, in which beneficial bacteria such as *Bifidobacteria* and *Lactobacilli* become of greater prominence[57]. Of interest, probiotics (mainly *Lactobacilli*) have been found to exert antinociceptive effects on stress-induced visceral hypersensitivity in rodents, particularly by increasing the expression of μ-opioid and cannabinoid receptors in intestinal epithelial cells[18, 58-60].

Another possible mechanism through which ERF diet may have enhanced visceral analgesia is by preventing rWAS-induced subtle immune and structural histological changes in colonic mucosa as demonstrated by the reduction in the percentage of rats exhibiting histological alterations. Recently, in a murine colitis model, 4% ERF diet has been shown to reduce inflammation by modulating colonic environment and regulating immune cell differentiation[12]. There is also evidence that rWAS in naïve animals increases colonic permeability[27,28,30], which combined with a longer small intestinal transit time may enhance bacterial translocation[61,62], a phenomenon involved in the development of visceral hypersensitivity in rats[29]. Prebiotics and probiotics have a beneficial influence on gastrointestinal motility arising from a combination of increased bacterial mass, increased stool water as well as increased colonic tone, all resulting in accelerated transit[8,63]. Likewise in the present study the well established defecation response to rWAS[23,48] seen in the standard diet group was increased in ERF fed rats either when expressed by rat or per 100 g body weight. WAS is a mild stressor that does not induce diarrhea, the maintenance of a higher defecation in rats fed 4% ERF diet may be beneficial by facilitating fecal evacuation.

Lastly, independently of its effects on visceral sensitivity, colonic epithelial, immune and motor functions, 4% ERF diet compared to standard diet reduced the body weight gain in rats. Numerous reports have described the effect of prebiotics on the food intake regulation, fat mass and weight gain in experimental studies[64]. Although we did not precisely evaluate food intake in our experiment, these data are consistent with our observation. rWAS however, did not alter rats weight gain in the different groups, confirming previous reports[24].

In conclusion, the present findings demonstrate that under conditions of non-invasive solid-state manometry method to monitor visceral pain, a repeated mild psychological homotypic stressor such as WAS induces stress-related visceral analgesia in rats which so far has been mainly established in the somatic pain field. In addition, our data support an enhancing effect of the prebiotic ERF diet on stress-related visceral analgesia together with increased evacuation of colonic content and reduction in body weight gain. When evaluated in the context of research supporting the use of pre- or probiotics as treatment option for IBS[65], these preclinical findings point toward ERF ability to enhance the analgesic response which may be beneficial in IBS patients in whom altered descending inhibitory pathways have been described[66,67].

COMMENTS

Background

Alterations in intestinal microbiota, mucosal barrier function, and immune system have been implicated to contribute to irritable bowel syndrome (IBS) pathogenesis. Visceral hypersensitivity, a key feature of IBS, can be associated with a low grade colonic mucosal inflammation in a subset of patients. Recently, a new prebiotic, enzyme-treated rice fiber (ERF), has been shown to reduce inflammation and major symptoms in the murine dextran sodium sulfate colitis model by modulating the colonic microbiota environment and regulating immune cell differentiation. This study aimed to evaluate in rats the effects of chronic prebiotic diet on stress-related alterations of visceral sensitivity and colonic motor functions when monitored non-invasively, using repeated intermittent exposure to a psychological stressor in the form of water avoidance stress (WAS).

Research frontiers

It has been recently suggested that the basal state of the animals largely influences the visceral pain responses to a psychological stressor. Indeed, in mice the impact of repeated intermittent exposure to WAS on the visceral pain responses to colorectal distension varies in function of the basal state of the animal. WAS was reported to induce analgesic response when mice were tested using the novel non-invasive method of solid-state manometry which avoids prior surgery to implant recording electrodes and subsequent single housing. By contrast, mice tested with the traditional method of electromyography with the electrode surgically implanted on the abdominal muscles and post-surgical single housing, developed visceral hyperalgesia following exposure to the same repeated WAS.

Innovations and breakthroughs

The results of the present study demonstrate that under conditions of a non-invasive manometry method to monitor visceral pain, a repeated mild psychological homotypic stressor such as WAS induces stress-related visceral analgesia in rats as well, expanding our previous reports in mice. This opens a new field of investigation on stress-related visceral analgesia in rodents which so far has been little explored compared with the somatic pain field. In addition, the data support an enhancing effect of the prebiotic ERF diet on WAS-related visceral analgesia together with increased evacuation of colonic content and reduction in body weight gain.

Applications

In the context of a critical relationship between the composition and stability of the microbiota and gastrointestinal sensory-motor function as well as neuroimmune interactions within the brain-gut axis, these preclinical findings point toward ERF ability to enhance the analgesic response. In the view of growing reports suggesting that IBS patients present altered descending pain inhibitory pathways, the use of ERF as a prebiotic to enhance visceral analgesia is clinically relevant and could be therapeutically beneficial.

Terminology

Non-invasive method of monitoring visceromotor response (VMR) to colorectal distension (CRD) is a novel surgery-free method of solid-state manometry assessing changes in intraluminal colonic pressure (ICP) induced by abdominal muscles contractions in response to discomfort/painful colorectal distensions.

Enzyme-treated rice fiber is a new prebiotic made from rice bran containing dietary fiber and fat soluble fraction.

Peer review

It is a very well designed investigation, the topic is very interesting for the readers, the article is very well written, the results are applicable, the conclusions are valuable.

Abstract

AIM: To clarify the relationship between age, menopause, and nonalcoholic fatty liver disease (NAFLD) in women.

METHODS: We conducted a follow-up study on nonalcoholic fatty liver disease by using abdominal ultrasonography, and investigated the relationship of age and menopause with the development of NAFLD in women. We followed 1829 women and 2572 men (response rate, 86%) selected in 2001 to represent the non-institutionalized adult population of Gifu, Japan. Data collected included self-reported medical history, lifestyle factors, and menopausal status. The postmenopausal state was defined as beginning 1 year after the cessation of menses. We diagnosed NAFLD with the aid of abdominal ultrasonography by using diagnostic criteria described previously.

RESULTS: The prevalence of NAFLD in women increases with age, but does not alter with age in men. Furthermore, the prevalence of NAFLD in premenopausal women (6%) was lower than that in men (24%) and in postmenopausal women (15%). The associations of the postmenopausal state and hormone replacement therapy with NAFLD were statistically significant in a univariate logistic regression model. At the follow-up examination, 67 women (5%) were newly diagnosed with NAFLD. The incidence of NAFLD was 3.5% (28/802) in premenopausal women, 7.5% (4/53) in menopausal women, 6.1% (24/392) in postmenopausal women, and 5.3% (11/206) in women receiving hormone replacement therapy. The weight gain in premenopausal women was equal to that in postmenopausal women. Metabolic syndrome and weight gain were independent risk factors for NAFLD in pre- and postmenopausal women, but age was an independent risk factor in premenopausal women only.

CONCLUSION: Aging is a risk factor for NAFLD in premenopausal women, independent of weight gain or influence of metabolic syndrome.

Key words: Nonalcoholic fatty liver disease; Cardiovascular disease; Risk factor; Steatohepatitis; Postmenopausal women

INTRODUCTION

Nonalcoholic fatty liver disease (NAFLD) is a common clinical condition with histological features that resemble those of alcohol-induced liver injury, but NAFLD occurs in patients who do not consume alcohol[1,2]. NAFLD encompasses a spectrum of conditions ranging from simple steatosis to steatohepatitis (NASH), advanced fibrosis and cirrhosis[1]. It is emerging as the most common chronic liver disease in Western countries and in other parts of the world[3]. The estimated prevalence of NAFLD in the general population in western countries is 20%-40%[3,4]. Frequent association with disturbances of glucose and lipid metabolism often renders NAFLD a "satellite" element of metabolic syndrome[5,6]. Metabolic syndrome is a cluster of metabolic and hemodynamic abnormalities linked with insulin resistance[7]. Metabolic syndrome is a strong predictor of NAFLD, particularly among people of Japanese descent[8]. Epidemiological studies have shown that metabolic syndrome is not rare and that it is a risk factor for cardiovascular disease (CVD) and stroke[9-11]. Previously, we reported that NAFLD was a predictor of CVD among apparently healthy Japanese men and women[12]. The association between NAFLD and future CVD events was independent of conventional cardiovascular risk factors, because vulnerable plaques tend to develop in patients with NAFLD[13].

Sex and age are conventional cardiovascular risk factors. The prevalence of NAFLD is higher in men than in women, particularly in Asians[14]; however, age is a risk factor for NAFLD in women, but not in men[8]. In this study, we performed a subanalysis within the patient group described in a previous report[8] and investigated the relationship of age and menopause with the development of NAFLD in women.

MATERIALS AND METHODS

Data sources

We accessed a database from a previously reported study[8] to evaluate the possibility that aging and menopause in women could be risk factors for NAFLD. We conducted a follow-up study on nonalcoholic fatty liver disease by using abdominal ultrasonography. All participants who were examined in health checkup programs between January and December 2001 were invited to enroll in the study and 1829 women and 2572 men that satisfied the inclusion criteria in 2001 were selected to represent the non-institutionalized adult population of Gifu, Japan. By the end of June 2003, 3876 of the 4401 participants (2271 men and 1605 women) had completed the second examination (response rate, 86%). The interval between the baseline and follow-up examinations was 414 d (SD = 128). Among the 1605 women, 1603 were available for longitudinal examinations.

We collected data from self-reported medical histories, assessments of lifestyle factors [e.g., age, sex, height, weight, smoking habits, alcohol consumption, menopause status, active or previous hormone replacement therapy (HRT)], and the results of health checkup programs (e.g., urinalysis, blood cell counts, blood chemistry, electrocardiography, chest radiography, barium examination of the upper gastrointestinal tract, and abdominal ultrasonography). The postmenopausal state was defined as beginning 1 year after the cessation of menses. Reports of smoking status included active and past smoking. Habits regarding alcohol consumption were evaluated by asking the participants about the amount and type of alcoholic beverages consumed per week and then estimating the mean ethanol intake per day. We defined an alcohol consumer as someone with a mean ethanol intake of more than 20 g/d. A light drinker was defined as someone with a mean ethanol intake of 0-20 g/d. On the questionnaire, participants reported the type, duration, and frequency of their participation in sports or recreational activities[15]. When participants performed any kind of sport regularly at least once a week, we categorized them as regular exercisers[16].

The ATP Ⅲ proposed the following 5 abnormalities to define metabolic syndrome: (1) abdominal obesity, abdominal circumference ≥ 102 cm for men and ≥ 88 cm for women; (2) elevated serum triglyceride level, ≥ 1.70 mmol/L (≥ 150 mg/dL); (3) decreased HDL cholesterol level, ≥ 1.04 mmol/L (≥ 40 mg/dL) for men and ≥ 1.30 mmol/L (≥ 50 mg/dL) for women; (4) elevated systolic and diastolic blood pressure, ≥ 130/85 mmHg; and (5) elevated fasting glucose level ≥ 6.11 mmol/L (≥ 110 mg/dL)[7]. Because waist measurements were not available for the entire study sample, we substituted a BMI of ≥ 25 kg/m^2 for all participants as an index of obesity. A BMI of ≥ 25 kg/m^2 has been proposed as a cutoff for the diagnosis of obesity in Asian people[17]. Individuals with ≥ 3 of the 5 abnormalities were considered to have metabolic syndrome.

We diagnosed NAFLD with the aid of abdominal ultrasonography by using diagnostic criteria described previously[18].

Statistical analysis

The SPSS statistical package, version 11.0.1 J (SPSS, Inc., Chicago, IL) was used for all statistical analyses, and a P value less than 0.05 was considered statistically significant. Because the incidence rate of NAFLD was unknown, a formal sample size estimate was not made a priori. Cases with and without follow-up visits were compared to determine the appropriateness of an analysis exclusively based on participants with complete data. Two groups of participants were compared using the unpaired t-test and the χ^2 test. Logistic regression was used to analyze associations between the development of NAFLD and metabolic syndrome, age, and weight gain. Adjusted odds ratios and 95% CIs were calculated. Data were expressed as means and SDs for continuous variables.

This table summarizes the baseline data of 1829 women and 2572 men. w/o: Without; NAFLD: Nonalcoholic fatty liver disease; HDL: High-density lipoprotein; LDL: Low-density lipoprotein; AST: Aspartate aminotransferase; ALT: Alanine aminotransferase; γGTP: γ-glutamyl transferase. Continuous variables were compared using the unpaired *t* test, and groups were compared with the χ^2 test.

RESULTS

Baseline characteristics of the study participants

We calculated the age-specific prevalence of NAFLD among 1829 women and 2572 men (Figure 1). The prevalence of NAFLD in women increased with age, but no significant trend for age was identified in men.

We grouped women according to whether they had NAFLD at baseline, and investigated differences in age, weight, components of metabolic syndrome, serum enzymes, menopausal state, alcohol consumption, and smoking history (Table 1). More subjects with NAFLD were postmenopausal, received HRT, and met more criteria of metabolic syndrome than those without NAFLD (Table 1). The prevalence of NAFLD in premenopausal women (6%) was lower than that in men (24%), postmenopausal women (15%), and women receiving HRT (14.0 %, 36/221). In the cross-sectional study, we applied a logistic model to investigate the association of the menopausal state or HRT with NAFLD (Table 2). Univariate analysis showed that the odds ratios of the postmenopausal state and HRT were 2.73 (1.92-3.87), and 2.57 (1.66-3.97), respectively. However, they were not statistically significant after adjusting for age and metabolic syndrome.

Next, we excluded 257 subjects with a history of hysterectomy or HRT. We separated the subjects into pre- or postmenopausal groups and investigated the difference in age, components of metabolic syndrome, alcohol consumption, and smoking history (Table 3). An association of age with NAFLD was identified in premenopausal women, but not in postmenopausal women. On the other hand, an association of the components of metabolic syndrome with NAFLD was identified in both groups.

Development of nonalcoholic fatty liver disease

Of the 1603 women who completed follow up, 1453 women did not have NAFLD at baseline. Of the 1453 women who were disease-free at the baseline examina-

Postmenopausal state	1.8 (1.03-3.15)	0.039	0.72 (0.31-1.66)	0.44
Active hormone replacement therapy	1.56 (0.76-3.19)	0.22	1.32 (0.6-2.88)	0.49
Presence of metabolic syndrome at baseline	9.89 (4.67-20.94)	< 0.001	11.7 (5.02-27.25)	< 0.001
Weight gain	1.50 (1.30-1.74)	< 0.001	1.63 (1.39-1.9)	< 0.001

We calculated the odds ratio of each factor for nonalcoholic fatty liver disease in a univariate logistic regression model. The columns to the left indicate unadjusted odds ratio [95% confidence interval (CI)]. We selected all parameters as cofactors in a multivariate logistic regression model. The columns to the right indicate adjusted odds ratio (95% CI).

tion and who had the follow-up examination, 67 women (5%) received new diagnoses of NAFLD at follow-up examination. Subjects with NAFLD were older, showed more weight gain, and met more criteria for metabolic syndrome than those without NAFLD, but the 2 groups showed no differences in menopausal state, HRT, alcohol consumption, and smoking history.

Among the 1453 disease-free women at baseline, there were 855 premenopausal women and 392 postmenopausal women. Of the 855 premenopausal women, 53 women were menopausal. During the study period, 206 women received HRT. The incidence of NAFLD was 3.5% (28/802) in premenopausal women, 7.5% (4/53) in menopausal women, 6.1% (24/392) in postmenopausal women, and 5.3% (11/206) in women receiving HRT.

We applied a logistic regression model to determine the risk factors for the development of NAFLD (Table 4). Univariate analysis indicated that the postmenopausal state was a risk factor for NAFLD [odds ratio 1.8 (1.03-3.15), $P = 0.039$], but it was not statistically significant after adjusting for age, metabolic syndrome, and weight gain. The cross-sectional study at baseline revealed that the prevalence of NAFLD was higher in women receiving HRT than in those in the premenopausal state, but the logistic model did not indicate that HRT was a risk factor for the development of NAFLD.

Table 6 Adjusted associations between nonalcoholic fatty liver disease and age in 855 premenopausal women and 392 postmenopausal women

	Premenopausal subjects (n = 855)		Postmenopausal subjects (n = 392)	
	Adjusted odds ratio (95% CI)	*P* Value	Adjusted odds ratio (95% CI)	*P* Value
Age	1.12 (1.05–1.2)	0.001	1 (0.93–1.07)	0.91
Presence of metabolic syndrome at baseline	43.06 (12.66–146.51)	< 0.001	4.87 (1.29–18.34)	0.019
Weight gain	1.76 (1.4–2.21)	< 0.001	1.67 (1.27–2.21)	< 0.001

We applied a multivariate logistic regression model to calculate the odds ratio for age for development of nonalcoholic fatty liver disease after adjusting for weight gain and metabolic syndrome. After completing follow-up examinations, 1247 women who received no hormone replacement therapy were divided into pre- or postmenopausal groups. CI: Confidence interval.

Next, we excluded 206 women with HRT at the baseline and/or follow up. We separated the subjects into pre- or postmenopausal groups and compared parameters in subjects with NAFLD to those without (Table 5). Weight gain was equal in pre- and postmenopausal women. There was an association of the number of women who met ⩾ 3 criteria of metabolic syndrome and weight gain with the development of NAFLD in pre- and postmenopausal women, but an association of age with development of NAFLD was identified in premenopausal subjects only.

Finally, we applied a multivariate logistic model to investigate the risk of NAFLD after separating women into pre- or postmenopausal groups (Table 6). Metabolic syndrome and weight gain were dependent risk factors for NAFLD in pre- and postmenopausal women, but age was a risk factor only in premenopausal women.

DISCUSSION

Both NAFLD and NASH are reported to be more prevalent in men than in women[19,20]. Our study indicates that the prevalence of NAFLD in women increases with age, but does not alter with age in men. Furthermore, the prevalence of NAFLD in premenopausal women (6%) was lower than that in men (24%) and in postmenopausal women (15%). A univariate logistic regression model indicated that when no adjustments were made for age or metabolic syndrome, the associations of the postmenopausal state and HRT with NAFLD were statistically significant.

The present prospective study revealed that the incidence of NAFLD was highest in women in menopause (7.5%, 4/53). The incidence of NAFLD was higher in postmenopausal women (6.1%, 24/392) or in women with HRT (5.3%, 11/206) than in premenopausal women (3.5%, 28/802). Our findings are in agreement with recent cross-sectional studies, which indicate that NAFLD is more prevalent in postmenopausal women than in premenopausal women[21-23].

The univariate logistic regression model indicated that the postmenopausal state was a risk factor for NAFLD, but this was not statistically significant after adjusting for age, metabolic syndrome, and weight gain. Age, metabolic syndrome, and body weight gain were independent risk factors for NAFLD in women. However, after separating women into pre- or postmenopausal groups, age remained

the only independent risk factor in premenopausal women. These results imply that aging increases the risk for NAFLD in premenopausal women, but poses no risk after menopause; thus, the influence of aging in postmenopausal women is similar to that in men. Furthermore, the proportion of premenopausal women with NAFLD was smaller than that in men, but the proportion of postmenopausal women with NAFLD was equal to that in men.

A possible underlying factor is estrogen-related sex hormones. Estrogens lead to preferential fat accumulation in the gluteofemoral region, and the loss of estrogens during the transition of menopause is associated with an increase in central fat[22]. Gutierrez-Grobe *et al*[21] reported that women without NAFLD had significantly higher levels of serum estradiol, which is a major form of estrogen, than those with NAFLD both at pre- and postmenopausal stages. Hepatic estrogen receptors mediate estrogen action in the liver, and estradiol has a favorable role in chronic liver disease[24], which is suggestive of a protective effect of estrogens against NAFLD in women[21]. The relationship between aging in premenopausal women and the development of NAFLD may thus reflect changes in levels of estrogen-related sex hormones. Unfortunately, we did not measure the levels of estrogen-related sex hormones in this study.

In the present cross-sectional study, we found that NAFLD was more prevalent in women receiving HRT than in premenopausal women, as reported elsewhere[23]. However, the logistic model did not indicate that HRT was a risk factor for NAFLD. The protective effect of estrogen-related sex hormones might be limited to endogenous estrogens. However, since the present prospective study was observational, several background factors, including age, differed between the HRT and non-HRT groups. A recent study suggested that HRT improved the results of liver-function tests[25]. Moreover, tamoxifen, an anti-estrogen compound used in the treatment of estrogen receptor positive breast cancer, is associated with an increased risk of fatty liver and NASH[26,27]. An animal study showed that hepatic steatosis occurs spontaneously in aromatase-deficient mice who lack the ability to produce estrogen and who have impaired hepatocellular lipid β-oxidation[28]. Estradiol replacement reduces hepatic steatosis and restores the impairment in mitochondrial and peroxisomal fatty acid β-oxidation to the level found in wild-type mice[29]. Thus, a well-designed randomized controlled study is required to determine the influence of HRT on NAFLD.

Recent studies have shown that visceral fat is an independent predictor of fatty liver, even in patients with normal BMI, and is much more harmful than subcutaneous accumulation of adipose tissue[30,31]. We demonstrated that metabolic syndrome and weight gain are risk factors of NAFLD[8] and evaluated these factors in pre- and postmenopausal women. The number of women who met the criteria for metabolic syndrome was larger among postmenopausal women, but weight gain was the same in both.

We note the following limitations in our study. We assessed active and past medical history, state of menses, smoking habits, drinking habits, and physical activities by conducting interviews. A trained nurse supported the interviewer, but we cannot exclude the possibility of interviewer bias. Furthermore, information on dietary composition was lacking.

In conclusion, aging is a risk factor for NAFLD in premenopausal women, but is not a risk factor in postmenopausal women or in men. This is one of the reasons that the number of women with NAFLD increases with age, and reaches the maximum level in women in their sixties.

COMMENTS

Background

Nonalcoholic fatty liver disease (NAFLD) is emerging as the most common chronic liver disease. NAFLD is more common in men than women, particularly in Asians.

Research frontiers

The prevalence of NAFLD in women increases with age, but not in men. Age and menopause may be risk factors for the incidence of NAFLD. But, this has not been clarified yet.

Innovations and breakthroughs

The prevalence of NAFLD was lower in premenopausal women than in men, but in postmenopausal women, the prevalence of NAFLD was similar to that in men. The prospective study indicated that aging is a risk factor for the development of NAFLD in premenopausal women independent of weight gain or metabolic syndrome.

Applications

The study suggests the possibility that premenopausal women have a protective factor against NAFLD, which is weakened by aging.

Peer review

NAFLD was less prevalent in females than in males, but only before menopause. The prevalence of NAFLD was lower in women than in men, and increased with age in women, but a significant trend for age was not identified in men. NAFLD was independently associated with BMI and metabolic syndrome in both pre- and postmenopausal women, but with age only in premenopausal women. The results are interesting and suggest that the premenopausal state may be associated with a protective factor against NAFLD, which weakens with age.

Abstract

AIM: To investigate the role of urokinase plasminogen activator (uPA) in cholangiocarcinoma (CCA) invasion and its correlation with clinicopathological parameters.

METHODS: uPA expression in CCA tissue was determined by immunohistochemistry. The level of uPA from two CCA cell lines (HuCCA-1 and KKU-M213) and a non-cancer immortalized cholangiocyte cell line (H69) was monitored by plasminogen-gelatin zymography and western blotting, whereas that of plasminogen activator inhibitor type 1 (PAI-1) protein and uPA receptor (uPAR) mRNA was monitored by western blotting and quantitative real-time reverse transcriptase polymerase chain reaction, respectively. Two independent methods were employed to suppress uPA function: a synthetic uPA inhibitor (B428) and silencing of uPA gene expression using siRNA. *In vitro* invasion of the uPA-disrupted cells was assessed by Matrigel-coated Transwell assay.

RESULTS: The immunohistochemical study showed that 75.3% (131/174) of CCA tissues expressed uPA. High uPA expression was correlated with lymphatic invasion and metastasis of CCA patients. Plasminogen-gelatin zymography of the conditioned media and cell-surface eluates showed that both CCA cell lines, but not H69, expressed both secreted and membrane-bound forms of uPA. Although the two CCA cell lines, HuCCA-1 and KKU-M213, expressed a relatively high level of uPA and uPAR, the latter exhibited a much lower degree of *in vitro* invasiveness, correlating with a high expression of PAI-1 in the latter, but not in the former. Suppressing uPA function with a specific uPA inhibitor, B428, or with siRNA against uPA reduced *in vitro* invasiveness of KKU-M213 cells, demonstrating the requirement for uPA in the invasiveness of CCA cells. Therefore, our *in vivo* and *in vitro* studies suggest that uPA is an important requirement for the invasion process of CCA.

CONCLUSION: uPA expression correlates with lymphatic invasion and metastasis *in vivo* and is required for CCA cell invasion *in vitro*, suggesting its potential as a therapeutic target.

INTRODUCTION

Cholangiocarcinoma (CCA) is a cancer that originates from the biliary epithelium, and it is the second most common form of liver cancer. Although it is a rare malignancy, the incidence and mortality rate has increased worldwide in the past decade[1]. The highest incident rate was observed in Northeast Thailand where there is a high prevalence of liver fluke (*Opisthorchis viverrini*) infection[2], a group I carcinogen classified by International Agency for Research on Cancer[3]. CCA is considered an incurable disease due to lack of efficient diagnosis, hence most patients at presentation have developed advanced disease with high rate of invasion and metastasis, resulting in a high mortality rate.

Metastasis is a multi-step process that involves spreading of cancer cells from the primary to the secondary site. During this process, cancer cells must invade the surrounding tissue, penetrate the blood or lymphatic vessels, and form a new tumor mass at distant sites. To invade, cancer cells degrade extracellular matrix (ECM) and basement membrane to generate a space for the cells to move out of the original site. This is accomplished by secretion of a variety of matrix-degrading enzymes including matrix metalloproteinases (MMPs) and serine proteases, such as plasminogen activator.

Urokinase plasminogen activator (uPA) is a serine protease that is involved in ECM degradation, cancer invasion and metastasis by regulating the plasminogen/plasmin system. uPA is synthesized as a single-chain proenzyme which is activated by proteolytic cleavage to form the high-molecular-weight two-chain active uPA or the low-molecular-weight uPA through the action of plasmin, kallikrein, or cathepsin B[4]. Active uPA cleaves inactive plasminogen to generate active plasmin, a broad-specific serine protease, which can degrade a variety of ECM proteins. Besides, plasmin and uPA can also activate several types of MMPs which, in turn, degrade ECM. Therefore, uPA amplifies proteolytic cascades in ECM degradation which is crucial for cancer invasion. uPA exerts its effect by binding to the uPA receptor (uPAR), which localizes uPA on the cell surface, enhancing its plasminogen activation capability[5]. This activity is, in turn, negatively regulated by the plasminogen activator inhibitor type 1 and 2 (PAI-1 and -2)[5].

uPA expression has been shown to be upregulated in many cancers, where its expression has been correlated with invasion and metastasis[6]. Although uPA expression has been demonstrated in some CCA cell lines[7,8], there has been no report of uPA expression in clinical specimens, nor a linkage between its expression with the clinical symptoms of CCA patients. In this study, we investigated the possible role of uPA in CCA development *in vivo* by examining the expression pattern of uPA in clinical samples and relating those findings to the various clinicopathological parameters of CCA patients. In addition, we determined the role of uPA *in vitro* using siRNA or specific inhibitor to suppress the uPA function and assessed the phenotype of the cells with uPA downregulation in an *in vitro* Transwell assay.

MATERIALS AND METHODS

Patients and tissue samples

Archival paraffin-embedded tissue samples were obtained from 174 patients (aged 32-75 years) who underwent liver resection at Srinagarind Hospital, Khon Kaen University, Thailand during 1999-2010. These samples were used to generate the tissue microarray for this retrospective study. All patients were diagnosed with intrahepatic CCA. Vascular, lymphatic and neural or perineural invasion were defined by the presence of tumor cells in the blood vessels, lymphatic vessels and in or around the nerve fibers in the liver, respectively. The study protocol was approved by the Ethical Committee of Khon Kaen University (HE 521209).

Cell lines and cell culture

Two human CCA cell lines developed from Thai patients, HuCCA-1[9] and KKU-M213 and one human immortalized cholangiocyte cell line, H69, were used. All cell culture materials (medium, serum and antibiotics) were purchased from Gibco Invitrogen (Auckland, New Zealand). The CCA cells were cultured in HAM's F-12 medium supplemented with 10% heat-inactivated fetal bovine serum (FBS), 2 mmol/L glutamine, 15 mmol/L HEPES and 14 mmol/L sodium bicarbonate, 100 U/mL penicillin G and 100 U/mL streptomycin. The cells were incubated at 37 ℃ under a humidified 5% CO_2 atmosphere. H69 was grown in Dulbecco's Modified Eagle's Medium (DMEM)/DMEM F12 (1:1) supplemented with 10% FBS, hormones and epidermal growth factor, as previously described[10].

Tissue microarray and immunohistochemical staining

Tissue microarray (TMA) was generated manually from the paraffin-embedded tissues. In brief, the region of interest from each paraffin block was identified on a hematoxylin-eosin-stained slide, after which the slide was aligned with the surface of the original paraffin block to locate the sampling area. The area of interest in the paraffin block was then punched with a 1-mm-diameter needle before each punched tissue was then manually transferred to a new recipient paraffin block to generate a TMA

block. Five-micrometer-thick sections were cut from the TMA block, mounted on a silane-coated glass slide, followed by immunohistochemical staining. The specimens were deparaffinized and dehydrated before the endogenous peroxidase activity in the tissue section was blocked with 0.5% H_2O_2 in methanol for 30 min. After washing with PBS, pH 7.4, and blocking with blocking solution containing 5% normal horse serum in PBS, pH 7.4, for 30 min, the specimens were hybridized with 0.5 μg/mL monoclonal antibody against uPA (Ab No. 3689; American Diagnostica, Stamford, CT, United States), followed by a horseradish peroxidase (HRP)-conjugated secondary antibody (Invitrogen, Carlsbad, CA, United States). The brown color corresponding to the peroxidase activity was developed using diaminobenzidine (Sigma, St Louis, MO, United States). The specimens were counter-stained with Mayer's hematoxylin. Negative controls were performed in a similar way, omitting the primary antibody. The uPA staining was scored based on signal intensity as follows: negative, weak (+), moderate (++) and strong (+++).

Determination of plasminogen activator activity by plasminogen-gelatin zymography

uPA activity secreted from cancer cells into the conditioned medium (CM) was determined by plasminogen-gelatin zymogaphy under non-reducing conditions. Cells (3.5×10^5) were cultured in six-well plates for 2 d, washed twice, and incubated in serum-free medium for 6 h. Proteins in CM were separated by 8% SDS-PAGE containing 10 μg/mL plasminogen (Roche Diagnostics GmbH, Mannheim, Germany) and 1 mg/mL gelatin (Sigma) under non-reducing conditions. After electrophoresis, the gel was washed twice with 2.5% TritonX-100 for 1 h to remove SDS, incubated for 18 h in the reaction buffer containing 100 mmol/L Tris-HCl, pH 7.8, 150 mmol/L NaCl and 1% TritronX-100, followed by staining with 0.25% Coomassie blue and destaining with 45% methanol and 10% acetic acid. A clear band with an estimated molecular weight of 43 kDa represented the uPA activity band. To confirm its PA (not gelatinase) activity, plasminogen-free gelatin zymogram gel was run in parallel as a negative control.

To detect the bound uPA, cells were washed twice with PBS before the bound uPA was eluted by elution buffer [100 mmol/L NaCl and 50 mmol/L glycine-HCl (pH 3.0)]. The eluate was neutralized by adding 0.5 mol/L Tris-HCl, (pH 7.8), at the ratio of eluate:neutralization buffer of 4:1, and analyzed by plasminogen-gelatin zymography.

Determination of uPA and PAI-1 proteins by western blotting

uPA and PAI-1 protein levels in 40× concentrated CM were determined by western blot analysis using anti-uPA and anti-PAI-1 antibodies (American Diagnostica), respectively. Proteins were separated by 8% SDS-PAGE, transferred to a nitrocellulose membrane, probed with anti-uPA and anti-PAI-1 antibodies, before being hybridized with HRP-conjugated secondary antibodies. The uPA and PAI-1 bands were developed by enhanced chemiluminescence ECL Plus reagent (GE Healthcare, Little Chalfont, Bucks, United Kingdom) and visualized by Fluor Chem SP (Alpha Innotech**,** San Leandro, CA, United States).

Quantitative real-time reverse transcriptase polymerase chain reaction

uPA and uPAR mRNA expression was determined by real-time reverse transcriptase polymerase chain reaction (RT-PCR) using ABI 7500 (Applied Biosystems, Foster City, CA, United States). RNA was extracted using RNeasy mini kit (Qiagen, Valencia, CA, United States) following the manufacturer's protocol. Two micrograms total RNA was converted to cDNA by SuperScript™ Ⅲ Reverse Transcriptase kit (Invitrogen, Grand Island, NY, United States) using random hexamer primer, and the cDNA was amplified by real-time PCR in a 20-μL reaction volume containing 0.5 U HotStart Taq polymerase (Qiagen), 1× FastStart Universal SYBR Green Master cocktail (Roche Diagnostics GmbH, Mannheim, Germany) and 4 pmol of each specific primer (5'-TTGCTCACCACAACGACATT-3' and 5'-ATTTTCAGCTGCTCCGGATA-3' for uPA[11], 5'-GGTGACGCCTTCAGCATGA-3' and 5'-CCCACTGCGGTACTGGACAT-3' for uPAR and 5'-GTAACCCGTTGAACCCCATT-3' and 5' -CCATCCAATCGGTAGTAGCG-3' for 18sRNA, as an internal control). The reactions were started with an initial heat activation step, followed by 40 thermal cycles. The mRNA levels among the test cells were analyzed by relative quantification $2^{-\Delta\Delta Ct}$ method.

Knock-down of uPA using siRNA against uPA

KKU-M213 cells were transiently transfected with siRNA against uPA (Santa Cruz Biotechnology, Santa Cruz, CA, United States) using siRNA transfection reagent (Santa Cruz Biotechnology) following the manufacturer's protocol with some modifications. In brief, 6 μL siRNA and 6 μL transfection reagent were separately diluted in 100 μL siRNA transfection medium. The diluted siRNA solution was mixed with the diluted transfection reagent, incubated at room temperature for 15 min, before being added to a six-well plate seeded with 2×10^5 CCA cells in 0.8 mL transfection medium. The level of uPA mRNA was accessed at 48 and 72 h after transfection. Silencer Negative Control siRNA #1 (Ambion, Austin, TX, United States), a non-targeted sequence, was used as the negative control.

Transwell in vitro invasion assay

The invasiveness of CCA cells was determined using a Matrigel-coated Transwell chamber (8-μm pore size polyvinylpyrrolidone-free polycarbonate filter with 6.5 mm diameter) (Corning Inc., Corning, NY, United States) precoated with 30 μg Matrigel (BD Biosciences, San Diego, CA, United States). One hundred thousand transfected cells at 66 h post-transfection in FBS-free media were added to the upper chamber of the Transwell, while 600 μL medium containing 10% FBS was added to the lower chamber. After incubation for 6 h at 37 ℃ in a CO_2 in-

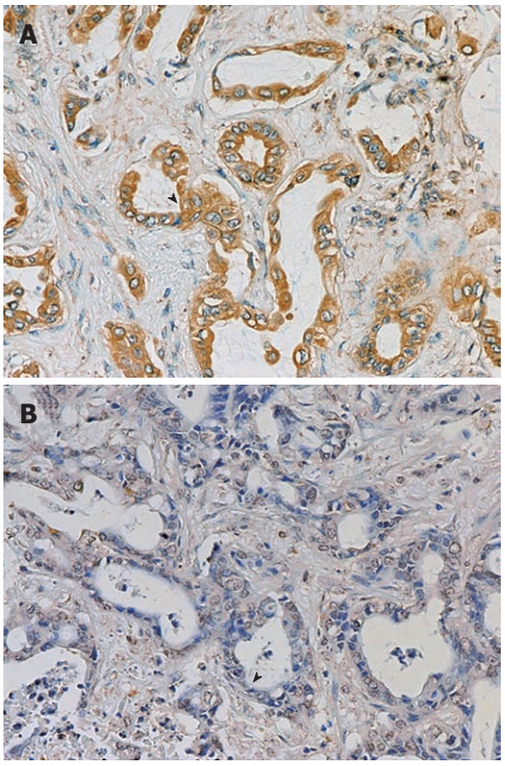

Figure 1 Immunohistochemical staining of urokinase plasminogen activator protein expression in cholangiocarcinoma tissues. Tissue microarray slide was stained with anti-urokinase plasminogen activator (uPA) antibody and counter-stained with Mayer's hematoxylin. Representative of +++ (A) and negative (B) uPA staining.

cubator, non-invaded cells were removed from the upper chamber, and invaded cells were fixed and stained for 30 min with 0.5% crystal violet in 25% methanol. The number of invaded cells in five random fields was counted under a light microscope using a 10× objective. Three independent experiments were performed, each done in duplicate.

Statistical analysis

All statistical analysis was performed using SPSS version 16.0 software. Correlation between uPA expression and clinicopathological factors was analyzed using the χ^2 test. Survival analysis was done by Kaplan-Meier and log-rank tests. mRNA and invasion data were expressed as mean ± SE from three independent experiments. Comparison of the data between groups was performed by *t* test. $P < 0.05$ was considered significant.

RESULTS

Level of uPA in CCA tissues using immunohistochemistry

We examined uPA expression in 174 CCA specimens by performing immunohistochemistry on the TMA. One hundred and thirty-one cases (75.3%) expressed uPA, which was mainly localized in cytoplasm of CCA cells (Figure 1). The low uPA expressing cells (negative and +) accounted for 50.6%, whereas those with high uPA expression (++ and +++) constituted 49.4% of the total sample number (Figure 1).

Table 1 Correlation between urokinase plasminogen activator expression and clinicopathological features

Variables	uPA		*P* value
	Low	High	
Age (yr)			
≤ 50	22	23	0.793
> 50	66	63	
Sex			
Male	61	55	0.453

[1]Classify as both mass forming and periductal or intraductal; [2]Statistically significant. uPA: Urokinase plasminogen activator.

The correlation between uPA expression and clinicopathological parameters is summarized in Table 1. There was no correlation between uPA expression level and age, sex, tumor size, histological type, vascular invasion, neural invasion (Table 1) and patients' survival (Figure 2). However, uPA expression level in the CCA tissues was positively correlated with lymphatic invasion ($P = 0.012$) and metastasis ($P = 0.048$).

Levels of secreted and cell surface-bound uPA in CCA cell lines

Expression pattern of the secreted form and the membrane-bound form of uPA was investigated using plasminogen-gelatin zymography in the CCA cell lines, HuCCA-1, and KKU-M213, compared with that of an immortalized cholangiocyte cell line, H69. Both CCA cell lines, but not the cholangiocytes, expressed a 43-kDa PA band on the plasminogen–gelatin zymogram (Figure 3A), and this was later confirmed by western blotting using anti-uPA antibody to correspond to uPA (Figure 3B). The discrepancy in the molecular weight of uPA determined by plasminogen–gelatin zymography (43 kDa) and by western blotting (50 kDa) could be accounted for by the different denaturation conditions employed by the two methods, in which

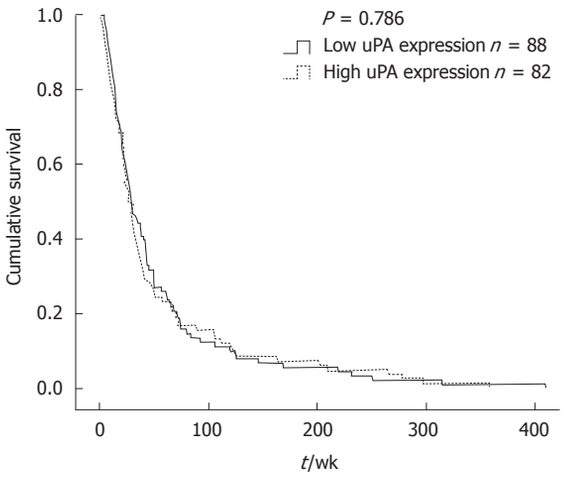

Figure 2 Correlation between urokinase plasminogen activator expression and patients' survival by Kaplan-Meier plot. Low urokinase plasminogen activator (uPA) expression was referred to as negative and +, whereas high uPA expression was ++ and +++.

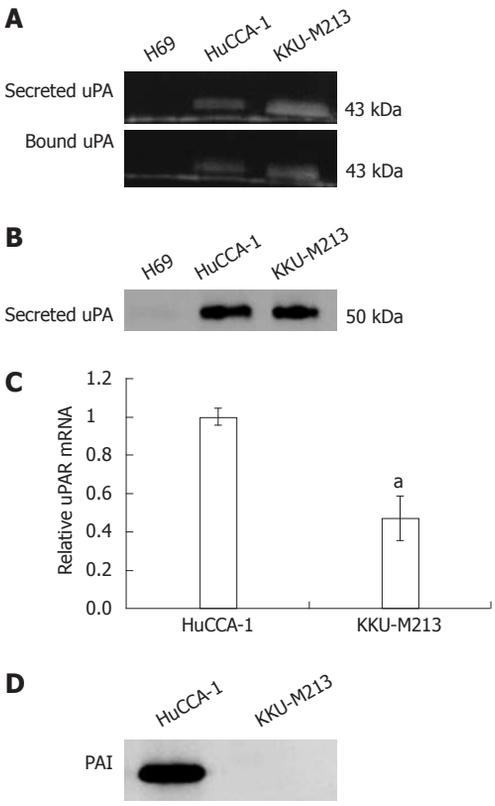

Figure 3 Levels of urokinase plasminogen activator, plasminogen activator inhibitor type 1 protein and urokinase plasminogen activator receptor expression in two cholangiocarcinoma cell lines and immortalized cholangiocytes. A: Levels of secreted urokinase plasminogen activator (uPA) in 40× concentrated conditioned medium and cell-surface-bound uPA were determined by plasminogen-gelatin zymography; B and D: Levels of secreted uPA (B); and secreted plasminogen activator inhibitor type 1 (PAI-1) (D) proteins were determined by western blotting; C: Level of uPAR mRNA was examined by SYBR Green-based qPCR and the data were calculated as relative uPAR expression compared to that of HuCCA-1, $2^{-\Delta\Delta Ct}$, and expressed as mean ± SE from three independent experiments. Significant difference is indicated by $^{a}P < 0.05$.

the protein was partially denatured by a non-reducing-unheated condition in the zymogram gel, whereas it was completely unfolded by a reducing-heated condition in the western blotting.

The uPA is under positive and negative regulation by uPAR and PAI-1, respectively. Using quantitative real-time PCR, we showed that both CCA cell lines expressed uPAR mRNA, where the expression level in HuCCA-1 was twice the level in KKU-M213 cells (Figure 3C). In addition, we showed by western blotting that PAI-1, a major uPA inhibitor, was secreted abundantly in HuCCA-1 but not in KKU-M213 cells (Figure 3D).

Effect of uPA inhibition on CCA cell invasion

Our immunohistochemical data showed that uPA expression in CCA specimens correlated with invasion and metastasis, thus, we investigated if uPA played a role *in vitro* by assaying for the invasiveness of the cancer cell line in which the uPA activity was inhibited. We showed that B428, a uPA-specific inhibitor[12], dose dependently reduced the invasiveness of KKU-M213 cells compared with controls (Figure 4). Treatment with 20 μmol/L B428 suppressed *in vitro* invasion by 32%, whereas uPA activity as determined by plasminogen-gelatin zymography, of which both gel and reaction buffer contained the inhibitor, was reduced by 64%. Suppression of *in vitro* invasion was not due to toxicity of B428, because the 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide assay showed that B428 had no significant effect on cell survival under these conditions (Figure 4).

The significance of uPA in the invasiveness of CCA cells was confirmed by silencing of uPA using siRNA to target *uPA* gene expression in KKU-M213 cells. Using quantitative real-time RT-PCR, we showed that the uPA mRNA level of cells transfected with siuPA was suppressed by about 60% compared to that of cells transfected with siNeg (Figure 5A). *In vitro* invasion of the uPA-silenced cells was reduced by 66% ± 12% compared to that in the negative controls (Figure 5B). Suppression of uPA activity using two independent methods confirmed that uPA is an important requirement for invasiveness of CCA cells.

DISCUSSION

One of the key features required for cancer invasion and metastasis is the ability to degrade ECM and basement membrane barrier. This process is accomplished by the action of a variety of proteolytic enzymes, including serine proteases and MMPs, which work in concert[5]. uPA, a plasminogen-specific serine protease, is one of the important proteolytic enzymes contributing to this process.

uPA has been reported to be upregulated in many cancer types, such as breast[13], prostate[14], colorectal[15], gastric[16], and thyroid[17], and its expression level correlates with cancer progression. Here, we used immunohistochemical analysis to demonstrate that uPA expression could be detected in the majority (75.3%) of CCA specimens, and that high level of uPA expression correlated with lymphatic invasion and metastasis in CCA patients.

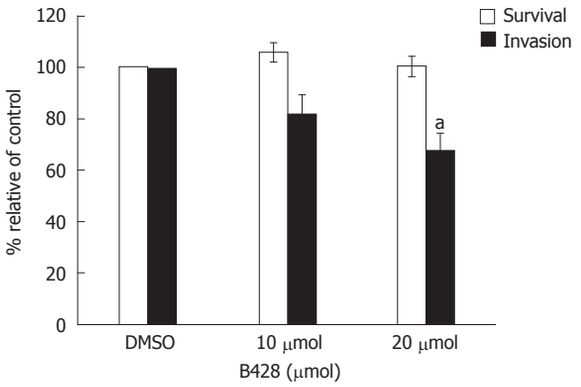

Figure 4 Effect of urokinase plasminogen activator inhibitor (B428) on KKU-M213 cell invasion. Cell suspension in medium containing B428 (10 and 20 μmol/L) and 0.1% dimethyl sulfoxide (as a control) were subjected to *in vitro* invasion assay for 6 h. Cell survival was analyzed by 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide assay after cells were incubated with the drug for 6 h. The results were presented as mean ± SE from three independent experiments. Significant difference is indicated by $^{a}P < 0.05$.

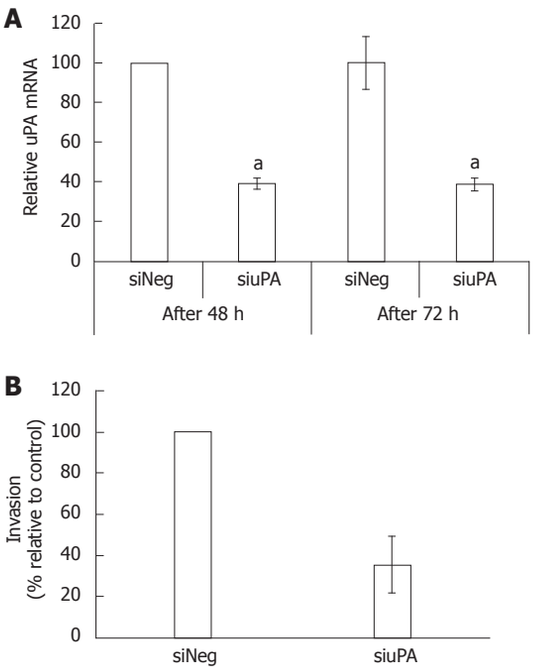

Figure 5 Effects of urokinase plasminogen activator knockdown on KKU-M213 cell invasion. A: Level of urokinase plasminogen activator (uPA) mRNA of the cells transfected with siRNA against uPA or non-targeting siRNA for 48 and 72 h were determined by real-time reverse transcriptase polymerase chain reaction. Significant difference is indicated by $^{a}P < 0.05$; B: Cells transfected with siRNA for 66 h were analyzed for cell invasiveness using Transwell *in vitro* invasion assay. The results were presented as mean ± SE from three independent experiments.

However, we found no significant correlation between uPA expression level and patients' survival rate. Several clinical features contribute to survival of intrahepatic CCA patients. Large tumor size, multifocal tumors, positive resection margin, gross appearance as mass-forming plus periductular infiltration, invasion and metastasis have been shown as clinicopathological features related to poor prognosis and short survival[18].

The role of uPA in CCA invasion was investigated *in vitro* using CCA cell lines, HuCCA-1 and KKU-M213, and compared with the non-cancer immortalized cholangiocytes, H69. Plasminogen-gelatin zymography and western blotting demonstrated that both CCA cell lines, but not the non-cancer immortalized cholangiocytes, expressed the cell-surface-bound and the secreted forms of uPA. Although the two cell lines expressed relatively high amounts of uPA, only KKU-M213, but not HuCCA-1 cells exhibited a high degree of invasiveness as previously determined by *in vitro* Transwell assay[19]. This could probably be explained by the fact that HuCCA-1, but not KKU-M213 cells expressed PAI-1, a uPA inhibitor, thereby attenuating uPA activity to promote matrix degradation and cell invasion. Expression of PAI-1 in HuCCA-1 cells may also explain why the level of cell-surface-bound uPA was similar in the two cell lines, although that of uPAR mRNA was twice as high in HuCCA-1 compared to KKU-M213 cells. Binding of PAI-1 to the uPA-uPAR complex has been reported to promote uPA-uPAR-PAI-1 complex internalization and lysosomal degradation of uPA and PAI-1[6], leading to a reduction of the bound uPA on the cell surface.

Inhibition of uPA or uPAR function by anti-uPA or anti-uPAR antibody or by non-specific serine protease inhibitor has been shown to reduce significantly *in vitro* invasiveness of papillary thyroid cancer cells[17]. Similarly, silencing of uPA and/or uPAR by siRNA has been shown to suppress *in vitro* invasion of many cancer types including those of the prostate[20] and breast[21], and glioma[22]. We showed that inhibition of uPA activity by specific uPA inhibitor, B428, or of uPA expression by siRNA efficiently suppressed *in vitro* invasion of KKU-M213 cells, consistent with a previous report in QBC939 cells, a uPA-expressing CCA cell line, whose invasiveness was markedly reduced by inhibiting plasminogen activation with tranexamic acid or 6-aminocaproic acid[7]. Observations of the importance of uPA in invasion in a variety of cancers suggest a common role of uPA in cancer invasion, including CCA. A drug inhibiting uPA is already undergoing clinical trial for some cancers[23] and if proven successful, could be applied to CCA.

In summary, we have showed by immunohistochemistry that high uPA expression in CCA tissue was correlated with lymphatic invasion and metastasis. Studies in cell lines confirmed the importance of uPA in cell invasiveness, but the presence of PAIs or uPAR can affect uPA-dependent cell invasion. The roles of these factors in modulating CCA invasion and metastasis clearly warrant future investigation.

ACKNOWLEDGMENTS

The authors thank Professor Sirisinha S (Mahidol University, Thailand) for providing us HuCCA-1 cell line and Professor Alpini G (Texas A and M University, TX, United States) and Professor Gores G (Mayo Clinic, MN, United States) for H69 cell line, and Professor Wilairat P and Dr. Kitjaroentham A for critical reading of the manuscript.

COMMENTS

Background

Cholangiocarcinoma (CCA), a cancer of the bile duct, is an aggressive cancer with high metastatic and short survival rate. One of the critical properties required for cancer metastasis is the ability to degrade extracellular matrix. Urokinase plasminogen activator (uPA), a key proteolytic enzyme involved for this process, is frequently overexpressed in many types of cancers.

Research frontiers

Although uPA has been demonstrated to play an important role in invasion of many cancer types, the correlation between uPA expression and CCA progression has not hitherto been reported.

Innovations and breakthroughs

The authors have demonstrated that high uPA expression in CCA tissue correlated with high lymphatic invasion and metastasis in patients. The importance of uPA in cell invasiveness was confirmed *in vitro* using uPA-expressing CCA cell lines. In addition, the *in vitro* study indicated that plasminogen activator inhibitors could have an important impact on uPA-mediated cancer cell invasiveness.

Applications

The requirement of uPA in CCA invasiveness highlights uPA as a potential therapeutic target.

Terminology

Urokinase plasminogen activator (uPA) is a plasminogen-specific serine protease. It converts inactive plasminogen to active plasmin, which degrades extracellular matrix and activates matrix metalloproteinases.

Peer review

This study investigated uPA expression in CCA tissues and its role in CCA cell invasion *in vitro*. The authors found that high uPA expression correlated with invasion and metastasis in CCA patients. The design of this research is good and the findings are novel and important, so it is suitable for our readers.

Abstract

AIM: To determine whether routine nasogastric (NG) decompression benefitted patients undergoing radical gastric surgery.

METHODS: Between January 1998 and December 2008, 519 patients who underwent distal gastrectomy for gastric cancer were retrospectively divided into 2 time-period cohorts; those treated with Billroth Ⅱ (BⅡ) reconstruction in the first 6 years and those with Roux-en-Y (RY) reconstruction in the last 5 years. In the latter group, the patients were further divided into 2 subgroups; with and without nasogastric decompression.

RESULTS: Postoperatively, there were no significant differences in the number of anastomotic leaks between the 3 groups. In the tubeless RY group, time to semi-liquid diet was significantly shorter than in the other 2 groups (4.4 d ± 1.4 d *vs* 7.2 d ± 1.3 d and 5.9 d ± 1.2 d, $P = 0.005$). The length of postoperative stay was significantly increased in patients with BⅡ reconstruction compared with patients with RY reconstruction with/without NG decompression (15.4 d ± 4.3 d in BⅡ group *vs* 12.6 d ± 3.1 d in decompressed RY and 11.4 d ± 3.4 d in the tubeless RY group, $P = 0.035$). The postoperative pneumonia rate was lowest in the tubeless group and highest in the BⅡ group (1.4% *vs* 4.6%, $P = 0.01$). Severe sore throat was noted in 59 (20.7%) members of the BⅡ group, 18 (17.4%) members of the decompressed RY group and 6 (4.2%) members of the tubeless RY group. Fewer patients in the tubeless group complained of severe sore throat ($P = 0.001$).

CONCLUSION: This study provides support for abandoning routine NG decompression in patients undergoing subtotal gastrectomy with Roux-en-Y gastrojejunostomy.

INTRODUCTION

It is a commonly held belief in clinical practice that nasogastric (NG) decompression after gastric surgery is essential to prevent postoperative complications, such as postoperative ileus or anastomotic leakage. Although the necessity of NG decompression following gastric surgery has been increasingly questioned over the last 2 decades, most general surgeons have routinely used NG decompression and recommended patients fast for a period of 3-5 d after surgery. Several prospective studies have suggested that this routine practice does not provide any benefit, but could make patients feel uncomfortable[1-5]. However, these studies enrolled gastric cancer patients who underwent a variety of operations.

Recently, to prevent enterogastric reflux into the gastric remnant and decrease biliary gastritis, Roux-en-Y (RY) reconstruction has become widely used after distal gastrectomy. We have previously reported the superiority of RY reconstruction over Billroth Ⅱ (BⅡ) anastomosis[6]. Another study showed that RY reconstruction after distal gastrectomy is a safer form of anastomosis, and could prevent anastomotic leakage[7]. Therefore, the safer procedure may dispel the common belief of general surgeons that NG decompression after gastric surgery is essential.

The Tri-Service General Hospital has performed RY reconstruction in all gastric cancer patients with distal gastrectomy since January 2003. Benefits of this approach include the reduction of the amount of drained gastric remnant content *via* NG tube. Additionally, the low incidence of possible complications, including biliary gastritis, gastroesophageal reflux and aspiration pneumonia, has supported our adherence to this technique[6]. In January 2005, we therefore decided to abandon the routine use of NG tube decompression postoperatively in patients undergoing distal gastrectomy after success with early discontinuation in a few patients.

In this study, we reviewed our experience with patients undergoing distal gastrectomy to investigate the difference in complication rates between patients without postoperative NG decompression and patients with postoperative NG decompression to determine the necessity of postoperative NG decompression after distal gastrectomy.

MATERIALS AND METHODS

A retrospective study spanning an 11-year period from January 1998 to December 2008 was performed, and a total of 519 patients who underwent distal gastrectomy for carcinoma of the stomach were identified. Criteria for inclusion in this cohort study were as follows: no previous chemoradiation treatments, having R0 resection (no macroscopic or microscopic residual tumor) according to the definition of the International Union Against Cancer (UICC), and having the operative procedures described below. Approval for chart review was obtained from the institutional review boards at Tri-Service General Hospital. Each patient's clinic chart was reviewed.

Cases were divided into 2 time-period cohorts; those treated in the first 6 years (TP1, $n = 283$) and those in the last 5 years (TP2, $n = 236$). After distal gastrectomy, gastrointestinal continuity was reconstructed with BⅡ gastrojejunostomy in all patients before January 2003 (TP1). Thereafter, we adapted RY gastrojejunostomy to restore gastrointestinal continuity (TP2). All patients underwent D1 or D2 lymph node dissection. The cancer was staged according to the UICC TNM classification. Preoperatively, all patients in each group were given a normal diet, unless there was gastric outlet obstruction. Patients with symptoms of obstruction were given NG decompression and parenteral nutrition support exclusively for at least 7 d before the operation. No attempt was made to employ gastric lavage in these patients.

In TP1, all patients received insertion of a 16-French single lumen NG tube for postoperative gastric decompression until the passage of flatus and drainage amounted to less than 100 cc per day. They were allowed glucose water to drink the day after the NG tube was removed. Diet was increased in a stepwise fashion from a clear liquid to a semi-liquid diet as tolerated. In TP2, patients were divided into 2 subgroups based on whether NG tube decompression was used or not. In the decompression group (TP2A), the patients received NG decompression and resumed an oral diet in the same way as in the TP1 group. In the tubeless group (TP2B), postoperative oral intake was started with water on the second postoperative day regardless of passage of flatus. Diet was advanced in the same way as in the other groups. Routine radiographic examination using water-soluble contrast material was not done before starting oral intake. The NG tube was reinserted when clinically indicated, such as when severe vomiting or abdominal distension occurred.

The following data were recorded by the attending surgeon: intra-abdominal complications (delayed gastric emptying or Roux stasis syndrome, small mechanical bowel obstruction, gastrojejunostomy leak and duodenal stump leak) and postoperative infection (wound infection, unknown fever, intra-abdominal abscess, and pneumonia). We adopted the 1992 Centers for Disease Control definition for superficial incisional, deep incisional and organ/space surgical site infection for hospital monitoring programs and surgical audits[7]. Patients were considered to have postoperative infections if they developed intra-abdominal abscesses, surgical wound infections, unknown fever, or pulmonary infiltrates shown by radiography[8]. Postoperative unknown fever was defined as a body temperature over 38 ℃ for at least 3 d without obvious infection source. Intra-abdominal abscess was defined as an abscess that needed to be resolved by percutaneous or open drainage. Wound infection was defined as a wound

that needed to be laid open. Mechanical small bowel obstruction was defined as an obstruction that needed to be resolved by surgical intervention. Delayed gastric emptying or Roux stasis syndrome was defined arbitrarily as the failure to intake food orally after the 7th postoperative day. The postoperative days until the first passage of stool was observed, when semi-liquid diet was permitted, and the length of postoperative hospital stay (LOS) were also recorded.

Statistical analysis

Results were expressed as mean ± SD. Statistical analysis was performed using the one-way analysis of variance test for continuous variables and the χ^2 test for categorical variables, when appropriate, respectively. *P* values less than 0.05 were considered statistically significant. Statistical analysis was carried out with the SPSS software package, version 13.0 (SPSS, Inc., Chicago, IL).

RESULTS

Of the 519 eligible patients, 283 (54.5%) were enrolled in TP1, 102 (19.7%) were in TP2A and 134 (25.8%) in TP2B. The characteristics of the 3 groups of patients are showed in Table 1. There was no significant difference with respect to age, gender, extent of lymphadenectomy, tumor stage, analgesic use or operation time except for type of reconstruction.

Five of the 134 (3.7%) tubeless patients (TP2B) who did not receive NG tube decompression developed vomiting or abdominal distension, and needed insertion of an NG tube for decompression (Table 2). Nineteen patients (6.7%) in the decompression group with BⅡ (TP1) and 3 patients (2.9%) in the decompression group with RY (TP2A) reconstruction required persistent NG decompression or reinsertion of an NG tube for vomiting or abdominal distension. More patients in the TP1 group needed persistent NG decompression or reinsertion of an NG tube ($P = 0.001$). In the decompression groups (TP1 and TP2A), the NG tube was removed after a mean of 5.3 d and 3.6 d, and the mean amounts of NG drainage were 465 cc and 58 cc per day in the first 3 operative days, respectively. The duration of NG decompression and the amount of NG drainage in the RY group were significantly less than in the BⅡ group ($P = 0.023$ and $P = 0.001$, respectively). Time to passage of flatus was no different for the 3 groups. However, in the tubeless RY group, time to semi-liquid diet and length of postoperative hospital stay were significantly shorter than in the other 2 groups ($P = 0.001$ and $P = 0.035$). The LOS was significantly increased in patients with BII reconstruction compared with patients with RY reconstruction with/without NG decompression (15.4 ± 4.3 d in BⅡ group *vs* 12.6 d ± 3.1 d in decompressed RY and 11.4 ± 3.4 d in the tubeless RY group, $P = 0.035$). The 27 patients who required persistent NG decompression or NG tube reinsertion were carefully examined for factors that might lead to predictive criteria for postoperative NG decompression. No factors, including analgesics use, preoperative gastric outlet obstruction, and history of diabetes, could be determined to be predictive of the need for postoperative NG decompression (data not shown).

There was no significant difference in the occurrence rate of each of the classified intra-abdominal complications in the 3 groups except for delayed gastric emptying or Roux stasis syndrome (Table 3). There were 18, 3 and 4 patients who developed delayed gastric emptying or Roux stasis syndrome in the TP1, TP2A and TP2B groups, respectively. All 25 patients were able to tolerate a normal diet from the 12th to the 43rd postoperative day without surgical treatment. The reoperation rate for early postoperative mechanical small bowel obstruction was

[1]Mortality is associated with aspiration pneumonia-related sepsis. NG: Nasogastric.

0.4% in the TP1 and 0.7% in the TP2B group. Omitting NG decompression did not increase the risk of gastrojejunostomy and duodenal stump leakage. Three patients in the TP1 group leaked from a BⅡ gastrojejunostomy and one of them developed an intra-abdominal abscess, which was treated by CT-guided percutaneous drainage. Two patients in the 2 RY groups who developed gastrojejunostomy leaks recovered spontaneously without further percutaneous drainage and did not develop intra-abdominal abscesses. Even though there were no differences in major life-threatening complications among the 3 groups, 1 patient died of aspiration pneumonia-related sepsis in the TP1 group. The postoperative pneumonia rate was lowest in the tubeless group (1.4%) and highest in the BⅡ group (1.4% *vs* 4.6%, $P = 0.01$). Fewer patients in the tubeless group complained of severe sore throat ($P = 0.001$). Severe sore throat was noted in 59 (20.7%) members of the TP1 group, 18 (17.4%) members of the TP2A group and 6 (4.2%) members of the TP2B group.

DISCUSSION

For the past century, NG decompression has been commonly thought to be necessary for patients undergoing gastric operation to protect against gastric or intestinal distension with subsequent anastomotic failure[9]. Even today, most general surgeons still follow the routine procedure[10]. Our study has demonstrated that NG decompression is not routinely required postoperatively after distal gastrectomy with RY reconstruction in patients with gastric cancer. Patients can be discharged more rapidly while tolerating semi-liquid diets without increasing postoperative complications.

Concerns regarding greater risks of anastomotic leak associated with distended gastric remnant and postoperative ileus are obstacles to the abandonment of postgastrectomy NG decompression. Historically, surgeons believed that a 3-5-d gastric decompression and fast after a gastric operation could prevent anastomotic leak resulting from increased intraluminal pressure of the postoperative atonic gastric remnant and physiologic ileus of the intestine. For radical gastrectomy, it is unavoidable that most autonomic nerve fibers controlling the upper gastrointestinal tract in the abdomen are destroyed by skeletonization of the celiac axis and lesser curvature during radical lymph node dissection. This may interfere with the motility of the gastrointestinal tract postoperatively. In addition, the bowel is much more extensively manipulated in gastric cancer surgery than in lower gastrointestinal tract surgery and may be a potential risk factor for the development of functional ileus during the early postoperative period. For these reasons, prophylactic NG decompression after operations for gastric cancer seems to be reasonable and very important. Until recently, therefore, NG intubation for gastric decompression has been a routine part of perioperative care after radical gastrectomy. However, the necessity of NG decompression after gastric surgery has been increasingly questioned over the past 2 decades. Studies regarding gastric decompression after gastric cancer surgery are very rare, because surgeons are concerned that swallowed saliva and gastric secretion can make direct contact with the anastomotic wound and consequent anastomotic disruption. Anastomotic disruption is a potentially fatal complication, and may lead to severe morbidity and mortality when it happens. Four prospective studies from Taiwan[1,2] and South Korea[3,4] have suggested that it is unnecessary to decompress the gastric remnant after gastrectomy for gastric cancer. Another European multicenter prospective study has also been performed to assess the use of a nasojejunal tube after total gastrectomy and the authors recommended that no use of postoperative NG decompression decrease postoperative fever and pulmonary problems, and improved patient comfort by decreasing sore throat and nausea[5]. However, these studies enrolled gastric cancer patients undergoing a variety of operations, such as total and subtotal gastrectomy. Our study focused on distal gastrectomy with BⅡ or RY reconstruction for gastric cancer and tried to abandon the routine use of NG decompression after distal gastrectomy. It did not increase the rates of intra-abdominal morbidities such as anastomotic leakage compared with the decompression group. Moreover, in our study, 5 of the 134 patients without NG decompression required reinsertion of the NG tube due to vomiting or abdominal distension. None developed anastomotic leaks. Temporary gastric remnant distension did not seem to disrupt anastomosis in patients receiving distal gastrectomy with RY reconstruction.

Interestingly, 2 patients in the RY groups who suffered from gastrojejunostomy leaks healed spontaneously with the drains placed during the operation and did not develop intra-abdominal abscesses, which means RY reconstruction may lower the risk of intra-abdominal abscess after anastomotic leakage. This may be due to a decreased amount of leaked fluid from the gastric remnant immediately following distal gastrectomy with RY reconstruction, which reduced the amount of gastric remnant content.

The magnitude of gastric remnant secretory output immediately following distal gastrectomy is unknown. In lower digestive tract surgery, the average volume of gastric juice in patients with gastrointestinal decompression was 200 mL daily postoperatively[11]. Normally, the daily secretion of gastric juice and saliva ranges between 2300 and 3000 mL[12]. Secretion of saliva and gastric juice is under the control of the autonomic nervous system. Surgical transection of the vagus nerve during radial subtotal gastrectomy may decrease salivatory and gastric secretion postoperatively. Our results showed that after distal gastrectomy with BⅡ reconstruction and RY reconstruction, the average daily outputs of gastric remnant drainage were 465 cc and 58 cc, respectively. Therefore, with RY reconstruction, the reason for the decreased drainage amount from the gastric remnant is that not only the salivatory and gastric remnant secretions decrease, but the pancreatic and biliary secretions could be diverted from the gastric remnant[6]. This is why there is no need for NG decompression in the patients with RY reconstruction compared with those with BⅡ reconstruction.

The avoidance of complications associated with NG decompression is another potential benefit of our approach. Most patients complained of discomfort secondary to NG intubation. This discomfort included sore throat, hoarseness, dysphagia, nasal trauma, sinusitis, and psychological problems[13,14]. Use of NG decompression also increased the risk of respiratory complications. Several studies indicated that NG intubation increased the risk of atelectasis and pneumonia[15,16]. The ability of patients to cough and breathe deeply after surgical intervention is severely compromised by discomfort from an NG tube. In addition, NG intubation causes gastroesophageal reflux, increasing the risk of postoperative pneumonia[17]. In our study, the difference in postoperative pneumonia (1.4% without NG *vs* 3.9% and 4.6% with NG, $P = 0.05$) and severe sore throat (2.1% without NG *vs* 20.7% and 17.4% with NG, $P = 0.01$) reached statistical significance.

In Taiwan, the use of the NG tube to decompress the gastric remnant after distal gastrectomy is still in widespread use by most general surgeons. It is well known that changing common practice in hospitals is difficult and at all levels resistance is usually abundant. In fact, our study showed that a minimal percentage of patients with distal gastrectomy with RY reconstruction required gastric decompression for relieving gastric distension, and the vast majority of patients with RY anastomosis did not need NG decompression after distal gastrectomy and could avoid the discomfort and morbidity associated with NG intubation. The data from the present study not only confirmed that placement of an NG tube can be safely omitted in distal gastrectomy with RY anastomosis, but also demonstrated that routine NG decompression may increase postoperative complications, such as pulmonary infection and pharyngolaryngitis. Our study comprises the largest reported series of patients undergoing a single type of gastrojejunal anastomosis, which provides a large enough series to support the avoidance of NG decompression after distal gastrectomy with RY reconstruction as a safe and effective modification of standard surgical practices.

There are several limitations to this study that are inherent in the source of our data. First, the retrospective nature of this study analysis limits the ability to attribute causality. Second, the comparison of BⅡ and Roux-Y is within different time periods. There could have been several events during such long periods. Third, the comparison between the nasal decompression group and non-decompression group in the latter phase was not randomized. However, our data show that the magnitude of gastric remnant content decreases immediately following subtotal gastrectomy with RY reconstruction. NG decompression offers no benefit for patients and increases patient discomfort and potential NG intubation-related morbidity, and it can therefore be omitted as a routine procedure in gastric cancer patients with distal gastrectomy and RY anastomosis. Further larger-scale properly designed prospective studies, ideally having validated data collections, will enable us to clearly determine the risks and/or benefits in naso-decompression after gastric cancer surgery.

COMMENTS

Background

The nasogastric (NG) decompression after gastric surgery is essential to prevent postoperative complications conventionally. However the necessity of NG decompression following gastric surgery has been increasingly questioned over the last 2 decades.

Research frontiers

Several prospective studies have suggested that the routine NG decompression after gastric surgery does not provide any benefit. Roux-en-Y (RY) reconstruction has become widely used after distal gastrectomy to prevent enterogastric reflux into the gastric remnant and decrease biliary gastritis.

Innovations and breakthroughs

The authors' hospital has performed RY reconstruction in all gastric cancer patients with distal gastrectomy since January 2003. Benefits of this approach include the reduction of the amount of drained gastric remnant content *via* NG tube. In January 2005, the authors abandoned the routine use of NG tube decompression postoperatively in patients undergoing distal gastrectomy.

Applications

The data show that the magnitude of gastric remnant content decreases immediately following subtotal gastrectomy with RY reconstruction. NG decompression offers no benefit for patients and increases patient discomfort and potential NG intubation-related morbidity, and it can therefore be omitted as a routine procedure in gastric cancer patients with distal gastrectomy and RY anastomosis.

Terminology

Nasogastric decompression: placement of a tube into the stomach through the nose to remove stomach contents; Roux-en-Y gastrojejunostomy: distal limb of jejunum is brought up through the mesocolon in a retrocolic fashion, and an end-to-side gastrojejunostomy is made, using a running inner layer of 3-0 absorbable suture and an interrupted outer layer of 3-0 silk Lambert sutures.

Peer review

The manuscript on the whole is well written. This study focused on the possibility of omitting nasogastric tubes in Roux-en-Y reconstruction after gastric cancer operation. It is well organized and very practical.

Abstract

AIM: To establish a more stable and accurate nude mouse model of pancreatic cancer using cancer cell microencapsulation.

METHODS: The assay is based on microencapsulation technology, wherein human tumor cells are encapsulated in small microcapsules (approximately 420 μm in diameter) constructed of semipermeable membranes. We implemented two kinds of subcutaneous implantation models in nude mice using the injection of single tumor cells and encapsulated pancreatic tumor cells. The size of subcutaneously implanted tumors was observed on a weekly basis using two methods, and growth curves were generated from these data. The growth and metastasis of orthotopically injected single tumor cells and encapsulated pancreatic tumor cells were evaluated at four and eight weeks postimplantation by positron emission tomography-computed tomography scan and necropsy. The pancreatic tumor samples obtained from each method were then sent for pathological examination. We evaluated differences in the rates of tumor incidence and the presence of metastasis and variations in tumor volume and tumor weight in the cancer microcapsules *vs* single-cell suspensions.

RESULTS: Sequential *in vitro* observations of the microcapsules showed that the cancer cells in microcapsules proliferated well and formed spheroids at days 4 to 6. Further *in vitro* culture resulted in bursting of the membrane of the microcapsules and cells deviated outward and continued to grow in flasks. The optimum injection time was found to be 5 d after tumor encapsulation. In the subcutaneous implantation model, there were no significant differences in terms of tumor volume between the encapsulated pancreatic tumor cells and cells alone and rate of tumor incidence. There was a significant difference in the rate of successful implantation between the cancer cell microencapsulation group and the single tumor-cell suspension group (100% *vs* 71.43%, respectively, $P = 0.0489$) in the orthotropic implantation model. The former method displayed an obvious advantage in tumor mass (4th wk: 0.0461 ± 0.0399 *vs* 0.0313 ± 0.021, $t = -0.81$, $P = 0.4379$; 8th wk: 0.1284 ± 0.0284 *vs* 0.0943 ± 0.0571, $t = -2.28$, respectively, $P = 0.0457$) compared with the latter in the orthotopic implantation model.

CONCLUSION: Encapsulation of pancreatic tumor cells is a reliable method for establishing a pancreatic tumor animal model.

INTRODUCTION

Pancreatic adenocarcinoma (PA) is an aggressive malignancy that is more common in elderly persons than in younger persons, and less than 20% of patients present with localized, potentially curable tumors. The overall 5-year survival rate among patients with pancreatic cancer is < 5%[1]. Despite advances in chemoradiation and adjuvant chemotherapy, chemotherapeutic options prolong life only minimally[2]. Therefore, animal models that allow further examination of pancreatic cancer progression are urgently needed.

The majority of *in vivo* experimental studies of human cancer have been conducted in subcutaneous, orthotopic and heterotopic implantation nude mouse models. Current animal models of PA have low rates of tumor progression and metastases[3]. A variety of techniques for inducing pancreatic cancer growth in immunodeficient mice have been described, and each is associated with potential shortcomings. We hypothesized that the delivery of tumor cells in three-dimensional microcapsules could overcome these shortcomings by providing a contained, growth-enhancing environment in which tumor cells can propagate. Therein, the tumor cells are likely to grow well or even progress to metastatic disease. Matrigel, a widely-used extracellular matrix, has severe technical limitations such as lot-to-lot variability and handling difficulties during the injection of cell suspensions. Since the introduction of alginate-poly-l-lysine-alginate membranes as an immunoisolation device by Chang *et al*[4] in 1966, further studies have been conducted on the use of microencapsulation in cancer therapies using immunodeficient animals[5]. The first stage of this study compared the growth of tumor cells in microcapsules with the growth of cells alone. Preclinical testing of novel therapeutic strategies in animal models also requires a meticulous assessment of the effects of treatment on local and systemic tumor growth. The second stage of this study evaluated local tumor progression and the systemic spread of tumor cells in microcapsules *vs* those with single tumor cells.

MATERIALS AND METHODS

Materials

Laboratory animals: In total, 82 82 nude mice (BALB/c nu/nu), between 4 and 6 wk of age, weighing 18-20 g, half males and half females, were purchased from Shanghai Laboratory Animal Co., Ltd and were kept in a specific pathogen-free laboratory. All the procedures and observations were performed in the laboratory animal center at the Shanghai JiaoTong University School of Medicine. All studies were conducted with the approval and guidance of Shanghai Jiao-Tong University Medical Animal Ethics Committees (approval ID: 2010060).

Cell lines: The undifferentiated human pancreatic cancer cell line MiaPaCa-2 was obtained from the Shanghai Institute of Digestive Surgery at the Ruijin Hospital, which is affiliated with the Shanghai JiaoTong University School of Medicine.

Encapsulation device: A high-frequency pulse microdroplet generator (Figure 1) was provided by the Biological Engineering Institute of the University of Shanghai for Science and Technology.

Animal *in-vivo* imaging system: An Inveon micro positron emission tomography-computed tomograph (PET-CT) was purchased from Siemens Ltd.

Methods

Cell culture: MiaPaCa-2s were maintained in Dulbecco's modified Eagle's medium supplemented with 10% heat-inactivated fetal bovine serum (Gibco, Grand Island, NY). Cells were cultured at 37 ℃ in an incubator with 50 mL/L CO_2. MiaPaCa-2 cells in logarithmic growth phase were harvested with 0.25% trypsin, centrifuged at 500 *g* for 15 min, washed 3 times in phosphate buffered saline (PBS) at 4 ℃ and the cell number was adjusted to 1×10^7 cells/mL.

Tumor cell encapsulation: The encapsulation process begun with the preparation of a suspension of tumor cells in 1.8% sodium alginate with Matrigel (BD Bioscience, Bedford, MA) in a 25% (v/v) at a final concentration of 2×10^7 cells/mL. Matrigel can accelerate the proliferation of the cell line. The cell-alginate mixture is then extruded from a 31-gauge needle at 4 mL/min to yield spherical microdroplets using a high frequency pulse microdroplets generator (Mode 1, Voltage 60, Frequency 90, Pulse 06). The microdroplets are formed into discrete insoluble gel spheres by immersion in 1.1% $CaCl_2$ to the neutralize of the negative charge on the surface of the microdroplet, causing gelation. The next step involves the formation of a semipermeable membrane on the surface of the gel beads by washing them with 0.05% (w/v) poly-L-lysine. The gel beads are then overcoated with 0.1% (w/v) alginate. The interior gel is liquefied by contact with a solution of 3% (w/v) sodium citrate. This process results in microcapsules with semipermeable membranes containing viable tumor cells in liquid suspension are made[5-8] (Figure 2A). Cancer

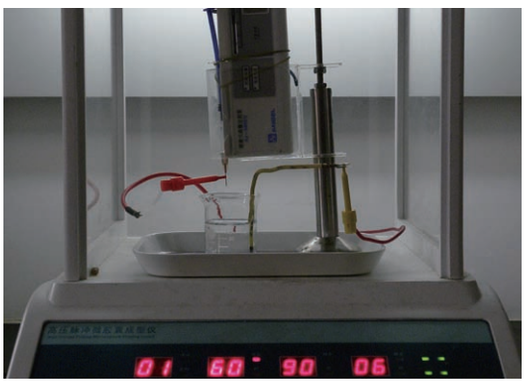

Figure 1 High frequency pulse microdroplet generator.

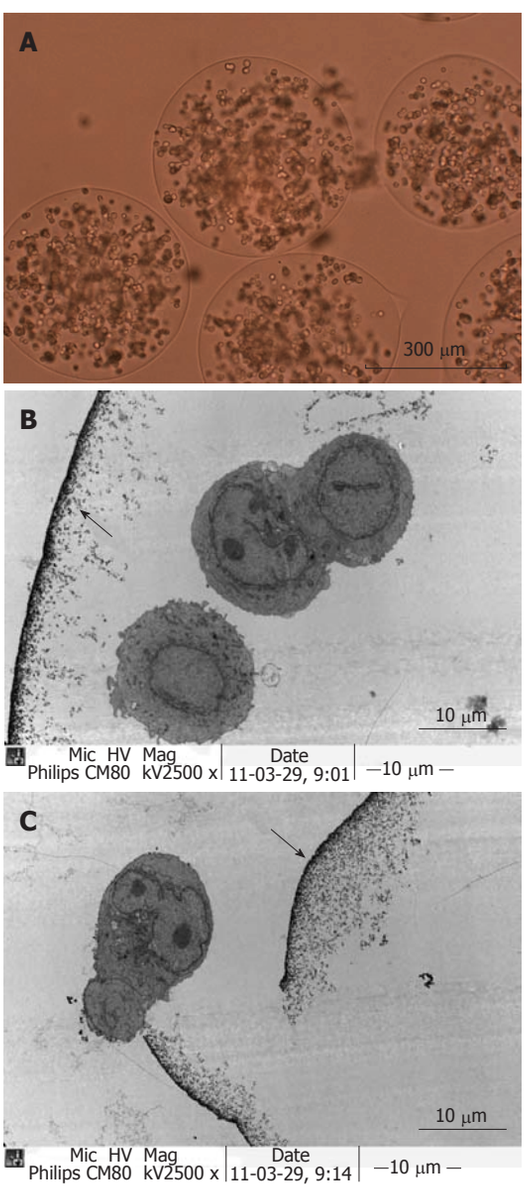

Figure 2 *In vitro* culture of cancer microcapsules after 5 to 7 d of *in vitro* incubation. A: Cancer microcapsules were filled with proliferated cells forming spheroids (× 100); B: Transmission electron microscope observation of encapsulated tumor cells (× 2500); C: Transmission electron microscope observation of encapsulated tumor cells after membrane burst (× 2500). Arrows are pointing to membrane of the microcapsule in B and C.

microcapsules were incubated in complete medium *in vitro* at 37 ℃ with 50 mL/L CO_2 to ensure that they were viable at the time of administration to the mice. The complete medium was removed and PBS was added to prepare a 50% (v/v) suspension of microcapsules.

Groups: The test groups were defined as follows, each consisting of 26 nude mice (half males and half females): The single-cell suspension group received single tumor-cell (MiaPaCa-2) suspensions. The cancer-cell microencapsulation group received encapsulated pancreatic tumor cells. The negative control group received saline instead of the tumor cells. As a positive control group, four additional mice were given intraperitoneal injections (IP) of tumor-cell suspensions to determine whether the metastases originated from cell contamination or genuine metastasis.

Establishing a subcutaneous implantation model for each group: Each of twelve nude mice was injected with 100 μL of the encapsulated tumor cell suspensions as described above, into the left flanks. Another twelve nude mice were injected with 100 μL of single tumor cell suspensions as described above, into the right flanks. Twelve nude mice were injected with saline as a negative control group.

Monitoring subcutaneous xenografts: Subcutaneous xenograft progression was measured with a vernier caliper on a weekly basis. Tumor volume was calculated according with the formula V = length × width × depth/2[9]. The growth curves were constructed accordingly.

Establishing an orthotopic implantation model for each group: Fourteen nude mice were employed for the injection of single tumor cell suspensions. For the tumor induction surgery, they were anesthetized by IP injection of 0.3% chloral hydrate (0.3 g/kg). All procedures were done under aseptic conditions in a laminar airflow workstation. The tail of the pancreas was gently exteriorized through a midline incision into the peritoneal cavity. Mice received a subcapsular injection of 50 μL of single tumor cells. A technically successfully injection was characterized by the formation of a visible bubble within the pancreatic parenchyma. The needle was slowly withdrawn to avoid macroscopic cell leakage from the injection site. The pancreas was closed with 7-0 Prolene. The abdomen was closed using interrupted 6-0 silk sutures closing both skin and muscle simultaneously.

Likewise, fourteen nude mice were injected subcapsularly with encapsulated pancreatic tumor cells 50 μL as described above, and another fourteen nude mice were additionally injected subcapsularly with saline as a negative control group. To determine whether the metastasis was seeding from tumor cell suspensions or were true metastasis originated from primary tumor development, four additional mice were given IP injections of tumor cell suspensions (1×10^7 cells/mL, 100 μL).

PET-CT scan and necropsy: Twenty-eight orthotop-

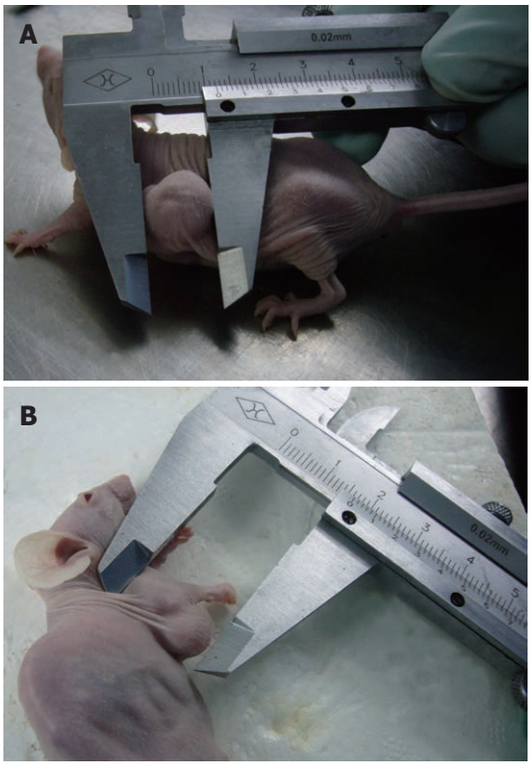

Figure 3 Progression of subcutaneous implantation tumor 8 wk after injection. A: Cancer cell microencapsulation group; B: Single cell suspensions group.

ically-injected mice, seven from the single tumor-cell suspension group and seven from the tumor-cell microencapsulation groupreceived PET-CT scans and were respectively sacrificed at at 4 and 8 wk post implantation, respectively, to ascertain the extent of metastasis and determine tumor weight. Whole-body imaging was used for primary tumor assessment *via* ^{18}fluorine-fluorinedeoxyglucose; necropsy was used for identification. Isolated tumor nodules with no anatomic connection to the primary tumor were judged as distant metastases.

To evaluate the occurrence of metastasis, organs and other areas, i.e., liver, kidney, spleen, mesentery, peritoneal cavity, injection site and lymph nodes, were carefully examined macroscopically. Any suspicious lesion was removed and subjected to histological analysis.

Ultrastructural observation: Microencapsulated tumor cells were sampled and fixed with 2.5% glutaraldehyde, 1% osmic acid, alcohol and epoxy. The samples were then sent for evaluation by transmission electron microscopy (JEM-1200EX) (Figure 2B and C).

Pathological examination: Specimens were embedded in paraffin, cut into 4-mm serial sections, stained with hematoxylin and eosin and tagged with the following immunohistochemical markers: AE1AE3, carbohydrate antigen 19-9 (CA199), CAM5.2, epidermal growth factor receptor (EGFR), MIB-1 and VIM.

Statistical analyses

Differences in the rates of tumor incidence and the presence of metastasis between the cancer-cell microencapsulation group and the single-cell suspension group were analyzed using Fisher's exact test. Variations in tumor volume and tumor weight between the cancer-cell microencapsulation group and the single-cell suspension group were analyzed using student's *t*-test. Differences in tumor weight were also analyzed with the Wilcoxon signed rank sum test. $P < 0.05$ was considered statistically significant. Statistical calculations were done with the SAS 8.0 statistical software package.

RESULTS

In vitro culture of cancer microcapsules

The size of cancer microcapsules engineered in this study were uniform in size. The average diameter of 20 randomly sampled microcapsules was 420 μm ± 24 μm.

The microcapsules are completely transparent, and cell growth within them can be readily visualized with the use of an inverted microscope. Sequential *in vitro* observations of microcapsules showed that the cancer cells within them proliferated well and formed spheroids from days 4 to 6. We observed that all microcapsules containing cancer cells proliferated in a three-dimensional manner. The microcapsule membranes *in vitro* burst with increasing culture time, and the cells deviated outward and continued to grow in the flasks. The bursting day was defined as the day on which more than 10% of the microcapsules burst. Two or three days before the bursting day was assumed to be the optimal time for injection. Typically, bursting occurred from day 6 to 8. Therefore, the microcapsules were injected at 5 d after tumor cell encapsulation. A total of 100 cancer cell microcapsules were observed in sequence. The proportion of ruptured microcapsules increased to 65% (65 of 100) at 10 d and 100% at 28 d.

Rate of tumor incidence in subcutaneous implantation model

Gray nodules growing in round or elliptical patterns were found at the injection site 3 to 5 d after implantation. All mice remained viable during 8 wk of sequential observations; two from the single tumor-cell suspension group (2/12) and one from the encapsulated tumor-cell group (1/12) presented no detectable tumors. None of the negative control group presented detectable tumors. The rate of tumor incidence was 83.3% in the single-cell suspension group and 91.67% in the cancer-cell microencapsulation group. There was no significant difference in the rate of tumor incidence between the cancer-cell microencapsulation group and the single-cell suspension group in the subcutaneous implantation model (91.67% *vs* 83.3%, respectively, $P = 0.5371$) (Figure 3A and B).

Progression of subcutaneous implantation tumor

The tumor size was measured with vernier calipers, and the tumor volume was calculated on a weekly basis (Table 1). There was no significant difference in terms of tumor volume between the encapsulated pancreatic tumor-cell

Table 1 Tumor's volume of subcutaneous implantation

At day post-implantaion (cm^3)	Tumor volume							
	4th d	11th d	18th d	25th d	32th d	39th d	46th d	53th d
Tumor volume of single cells	0.054 ± 0.038	0.092 ± 0.055	0.139 ± 0.082	0.267 ± 0.155	0.596 ± 0.296	1.188 ± 0.570	2.020 ± 0.989	2.602 ± 1.100
Tumor volume of microencapsulated cells	0.060 ± 0.070	0.083 ± 0.097	0.145 ± 0.140	0.316 ± 0.278	0.758 ± 0.655	1.316 ± 0.927	2.266 ± 1.307	2.794 ± 1.310

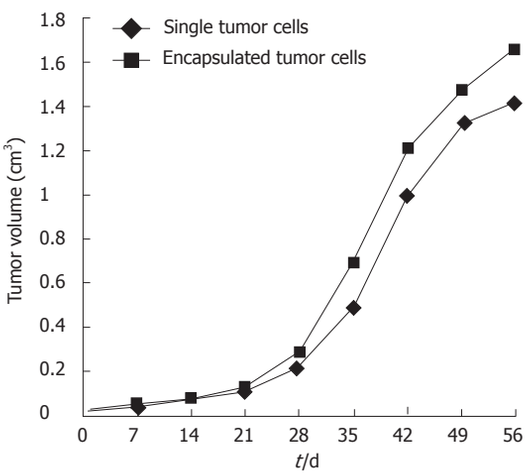

Figure 4 Growth curve of subcutaneous implantation tumor volume.

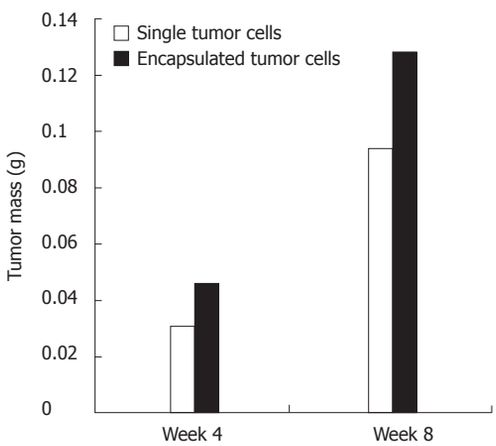

Figure 5 Tumor weights at different stages. Group of microencapsulation had statistically larger tumors at 8th wk compared with single tumor cells group yet no statistical differences at 4th wk.

group and the single tumor-cell group (6th wk: 1.316 ± 0.927 *vs* 1.188 ± 0.570, respectively, $P = 0.5348$, $P > 0.05$; 7th wk: 2.266 ± 1.307 *vs* 2.020 ± 0.989, $P = 0.5467$; 8th wk: 2.794 ± 1.310 *vs* 2.602 ± 1.100, $P = 0.5988$). The growth curve for the subcutaneous implantation tumors is shown in Figure 4.

Assessment of orthotopic implantation tumor progression

No nude mice orthotopically injected with microencapsulated cancer cells or single cancer-cell suspensions showed any signs of transplantation-related complications. No obvious changes were observed in the first four weeks postimplantation. Six weeks after implantation, the mice displayed marked abdominal distension with palpable abdominal masses. Symptoms such as obvious weight loss and anorexia were observed in nude mice injected with microcapsules or single cancer cells during the 8th wk postimplantation. As expected, no symptoms were observed in the negative control group.

It should be noted that 4 out of 14 mice from the single-cell suspension group (2 of 7 at the 4th wk and 2 of 7 at the 8th wk) in the single cell suspension group had sidewall implants. These implants were located on abdominal wall and appeared as groups of gray nodules around the site of injection; they were not counted as metastases. None of the microcapsule group had sidewall implants. The orthotopic implantation model was successfully established; the rate of successful implantation was 71.43% (10 of 14) in the single-cell suspension group and 100% (14 of 14) in the cancer-cell microencapsulation group. There was a significant difference (100% *vs* 71.43%, $P = 0.0489$) in the success rates of the cancer-cell microencapsulation and single-cell suspension groups. As a control, four additional mice were given IP injections of tumor cell suspensions (1×10^7 cells/mL 100 μL) to determine whether the metastasis was caused by seeding or represented true metastasis. These IP-injected cells resulted in tumors attached to the abdominal wall at various locations within the abdomen. However, none of the free IP injections resulted in tumor sites similar to those of the metastases from the orthotopically injected cells, such as the mesentery.

At the 4th wk postimplantation there were no statistical differences between the two groups in terms of tumor mass (0.0461 ± 0.0399 *vs* 0.0313 ± 0.021, $t = -0.81$, $P = 0.4379$). However, the microcapsules had significantly heavier tumors compared to the single tumor cells at eight weeks (0.1284 ± 0.0284 *vs* 0.0943 ± 0.0571, $t = -2.28$, $P = 0.0457$) (Figure 5). Another calculation method showed the same results (Table 2).

In terms of metastases, one mouse in the microcapsule group exhibited tumor spread to the small bowel mesentery (Figure 6C and D) at the 8th wk, which correlated with the PET-CT (Figure 7). No mice in either group had visible metastatic foci at the 4th week. At the 8th week, two mice in the microencapsulated group displayed metastatic spreading of the tumor to sites distant from the pancreas, which included the mesentery.

The histological characteristics of the primary tumors in the two groups exhibited similar morphologies at the 4th and 8th wk. Histopathological examinations confirmed that the suspected metastasis spots in the PET-CT truly originated from primary tumors. Immunohistochemical

Table 2 Number of mice related to the weight of tumor mass at different stages

Different stage (wk)	Group	No. of mice	No. of tumor mass > 500 mg	No. of tumor mass > 1000 mg	Z[1]	*P* value[1]
4th	Single cells	5	1	0	1.7618	0.0643
	Microencapsulation	7	2	3		
8th	Single cells	5	2	1	2.1971	0.0221
	Microencapsulation	7	1	6		

Data indicate the number of mice in each group that exhibited the characteristic listed. [1]Got by Wilcoxon signed rank sum test.

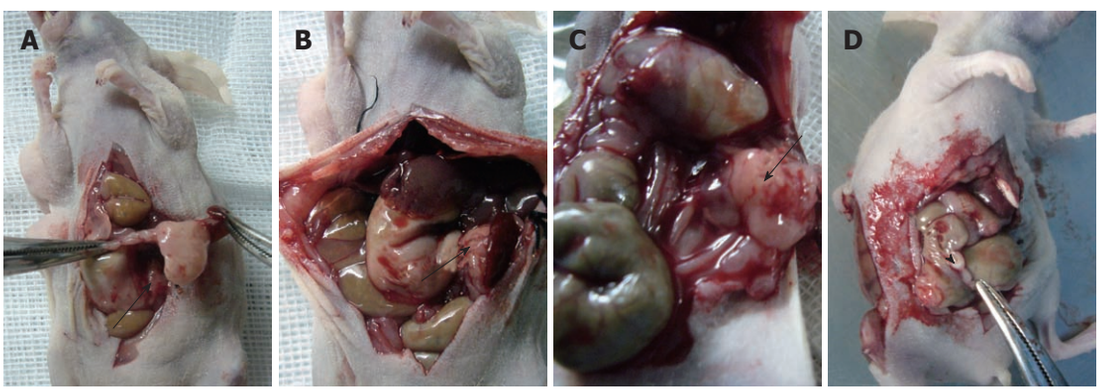

Figure 6 Orthotopic implantation tumor production. A: Single tumor cells at 4th wk post-implantation; B-D: Microencapsulated tumor cells at 8th wk post-implantation. Arrows: Primary tumor; Arrow head: Metastasis lesion.

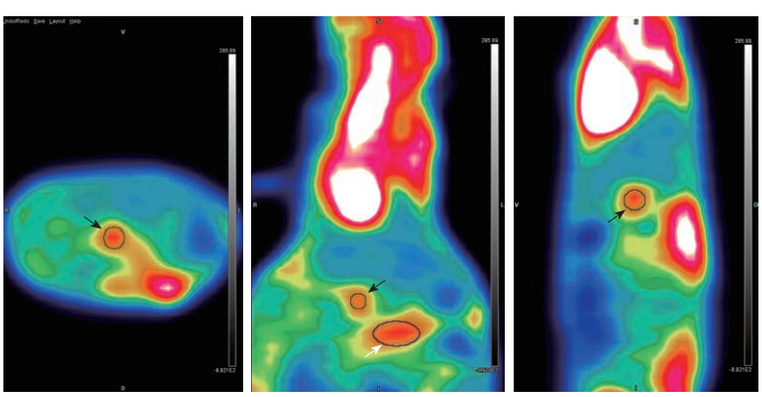

Figure 7 Positron emission tomography-computed tomography scan of mice from tumor cell microencapsulation group. White arrow points to the primary tumor, and black arrows point to metastasis lesions.

staining showed that tumors arising from both microencapsulated cells and single cells exhibited similar pathological characteristics: AE1AE3 (+), CAM 5.2 (+), EGFR (+), MIB-1 (60% +), CA199 (±), and VIM (-) (Figures 8-14).

DISCUSSION

Types of implantation nude mouse model

The majority of *in vivo* experimental studies of human cancer have been conducted *via* subcutaneous, orthotopic and heterotopic implantation nude mouse models. The subcutaneous model has the virtues of simplicity of operation, and ease of tumor assessment. Although subcutaneous xenografts generally grow well and may be phenotypically malignant locally, they tend to form pseudocapsules, resembling encapsulated benign tumors rather than infiltrative malignancies, even when derived from undifferentiated or poorly differentiated aggressive cell lines. Importantly, subcutaneously injected human cancer cells only rarely metastasize to the parenchymatous organs and do not display the signs and symptoms that may arise as a consequence of tumor growth within visceral organs[9-14]. Thus, the subcutaneous model is of limited clinical value.

Orthotopic tumor induction is regarded as being quite suitable for modeling clinical pathology because it mimics the entire process of primary tumor growth, local tumor infiltration, and subsequent distant metastatic spread. Previous studies have shown that injection of cell line suspensions[15-18] and the transplantation of tissue fragments from primary pancreatic tumors[19-21] into the pancreas of

nude mice or Syrian golden hamsters generally result in a high degree of tumorigenicity and the establishment of metastases, albeit at a varying rates[13,22]. Implantation of intact tumor fragments yields a higher rate of tumor incidence and avoids the artificial intraabdominal cell seeding associated with direct injection of pancreatic cancer cells[13].

In a clinical setting, patients with positive prognostic factors such as complete resection of the tumor and the absence of lymph node involvement or vascular invasion often succumb to metastatic disease, suggesting that metastasis may occur early in the course of the disease. Therefore, animal models that allow for the examination of cellular mechanisms in the early stage of pancreatic cancer progression are needed. Viable tumor implantation requires the preparation of subcutaneous donor tumors. Thus, implantation is more expensive and time consuming than the injection of cell-line suspensions. Moreover, transplantation of tissue fragments skips the early stage of tumor progression because the primary tumor does not develop orthotopically. Thus, the merits of injecting encapsulated tumor cells manifest themselves in a high rate of tumorigenicity and the establishment of metastases, a low rate of sidewall implants, and the ability to

mimic the early progression of tumor cells.

Advantages of the nude mouse model with microencapsulated cancer cells

Recently, immunoisolation technology has attracted increasing attention. Microcapsules were originally used for cell transplantation as an immunoisolation device[23]. The cell encapsulation techniques play a vital role in modern science. Microcapsules are spherical, with diameters that can be controlled in the range of 200-1500 μm, and feature a biocompatible semipermeable membrane that allows the bidirectional diffusion of nutrients, oxygen, secreted therapeutic products, and waste but prevents the passage of high-molecular-weight substances into the microcapsule, e.g., antibodies and immunocytes[24]. Immunodeficient mouse hosts were employed in our study; their immune systems were suppressed artificially. The mice did not exclude human tumor cells, which resulted in a higher rate of tumor incidence. Therefore, the immunoisolation function of microcapsules is not the key to this study. Most importantly, microcapsules in our study provide contained environments in which tumor cells grew in a three-dimensional manner and adjusted to the intravital environment of the host so that more viable tumor cells proliferated in the host and deviated to form tumor nodules.

Because nude mice are relatively expensive, delicate, and highly susceptible to infection, breeding and experimental conditions are strict, which means that nude mice cannot be used for large-scale studies. In large-scale studies with conventional mice, large quantities of tumor cells could be protected from immune eradication using tumor-cell encapsulation technology. Cancer cells would be efficiently protected by the outer layer of the microcapsule and could undergo interaction with the host in the process of initial administration and growth. Furthermore, prior studies have confirmed that encapsulated tumor cells are more viable than single cells, and the stability of tumor-associated genes is not affected[5,24].

The coupling of extracellular matrix (Matrigel) to alginate microcapsules enhanced cell proliferation by triggering a cascade of intracellular signaling events through cell-matrix interactions[25-27]. Due to the cell-matrix interactions, more membrane antigens such as AE1AE3 and ERGF may be present in the microencapsulated tumor cell membrane, as illustrated in Figures 9 and 12. Thus, more viable and adaptable cells are expected to proliferate during the primary period before bursting. Under our conditions, the cancer cells finally deviated outward and continued to grow in the flasks, unlike isolated cancer cells derived from a monolayer culture system. Thus, microencapsulated tumor cells are more likely to form tumor nodules.

Our experiments showed that in the subcutaneous implantation model, there were no statistical differences in terms of tumor volume and the rates of tumor incidence between the cancer-cell microencapsulation group and the single-cell suspension group. The former method displayed an obvious advantages in tumor mass (P = 0.0457, $P < 0.05$) and the rate of model success (P = 0.0489, $P < 0.05$) compared with the latter in the orthotopic implantation model. Additionally, it is impossible to distinguish sidewall implants from metastases using current pathological examinations. It is also very difficult to distinguish sidewall implants from metastases macroscopically in the advanced stage of pancreatic cancer. The fourth or eighth week postimplantation was not yet the terminal stage of pancreatic cancer according to the results of our experiments. Therefore, it was possible to distinguish seeding from true metastasis by the number and distribution of tumor nodules. Intraperitoneal tumor dissemination was an early event and macroscopically more extensive after injection and was most likely initiated by cells lost during the injection procedure. Thus, sidewall implants usually presented as clusters of gray nodules. For mice without distant tumors spreading to visceral organs such as the liver or mesentery at the 4th to 8th wk postimplantation, the tumor nodules described above can be seen as sidewall implants. During our experiments, we observed sidewall implants in four mice from the single-cell suspension group and did not count them as successful implantations. The primary modes for the spreading of tumors to distant sites are lymphatic and hematogeneous metastasis. Metastases usually appeared as a single nodule or dispersed nodules.

Previous studies using direct cell implantation into the peritoneal cavity, the portal vein, the spleen or the implantation of pancreatic tumor tissue grown subcutaneously in a primary animal have reported higher rates of distant tumor spread, but these models do not replicate the cell signaling and biological changes necessary for a primary tumor to develop viable secondary metastatic cell implantation and growth[3,14,22,28]. Matrigel has been reported to facilitate tumor formation and growth, but it is unknown whether such components exert similar effects on tumor metastasis[26,29]. Our experiments showed that the microencapsulated cancer-cell group was not statistically different from the single-cell suspension group with respect to metastases (2 *vs* 0, 28.57% *vs* 0%, χ^2 = 2.333, P = 0.2308, $P > 0.05$), which may be attributed to the small sample size ($n < 40$) and must be confirmed by further large-scale experiments.

The use of PET-CT in the model allowed for intravital monitoring of tumor growth and improved our evaluation of the extent of disease and metastasis at necropsy. The ability to monitor tumor progression intravitally will facilitate the evaluation of therapeutic interventions.

In summary, we have described a novel orthotopic implantation technique for human pancreatic cancer in a nude mouse model. Compared with the orthotopic implantation approach using direct tumor-cell injection, the implantation of encapsulated tumor cells yielded a comparably higher rate of tumorigenicity and avoided the typically associated artificial intra-abdominal cell seeding; it thus appears to be the favorable technical approach. It is worth attempting to apply tumor-cell encapsula-

tion technology in rats and even in conventional mice to establish an orthotopic model by exerting its advantage as an immunological barrier. By studying the pancreatic cancer model of microencapsulated tumor cells, it is possible to improve our ability to investigate the mechanism of tumor progression and metastasis. This technique provides a novel orthotopic model for anticancer drug development, screening and testing.

COMMENTS

Background

Pancreatic adenocarcinoma (PA) is an aggressive malignancy; therefore, animal models that allow further examination of pancreatic cancer progression are urgently needed. The majority of *in vivo* experimental studies of human cancer have been conducted in subcutaneous, orthotopic and heterotopic implantation nude mouse models. Current animal models of PA have low rates of tumor progression and metastasis.Microcapsules are spherical, with diameters that can be controlled in the range of 200-1,500 μm and a biocompatible semipermeable membrane, that allows the bidirectional diffusion of nutrients, oxygen, secreted therapeutic products, and waste but prevents the passage of high-molecular-weight substances such as antibodies and immunocytes into or out of the microcapsule.

Research frontiers

Orthotopic tumor induction is regarded as being highly suitable for modeling clinical pathology because it mimics the whole process of primary tumor growth, local tumor infiltration, and subsequent distant metastatic spread. The implantation of intact tumor fragments yields a higher rate of tumor incidence and avoids the artificial intra-abdominal cell seeding associated with the direct injection of pancreatic cancer cells but skips the early stages of tumor progression. Thus, animal models that allow for the examination of cellular mechanisms during the early stages of pancreatic cancer progression are needed.

Innovations and breakthroughs

The microencapsulation technique displays advantages in the rate of successful implantation and tumorigenicity.

Applications

It is possible to improve our ability to investigate the mechanism of tumor progression and metastasis using this new assay, which can provide a novel orthotopic model for anticancer drug development, screening and testing.

Terminology

Microencapsulation: a method of encapsulating cells in small microcapsules with semipermeable membranes.

Peer review

This study evaluated the effectiveness of a mouse model using an encapsulated pancreatic tumor cell line as a PA assay in comparison with the classical model using the injection of single tumor cells. The authors found no statistically significant differences among the different models used in terms of tumor mass and tumor presence.

Abstract

AIM: To establish a multiple detection method based on comparative polymerase chain reaction (cPCR) and ligase detection reaction (LDR)/ligase chain reaction (LCR) to quantify the intestinal bacterial components.

METHODS: Comparative quantification of 16S rDNAs from different intestinal bacterial components was used to quantify multiple intestinal bacteria. The 16S rDNAs of different bacteria were amplified simultaneously by cPCR. The LDR/LCR was examined to actualize the genotyping and quantification. Two beneficial (*Bifidobacterium*, *Lactobacillus*) and three conditionally pathogenic bacteria (*Enterococcus*, *Enterobacterium* and *Eubacterium*) were used in this detection. With cloned standard bacterial 16S rDNAs, standard curves were prepared to validate the quantitative relations between the ratio of original concentrations of two templates and the ratio of the fluorescence signals of their final ligation products. The internal controls were added to monitor the whole detection flow. The quantity ratio between two bacteria was tested.

RESULTS: cPCR and LDR revealed obvious linear correlations with standard DNAs, but cPCR and LCR did not. In the sample test, the distributions of the quantity ratio between each two bacterial species were obtained. There were significant differences among these distributions in the total samples. But these distributions of quantity ratio of each two bacteria remained stable among groups divided by age or sex.

CONCLUSION: The detection method in this study can be used to conduct multiple intestinal bacteria genotyping and quantification, and to monitor the human intestinal health status as well.

INTRODUCTION

Intestinal bacteria consist of more than 500 species with the concentrations ranging from 10^2-10^9/mL[1], and play

important roles in human growth, immunity, drug metabolism, pathogenesis and health maintenance. Intestinal bacterial components can be divided into beneficial and pathogenic bacteria according to their effects on human health[2]. Previous research showed the quantity of *Enterobacterim, Bifidobacterium, Enterococcus* and *Lactobacillus* varied largely among the infants, middle/old-aged and diarrhea groups[3], which was helpful to know the status of human intestinal ecology. Quantitative assay of such species are of great value in clinical practice and scientific researches. However, most of the interested bacteria differ a lot in the amount between samples[4,5], which is a big challenge to quantitatively detect multiple intestinal bacteria simultaneously.

In this study, comparative polymerase chain reaction (cPCR) and ligase detection reaction (LDR)/ligase chain reaction (LCR) methods were first employed to quantify five intestinal bacterial species simultaneously based on their 16s rDNAs. The selected target bacteria consisted of three conditional pathogenic bacteria (*Enterococcus, Enterobacterium, Eubacterium*) and two beneficial bacteria *Bifidobacterium* and *Lactobacillus*.

cPCR has been used to quantify nucleic acids for many years[6]. In a cPCR reaction, the target and the internal reference templates have the same primer recognition sequence and length, and similar internal sequences, which guarantee the amplification efficiency between the templates[7]. Therefore, the amount of the amplified products can precisely reflect the initial concentrations of their own templates. The highly conserved sequences of the bacterial 16s rDNAs fit well with the requirement of cPCR. We applied one pair of universal primers to amplify multiple target bacterial DNAs simultaneously, each kind of bacterial 16s rDNA was a competitive template of the others.

LDR is an eminent method to genotype low-abundant DNA under high backgrounds with a high specificity[8,9]. LCR has even higher amplification efficiency than LDR, which was introduced to this study to detect the lower abundant templates. Given that the ligation efficiency of different probes kept constant among tubes under the same reaction conditions with the same running cycle number, the ratio of fluorescence signals of the LDR/LCR products could reflect their initial ratio of the template concentrations.

Standard curves were made to verify the feasibility of our method and were applied to subsequent quantification of samples. Two internal controls were added to monitor the whole detection flow. One was applied to the LDR detection, the other to the LCR detection. The internal controls were added into the mixed standard DNAs or sampled DNAs at a fixed concentration before PCR amplification.

Eighty-two fecal samples (45 from males and 37 from females) were used to test the method for specimen detection, and all target bacteria could be detected in these samples. The distributions of the quantity ratio between each two bacterial species were obtained. Samples were also divided into groups by age or gender, the distribution diversities between groups were analyzed by non-parametric test.

MATERIALS AND METHODS

Bacterial strains and culture conditions

Bifidobacterium longum, *Lactobacillus acidophilus* and *Lactobacillus casei* strains were donated by Department of Medical Microbiology and Parasitology, Shanghai Jiao Tong University School of Medicine. *Bifidobacterium longum* was grown anaerobically in MRS broth with L-Cysteine hydrochloride at 37 ℃ for 48 h. *Lactobacillus* was grown anaerobically in MRS broth at 37 ℃ for 48 h.

Collection and preparation of fecal samples

Fecal samples were collected from healthy adults aged 20-86 years who had not received antibiotics or other intestinal drugs within 3 mo prior to sampling at the First Hospital of Suzhou University. Samples were collected in sterile bags, with the wet weight of 4 g. A fecal sample was added into 6 mL of sterile phosphate-buffered saline (PBS; 0.05 mmol/L, pH 7.4) and mixed by inverting and vortexed for 5-10 min. The sample was then centrifuged at 500 × *g* for 5 min to collect the upper phase. The upper phase was then centrifuged to collect the bacterial cells in the pellets. The resulting pellets were washed in 20 μL pre-cooled ethanol for three times and then stored at 4 ℃ until use.

DNA extraction from bacterial cultures and fecal samples

For cultured bacteria, genome DNA was extracted from 1 mL harvested culture using bacteria genome DNA extracting kit (HuaShun W6511, Shanghai, China). For fecal samples, 200 μL TE containing lysozyme (20 mg/mL) was added to each pretreated fecal sample, well mixed, and then incubated at room temperature for 40 min. The bacterial genome DNA was extracted using column bacterial genome DNA extraction kit (Sangon, Shanghai, China).

Preparation of bacterial standard plasmid DNA

The specific 16s rDNA of each bacterial species was am-

plified by genus or species specific primers (Table 1) with the PCR product about 1500 bp in length. The amplified bacterial 16s rDNA was cloned in *Escherichia coli* (*E. coli*) DH5α by the pMD 18-T Vector system (Takara, Japan). Colonies carrying the specific inserts were cultured and their plasmid DNAs were extracted using a Spin Column Plasmid DNA Minipreps Kit (Sangon, Shanghai, China). The concentration of the extracted plasmid DNA was measured by ultraviolet spectrophotometer and then diluted to a fixed concentration as genus standard plasmid DNA (equivalent to 10^9/μL).

Universal primers and specific probes

Universal primers and LDR probes were designed according to the DNA sequences of *16s rRNA* gene available at GenBank.

For each kind of bacteria, more than fifty 16s rDNA sequences were used to align together (DNAsistant 2.0), a section containing three conserved regions and two variable regions was selected as the target segment. Universal primers were complementary to the conserved sequence flanking the target region; the variable region was the target of their specific LDR/LCR probes. Therefore, all the sequences of each bacterial species could be amplified by universal primers. LDR/LCR probes were genus-specific, except for *Lactobacillus*. As there was not a specific region matching with all *Lactobacillus* species, the *Lactobacillus* genus could be divided into two groups. Each group had a specific uniform sequence, and two specific probe sets were designed for typing the two groups of *Lactobacillus* genus.

The GenBank program Basic Local Alignment Search Tool was used to ensure that the proposed primers and probes were target specific. Ligation probes are listed in Table 2. Two sets of probe mixture for multiplex ligation reactions are shown in Table 1. Universal primers: up (5'-CAGGATTAGATACCCTGGTAGT-3'), down (5'-TTGCGCTCGTTGCGGGACTT-3').

Construction of internal control

Two oligonucleotides of internal control were synthesized to monitor the whole detecting flow. These oligonucleotides were approximately 310 bp in length, comparative to that of the bacterial 16s rDNA aplicon amplified with universal primers. Sequences at both ends were completely complementary to the universal primers, but the middle part was random. The internal control DNA was inserted into a plasmid and the concentration of internal control plasmid DNA was fixed to the same as bacterial standard plasmid DNA (equivalent to 10^9/μL).

Preparation of standard curve

Standard bacterial and internal control plasmid DNA was used to simulate the sample detection and verify the feasibility of the quantitative genotyping method. Each standard DNA was diluted to five series of concentrations. Six standard DNAs and two internal control DNAs were mixed together according to the symmetrically distributing test design[10] (Tables 2 and 3). The mixed templates were then applied to cPCR and LDR/LCR by two sets of mixed probes, and the fluorescence signal was collected by the ABI 377 sequencing system. Data of each two

"1" is a fixed concentration unit equivalent to 10^5/μL which was diluted by 10^4 from standard DNA concentration. IC: internal control.

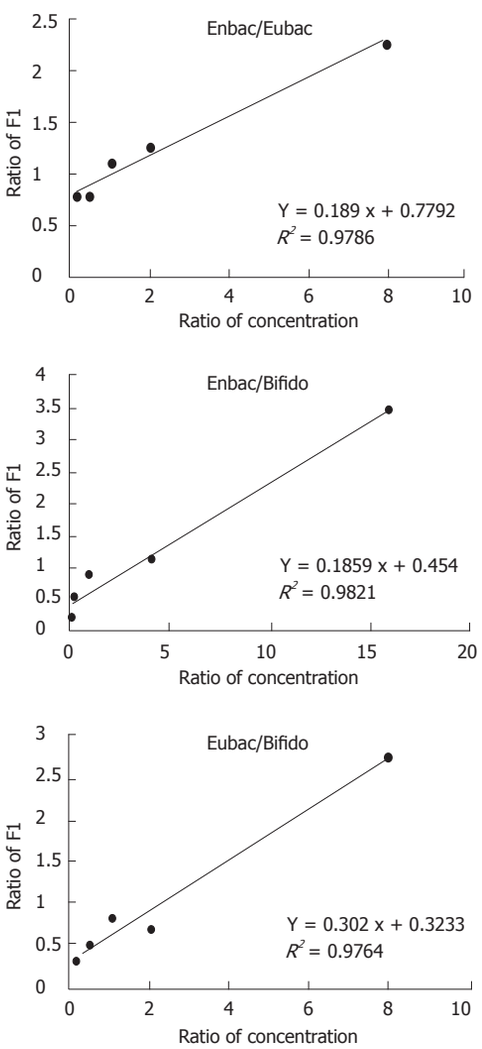

Figure 1 Linear relationship between the initial template concentrations and fluorescence signal intensity of ligase detection reaction/ligase chain reaction in standard curve test. The results of *Enterobacterium* (Enbac)/*Eubacterium* (Eubac), *Enbac/Bifidobacterium* (Bifido) and Eubac/Bifido tested by ligase detection reaction probes were presented. The linearity analyses were done twice, and results had a high reproducibility (data not shown).

kinds of standard DNAs were used to obtain the linear equation. The ratio of two collected fluorescence signals of two templates and the ratio of their concentrations were used to simulate the linearity. The standard curves were prepared by combining all the equations.

cPCR and LDR/LCR

The mixed standard DNA and sample DNA were processed as the same protocol. The cPCR reaction mixture consisted of 1 × PCR Buffer, 2 mmol/L $MgCl_2$, 0.2 mmol/L deoxynucleoside triphosphate, 0.5 mmol/L universal primers, 1.0 U *Taq* DNA polymerase, and 1 μL of template DNA in a final volume of 10 μL. The PCR thermocycling program was: 95 ℃ for 15 min; 40 cycles of 94 ℃ for 30 s, 55 ℃ for 30 s, and 72 ℃ for 60 s; and 72 ℃ for 7 min. The following LDR/LCR reaction mixture consisted of 1 × LDR Buffer, 0.1 mmol/L probe mixture No. 1 or No. 2 (Table 3), 4.0 U *Taq* ligase, and 1 μL of PCR products in a final volume of 10 μL. The LDR/LCR thermocycling program was: 94 ℃ for 2 min; 25 cycles of 94 ℃ for 30 s, and 60 ℃ for 2 min.

Sample detection

Before the detection, 10^5 copies of internal control template were added to each sample. The mixed samples were subject to cPCR and LDR (with probe mixture No. 1) along with designed mixed standard DNAs, 377 sequencer was used to collect the signals. If the fluorescence signal of any specific probe was not obtained by LDR, the PCR product was subject to LCR by probe mixture No. 2.

RESULTS

Linearity between template initial concentrations and their LDR/LCR fluorescence signals

Standard DNAs were mixed at different concentrations (Table 4) and applied to LDR and LCR test simultaneously. The results showed that the fluorescence intensity of each two templates was correlated with their initial concentrations in good linearity by LDR probes (R^2 > 0.97) (Figure 1) while the LCR probes could not contribute to a satisfactory linearity (R^2 ranged from 0.57 to 0.96).

Table 5 Statistics of sample detection

Bacterium	*Enterococcus*	*Enterobacterium*	*Eubacterium*	*Bifidobacterium*		*Lactobacillus casei*	*Lactobacillus acidophilus*

LDR: Ligase detection reaction; LCR: Ligase chain reaction.

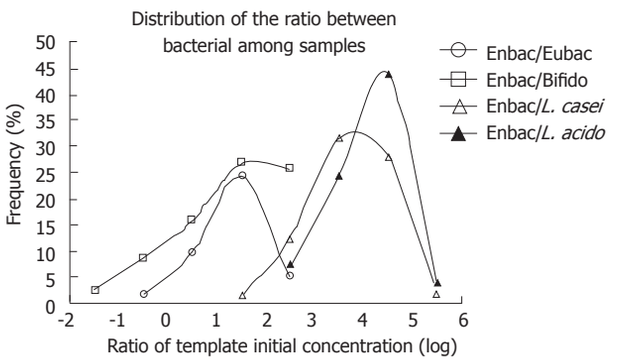

Figure 2 Distributions of ratio between each two bacteria. Enterobacterium was used to compare with other four species, respectively. The abscissa is the ratio of template concentration, divided into a 10-fold section. The ordinate is the frequency of each ratio section between two species. Enbac: *Enterobacterium*; Eubac: *Eubacterium*; Bifido: *Bifidobacterium; L. casei: Lactobacillus casei; L. acido: Lactobacillus acidophilus*.

Sample detection

Eighty-two samples were detected for the six bacterial strains. The detected rates ranked as: *Lactobacillus casei* > *Enterobacterium* = *Lactobacillus acidophilus* > *Bifidobacterium* > *Eubacterium* > *Enterococcus* (Table 5). *Eubacterium* and *Bifidobacterium* had the largest quantities among the six bacteria, which could be detected by LDR probes. In *Bifidobacterium,* 46 of the 82 samples could be detected by LDR probe, the other 23 samples were detected by LCR probe. *Lactobacillus* and *Enterococcus* were able to be detected only by LCR probes, while the detection rate of the former was much higher than the latter (> 90% *vs* 35.37%).

The ratio of the initial template concentrations between two bacteria were calculated by combining the LDR/LCR fluorescence signals and the standard curves. *Eubacterium* was selected as the comparing standard because of its highest detection rate and relatively steady quantity. The other bacteria were compared with *Eubacterium* except for *Enterococcus* because of its insufficient statistic data.

The ratio of two bacteria templates ranged from < 0.01 to > 10^4 deduced from the fluorescence signals and standard curves. In order to compensate the unsatisfactory linearity of the LCR products, the ratio of the initial template concentration was divided into several sections with 10-fold each. Frequencies of ratios in each section among all the samples were determined. The distributions of the quantity ratio between each two bacteria were plotted (Figure 2). Variations between distributions were analyzed by nonparametric test. There was on significant difference in the distributions between *Enterobacterium*/*Eubacterium* and *Enterobacterium*/*Bifidobacterium* (P = 0.605), which indicated that the quantity of *Bifidobacterium* and *Enterobacterium* kept constant in all the samples, while the distributions varied significantly among the other samples ($P < 0.05$).

These samples were divided into different groups by gender or age (young, 20-39 years; middle, 40-59; and old, above 60), and the bacterial ratio distribution was compared among groups through nonparametric test, without significant difference.

Detection sensitivity for single template

The *Bifidobacterium* standard DNA was selected and was serially diluted by 10-fold. The LDR and LCR detection could both obtain signals at a concentration of 10^{-9} of the original products (1-10 copies/μL) after 40 cycles of PCR and 25 cycles of LDR.

Detection limits for multiple templates

There is a detection limit of the concentration range of templates because of the amplification limit of PCR and LDR and the signal detection range of 377 sequencer.

The detection limit of LDR probes was tested by mixing standard DNAs of *Eubacterium* and internal control 1# at a serial ratio. The concentrations and detection results of the two components are shown in Table 6. The results showed that signals could be obtained by LDR probes simultaneously at the concentration varying between the two templates within 30 times.

The detection limit between LDR and LCR probes was tested by *Bifidobacterium* and internal control 1# standard DNAs. The concentrations and detection results of the two components are listed in Table 6. The results showed that both LDR and LCR signals could be detected simultaneously, even at template concentrations varying within 10 000 times. The detection limit between LCR probes was tested by *Bifidobacterium* and *Lactobacillus.casei* standard DNAs. The concentrations and detection results of the two components are shown in Table 6.

DISCUSSION

LDR and LCR were both introduced to this study to genotype and comparatively quantify the final cPCR products, which extended the quantitative detection range significantly. LDR is a linear amplification process, while LCR is an exponential one. The templates of high quantity samples were detected by LDR probes, while those of low quantity by LCR probes. Therefore, the ligation

[1]The standard concentration of standard DNA equivalent to 10^9/μL; [2]The 100 times dilution of the standard concentration.+: the positive result; -: the negative result. LDR: Ligase detection reaction; LCR: Ligase chain reaction; Bifido: *Bifidobacterium*; *L. casei*: *Lactobacillus casei*.

products of different templates could be detected on one platform simultaneously.

The universality of universal primers was validated as they could direct the amplification of all the investigated bacterial standard DNAs. By mixed LDR/LCR probes, only one fluorescence signal of the target product was obtained after the LDR/LCR reaction templated by all bacterial standard PCR products. PCR products of other bacterial 16s rDNA including *E. coli*, *Clostridium coccoides*, *Bacteroides* and *Clostridium leptum* were not able to produce fluorescence signals (data not shown).

According to the standard curves, the ratio of LDR products and that of the initial template concentrations have perfect linear relationship because of the stable ligation efficiency in the linear amplification process. However, the relationship between the ratio of signals from LCR probes and that of the initial template concentrations did not show good linearity, which implied that the efficiency of the exponentially amplifying process could not keep stable in every cycle and between different reaction tubes. Nevertheless, on a large scale (10-fold), the amount of the LCR product was able to reflect the concentration of the templates, because of the limited number of reaction cycles (25 cycles) and the same reaction condition.

The quantity differences were shown between bacterial species, while the distribution of quantity ratio among species showed no difference in healthy human population whether grouped by sex or by age.

In this study, a precise genotyping and a stable comparative quantification were achieved by combining cPCR and LDR, and the detection throughout could be developed to tens of target bacteria at one time. Although the template concentration range of quantification needs to be extended and optimized, the cPCR and LDR/LCR method has shown its potential in intestinal bacteria detection in both basic research and clinical practice.

ACKNOWLEDGMENTS

We would like to thank our colleagues from the Department of Medical Microbiology and Parasitology, Shanghai Jiao Tong University School of Medicine for donating the bacterial strains and those from the First Hospital of Suzhou University for their help in sample collection, and Chen B for her experimental assistance and cooperation.

COMMENTS

Background

Increasing researches suggested that the human health status was tightly correlated with the quantitative variation of intestinal bacterial components. However, it is a big challenge to quantify multiple intestinal bacterial components simultaneously, for the significantly quantitative variations between different components and individual samples.

Research frontiers

Comparative quantification polymerase chain reaction (cPCR) has been used to quantify nucleic acids for many years. Due to the similarity of 16S rDNAs of different intestinal bacteria, it is hard to quantify multiple intestinal bacteria by cPCR alone. ligase detection reaction/ ligase chain reaction (LDR/LCR) is an eminent method to genotype low-abundant DNA under high backgrounds and its merit of high specificity fits for multiple detections. In this study, the authors tried to combine the advantages of both cPCR and LDR/LCR to fulfill multiple quantitative detections.

Innovations and breakthroughs

Using the universal primer target at the 16S rDNA of intestinal bacteria, cPCR could get amplifying product of nearly all species with similar efficiency. LDR could achieve precise genotyping and quantification of different bacteria simultaneously. This study demonstrated the possibility to realize accurate multiple quantification of intestinal bacteria by the combined cPCR and LDR/LCR.

Applications

By the detection method used in this study, the authors could quantify tens of intestinal bacteria simultaneously after test optimization. And it could be used to monitor the intestinal health status of human as well.

Peer review

To quantify multiple intestinal bacterial components simultaneously, the authors described a multiple detection method for comparative quantification of 16S rDNA from different intestinal bacterial components based on cPCR and LDR/LCR methods. The results show differences between bacterial species, while the distribution of quantity ratio among species made no difference in healthy human population. This study indicates potential combination of cPCR and LDR/LCR method in measuring multiple intestinal bacterial components simultaneously.

Abstract

AIM: To evaluate the efficacy of intraductal ultrasonography (IDUS) in the diagnosis of non-opaque, common bile duct stones.

METHODS: A total of 183 patients (102 males, mean age 73 years; 81 females, mean age 70 years) with suspected common bile duct stones diagnosed through abdominal computed tomography (CT), magnetic resonance imaging (MRI), and abdominal Type-B ultrasound were included in the study. The diagnosis was confirmed through endoscopic retrograde cholangiopancreatography (ERCP) followed by IDUS.

RESULTS: A total of 183 patients with suspected common bile duct (CBD) stones were included in the study as follows: 36 patients with high-density CBD stones, 68 patients with sand-like stones, 44 patients with low-density stones, 21 patients with ampullary cancer, and 14 patients with pancreatic cancer. Conventional imaging revealed 124 cases of choledochectasia, and only 36 cases of suspected CBD stones; ERCP revealed 145 cases of CBD stones with three missed diagnoses. IDUS revealed 148 cases of CBD stones, 21 cases of ampullary tumors, and 14 cases of pancreatic cancer.

CONCLUSION: IDUS was more effective in the diagnosis of bile duct stones than ERCP, upper abdominal CT or upper abdominal MRI.

Key words: Biliary intraductal ultrasonography; Endoscopic retrograde cholangiopancreatography; Common bile duct stones; Non-opaque stones; Sand-like stones

INTRODUCTION

Common bile duct (CBD) stones can cause a range of serious complications such as obstructive jaundice, biliary tract infection, and pancreatitis. These stones may even cause severe septic shock and lead to life-threatening conditions[1]. With the continuous development of endoscopic technology, endoscopic treatment has now become a standard diagnostic procedure for bile duct stones. Endoscopic retrograde cholangiopancreatography (ERCP) has long been considered the gold standard for the diag-

nosis of CBD stones because it can accurately image the pancreatic duct system. With diagnostic accuracy higher than 90%, ECRP is significantly more effective in the diagnosis of extra-hepatic bile duct stones than computed tomography (CT), or magnetic resonance imaging (MRI). However, misdiagnoses and missed diagnoses still occur due to operator error and variations in the contrast agent concentration and stone density[2]. Biliary intraductal ultrasonography (IDUS), which has emerged as a safe and effective new method for the diagnosis of CBD stones in recent years, combines high-resolution ultrasound imaging with endoscopy, thereby preventing imaging of the pancreatic duct system from being affected by intestinal gas. It is accurate in the diagnosis of smaller non-opaque stones and low-density stones, i.e., stones with density similar to that of the contrast agent. Through the IDUS examination of ERCP surgery patients between January 2009 and August 2010, in this study we investigated the efficacy of IDUS combined with ERCP in the diagnosis of bile duct stones.

MATERIALS AND METHODS

Materials

A total of 183 ERCP surgery patients treated between January 2009 and August 2010 were retrospectively analyzed. The patient population was as follows: 102 males, mean age 69 years; 81 females, mean age 71 years. All patients exhibited upper abdominal pain, nausea, vomiting, chills, fever and jaundice. The preoperative imaging studies included abdominal CT or upper abdominal enhanced MRI + magnetic resonance cholangiopancreatography (slice thickness of 7 mm, plane scanning with layer gap of 3 mm, cross section T1W1/T2W1), and these examinations were done at the Radiology Department of Shanghai Tenth Hospital, revealing 124 patients with suspected choledochectasia, 36 patients with suspected common bile duct stones, and 23 patients with negative imaging but suspicious clinical presentation and laboratory test results.

Instruments and methods

IDUS surgery was performed in all cases. First, we conducted preoperative preparations for conventional ERCP. Next, ERCP was carried out with inclusion of the following three procedures: cholangiography after successful wire-guided bile duct intubation; a partial intraoperative duodenal papillotomy based on the specific circumstances; and biliary tract imaging to determine whether a stone or a stenosis was the cause of the clinical findings. This was followed by the insertion of an ultrasound scanning probe along the guide wire to observe the bile ducts. The ultrasound probe was removed after the IDUS examination was completed, and the subsequent stages of the ECRP procedure, which included biliary stent placement and nasal biliary drainage, were determined from the specifics of the clinical situation, e.g., the presence of bile duct stones. The criteria for IDUS diagnosis of bile duct stones were evaluated by experts who were experienced in IDUS imaging.

Statistical analysis

The sensitivity, specificity, negative predictive value, positive predictive value, and diagnostic accuracy of the comparisons were calculated. The SPSS13 statistical package was used for the statistical analysis. The χ^2 test was used to compare rates, and the Scheffé method was used for pairwise comparisons among groups. P values < 0.05 were considered statistically significant.

RESULTS

Case information

A total of 183 patients with suspected CBD stones were included in the study as follows: 36 patients with high-density CBD stones, 68 patients with sand-like stones, 44 patients with low-density stones, 21 patients with ampullary cancer, and 14 patients with pancreatic cancer.

Conventional imaging in the diagnosis of common bile duct stones

Conventional imaging revealed 124 cases of choledochectasia, and only 36 cases of suspected CBD stones in the 148 confirmed cases; this represents a diagnosis rate of 24.3%, sensitivity of 24.3%, specificity of 100%, and diagnostic accuracy of 38.3%.

Endoscopic retrograde cholangiopancreatography in the diagnosis of common bile duct stones

ERCP revealed 145 cases of CBD stones with three missed diagnoses, which resulted in a diagnostic accuracy of 98%. The remaining 35 cases that did not involve CBD stones comprised 21 cases of ampullary tumors and 14 cases of pancreatic cancer; all were diagnosed with an accuracy of 100%. The sensitivity, specificity, and accuracy of ERCP were 98%, 100% and 98.4%, respectively.

Intraductal ultrasonography in the diagnosis of common bile duct stones

IDUS revealed 148 cases of CBD stones, 21 cases of ampullary tumors (Figure 1), and 14 cases of pancreatic cancer (Figure 2), which resulted in a specificity of 100%, sensitivity of 100%, and accuracy of 100%. Of the 148 cases of CBD stones, 27 patients underwent cholecystectomy and CBD stones were intraoperatively confirmed in all cases.

Complications

Of the 183 cases included in the study, 3 patients showed pancreatitis after ERCP, which represents an incidence rate of 1.64% (3/183). The pancreatitis complications improved after conservative treatment that included fasting, acid-suppression, inhibition of enzymes, and anti-inflammatory drugs. No other complications such as bleeding or perforation were observed (Table 1).

DISCUSSION

CBD stones are commonly encountered in clinical settings, and jaundice is usually observed as the first symp-

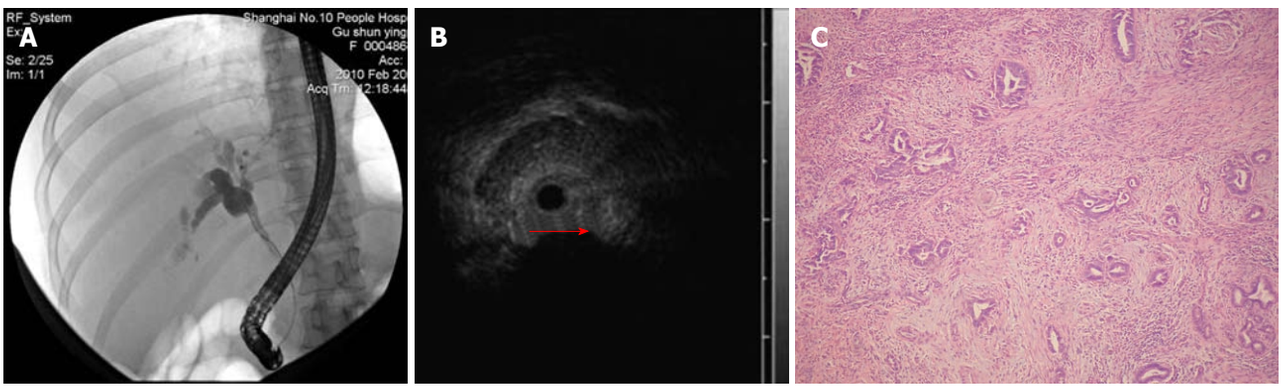

Figure 1 Ampullary tumor. A: Presentation in endoscopic retrograde cholangiopancreatography; B: Presentation in intraductal ultrasonography, red tag displays the focus; C: Histopathology change.

Table 1 Comparison of the diagnostic accuracy of common imaging procedures with that of endoscopic retrograde cholangiopancreatography and intraductal ultrasonography + endoscopic retrograde cholangiopancreatography for common bile duct stones

	Diagnosis	Missed diagnosis	Accuracy (%)
Common imaging (n = 148)	36	112	24.3
ERCP (n = 148)	145	3	98
ERCP + IDUS (n = 148)	148	0	100

ERCP: Endoscopic retrograde cholangiopancreatography; IDUS: Intraductal ultrasonography.

tom[3]. Although the diagnosis of such a disease using surface ultrasonography, CT and MRI has been greatly improved, their diagnostic accuracy is still not ideal[4]. In this study, conventional imaging showed an accurate preoperative diagnosis rate of 24.3%.

In ERCP images, opaque CBD stones clearly appear as round or crescent shaped objects. Although cholangiectasis is also typically observed, other low-density and sand-like stones are not visible[5]. ERCP, as a direct biliary imaging method, exhibits high resolution, which not only helps in further clarifying the location and number of stones, but also facilitates further interventions. Therefore, since the 1970s, ERCP has been the gold standard for the diagnosis of extrahepatic bile duct stones[6]. However, the evaluation of biliary pathological changes through ERCP is evaluated by contrast agent and image shapes of X-ray. Therefore, several factors may contribute to misdiagnosis and missed diagnoses using ERCP, such as the nature and size of the stones, air bubbles in the bile duct, variations in contrast agent concentration, and the injection rate[7]. The diagnostic accuracy of ERCP in this study was 98%. Endo-ultrasonography (EUS), which is a technological combination of ultrasonography and direct endoscopic visual inspection, was introduced in the 1980s. After years of technological development, EUS now plays an important role in the diagnosis and treatment of digestive diseases[8]. Miniature ultrasonic probes exhibit small diameters and high frequencies. In this manner, IDUS can be used to explore the pancreatic duct *via* the guide wire during ERCP. When used in the bile duct, IDUS repeatedly scans the involved anatomy and generates cross-sectional images of the bile duct wall and the lesion, which clearly show the inner structures with reduced interference. Lesions that are at least 0.5 cm in diameter, as well as the structure of adjacent organs such as the liver, portal vein, pancreas and portions of the pancreatic duct, can be clearly observed. Determining the specific causes of obstructive jaundice and evaluating the severity of such lesions is valuable[9]. In this study, based on the previously reported criteria for the diagnosis

of CBD stones, IDUS showed a diagnostic accuracy of 100%, which is significantly higher than that of ERCP and other imaging methods. For the diagnosis of CBD malignant strictures, IDUS is also more accurate than surface imaging and ERCP. In this study, no malignant lesions were diagnosed prior to the ERCP procedures; however, with the use of IDUS, 21 cases of ampullary cancer and 14 cases of pancreatic cancer were found. Therefore, IDUS is useful in the early diagnosis of bile duct or ampullary tumors[10].

Bleeding, perforation, and acute pancreatitis are major complications of ERCP[11]. In this study, severe pancreatitis and gastrointestinal perforation did not occur in any of the cases; however, there were three cases of pancreatitis after ERCP with minimal edema that improved after conservative treatment such as enzyme inhibition, acid-suppression, and anti-inflammatory drug administration. In conclusion, the use of IDUS in combination with ERCP is a safe and reliable method of increasing the diagnostic accuracy of ERCP.

COMMENTS

Background

The incidence of choledocholith is currently rising with the improvement of living standards and changes in food habits. Common bile duct (CBD) stones can cause a range of serious complications such as obstructive jaundice, biliary tract infection, and pancreatitis. A safe and accurate method to diagnosis CBD stones is urgently needed.

Research frontiers

Endoscopic retrograde cholangiopancreatography (ERCP) is a significant method in the diagnosis of CBD stones. However, misdiagnoses still occur. IDUS is a new, safe method for the diagnosis of bile duct pathological changes.

Innovations and breakthroughs

This is the first research to report the outcome of intraductal ultrasonography (IDUS) in the diagnosis of non-opaque stones. IDUS showed a diagnostic accuracy of 100%.

Applications

IDUS is useful in the diagnosis of non-opaque, common bile duct stones and early diagnosis of bile duct or ampullary tumors.

Peer review

The paper evaluates the efficacy of intraductal ultrasonography (IDUS) in the diagnosis of non-opaque, common bile duct stones. The study is very interesting.

Abstract

AIM: To investigate the role of prophylactic antibiotics in the reduction of mortality of severe acute pancreatitis (SAP) patients, which is highly questioned by more and more randomized controlled trials (RCTs) and meta-analyses.

METHODS: An updated meta-analysis was performed. RCTs comparing prophylactic antibiotics for SAP with control or placebo were included for meta-analysis. The mortality outcomes were pooled for estimation, and re-pooled estimation was performed by the sensitivity analysis of an ideal large-scale RCT.

RESULTS: Currently available 11 RCTs were included. Subgroup analysis showed that there was significant reduction of mortality rate in the period before 2000, while no significant reduction in the period from 2000 [Risk Ratio, (*RR*) = 1.01, *P* = 0.98]. Funnel plot indicated that there might be apparent publication bias in the period before 2000. Sensitivity analysis showed that the *RR* of mortality rate ranged from 0.77 to 1.00 with a relatively narrow confidence interval ($P < 0.05$). However, the number needed to treat having a minor lower limit of the range (7-5096 patients) implied that certain SAP patients could still potentially prevent death by antibiotic prophylaxis.

CONCLUSION: Current evidences do not support prophylactic antibiotics as a routine treatment for SAP, but the potentially benefited sub-population requires further investigations.

Key words: Severe acute pancreatitis; Prophylactic antibiotics; Mortality; Meta-analysis

INTRODUCTION

Acute pancreatitis (AP) is still a common pancreatic disease, with an increasing incidence rate during the past two decades[1]. In the United States, AP accounts for more than 220 000 hospital admissions annually[2]. Severe acute pancreatitis (SAP) composes about 20% of AP, with a high mortality rate around 20%[3]. For several decades, the administration of prophylactic antibiotics has been one of the great controversies worldwide about the management of SAP.

Totally, the mortality rate for SAP is 10% with sterile and increased to 25% with infected pancreatic necrosis[4]. Hospitalization for patients with SAP may frequently extend beyond 2 wk and often involves an intensive care unit stay and increased infection rate[4]. Up to the late period of last century, complications of infection account for 80% of deaths from AP[5]. Currently, 30%-50% of the dead cases were due to infectious complications for 2 wk from onset[6]. Therefore, theoretically, no antibiotics are indicated in mild cases, but antibiotics were considered to play an important role in either therapeutic or prophylactic intention for SAP. The recognition and exploration of antibiotic prophylaxis for SAP experienced more than a half of a century. However, there was still a gap between theory and truth, and the proper role of antibiotics in SAP remains controversial[7].

Why pancreatologists keep dwelling on this controversy? In this review, we critically estimated the currently available evidence to find out the gap between theory and clinical practice. Moreover, through our hypothesis and calculation, we predicted what would occur in antibiotic prophylaxis for SAP if robust evidence was available in the future.

MATERIALS AND METHODS

Search strategy

We searched the electronic databases of PubMed up to 2009. The reference lists from relevant articles, containing meta-analysis, systematic reviews or clinical trials, were screened for potential eligible studies. There was no limitation of publication date and language. The following strings were used in the search strategy for PubMed: "pancreatitis" (MeSH Terms) or "pancreatitis" (All Fields); "antibacterial agents" (MeSH Terms) or "anti-bacterial" (All Fields); "agents" (All Fields) or "anti-bacterial agents" (All Fields) or "antibiotics" (All Fields) or "anti-bacterial agents" (Pharmacological Action); "randomized controlled trial" (Publication Type) or "randomized controlled trials as topic" (MeSH Terms) or "randomized controlled trials" (All Fields) or "clinical trial" (Publication Type) or "clinical trials" (MeSH Terms) or "clinical trial" (All Fields); "meta-analysis" (Publication Type) or "meta-analysis" (MeSH Terms) or "meta-analysis" (All Fields); and "review literature" (MeSH Terms) or "systematic review" (All Fields).

Inclusion and exclusion criteria

The currently available meta-analyses and randomized controlled trials were analyzed by meta-analysis. The patients were all diagnosed as having SAP. The intervention group received prophylactic antibiotics. The control group received placebo or none-treatment. All potentially eligible meta-analyses or trials should report the mortality rate of each group. There were no limitations for race, age or gender. If any conditions did not conform to the above criteria or the essential data could not be extracted, the meta-analyses of trials were excluded.

Selection and data collection

All procedures were reviewed by two independent reviewers: (1) for descriptive review of available meta-analyses, the publication year, the number of included trials, and the effect sizes of mortality or infected necrosis were extracted. The effect sizes involved risk ratio (*RR*), odds ratio (OR), absolute risk reduction (ARR) and their 95% confidence interval (CI); (2) for updating meta-analysis, the general information including publication year, sample size, study design, general characteristics of patients, and intervention details were extracted. The dichotomous data for the mortality were extracted, including total number of participants and events for each group. The number of events was calculated by the reported percentage if possible; and (3) For the predication of the future meta-analysis, the synthesized mortality rate of each group was extracted by our updated meta-analysis.

Statistics analysis

Meta-analysis: Outcomes of eligible studies were statistically synthesized by Reviewer Manager 5.0 (The Nordic Cochrane Center, Cochrane Collaboration, Copenhagen, Denmark). The statistical method was referred to the Cochrane Handbook for Systematic Review of Intervention. The pooled statistics were calculated using a fixed effects model initially. The *RR* was reported for dichotomous data. The 95% CI was also calculated. The Mantel-Haenszel method was used to test significance of dichotomous data. *P* value less than 0.05 was considered statistically significant. Heterogeneity between comparable studies was tested in all analyses using a standard χ^2 test for between-study statistical heterogeneity and considered significant at $P < 0.1$. If heterogeneity existed, the random effects model was used for analysis.

Sample size calculation: The format for equivalency estimate of rates between two arms is shown below.

Expected sample size in each group = $(\mu_\alpha + \mu_\beta)^2[p_1(1 - p_1) + p_2(1-p_2)]/(\Delta - |p_1-p_2|)^2$; Limitation: $\Delta > |p_1-p_2|$

(Δ: threshold of difference value; α: possibility of type I error; β: possibility of type Ⅱ error; μ_α: critical value corresponding to α; μ_β: critical value corresponding to β; p_1: possibility of mortality in prophylactic antibiotics group; p_2: possibility of mortality in placebo or blank control group; $|p_1-p_2|$: absolute value of difference between two groups.)

Hypothesis test: SPSS 13.0 (SPSS, Chicago, IL, United States) was used for statistical analysis. For dichotomous data, the χ^2 test was used to compare frequencies of mortality. Linear correlation between accumulated sample size and time (year) was analyzed by the Pearson correlation test. *P* value of less than 0.05 (two-sided) was considered significant.

RESULTS

Current evidences

Published meta-analysis: Recently, there have been several RCTs on prophylactic antibiotic for SAP[8-14], and therefore several meta-analyses on this topic have already published (Table 1, Figure 1). For the primary outcome

in mortality rate, only one meta-analysis showed a significant reduction by antibiotic prophylaxis. Moreover, only two other meta-analyses showed a significant preventive effect on infected necrosis for SAP by antibiotic prophylaxis. More than a half of the meta-analyses did not recommend the administration of antibiotic prophylaxis, while the others suggested that the effectiveness of antibiotic prophylaxis was still controversial.

Update on meta-analysis: To improve the robustness of evidence, the meta-analysis was updated in present review. We comprehensively searched the PubMed database to identify available RCTs on the comparison between prophylactic antibiotics and placebo/none-treatment for SAP. There were 11 eligible RCTs (Figure 1)[8-14,24-27], which were re-pooled to update the meta-analysis (Figure 2). There were two newly published RCTs in 2009[13,14], which was different from previous meta-analysis[15].

Interestingly, we found that before 2000 the pooling estimate of 4 RCTs (183 patients) showed a significant benefit to reduce the mortality of SAP (*RR* = 0.31, 95% CI: 0.12-0.79, $P = 0.01$)[24-27]. The mortality rates were 5.26% (5/95) and 18.18% (16/88) in prophylactic antibiotics and placebo/none-treatment groups, respectively. The number needed to treat (NNT) was one of 8 treated patients potentially being benefited to prevent death by prophylactic antibiotics (Table 2).

However, since 2000, seven RCTs (439 patients) have been identified and pooled to meta-analysis[8-14]. Differently, the result indicated that there was no benefit of preventing death in the prophylactic antibiotics group (*RR* = 1.01, 95% CI: 0.65-1.56, $P = 0.98$). The mortality rates were 15.00% (33/220) and 15.07% (33/219) in the prophylactic antibiotics and placebo/none-treatment groups, respectively. Sadly, the NNT was one of 1429 treated patients potentially being benefited (Table 2), and it was indeed a negative evidence to support administration of prophylactic antibiotics.

In the funnel plot, the asymmetric distribution of RCTs before 2000 implied that there might be apparent publication bias (Figure 3). Moreover, the distribution of RCTs from 2000 was relatively symmetric.

How long a way to end the controversy?

What a scale does a trial require? To the best of our knowledge, the key to end the controversy is to conduct a large-scale RCT so as to control the random sampling error. To perform an ideal RCT, we have to calculate the required sample size by statistical approach. The mortality rates were calculated based on the pooling estimate from 2000, and the results of calculation are shown in Table 3.

If the difference between mortality rates was no more than 10% as an acceptable threshold of equivalence, at least 544 patients would be required for a single robust trial (Table 3), while the difference was limited to no more than 5%, 3230 patients would be demanded in a single trial (Table 3).

In practice, it is hard to conduct a single-center randomized trial of such large scale in the study of SAP treatment. A multi-center trial might be a way out of this corner, but difficulties in quality control and possible performance bias might occur. Among the included RCTs in the above updated meta-analysis, the absolute value of difference between mortality rates $|p_1-p_2|$ was 6.7% ± 5.9% (range, 2.0%-19.3%), and the mean was more than 5%. Therefore, the threshold of 10% and the sample size of 544 patients could be rational. It would take more than two years to complete a large-scale multi-center RCT.

The above meta-analysis showed a minor difference between mortality rates, $|p_1-p_2| = 0.0007$. Thus, we have to choose the lower threshold 5% to calculate the required accumulated sample size, and the calculation result

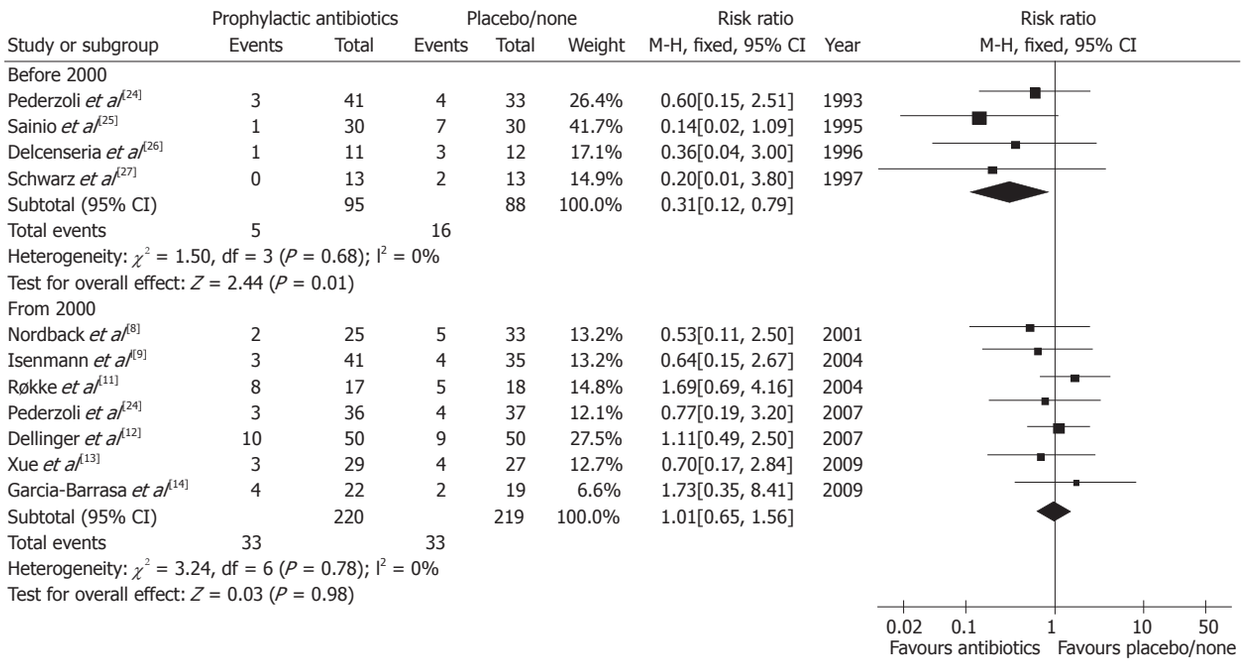

Figure 2 Updated meta-analysis of antibiotic prophylaxis *vs* placebo/none-treatment. The meta-analysis was stratified into two periods, i.e., before 2000 and from 2000. In the later period, no benefit was obtained from prophylactic antibiotics (RR = 1.01, *P*=0.98; Mantel-Haenszel test, fixed effect model, two-sided).

Table 2 Mortality rates and related parameters between different periods

Period	Antibiotics[1] (%)	Control[2] (%)	ARR (%)	RRR (%)	NNT
Before 2000	5.26	18.18	12.92	71.07	8
From 2000	15.00	15.07	0.07	0.46	1429

[1]The mortality rate of the subgroup before 2000 was significantly lower than the subgroup from 2000 ($P = 0.019$; by SPSS 13.0, Pearson χ^2 test, two-sided); [2]No significant difference of mortality rate between two periods ($P = 0.571$; by SPSS 13.0, Pearson χ^2 test, two-sided). ARR: Absolute risk reduction; RRR: Relative risk reduction; NNT: Number needed to treat.

Table 3 Estimate of required sample size based on the pooling estimate from 2000

Δ	α	β	μα	μβ	p1	p2	|p1-p2|	Group	Study
0.10	0.05	0.10	1.9600	1.2816	0.1500	0.1507	0.0007	272	544
0.05	0.05	0.05	1.9600	1.9600	0.1500	0.1507	0.0007	1615	3230

Δ: Threshold of difference value; α: Possibility of type I error; β: Possibility of type Ⅱ error; μα: Critical value corresponding to α; μβ: Critical value corresponding to β; p1: Possibility of mortality in prophylactic antibiotics group; p2: Possibility of mortality in placebo or blank control group; |p1-p2|: Absolute value of difference between two groups.

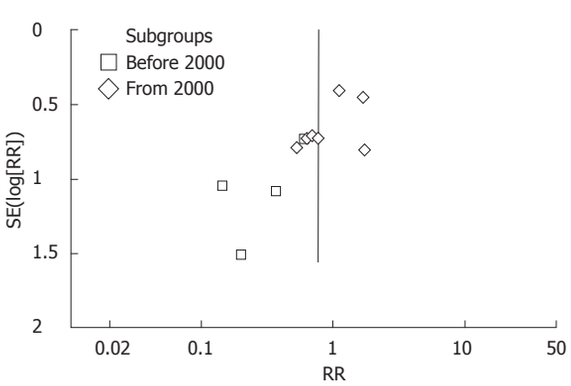

Figure 3 Funnel plot of the meta-analysis. Apparently asymmetrical distribution was found in the period before 2000.

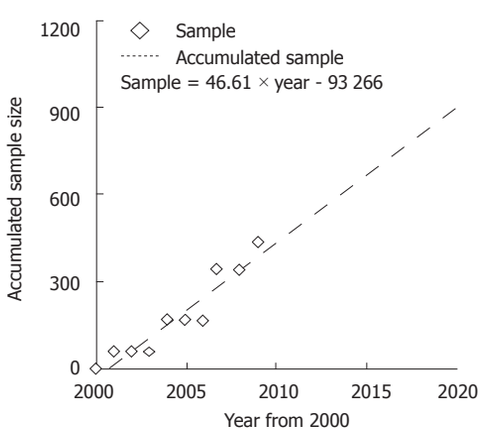

Figure 4 Linear correlation of accumulated sample size from 2000. There is highly positive correlation between the accumulated sample size and the year from 2000 ($r = 0.954$, $P = 0.000$; Pearson correlation test, two-sided).

indicated that the overall accumulated sample size need 3230 patients. The linear regression test showed the accumulated sample size is positively correlated with the time period (year by year from 2000) (Figure 4). If there were no larger-scale RCTs, it would take a long time to achieve the statistical goal, and the controversy would continue.

An assumed large-scale trial (sensitivity analysis): If years later a large-scale RCT is completed, how will it contribute to addressing the controversy on prophylactic antibiotics for SAP? Thus, we carried out a sensitivity analysis

Table 4 Sensitivity analysis by adding a large-scaled randomized controlled trial

	Antibiotics		Placebo/none-treatment	
	Mortality rate	No. of events	Mortality rate	No. of events
By best/worst data[1]	7.32%	40/544	27.78%	151/544
Meta-analysis[3]	*RR* = 0.76, 95% CI: 0.38-1.53, *P* = 0.44 (random effect model)			
By pooling data[2]	15.00%	82/544	15.07%	82/544
Meta-analysis[3]	*RR*=1.00, 95% CI: 0.79-1.27, *P* = 0.99 (fixed effect model)			

[1]The mortality rate of antibiotic prophylaxis was obtained from the best outcome in a randomized controlled trial (RCT) after 2000, while that of placebo/none-treatment was from the worst outcome in another RCT after 2000; [2]The mortality rates were from the pooling data of the subgroup from 2000 in the updated meta-analysis; [3]The meta-analysis included both the 7 RCTs published from 2000 and an assumed large-scale RCT (by Cochrane RevMan 5.0, Mantel-Haenszel test, two-sided).

to estimate the margin of potential benefit from prophylactic antibiotics (Table 4). It was performed by re-pooling both the 7 RCTs from 2000 and an assumed large-scale RCT containing 544 patients for meta-analysis[8-14]. The theoretical mortality rates of assumed RCT were evaluated as follows.

Given there was obvious random sampling error, the best-worst method was used to calculate the best marginal benefit (Table 4). Since there was between-study heterogeneity ($P = 0.0003$), the meta-analysis was performed by random effect model. The result of sensitivity analysis showed no significant benefit of antibiotic prophylaxis for SAP ($RR = 0.76$, $P = 0.44$), which was similar with the previous meta-analyses (forest plot not shown).

If there was no random sampling error, the mortality rates would be equal to the pooling data from above updated meta-analysis (Table 4). The heterogeneity of repooling estimate was not significant ($P = 0.86$), so fixed effect model was used. The result of sensitivity analysis showed nearly equivalent efficacy between antibiotic prophylaxis and non-antibiotic treatment ($RR = 1.00$, $P = 0.99$) (forest plot not shown).

Therefore, we can assume that even if a large-scale RCT was completed, the *RR* of the mortality rate would only range from 0.77 to 1.00 with a relatively narrow confidence interval ($P < 0.05$). It means, as a whole, that antibiotic prophylaxis is not effective for SAP patients. Moreover, by the sensitivity analysis, the NNT ranged from 7 to 5069 patients.

DISCUSSION

As the mortality of SAP is obviously associated with the complications of infection, prophylactic antibiotics have been administrated for SAP patients for several decades, which seemed to play an important role in the treatment of SAP. However, currently, its role is highly questioned by more and more RCTs and meta-analyses, and the controversies continue due to insufficient evidence.

Among the existing meta-analyses, only one meta-analysis showed a significant reduction in the mortality rate by antibiotic prophylaxis, and most of the meta-analyses did not recommend the administration of antibiotic prophylaxis. Therefore, the current academic opinion obviously trends to be unfavorable for antibiotic prophylaxis for SAP. However, antibiotic prophylaxis has not been given up in clinical practice in the treatment of SAP. Why do physicians often go reversely in aspect of the decision-making on antibiotic prophylaxis for SAP?

Practice of evidence-based medicine is a procedure of integrating the best available external clinical evidence with clinical expertise and patient needs[28]. There should be a balance among these three aspects. If the power of current available evidence is not robust enough, the influence of clinical expertise will be inevitably enhanced. Thus, physicians are quite cautious to the available evidence due to the weakness in the meta-analyses. Firstly, the eligible RCTs are fairly small-sized and the accumulated sample size is also limited. Secondly, the validity of some RCTs in earlier period is affected by the absence of blinding method.

In the funnel plot of our updated meta-analysis, the asymmetric distribution of RCTs before 2000 implied that there might be apparent publication bias. At that period, the positive results of trials tended to be accepted for publication more easily. Therefore, most of the scholars believed that the evidence before 2000 would be weak to validate. Another critical reason is that blinding method was not used in these trials, which may result in performance and observation biases. Thus, positive results might be more easily to reach under that condition. Since the year of 2000, the improved methodology of RCTs has made the pooling estimate non-significant.

By now, physicians have become more conservative and suspicious about the administration of prophylactic antibiotics for SAP. The effectiveness of prophylactic antibiotics seemed to be equal to the placebo or blank control. Whether the evidence obtained in the current decade is robust enough to make a mandatory recommendation to quit the administration of prophylactic antibiotics for SAP? As small-sized RCTs inevitably result in the random sampling error. Thus, there must be a long way to go to answer this question.

Through our hypothesis and calculation, we predict that antibiotic prophylaxis would not be effective as a whole in reducing the mortality of SAP patients, even if a large enough RCT was completed. However, the minor lower limit of NNT range implies that certain SAP patients might potentially be benefited by antibiotic prophylaxis. Therefore, if possible, the individual patient data analysis will be meaningful to identify potential candidates who can gain survival benefit from antibiotic prophylaxis.

COMMENTS

Background

The mortality of severe acute pancreatitis (SAP) is obviously associated with the infectious complications, so prophylactic antibiotics have been administrated for SAP patients for several decades. However, the role of prophylactic antibiotics in reduction of mortality of SAP patients has been highly questioned by more and more randomized controlled trials (RCTs) and meta-analyses.

Research frontiers

Evidence-based medicine is frequently used in clinical practice. Although there have been several meta-analyses on the administration of prophylactic antibiotics for SAP, the conclusion is still not confirmed. By now, some new reports on this topic have become available for updated review and analysis.

Innovations and breakthroughs

An updated meta-analysis on the mortality of SAP patients was performed. Prophylactic antibiotics for SAP was compared with control or placebo. Subgroup analysis showed that there was significant reduction of mortality rate in the period before 2000, while no significant reduction in the period from 2000. Sensitivity analysis by assuming an ideal large-scale RCT was performed to prove the results, and found that SAP patients did benefit from prophylactic antibiotics. In addition, current evidences do not support administration of prophylactic antibiotics as a routine treatment for SAP.

Applications

Although the administration of prophylactic antibiotics for SAP in general practice is controversial, there is still a potentially high-risk sub-population who could benefit from prophylactic antibiotics.

Terminology

Prophylactic antibiotics, is administrated to the sterile SAP patients to prevent the potential and even fatal complications, involving both peri-pancreatic and systematic infection.

Peer review

The paper investigates the role of prophylactic antibiotics on mortality of severe acute pancreatitis. The statistical analysis used in the study is appropriate and the results are reliable.

Abstract

AIM: To study the metabolic profiling of serum samples from compensated and decompensated cirrhosis patients.

METHODS: A pilot metabolic profiling study was conducted using three groups: compensated cirrhosis patients (n = 30), decompensated cirrhosis patients (n = 30) and healthy controls (n = 30). A ^{1}H nuclear magnetic resonance (NMR)-based metabonomics approach was used to obtain the serum metabolic profiles of the samples. The acquired data were processed by multivariate principal component analysis and orthogonal partial least-squares discriminant analysis (OPLS-DA).

RESULTS: The OPLS-DA model was capable of distinguishing between decompensated and compensated cirrhosis patients, with an R^2Y of 0.784 and a Q^2Y of 0.598. Twelve metabolites, such as pyruvate, phenylalanine and succinate, were identified as the most influential factors for the difference between the two groups. The validation of the diagnosis prediction showed that the accuracy of the OPLS-DA model was 85% (17/20).

CONCLUSION: ^{1}H NMR spectra combined with pattern recognition analysis techniques offer a new way to diagnose compensated and decompensated cirrhosis in the future.

Key words: Liver cirrhosis; Metabolic profiling; Orthogonal partial least-squares discriminant analysis

INTRODUCTION

Liver cirrhosis (LC) and its associated complications are a major cause of morbidity and mortality worldwide[1,2]. During early cirrhosis, the liver is able to compensate the changes resulting from bridging fibrosis, and most patients do not show specific symptoms until they enter the stage of decompensated cirrhosis[3]. Patients often miss the best opportunity for therapy because the hepatic reserve in the decompensated stage is unable to compensate for hepatocyte loss and structural distortions.

The diagnostic confirmation of cirrhosis is based on a histological examination or the combined results of clinical and imaging examinations[1]. However, the proposed

methods cannot be satisfactorily applied to a clinical diagnosis. Firstly, histological examination requires the puncturing of liver tissue and causes substantial pain. Secondly, the clinical results derived from a series of laboratory assays are costly and require long periods of time. Finally, imaging studies cannot provide sensitive diagnoses and are vulnerable to the influence of subjective factors. Therefore, establishing a simple and specific strategy to diagnose cirrhosis and distinguish decompensated LC from compensated LC is important for patient care and treatment decisions.

Metabonomics is a comprehensive and fully quantitative analysis of low molecular weight molecules within a particular biological sample. ^{1}H nuclear magnetic resonance (NMR) spectra combined with principal component analysis (PCA) and orthogonal partial least-squares discriminant analysis (OPLS-DA) are frequently conducted in metabolic profiling studies[4-6].

The incidence of acute and chronic viral hepatitis in China is very high and hepatitis B virus (HBV) contributes to 80% of liver cirrhosis[7]. Thus, in the present study, we employed quantitative ^{1}H NMR to analyze the serum metabolic profiling in HBV-infected cirrhosis patients. Our purpose was to establish a diagnostic method for decompensated and compensated cirrhosis and to discover metabolomic biomarkers related to the cirrhosis conditions.

MATERIALS AND METHODS

Patients and controls

This study enrolled 60 patients (30 compensated and 30 decompensated cirrhosis patients) from the Department of Gastroenterology and Infectious Diseases of Shenzhen People's Hospital from November 2009 to July 2010. We excluded patients with past or current hepatocellular carcinoma, alcoholic cirrhosis, diabetes, cardiovascular and cerebrovascular disease, kidney disease and any other viral co-infection, including human immunodeficiency virus, hepatitis delta or hepatitis C virus. Thirty healthy volunteers served as controls. The baseline clinical characteristics of the cirrhotic patients and controls are summarized in Table 1. This study was performed according to the guidelines of Chongqing Medical University, which abides by the Declaration of Helsinki on ethical principles for medical research involving human subjects.

Clinical criteria

All patients were positive for hepatitis B surface antigen for at least 1 year before screening. Cirrhosis patients were diagnosed according to the results of histological examination or the combined results of clinical and imaging examinations. Decompensated cirrhosis was defined as the presence of at least two of the following five criteria: ascites, hyperbilirubinemia, peripheral edema of noncardiac or renal origin, hypoalbuminemia and an INR (clotting times, as reflected by the international normalized ratio) > 1.3[8]. The severity of liver disease was calculated according to the model for end-stage liver disease[9].

Table 1 Clinical and biochemical characteristics of the cirrhotic patients and controls

Parameter	Control (n = 30)	Liver cirrhosis	
		Compensated LC (n = 30)	Decompensated LC (n = 30)
Age (yr)	48.8 ± 10.5	56.3 ± 12.9	58.7 ± 14.5

Metabolomic and clinical chemistry analysis

Approximately 5 mL of peripheral venous blood from fasted healthy volunteers and LC patients was collected. The blood was allowed to clot for 30 min at room temperature before being centrifuged at 2000 *g* for 10 min at 25 ℃; the serum was separated and stored at -80 ℃. Prior to NMR analysis, serum samples were thawed and 400 μL aliquots were mixed with 150 μL of deuterium oxide. The serum samples were centrifuged at 12 000 *g* for 10 min at 4 ℃, and 500 μL aliquots of the resulting supernatants were placed into 5 mm NMR tubes. All NMR spectra were recorded at 25 ℃ on a Varian Unity INOVA 600 NMR spectrometer. One-dimensional spectra were recorded using the Carr-Purcell-Meiboom-Gill sequence[10,11] with a spin-spin relaxation delay of 120 ms and a spectral width of 8000 Hz. All spectra were carefully phase- and baseline-corrected and referenced to the internal lactic acid CH3 resonance at 1.33 ppm. Spectra were segmented into 0.005-ppm chemical shift "bins" between 0.5 and 9.0 ppm, and the spectral area within each bin was integrated. Bins between 4.7 and 5.2 ppm containing residual water were removed. The free induction decay was zero-filled to 64 K and multiplied by an exponential line-broadening function of 0.3 Hz prior to Fourier transformation.

Multivariate analysis

Multivariate statistics, including unsupervised PCA and supervised OPLS-DA, were performed using SIMCA-P 11.0 software (Umetrics, Umea, Sweden). Analysis of the metabolite signals in the ^{1}H NMR serum profiles was first performed using unsupervised PCA, which displays the internal structure of datasets in an unbiased way and decreases the dimensionality of data[12-14]. After an initial overview of the PCA analysis, we obtained a more sophisticated OPLS-DA model with the specific discriminant information between the different groups[15,16]. The differences in the metabolites between groups were shown as coefficient of variation plots. Using a significance level of

The region of δ5.2-9.0 (in the dashed box) is magnified 8 times compared to the corresponding region of δ0.5-4.7 for the purpose of clarity. 3-HB: 3-Hydroxybutyrate; Ace: Acetate; Acet: Acetone; Ala: Alanine; Cit: Citrate; Cr: Creatine; FD: Formaldehyde; Glu: Glutamate; Gln: Glutamine; Gly: Glycine; GPC: Glycerophosphocholine; His: Histidine; Ile: Isoleucine; IB: Isobutyrate; Lac: Lactate; Leu: Leucine; L1 Lipid: CH_3-$(CH_2)n$-(LDL&VLDL); L2 Lipid: CH_3-$(CH_2)n$-(LDL&VLDL); L3 Lipid: -CH_2-CH_2-C=O; L4 Lipid: -CH_2-CH=CH-; L5 Lipid: =CH-CH_2-CH=; L6 Lipid: -CH=CH-; Lys: Lysine; NAG: N-acetyl glycoprotein signals; PC: Phosphocholine; Phe: Phenylalanine; Py: Pyruvate; Suc: Succinate; TMA: Trimethylamine; Tyr: Tyrosine; Val: Valine; α-Glc: α-Glucose; β-Glc: β-Glucose.

0.05, we employed a correlation coefficient of ± 0.355 as the threshold to choose the variables that best correlated with the OPLS-DA discriminative scores. To further test whether the metabolic profiling can effectively distinguish decompensated cirrhosis patients from compensated cirrhosis ones, we randomly selected 20 cirrhotic patients (10 compensated and 10 decompensated cirrhosis patients) to validate the discriminatory power of the OPLS-DA model.

Statistical analyses were performed using SPSS 11.5 software (SPSS Company, Chicago, IL, United States). The threshold *P* value was set at 0.05 throughout the study.

RESULTS

^{1}H NMR spectroscopy of serum samples

The ^{1}H-NMR signals of all common metabolites, such as amino-acids, organic acids and carbohydrates, were assigned according to previous publications[10]. Examples of typical serum spectra from control, compensated and decompensated cirrhosis groups are shown in Figure 1. The 600 MHz ^{1}H NMR spectra demonstrated resonances arising from glucose, glutamine, acetate, leucine, glycerophosphocholine, histidine, isoleucine, citrate, etc. The useful extracted information was subsequently analyzed using multivariate statistics including PCA and OPLS-DA.

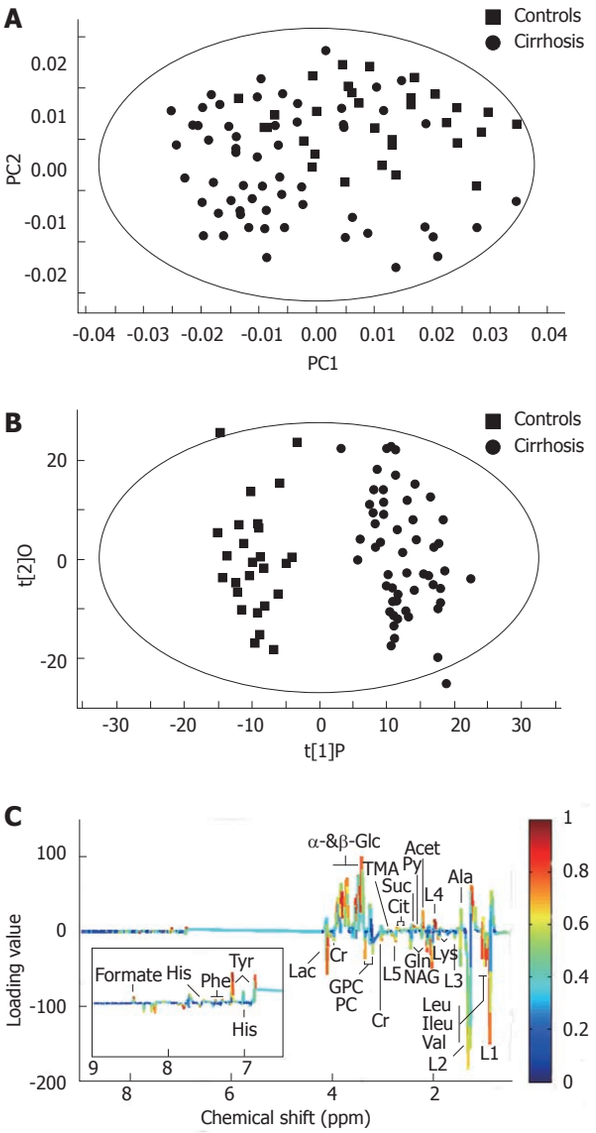
Multivariate statistics

As a proof of principle, we first evaluated whether a metabonomics approach would be capable of distinguishing cirrhotic patients (included compensated and decompensated cirrhosis) from healthy controls.

At first, we analyzed the serum metabolic profiles using unsupervised PCA. Figure 2A displays the PCA score plots of cirrhotic patients and healthy controls, with an R^2X of 0.812 and a Q^2Y of 786. The PCA was followed by OPLS-DA, which is more focused on discriminatory variations. Excellent separation with negligible overlapping was observed in OPLS-DA score plots between controls and cirrhosis patients. This model showed very good fit and predictability values with an R^2Y of 0.941 and a Q^2Y of 0.836 (Figure 2B). The loading plots (Figure 2C) revealed that the responsible variables were those corresponding to β-glucose, α-glucose, low-density lipoproteins (LDL), very low-density lipoproteins (VLDL), valine, tyrosine, succinate, lipid, isobutyrate, glutamine, glutamate, *etc*.

A similar procedure was performed to assess the utility of metabonomics to distinguish decompensated LC from compensated LC patients. A PCA score plot (Figure 3A) could not reveal an obvious separation between compensated and decompensated LC, with an R^2X of 0.795 and a Q^2Y of 0.736. The overlap in PCA score plots suggested that there was some metabolic variation between the two classes not related to the disease state. OPLS-DA revealed a clear separation between decompensated and compensated LC patients (Figure 3B), with an R^2Y of 0.784 and a Q^2Y of 0.598. The majority of the disease-related variance could be explained by the first component of the model. The OPLS-DA loading plot (Figure 3C) revealed that the significant variables were those corresponding to pyruvate, phenylalanine, succinate, lysine, *etc*. The variables meeting the cutoff value (i.e., |correlation coefficient| > 0.355) are summarized in Table 2.

The serum metabolic profiles of 20 cirrhotic patients were overlaid in the OPLS-DA model to evaluate the diagnostic performance (Figure 3D). Of these, eight compensated cirrhosis patients were clustered together in the left section of the OPLS-DA model (compensated group), nine decompensated cirrhosis patients were clustered together in the right section of the OPLS-DA model (decompensated group), and the three remaining cirrhosis patients were situated in an intermediate area between the decompensated and compensated cirrhosis patients.



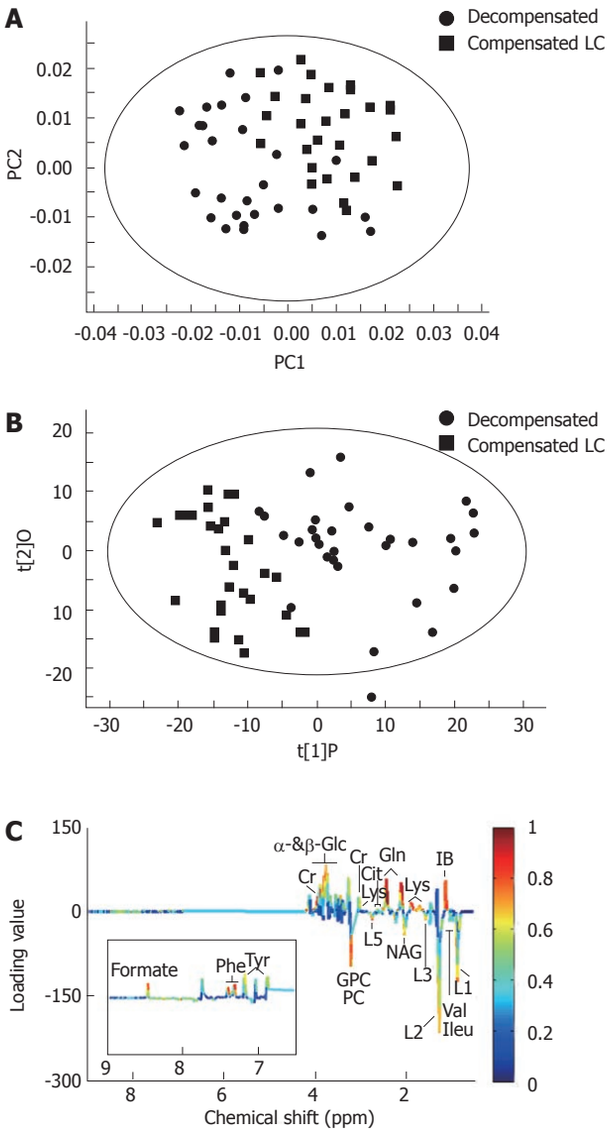


Figure 2 Multivariate modeling of control and cirrhotic subjects. A: Principal component analysis score plot of the serum ^{1}H nuclear magnetic resonance spectra from controls (squares) and cirrhotic patients (dots); B: Orthogonal partial least-squares discriminant analysis (OPLS-DA) score plot of controls (squares) and cirrhotic patients (dots); C: Corresponding coefficient loading plots for the discrimination of the OPLS-DA model.

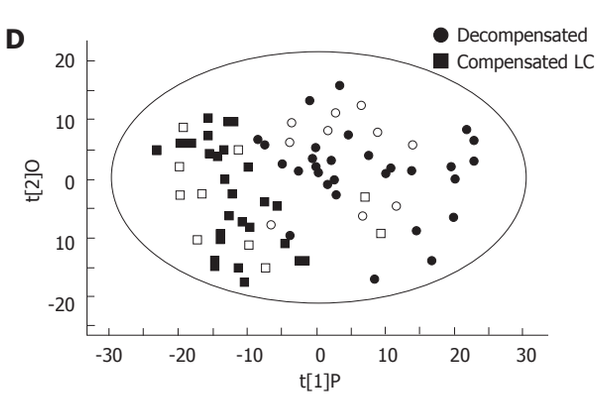

Figure 3 Multivariate modeling of compensated and decompensated liver cirrhosis patients. A: Principal component analysis score plot of the serum ^{1}H nuclear magnetic resonance spectra from compensated liver cirrhosis (LC) (squares) and decompensated LC (black dots) patients. B: Orthogonal partial least-squares discriminant analysis (OPLS-DA) score plot of compensated LC (squares) and decompensated LC (dots) patients; C: Corresponding coefficient loading plots for the discrimination of the OPLS-DA model; D: Validation tests of the discriminatory power using the OPLS-DA model. Twenty cirrhotic patients were selected randomly and included 10 compensated LC (empty squares) and 10 decompensated LC (empty dots) patients.

DISCUSSION

Previous studies have shown that the transition from compensated to decompensated cirrhosis is so insidious that many patients miss the best opportunity for treatment[8,17]. In the present study, we applied NMR-based metabolic profiling to examine the serum from decompensated and compensated LC patients and identified low molecular weight biomarkers for the diseases.

The findings of this pilot study showed that the ^{1}H NMR serum metabolic profiling of cirrhotic patients and control subjects was clearly separated. Compared with healthy controls, the serum metabolic profiling of cirrhotic patients showed increased levels of glucose and lactate and decreased levels of lipids and choline. In

Table 2 Orthogonal partial least-squares discriminant analysis coefficients derived from the nuclear magnetic resonance data of metabolites in serum obtained from compensated and decompensated cirrhosis patients

Metabolites	δ^1H	Correlation coefficients	
		Compensated LC	Decompensated LC
β-Glucose	3.24, 4.65	0.654	0.722

The positive and negative signs indicate a positive and negative correlation in the concentrations, respectively. "-": The |correlation coefficient| is less than 0.355.

this context, our results are consistent with the studies of Gao *et al*[18], which showed that ^{1}H NMR metabonomics analysis of serum is helpful for differentiating cirrhotic patients from healthy subjects.

However, little work has been done to discriminate patients with compensated and compensated cirrhosis through metabonomics. Corbin *et al*[8] used phosphorus-31 magnetic resonance spectroscopy to document the differences in the hepatic metabolite concentrations among patients with compensated and decompensated cirrhosis. Although this study provided a useful and noninvasive diagnostic tool, the researchers only studied five metabolites and did not investigate all metabolites related to cirrhosis.

In contrast, NMR has the advantage of full quantitative analysis and minimal requirements for sample preparation[5]. In the present study, we obtained a 'metabolic fingerprint' from the pathological process of cirrhosis. Compared with compensated LC patients, the decompensated LC patients displayed higher levels of pyruvate, phenylalanine, succinate, lysine, histidine, alanine, glutamate, glutamine, creatine and lower levels of LDL, VLDL and acetone.

The increased concentration of pyruvate and succinate in decompensated LC serum is possibly due to the reduced utilization of pyruvate and succinate into the tricarboxylic acid cycle[19]. Phenylalanine belongs to the aromatic group of amino acids, and it is converted to tyrosine by the catalysis of phenylalanine hydroxylase, which is a liver-specific enzyme[20]. The increase in phenylalanine suggests that the BCAA/AAA ratio has changed in patients with decompensated LC. Glutamate is at the very center of hepatic amino acid metabolism. Glutamine, histidine, arginine, ornithine, proline, and glutamate comprise the 'glutamate family' of amino acids[21]. The elevated levels of glutamate, glutamine and histidine reflect the abnormal metabolism of amino acids with cirrhosis progression.

Our study showed that the levels of VLDL and LDL were reduced in the decompensated LC group compared to the compensated LC group. Because liver tissue loses some degree of its lipid synthesizing ability in the later stage of cirrhosis, the blood lipid level decreases in the serum of decompensated LC patients[22].

The remaining metabolite changes include increased lysine and alanine and decreased acetone; altered levels of these metabolites in decompensated LC patients may be the result of the impairment of hepatocytes, but may also be the result of liver perfusion.

Taken together, these results imply that hypermetabolism of the liver was prevalent when compensated cirrhosis developed into the decompensated stage. Hence, these metabolites may serve as biomarkers that can be used to monitor the changes in LC patients.

Regarding predictive tests of the discriminatory power, the results showed that the accuracy of the OPLS-DA was 85% (17/20). Three patients located in the middle area of the OPLS-DA model were observed carefully in the following two months. One compensated LC patient developed decompensated cirrhosis, and the remaining two LC patients did not exhibit distinct changes. It is conceivable that the metabolic changes revealed by the NMR spectra could be more sensitive than other clinical symptom and lab tests.

Serum metabolic analysis bears the potential to be a useful and convenient method to diagnose LC patients. However, there are some potential limitations of the present study that require consideration. Firstly, a limited number of samples prevented us from drawing a more reliable conclusion about the predictive power of this model. Larger numbers of patients and controls will be crucial to validate this model. Secondly, the specificity of the biomarkers indentified by OPLS-DA requires a longitudinal study to determine their validity.

In summary, the metabolic profiling obtained from ^{1}H NMR-based metabonomics analysis of serum may be a simple and reliable way to diagnose compensated and decompensated LC. The metabolic differences between the two groups also facilitate a better understanding of the metabolic changes associated with cirrhosis progression.

COMMENTS

Background

The diagnostic confirmation of cirrhosis is based on histological examination or the combined results of clinical and imaging examinations. However, the proposed methods cannot be satisfactorily applied in clinical diagnosis.

Research frontiers

^{1}H nuclear magnetic resonance (NMR) is an ideal instrumental platform for metabolic analysis of biofluids, and NMR analysis has been reported as successfully applied in the diagnosis and prognosis of some human diseases.

Innovations and breakthroughs

The authors compared the serum metabolic profiling of compensated and decompensated cirrhosis patients. The orthogonal partial least-squares discriminant analysis (OPLS-DA) model was successful in distinguishing decompensated cirrhosis from compensated cirrhosis. Twelve metabolites were identified as the most influential biomarkers for the difference between the two groups.

Applications

Serum metabolic analysis bears the potential to be a useful and convenient method to diagnose compensated and decompensated cirrhosis.

Terminology

Principal component analysis (PCA): PCA is a mathematical procedure that uses an orthogonal transformation to convert a set of observations of possibly correlated variables into a set of values of uncorrelated variables called principal components; orthogonal partial least-squares discriminant analysis (OPLS-DA): OPLS-DA is a method of discriminating between two or more groups. The variables responsible for the differences may be identified.

Peer review

In this manuscript, the authors employed metabolomics to compare serum metabolic profiles among control, compensated and decompensated cirrhosis patients. Rationale and results are sound.

Abstract

Endoscopic submucosal dissection is a challenging technique that enables *en-bloc* resection for large colorectal tumors, as laterally spreading tumors, particularly difficult, if the ileocecal valve and terminal ileum is involved. Herein, we report on one of 4 cases. The procedures, using a bipolar needle knife (B-Knife) to reduce the perforation risk and carbon dioxide instead of conventional air insufflation for patient comfort, achieved curative resections without any complications.

Key words: Ileocecal valve; Colorectal neoplasms; Laterally spreading tumor; Endoscopic mucosal resection; Endoscopic submucosal dissection; Bipolar current needle knife; B-Knife; IT-Knife

INTRODUCTION

Laterally spreading tumors (LSTs)[1] are mainly located in the cecum and rectum and endoscopic mucosal resection (EMR) is the therapeutic choice[2,3] because of their lower incidence of submucosal (sm) invasion. Involvement of the ileocecal valve with possible spreading to the terminal ileum, however, complicates the EMR and resulting in piecemeal resection in which persistent recurrence leads to surgery even for adenomas and intramucosal cancers[4]. In addition, the thin wall of the narrow ileum increases the risk of perforation during EMR[5].

Our experience suggests that the well-established endoscopic submucosal dissection (ESD) also produces good results in colorectal cases as in early gastric cancer treatment[6]. Unlike the stomach, colonic ESD presents high risk of complications[7] and increased patient discomfort. These factors motivated us to develop better techniques to achieve successful ESDs such as using a bipolar needle knife (B-Knife® Zeon Medical Co. Tokyo, Japan)[8] to reduce the risk of perforation and carbon dioxide (CO_2) instead of conventional air insufflation for patient comfort[9].

In the present report, we describe our experience and the utility of using ESD on one of 4 complete resections of large LSTs (70 mm in diameter) involving the ileocecal valve and terminal ileum.

CASE REPORT

A 76-year-old woman was referred to our hospital for endoscopic treatment of a neoplastic lesion located at the

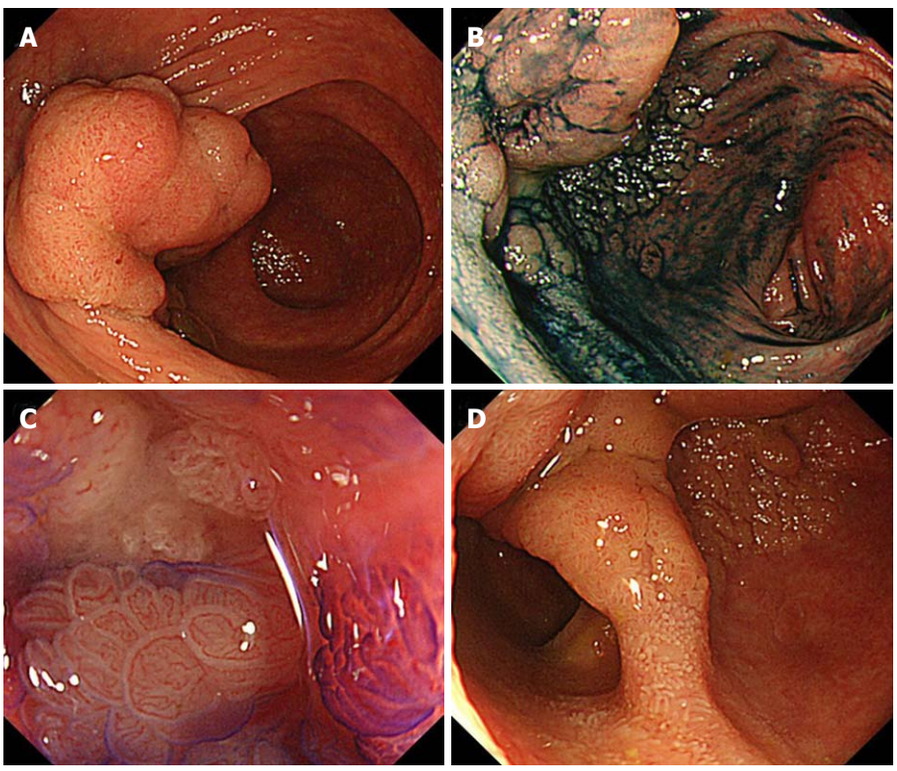

Figure 1 Pre-treatment endoscopic evaluation. A: Close view of the cecum revealed a 70 mm Ⅰs+Ⅱa, LST granular type (LST-G) lesion; B: Clearly delineated margin of the LST-G lesion after 0.4% indigo-carmine dye spraying; C: Magnification view of the Is component of the Ⅰs+Ⅱa (LST-G); D: Spreading confirmation of the tumor through the ileocecal valve to the terminal ileum.

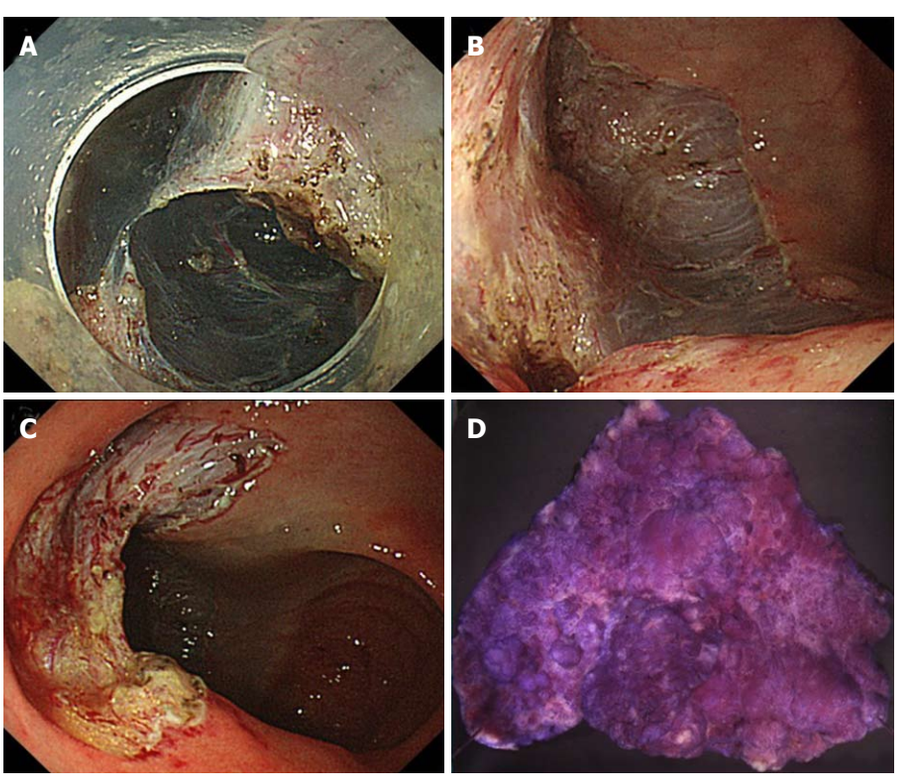

Figure 2 Procedure. A: Endoscopic view through the distal attachment showing dissection with insulation-tip knife; B: Carefully check for bleeding throughout the ileocecal region; C: The ulcer bed of ileum after *en-bloc* endoscopic submucosal dissection; D: Stereomicroscopic view presenting the resected specimen, which pathology reported as a Ⅰs+Ⅱa intramucosal cancer with tumor-free margins of 70 mm in diameter.

cecum. Conventional colonoscopy revealed a broad base, flat tumor. After 0.4% indigo-carmine dye spraying, the margin of the 70 mm-lesion was clearly delineated (Figure 1A and B). High-magnification colonoscopy (PCF-Q240ZI; Olympus Optical Co. Ltd, Tokyo, Japan) disclosed a non-invasive pit pattern[10-12] indicating an intramucosal cancer despite the lesion's large size (Figure 1C). Extension onto the terminal ileum until 1.5 cm from the ileocecal valve was also observed (Figure 1D). After diagnosing a Ⅰs+Ⅱa, LST granular type (LST-G), we performed ESD using B-Knife and insulation-tip knife (IT-Knife) (Olympus Optical Co., Tokyo, Japan) (Figure 2A). During the procedure, we used CO_2 instead of air insufflation to reduce patient's intraoperative abdominal discomfort. This is a safe and effective technique suitable in lengthy colonic endoscopic procedures with the patient under

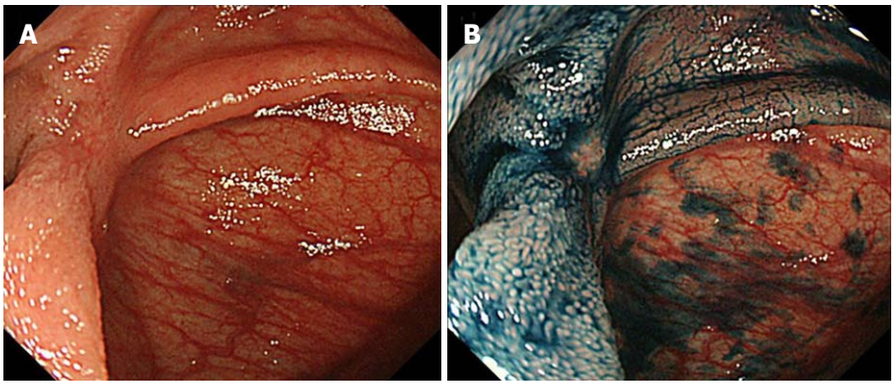

Figure 3 Post-endoscopic submucosal dissection follow-up endoscopic view of the cecum. A: After 6 mo, it shows mildly deformed ileocecal valve due to post-operative scar; B: Following indigo-carmine spraying, no recurrence can be seen.

conscious sedation[13]. Following the injection of glycerol and sodium hyaluronate solution into the sm layer[14,15], a circumferential incision was made using a B-Knife. The thickened sm layer was then dissected (oral to anal) across the ileocecal valve using both the B-Knife and IT-Knife. Finally, hemostasis was carefully checked throughout the ileocecal region (Figure 2B and C). The procedure took 150 min and neither perforation nor delayed bleeding was recognized. Hospitalization lasted four days with no further complications. Histopathology disclosed that the 70 mm resected specimen was an intramucosal cancer with tumor-free margins (Figure 2D). Although some retraction of the ileocecal valve could be observed, follow-up examinations after 6 mo revealed no residual tumor or recurrence (Figure 3A and B).

DISCUSSION

In the present report, en-bloc resection was successfully achieved by ESD using B-Knife and IT-Knife, despite the difficult location involving the ileocecal valve and terminal ileum and the large size of the lesion. IT-Knife, a developed insulation-tipped monopolar electrosurgical knife for removing large gastric lesions en-bloc, is not widely accepted in the colorectum because of its technical difficulty and the risk of complications, such as perforation and bleeding. On the other hand, a bipolar current minimizes the damage to deeper tissues. Thus, the current flow characteristics of the B-Knife reduce the vertical damage and risk of perforation demonstrating its utility for ileocecal ESDs[9,10].

Another important consideration was patient discomfort with air insufflation in long procedures. The supply of air can easily flow into the ileum causing painful distension even in EMRs for cecal lesions. In an earlier study aimed at reducing abdominal discomfort using CO_2 in colorectal ESDs, we demonstrated the advantages and safety of CO_2 compared to conventional air[14]. This factor was evident in the present case. Although a large amount of CO_2 was supplied to the ileum, only a small amount of midazolam (4 mg in both cases) was required for intra-operative sedation.

Considering the indications for colorectal ESD, we generally recommend ESD for LST-non granular type lesions > 20 mm and planned piecemeal EMR for LST-Gs M < 40 mm[3]. In these four cases, we decided to perform ESD because of the LST-Gs large size, their location at the ileocecal valve and terminal ileum spreading, the probability of sm infiltration, and an increased likelihood of incomplete resections and recurrence.

Limitations

In our institution, we have performed colorectal ESD using a B-Knife and an IT-Knife in 500 cases. Among of these 500 ESDs, large LST involving the ileocecal valve were only 4 cases, including the presented case. Based on our experience, lesions should be limited at most to 1 or 2 cm into the ileum and not circumferential. If the extension is more than 2 cm or circumferential, ESD would be very difficult and hazardous, so laparoscopy-assisted colectomy should be recommended. The reported case extended 1.5 cm into the ileum, making the most challenging one. Compared with conventional EMR[16], however, the longer procedure time for colorectal ESDs is still a problem. Nevertheless, we are improving our learning curve and using newly developed devices to reduce the length of the procedure and associated complications in order to increase the widespread use of colorectal ESD.

In conclusion, we successfully performed ESD in large LST-G involving the ileocecal valve and terminal ileum using a B-Knife and an IT-Knife with CO_2 insufflation.

GENERAL INFORMATION

World Journal of Gastroenterology (*World J Gastroenterol*, *WJG*, print ISSN 1007-9327, online ISSN 2219-2840, DOI: 10.3748) is a weekly, open-access (OA), peer-reviewed journal supported by an editorial board of 1361 experts in gastroenterology and hepatology from 64 countries.

The biggest advantage of the OA model is that it provides free, full-text articles in PDF and other formats for experts and the public without registration, which eliminates the obstacle that traditional journals possess and usually delays the speed of the propagation and communication of scientific research results. The open access model has been proven to be a true approach that may achieve the ultimate goal of the journals, i.e. the maximization of the value to the readers, authors and society.

Maximization of personal benefits

The role of academic journals is to exhibit the scientific levels of a country, a university, a center, a department, and even a scientist, and build an important bridge for communication between scientists and the public. As we all know, the significance of the publication of scientific articles lies not only in disseminating and communicating innovative scientific achievements and academic views, as well as promoting the application of scientific achievements, but also in formally recognizing the "priority" and "copyright" of innovative achievements published, as well as evaluating research performance and academic levels. So, to realize these desired attributes of *WJG* and create a well-recognized journal, the following four types of personal benefits should be maximized. The maximization of personal benefits refers to the pursuit of the maximum personal benefits in a well-considered optimal manner without violation of the laws, ethical rules and the benefits of others. (1) Maximization of the benefits of editorial board members: The primary task of editorial board members is to give a peer review of an unpublished scientific article via online office system to evaluate its innovativeness, scientific and practical values and determine whether it should be published or not. During peer review, editorial board members can also obtain cutting-edge information in that field at first hand. As leaders in their field, they have priority to be invited to write articles and publish commentary articles. We will put peer reviewers' names and affiliations along with the article they reviewed in the journal to acknowledge their contribution; (2) Maximization of the benefits of authors: Since *WJG* is an open-access journal, readers around the world can immediately download and read, free of charge, high-quality, peer-reviewed articles from *WJG* official website, thereby realizing the goals and significance of the communication between authors and peers as well as public reading; (3) Maximization of the benefits of readers: Readers can read or use, free of charge, high-quality peer-reviewed articles without any limits, and cite the arguments, viewpoints, concepts, theories, methods, results, conclusion or facts and data of pertinent literature so as to validate the innovativeness, scientific and practical values of their own research achievements, thus ensuring that their articles have novel arguments or viewpoints, solid evidence and correct conclusion; and (4) Maximization of the benefits of employees: It is an iron law that a first-class journal is unable to exist without first-class editors, and only first-class editors can create a first-class academic journal. We insist on strengthening our team cultivation and construction so that every employee, in an open, fair and transparent environment, could contribute their wisdom to edit and publish high-quality articles, thereby realizing the maximization of the personal benefits of editorial board members, authors and readers, and yielding the greatest social and economic benefits.

Aims and scope

The major task of *WJG* is to report rapidly the most recent results in basic and clinical research on esophageal, gastrointestinal, liver, pancreas and biliary tract diseases, *Helicobacter pylori*, endoscopy and gastrointestinal surgery, including: gastroesophageal reflux disease, gastrointestinal bleeding, infection and tumors; gastric and duodenal disorders; intestinal inflammation, microflora and immunity; celiac disease, dyspepsia and nutrition; viral hepatitis, portal hypertension, liver fibrosis, liver cirrhosis, liver transplantation, and metabolic liver disease; molecular and cell biology; geriatric and pediatric gastroenterology; diagnosis and screening, imaging and advanced technology.

Columns

The columns in the issues of *WJG* will include: (1) Editorial: To introduce and comment on major advances and developments in the field; (2) Frontier: To review representative achievements, comment on the state of current research, and propose directions for future research; (3) Topic Highlight: This column consists of three formats, including (A) 10 invited review articles on a hot topic, (B) a commentary on common issues of this hot topic, and (C) a commentary on the 10 individual articles; (4) Observation: To update the development of old and new questions, highlight unsolved problems, and provide strategies on how to solve the questions; (5) Guidelines for Basic Research: To provide guidelines for basic research; (6) Guidelines for Clinical Practice: To provide guidelines for clinical diagnosis and treatment; (7) Review: To review systemically progress and unresolved problems in the field, comment on the state of current research, and make suggestions for future work; (8) Original Article: To report innovative and original findings in gastroenterology; (9) Brief Article: To briefly report the novel and innovative findings in gastroenterology and hepatology; (10) Case Report: To report a rare or typical case; (11) Letters to the Editor: To discuss and make reply to the contributions published in *WJG*, or to introduce and comment on a controversial issue of general interest; (12) Book Reviews: To introduce and comment on quality monographs of gastroenterology and hepatology; and (13) Guidelines: To introduce consensuses and guidelines reached by international and national academic authorities worldwide on basic research and clinical practice gastroenterology and hepatology.

SPECIAL STATEMENT

All articles published in this journal represent the viewpoints of the authors except where indicated otherwise.

Biostatistical editing
Statistical review is performed after peer review. We invite an expert in Biomedical Statistics from to evaluate the statistical method used in the paper, including *t*-test (group or paired comparisons), chi-squared test, Ridit, probit, logit, regression (linear, curvilinear, or stepwise), correlation, analysis of variance, analysis of covariance, *etc*. The reviewing points include: (1) Statistical methods should be described when they are used to verify the results; (2) Whether the statistical techniques are suitable or correct; (3) Only homogeneous data can be averaged. Standard deviations are preferred to standard errors. Give the number of observations and subjects (*n*). Losses in observations, such as drop-outs from the study should be reported; (4) Values such as ED50, LD50, IC50 should have their 95% confidence limits calculated and compared by weighted probit analysis (Bliss and Finney); and (5) The word 'significantly' should be replaced by its synonyms (if it indicates extent) or the *P* value (if it indicates statistical significance).

Conflict-of-interest statement
In the interests of transparency and to help reviewers assess any potential bias, *WJG* requires authors of all papers to declare any competing commercial, personal, political, intellectual, or religious interests in relation to the submitted work. Referees are also asked to indicate any potential conflict they might have reviewing a particular paper. Before submitting, authors are suggested to read "Uniform Requirements for Manuscripts Submitted to Biomedical Journals: Ethical Considerations in the Conduct and Reporting of Research: Conflicts of Interest" from International Committee of Medical Journal Editors (ICMJE), which is available at: http://www.icmje.org/ethical_4conflicts.html.

Sample wording: [Name of individual] has received fees for serving as a speaker, a consultant and an advisory board member for [names of organizations], and has received research funding from [names of organization]. [Name of individual] is an employee of [name of organization]. [Name of individual] owns stocks and shares in [name of organization]. [Name of individual] owns patent [patent identification and brief description].

Statement of informed consent
Manuscripts should contain a statement to the effect that all human studies have been reviewed by the appropriate ethics committee or it should be stated clearly in the text that all persons gave their informed consent prior to their inclusion in the study. Details that might disclose the identity of the subjects under study should be omitted. Authors should also draw attention to the Code of Ethics of the World Medical Association (Declaration of Helsinki, 1964, as revised in 2004).

Statement of human and animal rights
When reporting the results from experiments, authors should follow the highest standards and the trial should conform to Good Clinical Practice (for example, US Food and Drug Administration Good Clinical Practice in FDA-Regulated Clinical Trials; UK Medicines Research Council Guidelines for Good Clinical Practice in Clinical Trials) and/or the World Medical Association Declaration of Helsinki. Generally, we suggest authors follow the lead investigator's national standard. If doubt exists whether the research was conducted in accordance with the above standards, the authors must explain the rationale for their approach and demonstrate that the institutional review body explicitly approved the doubtful aspects of the study.

Before submitting, authors should make their study approved by the relevant research ethics committee or institutional review board. If human participants were involved, manuscripts must be accompanied by a statement that the experiments were undertaken with the understanding and appropriate informed consent of each. Any personal item or information will not be published without explicit consents from the involved patients. If experimental animals were used, the materials and methods (experimental procedures) section must clearly indicate that appropriate measures were taken to minimize pain or discomfort, and details of animal care should be provided.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Number all pages consecutively, and start each of the following sections on a new page: Title Page, Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures, and Figure Legends. Neither the editors nor the publisher are responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of Baishideng Publishing Group Co., Limited, and may not be reproduced by any means, in whole or in part, without the written permission of both the authors and the publisher. We reserve the right to copy-edit and put onto our website accepted manuscripts. Authors should follow the relevant guidelines for the care and use of laboratory animals of their institution or national animal welfare committee. For the sake of transparency in regard to the performance and reporting of clinical trials, we endorse the policy of the ICMJE to refuse to publish papers on clinical trial results if the trial was not recorded in a publicly-accessible registry at its outset. The only register now available, to our knowledge, is http://www.clinicaltrials.gov sponsored by the United States National Library of Medicine and we encourage all potential contributors to register with it. However, in the case that other registers become available you will be duly notified. A letter of recommendation from each author's organization should be provided with the contributed article to ensure the privacy and secrecy of research is protected.

Authors should retain one copy of the text, tables, photographs and illustrations because rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for loss or damage to photographs and illustrations sustained during mailing.

Online submissions

Manuscripts should be submitted through the Online Submission System at: http://www.wjgnet.com/1007-9327office. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm) before attempting to submit online. For assistance, authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com, or by telephone: +86-10-5908-0039. If you submit your manuscript online, do not make a postal contribution. Repeated online submission for the same manuscript is strictly prohibited.

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using word-processing software. All submissions must be typed in 1.5 line spacing and 12 pt. Book Antiqua with ample margins. Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page

Title: Title should be less than 12 words.

Running title: A short running title of less than 6 words should be provided.

Authorship: Authorship credit should be in accordance with the standard proposed by ICMJE, based on (1) substantial contributions to conception and design, acquisition of data, or analysis and interpretation of data; (2) drafting the article or revising it critically for important intellectual content; and (3) final approval of the version to be published. Authors should meet conditions 1, 2, and 3.

Institution: Author names should be given first, then the complete name of institution, city, province and postcode. For example, Xu-Chen Zhang, Li-Xin Mei, Department of Pathology, Chengde Medical College, Chengde 067000, Hebei Province, China. One author may be represented from two institutions, for example, George Sgourakis, Department of General, Visceral, and Transplantation Surgery, Essen 45122, Germany; George Sgourakis, 2nd Surgical Department, Korgialenio-Benakio Red Cross Hospital, Athens 15451, Greece.

Author contributions: The format of this section should be: Author contributions: Wang CL and Liang L contributed equally to this work; Wang CL, Liang L, Fu JF, Zou CC, Hong F and Wu XM designed the research; Wang CL, Zou CC, Hong F and Wu XM performed the research; Xue JZ and Lu JR contributed new reagents/analytic tools; Wang CL, Liang L and Fu JF analyzed the data; and Wang CL, Liang L and Fu JF wrote the paper.

Supportive foundations: The complete name and number of supportive foundations should be provided, e.g. Supported by National Natural Science Foundation of China, No. 30224801

Correspondence to: Only one corresponding address should be provided. Author names should be given first, then author title, affiliation, the complete name of institution, city, postcode, province, country, and email. All the letters in the email should be in lower case. A space interval should be inserted between country name and email address. For example, Montgomery Bissell, MD, Professor of Medicine, Chief, Liver Center, Gastroenterology Division, University of California, Box 0538, San Francisco, CA 94143, United States. montgomery.bissell@ucsf.edu

Telephone and fax: Telephone and fax should consist of +, country number, district number and telephone or fax number, e.g. Telephone: +86-10-59080039 Fax: +86-10-85381893

Peer reviewers: All articles received are subject to peer review. Normally, three experts are invited for each article. Decision for acceptance is made only when at least two experts recommend an article for publication. Reviewers for accepted manuscripts are acknowledged in each manuscript, and reviewers of articles which were not accepted will be acknowledged at the end of each issue. To ensure the quality of the articles published in *WJG*, reviewers of accepted manuscripts will be announced by publishing the name, title/position and institution of the reviewer in the footnote accompanying the printed article. For example, reviewers: Professor Jing-Yuan Fang, Shanghai Institute of Digestive Disease, Shanghai, Affiliated Renji Hospital, Medical Faculty, Shanghai Jiaotong University, Shanghai, China; Professor Xin-Wei Han, Department of Radiology, The First Affiliated Hospital, Zhengzhou University, Zhengzhou, Henan Province, China; and Professor Anren Kuang, Department of Nuclear Medicine, Huaxi Hospital, Sichuan University, Chengdu, Sichuan Province, China.

Abstract

There are unstructured abstracts (no less than 256 words) and structured abstracts (no less than 480). The specific requirements for structured abstracts are as follows:

An informative, structured abstracts of no less than 480 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections.

AIM (no more than 20 words): Only the purpose should be included. Please write the aim as the form of "To investigate/study/…"; MATERIALS AND METHODS (no less than 140 words); RESULTS (no less than 294 words): You should present *P* values where appropriate and must provide relevant data to illustrate how they were obtained, e.g. 6.92 ± 3.86 *vs* 3.61 ± 1.67, $P < 0.001$; CONCLUSION (no more than 26 words).

Key words

Please list 5-10 key words, selected mainly from *Index Medicus*, which reflect the content of the study.

Text

For articles of these sections, original articles and brief articles, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the main text or in Figures and Tables, but not in both. The main text format of these sections, editorial, topic highlight, case report, letters to the editors, can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315215714.htm.

Illustrations

Figures should be numbered as 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. Detailed legends should not be provided under the figures. This part should be added into the text where the figures are applicable. Figures should be either Photoshop or Illustrator files (in tiff, eps, jpeg formats) at high-resolution. Examples can be found at: http://www.wjgnet.com/1007-9327/13/4520.pdf; http://www.wjgnet.com/1007-9327/13/4554.pdf; http://www.wjgnet.com/1007-9327/13/4891.pdf; http://www.wjgnet.com/1007-9327/13/4986.pdf; http://www.wjgnet.com/1007-9327/13/4498.pdf. Keeping all elements compiled is necessary in line-art image. Scale bars should be used rather than magnification factors, with the length of the bar defined in the legend rather than on the bar itself. File names should identify the figure and panel. Avoid layering type directly over shaded or textured areas. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes in atrophic gastritis after treatment. A:...; B:...; C:...; D:...; E:...; F:...; G: …*etc.* It is our principle to publish high resolution-figures for the printed and E-versions.

Tables

Three-line tables should be numbered 1, 2, 3, *etc.*, and mentioned clearly in the main text. Provide a brief title for each table. Detailed legends should not be included under tables, but rather added into the text where applicable. The information should complement, but not duplicate the text. Use one horizontal line under the title, a second under column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations

Data that are not statistically significant should not be noted. $^{a}P < 0.05$, $^{b}P < 0.01$ should be noted ($P > 0.05$ should not be noted). If there are other series of *P* values, $^{c}P < 0.05$ and $^{d}P < 0.01$ are used. A third series of *P* values can be expressed as $^{e}P < 0.05$ and $^{f}P < 0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or sometimes as other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.*, in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscript and who endorse the data and conclusions should be included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

REFERENCES

Coding system

The author should number the references in Arabic numerals according to the citation order in the text. Put reference numbers in square brackets in superscript at the end of citation content or after the cited author's name. For citation content which is part of the narration, the coding number and square brackets should be typeset normally. For example, "Crohn's disease (CD) is associated with increased intestinal permeability[1,2]". If references are cited directly in the text, they should be put together within the text, for example, "From references[19,22-24], we know that...".

When the authors write the references, please ensure that the order in text is the same as in the references section, and also ensure the spelling accuracy of the first author's name. Do not list the same citation twice.

PMID and DOI

Pleased provide PubMed citation numbers to the reference list, e.g. PMID and DOI, which can be found at http://www.ncbi.nlm.nih.gov/sites/entrez?db=pubmed and http://www.crossref.org/SimpleTextQuery/, respectively. The numbers will be used in E-version of this journal.

Style for journal references

Authors: the name of the first author should be typed in boldfaced letters. The family name of all authors should be typed with the initial letter capitalized, followed by their abbreviated first and middle initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). The title of the cited article and italicized journal title (journal title should be in its abbreviated form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634 DOI: 10.3748/wjg.13.5396].

Style for book references

Authors: the name of the first author should be typed in boldfaced letters. The surname of all authors should be typed with the initial letter capitalized, followed by their abbreviated middle and first initials. (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

Statistical data

Write as mean ± SD or mean ± SE.

Statistical expression

Express *t* test as *t* (in italics), *F* test as *F* (in italics), chi square test as χ^2 (in Greek), related coefficient as *r* (in italics), degree of freedom as υ (in Greek), sample number as *n* (in italics), and probability as *P* (in italics).

Units

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, p (B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2, not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format for how to accurately write common units and quantums can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315223018.htm.

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further explanation.

Italics

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyrA*, *arg* 1, *c myc*, *c fos*, *etc.*

Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*

Biology: *H. pylori*, *E coli*, *etc.*

RESUBMISSION OF THE REVISED MANUSCRIPTS

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be re-submitted online (http://www.wjgnet.com/1007-9327office/). The author should send the copyright transfer letter, responses to the reviewers, English language Grade B certificate (for non-native speakers of English) and final manuscript checklist to wjg@wjgnet.com.

Language evaluation

The language of a manuscript will be graded before it is sent for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing needed; and (4) Grade D: rejected. Revised articles should reach Grade A or B.

Copyright assignment form

Please download a Copyright assignment form from http://www.wjgnet.com/1007-9327/g_info_20100315222818.htm.

Responses to reviewers

Please revise your article according to the comments/suggestions provided by the reviewers. The format for responses to the reviewers' comments can be found at: http://www.wjgnet.com/1007-9327/g_info_20100315222607.htm.

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Links to documents related to the manuscript

WJG will be initiating a platform to promote dynamic interactions between the editors, peer reviewers, readers and authors. After a manuscript is published online, links to the PDF version of the submitted manuscript, the peer-reviewers' report and the revised manuscript will be put on-line. Readers can make comments on the peer reviewer's report, authors' responses to peer reviewers, and the revised manuscript. We hope that authors will benefit from this feedback and be able to revise the manuscript accordingly in a timely manner.

Science news releases

Authors of accepted manuscripts are suggested to write a science news item to promote their articles. The news will be released rapidly at EurekAlert/AAAS (http://www.eurekalert.org). The title for news items should be less than 90 characters; the summary should be less than 75 words; and main body less than 500 words. Science news items should be lawful, ethical, and strictly based on your original content with an attractive title and interesting pictures.

Publication fee

WJG is an international, peer-reviewed, Open-Access, online journal. Articles published by this journal are distributed under the terms of the Creative Commons Attribution Non-commercial License, which permits use, distribution, and reproduction in any medium, provided the original work is properly cited, the use is non commercial and is otherwise in compliance with the license. Authors of accepted articles must pay a publication fee. The related standards are as follows. Publication fee: 1300 USD per article. Editorial, topic highlights, book reviews and letters to the editor are published free of charge.

Abstract

The latest avenue of research is revealing the existence of and role for the colonic stem cells in the physiological renewal of the mucosa and in pathological circumstances where they have both positive and negative effects. In the case of human colon, different levels of stem cell compartments exist. First, the crypt epithelial stem cells, which have a role in the normal crypt epithelial cell dynamics and in colorectal carcinogenesis. Close to the crypts, the second layer of stem cells can be found; the local subepithelial stem cell niche, including the pericryptic subepithelial myofibroblasts that regulate the epithelial cell differentiation and have a crucial role in cancer progression and chronic inflammation-related fibrosis. The third level of stem cell compartment is the immigrating bone-marrow-derived stem cells, which have an important role in wound healing after severe mucosal inflammation, but are also involved in cancer invasion. This paper focuses on stem cell biology in the context of physiological and pathological processes in the human colon.

Key words: Colon; Mesencyhmal stem cells; Bone marrow; Myofibroblast; Fibrosis; Colorectal cancer; Parathyroid hormone; Transforming growth factor-β

INTRODUCTION

Beside water and electrolyte absorption, barrier function is a major physiological function of the colonic mucosa, which is the basis of the defense against the luminal pathogens and toxins. Keeping the integrity of the epithelial layer therefore is of great importance, in which stem cells as the key elements of the mucosal regeneration have an important role.

The epithelial layer of the colon consists of a single sheet of columnar epithelial cells folded into finger-like invaginations that are surrounded by the lamina propria to form a functional unit, called Lieberkühn's crypt. It has been estimated that there are about 20 million of these crypts in the human colon[1]. There are four epithelial cell lineages within the crypt. Enterocytes, goblet cells and endocrine cells are terminally differentiated cells, which are found in the upper third of the crypt, and are derived from multipotent stem cells located at the bottom of the crypt. During asymmetric division, these epithelial stem cells undergo self-renewal and generate a population of transit amplifying cells that, upon migration upward

through the crypt, proliferate and differentiate into one of the epithelial cell types of the crypt wall. The fourth type is the Paneth cell, which differentiates during a downward migration to the base of the crypt, where they reside below the crypt epithelial stem cell population[2].

Extensive experimental evidence has demonstrated that Wnt/β-catenin signaling plays a central role in maintaining the intestinal stem-cell niche and regulating normal crypt dynamics[3-7].

The origin of crypt epithelial stem cells is probably dual. Regarding their origin, there are two major kinds of stem cells in the subepithelial layer of the colonic mucosa: the local mesenchymal stem cells (MSCs) and the immigrating bone-marrow-derived stem cells[8,9] (Figures 1 and 2). In the case of mild to moderate mucosal injury, the local subepithelial stem cell niche is enough for differentiating to the epithelial lineage[8]. In the adult gut, both the number and differentiation capacity of the local stem cells are low. In the case of serious tissue injury [i.e., graft-versus-host disease, inflammatory bowel disease (IBD)] the regenerative capacity of local stem cells is not enough to complete tissue healing. In this case, bone-marrow-derived MSCs (BM-MSCs) migrate into the gastrointestinal wall, where they may contribute to the repair progress[9-11] as differentiated mesenchymal cells (e.g., myofibroblasts)[12,13]. Intestinal subepithelial myofibroblasts have a key role in the support of the epithelial stem cell compartment. They can originate from local subepithelial fibroblasts[14], and from immigrating bone marrow derived cells[15]. The bone marrow origin of these cells may be supposed by such observations in which co-expression of epithelial and hematopoietic lineage markers on them were found in inflamed mucosa adjacent to subepithelial lymphoid aggregates[16-20]. Both processes are regulated by transforming growth β-1 (TGF-β1), which plays an important role in intestinal mucosal healing[21].

Although our knowledge is expanding about the origin and behavior of subepithelial colonic stem cells, data about their effect in pathological circumstances like inflammation, fibrosis or cancer development are scattered throughout the literature. A better understanding of the regulation of their differentiation may help to establish new therapeutic strategies.

LOCAL SUBEPITHELIAL STEM CELL COMPARTMENT OF THE COLON

The local MSCs, namely the pericryptal myofibroblasts, which form the epithelial stem cell niche and also regulate epithelial cell differentiation are important cells orchestrating many diverse functions in the intestine, and are involved in growth and repair, tumorigenesis, inflammation, and fibrosis[22]. Adult myofibroblasts are derived or replenished after injury or in response to neoplastic transformation from several sources: differentiation or activation of resident fibroblasts, dedifferentiation from perivascular smooth muscle cells and adipocytes, epithelial-to-mesenchymal transition of epithelial and endothelial cells, and bone-marrow-derived stem cells. MSCs or hematopoietic stem cells, *via* $CD14^+$ monocytes, transdifferentiate into circulating $CD34^+$ fibrocytes, which become resident $CD34^+$ fibrocytes[7,12].

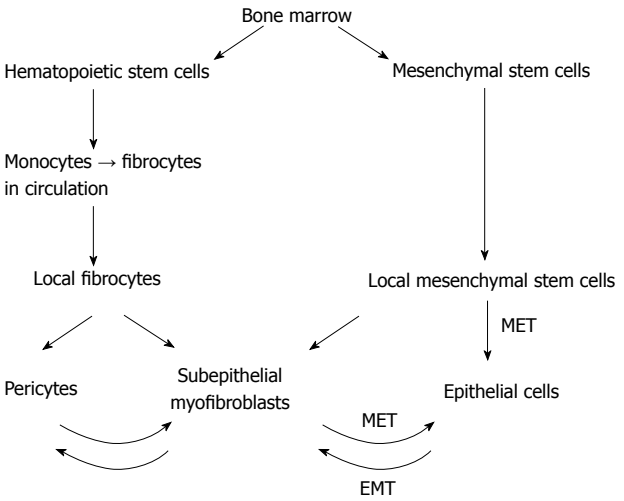

Figure 1 Possible origin of the colonic mesenchymal and epithelial cells. Arrows represents possible stem cell origin and routes for derivation of colonic mesenchymal and epithelial cells. MET: Mesenchymal-to-epithelial transition; EMT: Epithelial-to-mesenchymal transition.

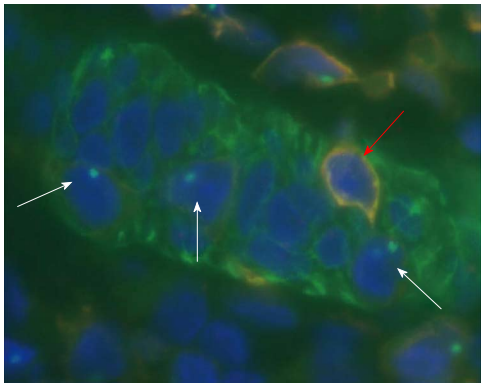

Figure 2 $CD45^-$/cytokeratin$^+$ epithelial cells (green cytoplasmic immunoreaction) containing Y chromosomes (green nuclear dots; white arrows) in the germinative zone of a colonic crypt are well differentiating from the $CD45^+$ intraepithelial lymphocyte (red arrow) (cytokeratin-fluorescein isothiocyanate; CD45-rhodamine; Y-chromosome fluorescence in situ hybridization in a biopsy sample of male bone marrow recipient female patient with moderate non-specific colitis; 100 × magnification).

Migration of colonic fibroblasts into and through the extracellular matrix during the initial phase of mucosal healing appears to be a fundamental component of wound contraction. In recent studies, it has been shown that colonic lamina propria fibroblast-conditioned media induce migration of primary human colonic fibroblasts in the modified Boyden chamber, and fibronectin is mainly responsible for this autocrine migration induction[23]. The differentiation of fibroblasts into myofibroblasts is an important step in tissue repair. It has been described that TGF-β1 potently stimulates the production of smooth muscle actin and stress fiber formation in fibroblasts and therefore their differentiation into myofibroblasts[24]; moreover, it also regulates their migration[14]. Only fibroblasts expressing Thy-1 (CD90), a cell-surface glycoprotein of T-cells, can differentiate into myofibroblasts

Table 1 Summary of the characteristics of the different types of stem cells in the human colon

	Crypt epithelial stem cells	Subepithelial (pericryptal) myofibroblasts-local stem cell niche	BM-MSCs
Origin	Pericryptal myofibroblasts	Subepithelial CD34+ fibroblasts, perivascular smooth muscle cells, adipocytes, endothelial- and epithelial cells (*via* EMT), BM-MSCs	Bone marrow
Daughter cells	Enterocytes, goblet cells, endocrine cells, paneth cells	Follicular dendritic cells, crypt epithelial stem cells, pericytes	Subepithelial myofibroblasts, fibrocytes, pericytes, adipocytes, crypt epithelial stem cells
Main regulator pathways of differentiation and/or homing	Wnt/β-catenin, Lgr-5, integrins, growth factor receptors (EGFR, HGFR, I1GFR)	TGF-β1, cytokines (IL-1, -6, -10, TNFα), growth factors (TGFα, GM-CSF, PDGF-AA, -BB, bFGF, KGF, HGF), chemokines (IL-8, MCP1, MIP-1α,-2), inflammatory mediators (PGE2, PAF, PGI2)	Chemokine receptors (CCR-1,-2,-7,-8,-9; CXCR-1,-2,-4,-5,-6), cell adhesion molecules involved in extravasation (VCAM, ICAM, selectins), proinflammatory cytokines (TNFα, IL-8), von Willebrand factor
Physiological function	Epithelial renewal	Growth, repair	Growth, repair, wound healing
Pathological function	Tumorigenesis, ulcer development	Tumorigenesis, cancer progression, inflammation, fibrosis	Tumorigenesis, inflammation, fibrosis
Cell type specific markers	Positive markers: Lgr-5, Musashi-1, CDX-2	Negative markers: smoothelin, caldesmon, desmin Positive markers: α-SMA, vimentin, SMM, prolyl 4-hydroxylase, CD90	Negative markers: CD13, -14, -45, c-Kit, MHC class Ⅰ and Ⅱ Positive markers: CD54,-90,-133,-146,-166, Flk-1, Sca-1, stage-specific antigen Ⅰ, musashi-1, HLA class Ⅰ

Lgr-5: Leucine-rich repeat-containing G-protein coupled receptor 5; EGFR: Epithelial growth factor receptor; HGFR: Hepatocyte growth factor receptor; I1GFR: Insulin-like growth factor receptor-1; CDX2: Caudal type homeobox transcription factor 2; EMT: Epithelial-to-mesenchymal transition; TGF: Transforming growth factor; IL: Interleukin; TNF: Tumor necrosis factor; GM-CSF: Granulocyte macrophage colony-stimulating factor; PDGF: Platelet-derived growth factor; bFGF: Basic fibroblast growth factor; KGF: Keratinocyte growth factor; HGF: Hepatocyte growth factor; MCP1: Monocyte chemotactic protein 1; MIP: Macrophage inflammatory protein; PGE2: Prostaglandin E2; PAF: Platelet-activating factor; PGI2: Prostacyclin; SMA: Smooth muscle actin; SMM: Smooth muscle myosin; CCR: Chemokine receptor; CXCR: Chemokine CXC motif receptor; VCAM: Vascular cell adhesion molecule; ICAM: Intercellular cell adhesion molecule; MHC: Major histocompatibility complex; Flk-1: Fetal liver kinase-1; Sca-1: Stem cell antigen-1; HLA: Human leukocyte antigen.

after treatment with TGF-β, whereas only Thy-1$^-$ fibroblasts differentiate into lipofibroblasts upon exposure to 15-deoxy-δ-prostaglandin J2[25]. After differentiation, subepithelial myofibroblasts form pericryptal fibroblast sheet adjacent to the basal lamina of colonic crypts[10,26]. Intestinal subepithelial myofibroblasts contribute to the coordination of tissue regeneration by producing TGF-β, epidermal growth factor, basic fibroblast growth factor, proinflammatory cytokines, and the formation of new basement membrane[27].

Brown *et al*[28] have reported a cyclooxygenase-2-expressing stromal cell that moves in response to Toll-like receptor (TLR) signals from a position in the upper aspect of the lamina propria to a position adjacent to the pericryptal myofibroblasts in the base of the crypts, where the crypt epithelial stem cells reside. This relocation and the prostaglandin secretion appear critical to colonic epithelial repair in a dextran sodium sulfate colitis model. Their study has not ruled out a role for prostaglandin production or TLR responses by the conventional myofibroblasts or pericytes that are also present.

COLONIC BM-MSCs

The number of myofibroblasts originating from the bone marrow significantly increased in the lamina propria of severe colitis compared to the healthy colon[9,13]. This homing process is driven by chemokines and adhesion molecules[29] (Table 1). Based on the former results[30-32], emerging evidence suggests that bone-marrow-derived stem cells contribute to tissue regeneration in the colon partly by promoting neovascularization or arteriogenesis. After human hematopoietic cell transplantation, epithelial tissue chimerism appears[33-35]. The bone marrow origin of subepithelial stem cells may be supposed by observations in which epithelial cell markers and leukocyte markers show that double positive cells are found in inflamed mucosa adjacent to lymphoid aggregates[18,19,36]. The presence of cytokeratin, epithelial growth factor receptor, hepatocyte-derived growth factor receptor or CDX2 co-expression in CD45$^+$ cells of subepithelial lymphoid aggregates may support the mesenchymal origin of epithelial stem cells.

Presumably, intestinal subepithelial myofibroblasts originated from BM-MSCs and may create a local microenvironment for the immigrated BM-MSCs that are committed to the epithelial lineage. The high percentages of intraepithelial cells of bone marrow origin are immune cells, such as CD45$^+$ leukocytes. In bone-marrow-transplanted patients, the numbers of CD45$^+$ and Y-FISH$^+$ (male donor origin) double-positive, intraepithelial lymphocytes were significantly higher number in regenerating

colonic epithelium than in the normal samples[35].

Previous studies using animal models of IBD have shown that transplanted bone marrow cells contribute to tissue repair by forming epithelial cells, activated myofibroblasts, and can also contribute to neovasculogenesis in the inflamed colon *via* the formation of entire new blood vessels[37]. It has also been shown that myofibroblasts of bone marrow origin are functional in their production of pro-collagen α1 mRNA[38]. These studies showing bone marrow contribution to tissue regeneration in IBD are now supported by the results of Khalil *et al*[39], who have further shown that regeneration can occur from a defined subpopulation of $CD34^-$ stem cells, present in both the bone marrow and peripheral blood, and moreover, that these stem cells can significantly enhance tissue regeneration in IBD without the need for prior ablation of the recipient's immune system by irradiation.

REGULATION OF STEM CELL HOMING IN THE COLON

The homing of BM-MSCs to colonic mucosa has been poorly revealed to date. BM-MSCs migrate *via* the bloodstream to the sites of colonic mucosal damage, which have been certified in several *in vivo* experiments[11,35,40]. Regulation of BM-MSC migration may happen as an effect of chemical signals, which are upregulated during injury.

Systemically delivered or natively circulating MSCs accumulate in injured tissues. During homing, MSCs adhere to endothelial cells and infiltrate underlying tissue. Previously, it has been shown that adhesiveness of endothelial cells for MSCs correlates with the inhibition of mitochondrial function of endothelial cells and secretion of von Willebrand factor (vWF)[41]. Potapova *et al*[42] have demonstrated that the treatment of endothelial cells with vWF stimulates MSC adhesion in a time- and concentration-dependent manner. MSCs do not adhere to immobilized vWF and do not express receptors for vWF, suggesting that the stimulation of MSC adhesion is a result of endothelial cell activation with vWF. In cell culture experiments, it has also been shown that normal colonic endothelial cells highly express vWF[43]. Based on these results, vWF seems to be an auto/paracrine regulator of colonic endothelial cells. Activation of p38 mitogen-activate protein kinase (MAPK) in endothelial cells by vWF may be responsible for the regulation of endothelial cell adhesiveness for MSCs in the colon.

CXC chemokine receptor (CXCR)4 has also a pivotal role in stem cell homing. It has recently been shown that CXC chemokine ligand 12 and CXCR4 are constitutively expressed on intestinal epithelial cells, lamina propria T cells, and the expression is increased in those of ulcerative colitis patients[44,45]. Induction of CXCR4 is associated with upregulation of two genes encoding transcription factors previously shown to control CXCR4 expression (hypoxia-inducible factor-2α and achaete scute complex like protein 2) and maintenance of crypt epithelial stem cells[46,47].

Subepithelial isolated lymphoid follicles and lymphoid aggregates of the colon are supposed to be the central organizer elements of stem cell homing and the mesenchymal-to-epithelial transition by producing an ideal cytokine, chemokine and cellular milieu[48,49].

PATHOLOGICAL ROLE OF COLONIC STEM CELLS

Epithelial cancer stem cell development

Cancer stem cells are defined as cells that are endowed with both self-renewal and multilineage differentiation potential and, as such, are believed to expand clonally and repopulate the various types of differentiation lineages present within the tumor[50,51].

Crypt epithelial stem cells appear to be the cell of origin of colorectal cancer, based on their existence throughout the lifetime of an individual, and thus, their capacity to acquire multiple genetic mutations leads to carcinogenesis. Direct evidence for crypt epithelial stem cells as the source of intestinal tumors has come from a study of tissue-specific expression of Cre recombinases to inactivate a conditional Apc allele[52]. Although deletion of Apc in epithelial cells results in adenomas at very low frequency and with long latency, inactivation of Apc within epithelial stem cells leads to formation of macroscopic adenomas within 36 d. Moreover, these adenomas retain a small percentage of cells expressing Lgr5, an intestinal stem cell marker. These data support the view that crypt epithelial stem cells are the target of the origin of colorectal cancer. Alteration of crypt epithelial stem cell number or proliferation state may increase the probability of intestinal tumorigenesis.

Múnera *et al*[53] have tested the epithelial cell autonomous function of Ets2, a member of the Ets family of transcription factors, which is located on human chromosome 21, and has been identified as a Wnt target in colorectal cancer cells and crypt epithelial stem cells[54], during chemical carcinogenesis of the colon by using a conditional Ets2 allele and a transgene expressing Cre recombinase only in intestinal epithelial cells. Their results indicate that, although Ets2 is a Wnt pathway target gene within crypt epithelial stem cells, its loss provides a competitive advantage for crypt epithelial stem cells to colonize crypts, increase basal crypt cell proliferation, and increase crypt fission. Ets2 loss may increase the number or sensitivity of colon stem cells for tumor initiation.

The results of Deka *et al*[55] have revealed the essential role for Bcl9/Bcl9l in regulating a subset of Wnt target genes involved in controlling epithelial-to-mesenchymal transition and stem-cell-related features and suggest that targeting the Bcl9/Bcl9l arm of Wnt signaling in Wnt-activated cancers might attenuate these traits, which are associated with tumor invasion, metastasis, and resistance to therapy.

Role of subepithelial stem cells in carcinogenesis and cancer progression

The interaction between cancer cells and non-trans-

formed cells in the tumor microenvironment is essential for tumor growth and progression[56]. The tumor stroma includes several non-transformed cell types, such as endothelial cells, immune cells, and fibroblastic stromal cells (cancer-associated fibroblasts). This latter cell type plays an important role in cancer progression by promoting angiogenesis, epithelial-to-mesenchymal transition, and genetic instability[57-59]. Although tumor stromal fibroblasts are mainly recruited from local tissue fibroblasts, it has been proposed that BM-MSCs are recruited into the stroma of developing tumors[57,60]. Several studies have demonstrated that BM-MSCs can selectively migrate to sites of mucosal damage and wound healing including colorectal cancers, where a number of tumor-related inflammatory reactions and abnormal tissue regeneration phenomena take place actively. It also has been shown that cancer cells release specific factors that induce BM-MSC mobilization and recruitment to the tumor stroma where they eventually contribute to the formation of a tumor-supportive microenvironment[57].

The cause of metastasis remains elusive despite a vast amount of information on cancer cells. According to recent research, cancer cell fusion with macrophages or immigrating BM-MSCs provides an explanation[49,61,62]. BM-MSCs fused with tumor cells are present not just in animal tumor xenografts where they are associated with metastases, but in human carcinomas, including colon cancer. BM-MSC-tumor cell fusion explains the epithelial-to-mesenchymal transition in cancer since BM-MSCs express mesodermal traits and epithelial-to-mesenchymal transition regulators like Twist and SPARC (secreted protein acidic and rich in cysteine). If bone-marrow-derived-tumor cell fusion underlies invasion and metastasis in human cancer, new therapeutic strategies would be mandated.

A new association between parathyroid hormone (PTH) and cancer development has been revealed recently. Based on recent results, PTH can stimulate the phosphoinositide 3-kinase/MAPK-mediated proliferation of rat enterocytes, and primary hyperparathyroidism in humans is associated with an increased incidence of colon cancer[63]. It has been shown in a large cohort[64] that high serum PTH levels may be associated with incident, sporadic colorectal cancer in Western European populations, and in particular among men. PTH has its effect on MSCs/progenitors as they express PTH receptor[65]. Taking together these data, further investigations on PTH and colorectal carcinogenesis would be of great clinical importance.

Stem cells in chronic inflammation-related intestinal fibrosis

Intestinal fibrosis is among the most common complications of IBD, especially Crohn's disease (CD), resulting in stricture formation in the small intestine and colon. About 75% of CD patients will undergo surgery at least once over the course of their disease, and fibrotic strictures represent the main indication for surgery and the first cause of hospitalization and costs for CD patients[66]. Fibrosis in CD is the result of transmural chronic inflammation with repeated episodes of immune-mediated damage and repair[67]. Key factors for intestinal fibrosis are excessive deposition of extracellular matrix, proliferation of profibrogenic mesenchymal cells in the colon, thickening of all layers of the bowel wall, overgrowth of muscular layers of the intestine, enhanced local Th-1 type immune response, and overexpression of profibrogenic cytokines and growth factors[68]. As mentioned above, stromal cells derived from MSCs, fibrocytes, or BM-MSCs may also home to sites of inflammation and, in the presence of ongoing inflammation, become activated myofibroblasts/fibroblasts and contribute to tissue fibrosis[22]. Specific inhibition of the TGF-β signaling pathway, the key regulator of this pathologic process may be a promising therapeutic strategy to reduce the number of profibrogenic mesenchymal cells in chronic intestinal fibrosis[69].

CONCLUSION

The local and immigrating stem cells of the human colon are of major clinical importance because they are all involved in the regeneration of the damaged mucosa (Table 1). The results of the first attempts of MSC therapy in IBD are promising[70-72]. The regulation of the homing and differentiation of stem cells also provides new, individual and disease-specific therapeutic targets in the case of colorectal cancer. Inhibition of the TGF-β signaling pathway may be a promising therapeutic strategy in chronic inflammation-related colon fibrosis. The expected results of the ongoing and forthcoming studies hopefully will open the door to the development of new cures for old diseases.

Abstract

Reactive oxygen species (ROS) attack guanine bases in DNA easily and form 8-hydroxydeoxyguanosine (8-OHdG), which can bind to thymidine rather than cytosine, based on which, the level of 8-OHdG is generally regarded as a biomarker of mutagenesis consequent to oxidative stress. For example, higher levels of 8-OHdG are noted in *Helicobacter pylori*-associated chronic atrophic gastritis as well as gastric cancer. However, we have found that exogenous 8-OHdG can paradoxically reduce ROS production, attenuate the nuclear factor-κB signaling pathway, and ameliorate the expression of proinflammatory mediators such as interleukin (IL)-1, IL-6, cyclo-oxygenase-2, and inducible nitric oxide synthase in addition to expression of nicotinamide adenine dinucleotide phosphate oxidase (NOX)-1, NOX organizer-1 and NOX activator-1 in various conditions of inflammation-based gastrointestinal (GI) diseases including gastritis, inflammatory bowel disease, pancreatitis, and even colitis-associated carcinogenesis. Our recent finding that exogenous 8-OHdG was very effective in either inflammation-based or oxidative-stress-associated diseases of stress-related mucosal damage has inspired the hope that synthetic 8-OHdG can be a potential candidate for the treatment of inflammation-based GI diseases, as well as the prevention of inflammation-associated GI cancer. In this editorial review, the novel fact that exogenous 8-OHdG can be a functional molecule regulating oxidative-stress-induced gastritis through either antagonizing Rac-guanosine triphosphate binding or blocking the signals responsible for gastric inflammatory cascade is introduced.

Key words: 8-hydroxydeoxyguanosine; Oxidative stress; Inflammation; Carcinogenesis; Prevention

INTRODUCTION

When we consume a soft drink or eat a meal, the gastrointestinal (GI) mucosa is continuously stressed with various antigens that we have ingested because the GI lumen is actually outside the body[1]. As far as the interaction between materials from outside and the physiological barriers of the GI tract is concerned, everything existing outside the GI lumen can cause stressful reactions at the cellular level through mechanisms including antigen challenge, concurring oxidative stress, and some inflammatory assaults. The GI lumen can come under attack by many factors, including solid food, *Helicobacter pylori* (*H. pylori*) and other commensal bacteria, nonsteroidal anti-inflammatory drugs, and gastric acid[2-4]. In particular, one important means of attack is mediated by oxygen, which is also the most important metabolic substance in the body. In spite of being essential for life, oxygen can cause various cellular stresses called oxidative stress by generating reactive oxygen species (ROS)[5]. The definition of oxidative stress is a disturbance of oxidant-antioxidant homeostasis, leading to potential cellular damage. Even though the existence of ROS and their pathological implications were discovered < 50 years ago, it is surprising that many diseases can be explained by oxidative stress and its subsequent dysregulation. Although ROS are a crucial regulator of cellular signal transduction and energy transmission, disturbance of the balance between generating and scavenging capability of ROS might lead to cell damage. ROS can react with cellular proteins or lipids, transforming them into oxidized forms, or bind with nucleic acids, turning them into mutated forms. It is particularly interesting that oxidative stress is closely associated with carcinogenesis.

Fortunately, to cope with these harmful effects of oxidative stress, cells may endeavor to enhance defensive factors of various types. The common examples of defense factors are reduced glutathione/oxidized glutathione, superoxide dismutase, catalase, heme oxygenase 1, G protein gamma-like, and nicotinamide adenine dinucleotide phosphate (NADPH) dehydrogenase, quinine 1[6-8]. However, disease can occur if there are insufficient defense factors or overwhelming offensive factors. Therefore, if we set up a sensitive marker that predicts the degree of oxidative stress, we can prevent the initiation or progression of disease by measuring this marker[9]. Moreover, if the level of this marker reflects the severity of disease, appropriate levels of scavenging agents can prevent complications of the disease, because the extreme is organ dysfunction or cancer. Several biomarkers to estimate oxidative stress have been suggested, but most of them have failed to reach clinical significance. One successful discovery of the late 1980s was the level of 8-hydroxydeoxyguanosine (8-oxo-7, 8-dihydroguanosine, 8-OHdG), because it has been proven to be increased in serum or urine of patients who have oxidative-stress-associated disease[10].

8-OHdG: GENERATION AND SIGNIFICANCE AS A BIOMARKER FOR OXIDATIVE STRESS

Generation and metabolism of 8-OHdG

When DNA is attacked by oxidative stress such as ROS, ultraviolet light, or genotoxic agents, guanine is easily oxidized into 8-oxo-7,8-dihydroguanine (8-oxo-Gua)[11]. The existence of this oxidized guanine in genomic DNA can cause transversion mutation such as G-T or G-A binding, accumulation of which can lead to detrimental consequences[12-14]. Fortunately, mammalian cells have multiple repair systems such as base excision repair enzymes or nucleotide excision repair (NER) enzymes, which counteract the hazardous effects of 8-oxo-Gua. Consequently, 8-OHdG, a nucleoside form of 8-oxo-Gua, is generated from either damaged oligomer which contains 8-oxo-Gua by NER or from cytoplasmic oxidized nucleotides like 8-hydroxy-deoxyguanosine triphosphate (8-hydroxy-dGTP). Fortunately, exogenously administered 8-OHdG cannot reincorporate into genomic DNA because the activity of deoxynucleotide kinase which converts 8-OHdG into 8-hydroxy-dGTP is very low, although wild deoxyguanosine can be actively converted to deoxyguanosine triphosphate which can be used as a substrate of DNA polymerase[15-22].

Biological significance of 8-OHdG

8-OHdG can cross the cell membrane unlike any other species that contains oxidized guanine, thus, it is usually detected in the urine or serum of patients who have diseases associated with oxidative stress[23]. Examples of application of 8-OHdG as a disease-associated clinical marker are summarized in Table 1.

8-OHdG: NEW FOCUS ON PARADOXICALLY RELIEVING ACTION OF OXIDATIVE STRESS

Anti-oxidative and anti-inflammatory actions of 8-OHdG

Although many studies have shown increased levels of 8-OHdG in oxidative-stress-associated diseases, the exact biological role of 8-OHdG has not been investigated. Oxidized deoxyguanosine is notorious for inducing mutagenesis, therefore, most researchers have felt that 8-OHdG might have mutagenic or at least harmful effects in cells, and that is why mammalian physiology tries hard to excrete this oxidized guanosine. However, under the innovative hypothesis that the generation of this molecule can be one of the defense mechanisms of cells against oxidative-stress-induced inflammation, we have tried to obtain evidence that oxidized guanosine can interact with the GTPase family, which is broadly involved in cytoskeleton modification, triggering inflammation, regulating apoptosis, and carcinogenesis[24-27]. Interestingly, genetically modified oxidized GTP, 8-oxo-GTPγS, seems to interact with the small GTPase family such as Ras, Rho, Rac and cdc42[28]. Among these, we have focused on the role of Rac1 in inflammatory cascades[29,30] because Rac1 activation is crucial for aggregating NADPH oxidase (NOX) complex and subsequent ROS production[31]. As a result, we have concluded that inhibition of Rac1 by exogenous 8-OHdG, which is a transmittable form of oxidized guanosine, can significantly block ROS-mediated inflammation. Compared with other nucleoside products, 8-OHdG has a potent anti-inflammatory effect by inhibiting the activity of Rac1 on lipopolysaccharide (LPS)-stimulated microglial cells, chemokine-activated neutrophils, and inflammatory mediator-stimulated macrophages[21,32-34]. Moreover, since endogenously produced 8-OHdG is much lower than exogenously treated concentrations of 8-OHdG, we propose the biological role of the antioxidative and anti-inflammatory actions of 8-OHdG, implying that 8-OHdG formation can be a defense mechanism against oxidative stress, and enrichment with exogenous 8-OHdG can be a strategy to prevent the initiation or progression of inflammatory disease, backed up with additional fact that only pretreatment or earlier administration of 8-OHdH is effective. To clarify and compare the cellular effect of 8-OHdG with existing anti-inflammatory agents, we have also investigated several animal models of acute inflammation. Intraperitoneal LPS injection to mice causes severe inflammation in lung tissues by inducing tumor necrosis factor (TNF)-α, interleukins, and myeloperoxidase activity and recruiting neutrophils. Simultaneous treatment with 8-OHdG significantly decreases the level of the above markers, and the efficacy of 8-OHdG is even more potent than that of aspirin; a conventional anti-inflammatory agent[35]. We also have investigated the antiallergic effects of 8-OHdG in ovalbumin-sensitized mice[36,37]. One of the major phenomena of oxidative stress is stress-related mucosal disease (SRMD), the mechanism of which is mucosal damage induced by ROS involved in reperfusion injury after local ischemia. We established a water-immersion restraint stress model, which mimics SRMD, causing severe ulceration and hemorrhagic lesions in gastric mucosa. Treatment with 8-OHdG reduces the pathological lesions, as well as other angiogenesis mediators such as TNF-α and vascular endothelial growth factor[21]. Recently, we have established an animal model of *H. pylori*-infected gastric inflammation by infecting four times with bacteria, followed by ingestion of a high-salt diet for > 16 wk. The degree of gastric inflammation induced by *H. pylori* is significantly decreased by continuous ingestion of 8-OHdG-dissolved water ad libitum. Moreover, dysplastic and precancerous lesions are observed in this animal model with chronic *H. pylori* infection, but curiously, the carcinogenesis that results from chronic *H. pylori* infection is apparently ameliorated with exogenous administration of 8-OHdG (Figure 1).

Molecular mechanisms to impose anti-inflammatory action of 8-OHdG

Although the possible mechanism to explain how 8-OHdG inhibits the activity of Rac1 has not been clearly documented yet, we hypothesize that 8-OHdG can interfere with the GTP-binding pocket of Rac1, because GTP and 8-OHdG share a similar conformation with a guanine base. 8-OHdG does not affect the activity of phosphoinositide 3-kinase/AKT or that of Rac1-guanosine exchange factor, which is an upstream pathway of Rac1 activation by exchanging Rac1-bound-GDP into GTP, turning inactive Rac1 into the active form[38-40]. However, treatment with 8-OHdG dramatically decreases the portion of Rac1-GTP, implying the specific molecular target of 8-OHdG might be Rac1 inactivation[21]. Rac1 is a crucial mediator of activating NOX complex[41,42], therefore, inactivating Rac1 could decrease the generation of ROS, and block the redox-sensitive nuclear factor (NF)-κB pathway. Rac1 also directly binds to signal transducer and activator of transcription (STAT)3 and regulates its activity[43], therefore, the ratio of phosphorylated to total STAT3 would be decreased by treatment with 8-OHdG[32]. The regulation of Rac1-mediated ROS, NF-κB and STAT3, which are the important mediators of inflammatory cascades, is the latest possibility of how 8-OHdG exerts an anti-inflammatory action.

Antitumorigenic action of 8-OHdG based on an efficient anti-inflammatory action

8-oxoguanine DNA glycosylase 1 (OGG1) is an endogenous DNA repair enzyme that repairs 8-OH-Gua in genomic DNA, cutting it into 8-OHdG (Figure 2). Although 8-OHdG does not reincorporate into genomic DNA as explained above, exogenously administered 8-OHdG can increase the ratio of 8-OH-Gua in genomic DNA by increasing error-prone DNA polymerase in the specific types of cells that have mutated forms of OGG1[19,44]. Although wild-type OGG1 can correct and repair 8-OH-Gua, OGG1 mutation cannot remove this harmful oxidized guanine, causing mutation and apoptosis. Treatment with 8-OHdG induces G1 arrest and

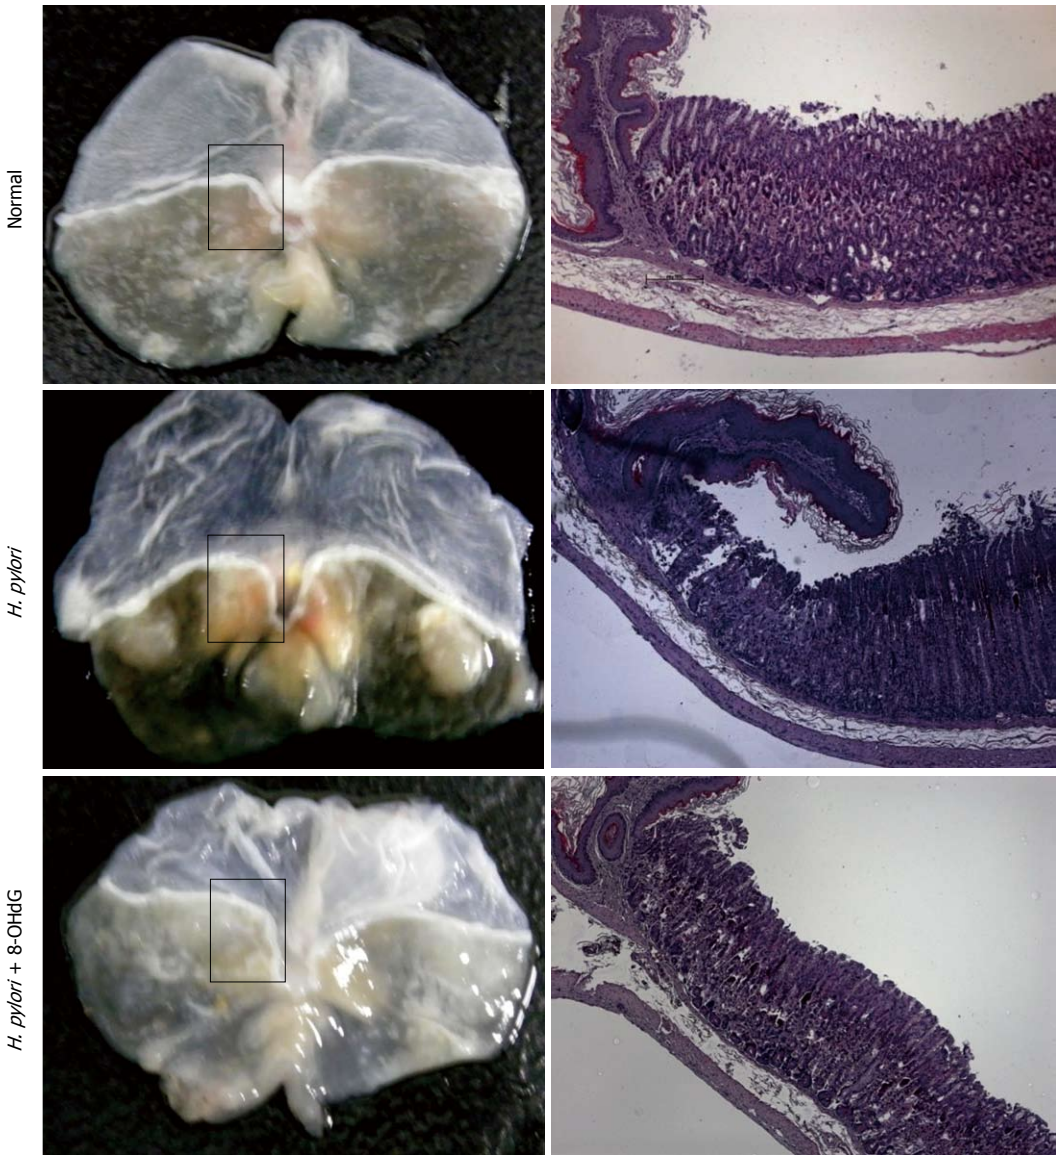

Figure 1 Antitumorigenic action of exogenous 8-hydroxydeoxyguanosine on *Helicobacter pylori*-induced gastric tumorigenesis. *Helicobacter pylori* (*H. pylori*) infection with additional administration of high-salt diet resulted in gastric tumorigenesis in interleukin-10 knockout mice. Continuous administration of exogenous 8-hydroxydeoxyguanosine (8-OHdG) led to significant prevention of *H. pylori*-induced gastric tumorigenesis as well as amelioration of gastritis. *H. pylori* infection followed with high-salt diet resulted in significant tumorigenesis as well as atrophic changes in gastric mucosa, whereas the gastric mucosa co-treated with 8-OHdG was free from tumorigenesis or atrophic changes.

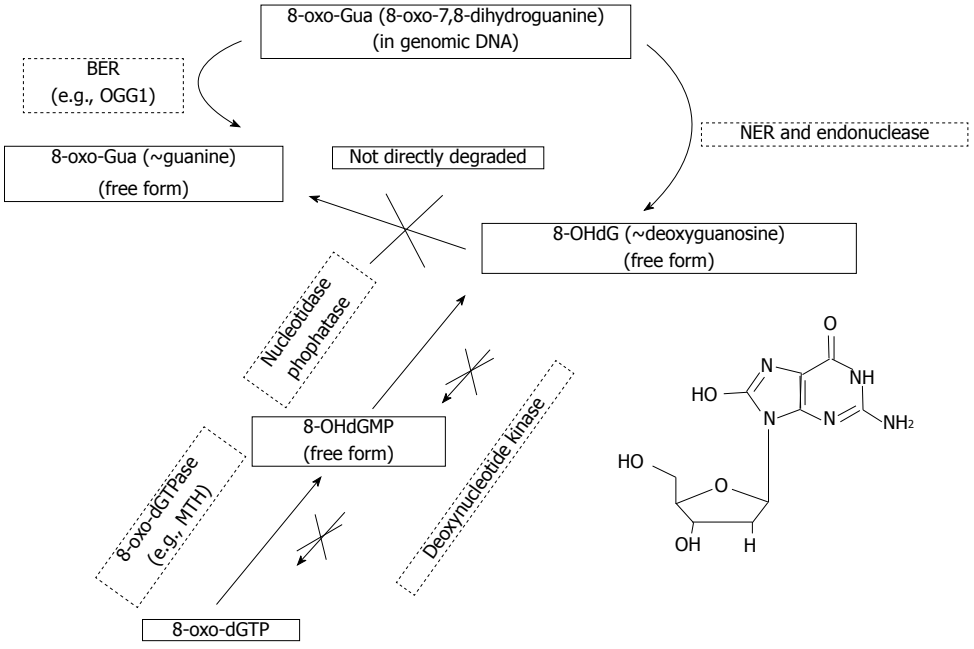

Figure 2 Generation and metabolism of 8-hydroxydeoxyguanosine. 8-oxoguanine DNA glycosylase 1 (OGG1) is a DNA glycosylase enzyme involved in base excision repair (BER), and is the primary enzyme responsible for excision of 7,7-dihydro-8-oxoguanine that occurs as a result of exposure to reactive oxygen species (ROS). OGG1 is a bifunctional glycosylase, because it is able to both cleave the glycosidic bond of the mutagenic lesion, and cause strand breakage in the DNA backbone. Nucleotide excision repair (NER) is a DNA repair mechanism, which is a particularly important mechanism by which the cell can prevent unwanted mutations by removing the vast majority of ROS-induced DNA damage.

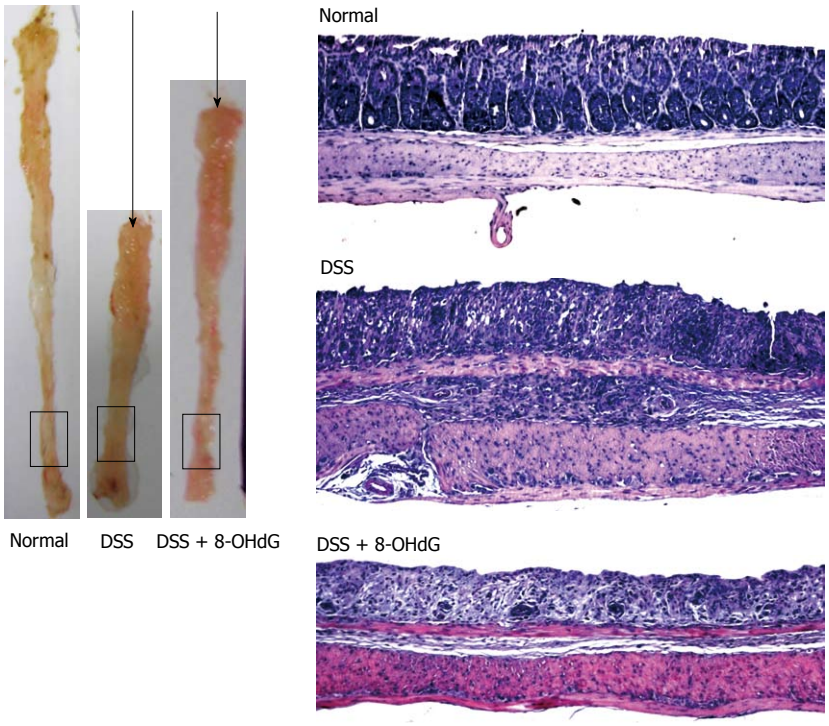

Figure 3 Ameliorating effect of exogenous 8-hydroxydeoxyguanosine against dextran sodium sulfate-induced colitis. Dextran sodium sulfate (DSS) administration resulted in moderate to severe colitis manifested as significantly shortened colon length. However, colon length was significantly preserved by exogenous administration of 8-hydroxydeoxyguanosine (8-OHdG) (see arrows to compare the colon length), as shown by the pathological observation that the degree of DSS-induced colitis was apparently improved, suggesting that exogenous 8-OHdG had a significant preventive effect against DSS-induced colitis[47]. Eighteen mice were divided into three groups of six: a non-treated control group (Normal group); 5% DSS in tap water ingestion for 1 wk (DSS group); and DSS with daily injection of 8-OHdG (DSS + 8-OHdG group). 8-OHdG powder was dissolved in PBS and the Normal and DSS groups were treated as a negative control. Clinical phenotypes such as hematochezia and rectal prolapse were investigated and charted daily. There was no mortality observed in any of the groups. After 7 d DSS ingestion, all mice were killed and colons were removed, opened longitudinally, and rinsed with phosphate buffer solution. The lengths of colon were measured, and isolated tissues were subjected to histological examination.

apoptosis in KG-1 leukemia cells, which have an OGG1 mutation, but not in U937 leukemia cells, which have wild-type OGG1[45-48]. The wide profile of OGG1 mutations in human cancer is now actively under investigation[49-54], therefore, treatment of cancer that has OGG1 mutations with 8-OHdG might be developed as a new model of targeted chemotherapy. For example, we have investigated models of colitis induced by dextran sodium sulfate (DSS) and colitis-associated cancer induced by DSS combined with azoxymethane (AOM + DSS)[55-57], and determined whether exogenous 8-OHdG has a preventive effect on colitis and colitis-associated cancer[57]. Daily injection of 8-OHdG significantly inhibits recruitment of inflammatory cells in DSS-induced colitis, and chronic ingestion of diet containing 8-OHdG exerts a chemopreventive role in AOM + DSS-induced colitis-associated cancer (Figure 3)[47].

CONCLUSION

There is extensive experimental evidence that oxidative damage permanently occurs to lipids of cellular membranes, proteins and DNA. In nuclear and mitochondrial DNA, 8-OHdG or 8-oxodG is one of the predominant agents of free-radical-induced oxidative lesions. This is why 8-OHdG has been used widely in many studies as a biomarker for the measurement of endogenous oxidative DNA damage, and as a risk factor for many diseases including cancer, because urinary 8-OHdG is a good biomarker for risk assessment of various cancers and other degenerative diseases. Several lines of evidence[7,29-32,47] show that exogenous 8-OHdG can: inhibit allergy-induced inflammation; remodel airway and lung tissues through Rac inactivation; regulate oxidative-stress-induced gastritis through antagonizing Rac-GTP binding or blocking the signals responsible for gastric inflammatory cascade; play a role in anti-inflammatory actions *via* suppression of intercellular adhesion molecule-1 gene expression by blockade of the Toll-like receptor 4/STAT3 signal cascade in inflammation-enhanced brain microglia; and prevent colitis-associated carcinogenesis based on efficient TNF-α inhibition or *H. pylori*-associated gastric carcinogenesis based on inhibition of cytokine generation. All this clearly suggests that 8-OHdG could be used as a potential tool to modulate GI tract inflammation as well as allergy-related bronchial disease, and is especially applicable to diverse inflammation-based diseases including gastritis, colitis, and esophagitis, as well as GI cancer, including esophageal, gastric and colon cancer, for which more extensive and well-designed clinical trials are required.

Abstract

AIM: To investigate the efficacy and mechanism of action of allogeneic embryonic hepatocyte transplantation for the treatment of hepatic cirrhosis.

METHODS: Rat embryonic hepatocytes were characterized by examining cell markers. Wistar rats with CCl_4-induced cirrhosis were randomly divided into two groups: a model group receiving continuous CCl_4, and a cell transplantation group receiving continuous CCl_4 and transplanted with embryonic fluorescent-labeled hepatocytes. In addition, a normal control group was composed of healthy rats. All rats were sacrificed after 2 wk following the initiation of the cell transplant. Ultrasound, pathological analyses and serum biochemical tests were used to evaluate the efficacy of embryonic hepatocyte transplantation. To analyze the recovery status of cirrhotic hepatocytes and the signaling pathways influenced by embryonic hepatocyte transplantation, real-time polymerase chain reaction was performed to examine the mRNA expression of stellate activation-associated protein (STAP), c-myb, α smooth muscle actin (α-SMA) and endothelin-1 (ET-1). Western blotting and immunohistochemistry were employed to detect α-SMA and ET-1 protein expression in hepatic tissues.

RESULTS: Gross morphological, ultrasound and histopathological examinations, serum biochemical tests and radioimmunoassays demonstrated that hepatic cirrhosis was successfully established in the Wistar rats. Stem cell factor receptor (c-kit), hepatocyte growth factor receptor (c-Met), Nestin, α fetal protein, albumin and cytokeratin19 markers were observed in the rat embryonic hepatocytes. Following embryonic hepatocyte transplantation, there was a significant reversal in the gross appearance, ultrasound findings, histopathological properties, and serum biochemical parameters of the rat liver. In addition, after the activation of hepatic stellate cells and STAP signaling, α-SMA, c-myb and ET-1 mRNA levels became significantly lower than in the untreated cirrhotic group ($P < 0.05$). These levels, however, were not statistically different from those of the normal healthy group. Immunohistochemical staining and Western blot analyses revealed that α-SMA and ET-1 protein expression levels in the transplantation group were significantly lower than in the untreated cirrhotic group, but being not statistically different from the normal group.

CONCLUSION: Transplantation of embryonic hepatocytes in rats has therapeutic effects on cirrhosis. The described treatment may significantly reduce the expression of STAP and ET-1.

Key words: Embryonic hepatocytes; Cirrhosis; Stellate activation-associated protein; Endothelin-1; Cell transplantation

INTRODUCTION

Clinical studies of liver cell transplantation are primarily performed with adult hepatocytes and liver stem cells[1]. Adult hepatocytes are highly differentiated cells and cannot produce sufficient and sustained biological effects[2,3]. However, *in vitro* proliferation of liver stem cells allows for the generation of a sufficient number of cells to be used in clinical practice[4]. Following transplantation, liver stem cells continue to proliferate and may play an important role in liver regeneration[5,6].

There are currently several types of liver stem cells used in experimental research to treat cirrhosis, including adult liver stem/progenitor cells from the liver portal canal, which are activated and differentiate into hepatic oval cells following severe liver damage[7,8]. Other types of liver stem cells include embryonic hepatocytes[9,10], bone marrow/hematopoietic stem cells[11-16], and embryonic stem cells[17-19].

Early embryonic hepatocytes are self-renewing progenitor cells with the capacity to differentiate into adult hepatocytes and bile duct cells[20]. On embryonic days (E) 16 and 17, rat hepatic stem cells begin to differentiate. On E16, the gene expression profiles of rat embryonic liver epithelial cells change abruptly and become similar to those of mature cells; at this point, the bi-differentiation potential of these cells is significantly reduced[21]. On E9.5-15 in rats, most hepatocytes are liver stem cells, which possess potent proliferative capacity as compared with adult hepatocytes. After transplanted into injured livers, these cells can improve liver function and reduce animal mortality[22,23]. To investigate the effects of allogeneic embryonic hepatocyte transplantation on hepatic cirrhosis and the associated mechanisms of action, we utilized E15 rat hepatocytes as seed cells. The results presented here provide a theoretical and experimental framework for future studies of embryonic liver stem cell transplantation for the treatment of hepatic cirrhosis.

MATERIALS AND METHODS

Materials

Experimental animals: One hundred adult female Wistar rats and 6 male rats were purchased from the Specific Pathogen Free Grade Animal Department, Peking Union Medical College.

Primary reagents: Rabbit anti-human albumin (ALB) antibody and rabbit anti-rat cytokeratin 19 (CK19) antibodies were purchased from Beijing Gene Biology (Beijing, China). The rabbit anti-human α-fetoprotein (AFP) polyclonal antibody, the PV-6001 immunohistochemistry kit, PV-9003 immunohistochemistry kit and the chromogenic kit were purchased from Beijing Zhongshan Biology (Beijing, China). The rabbit anti-human/mouse/rat stem cell factor receptor (c-kit) antibody, the rabbit anti-human/mouse/rat hepatocyte growth factor receptor (c-Met) antibody, rabbit anti-human/mouse/rat Nestin antibodies were purchased from Wuhan Boster Biology (Wuhan, China). Percoll centrifugal liquid was purchased from Beijing Kehaijunzhou Bitechnology (Beijing, China). Collagenase type Ⅳ was purchased from Beijing Tianlai Biotech. Co. (Beijing, China). The rabbit anti-human/mouse/rat α smooth muscle actin (α-SMA) polyclonal antibody (ab66133) was purchased from Abcam (Cambridge, United Kingdom), the goat anti-human/mouse/rat endothelin-1 (ET-1) polyclonal antibody was purchased from Santa Cruz Biotechnology (California, United States), the biotinylated goat anti-rabbit immunoglobulin G (IgG) and anti-goat IgG antibodies were purchased from Beijing Zhongshan Biology (Beijing, China). β-actin was purchased from Santa Cruz Biotechnology (California, United States). The Power SYBR Green polymerase chain reaction (PCR) Master mix was purchased from ABI (California, United States), the M-MLV, dNTP Mix and Oligo (dT15) were purchased from Promega Corporation (Wisconsin, United States), and the Taq enzyme was purchased from TIANGEN (Beijing, China). Primers for stellate activation-associated protein (STAP), c-myb, α-SMA and ET-1 were purchased from Invitrogen Corporation (California, United States) and were synthesized by Beijing GENELIFE Biotech Co., Ltd (Beijing, China).

Experimental methods

Experimental animals: Females and male rats (2 females/1 male) were housed together overnight. Female vaginal smears were examined the following morning. The day when the sperm was detected was defined as day 0 of the pregnancy. Pregnant female rats at E15 were used to isolate embryonic hepatocytes.

Isolation of embryonic hepatocytes: The hepatocyte suspension was prepared using the enzymatic digestion method, and the hepatocytes were separated using Percoll gradient centrifugation. Percoll and a 9% NaCl solution were mixed at a ratio of 9:1. This solution was then diluted with D-F12 culture medium to 50%, 70% and 90% gradient centrifugation solutions. Each dilution of Percoll solution (5 mL) was added sequentially into a centrifuge tube, and the cell suspension was placed on the top of these solutions. The tube was centrifuged at 4330 *g* for 30 min at 4 ℃. The cells between the 50% and 70% Percoll layers were carefully removed and washed twice with Hank's balanced salt solution by centrifuging at 719 *g* and 4 ℃. The supernatant was discarded, and culture medium was added to the tube to a final volume of 1 mL. Cells

were counted using trypan blue after being re-suspended in the medium. Following calculation of the cell density, 2 × 10^6/mL cells were cultured in a 25-mm^2 flask.

***In vitro* culture of embryonic hepatocytes:** The flask was placed in a 37 ℃ incubator filled with 50 mL/L carbon dioxide. The D-F12 culture solution contained 15% fetal bovine serum (FBS), and the medium was replaced every 24 h. Cells were microscopically analyzed for growth and proliferation status, and the number of colonies was recorded.

Identification of colonies: Colonies were marked with a variety of liver stem cell markers using the two-step immunoperoxidase method. The analyzed markers included ALB (1:2000), AFP, c-kit, c-Met, Nestin and CK19 (all 1:1000).

Experimental groups: The Wistar rats were randomly divided into a cirrhotic group (n = 50) and a normal control group (n = 10). In the normal control group, olive oil was injected subcutaneously into the abdomen. In the cirrhotic group, 50% CCl_4 in olive oil was injected subcutaneously into the abdomen; the first four and final four doses were 0.5 mL/100 g body weight, and the other doses were 0.3 mL/100 g body weight. The 50% CCl_4 solution was injected every four days for a total of 15 injections. A 10% ethanol solution, which was prepared with white wine and distilled water, constituted the only liquid drank by the rats in the cirrhotic group.

After 63 d, the 24 surviving rats in the cirrhotic group (16 rats died during the induction of cirrhosis) were randomly divided into two groups: a control cirrhotic group (n = 12) and a cell transplantation group (n = 12). Rats in the control cirrhotic group received continuous CCl_4. In the cell transplantation group, rats were transplanted with E15 rat hepatocytes labeled with carboxyfluorescein diacetate and succinimidyl ester (CFSE) fluorescent molecules. CCl_4 was also continuously administered in this group. The rats were sacrificed 2 wk after the beginning of the transplantation treatment, and their serum was collected. A portion of liver tissue from the rats was used to prepare frozen and paraffin sections, and the remaining hepatic tissue was stored in liquid nitrogen for Western blotting and real time-PCR.

B-ultrasound image analysis: A solution of 0.5 mL/100 g chloral hydrate was used to anesthetize rats, and hair removal agents were used for skin preparation. Rats were immobilized on the operating table prior to the procedure. A small animal, high-resolution ultrasound system (Vevo 770TM) was used for image collection and analysis, and a PEF-704LA laparoscopic linear probe was used for abdominal exploration. The following ultrasound parameters were included: 2-D measurement of the portal vein and hepatic vein, Doppler imaging measurement of portal vein velocity (PVV) and hepatic vein velocity (HVV), echo intensity, the liver morphology and angle of the liver's blunt edge. SPSS13.0 software was used for statistical analyses following a completely randomized single-factor F test and paired t test.

Fluorescent labeling and tracking of E15 hepatocytes: CFSE was dissolved in dimethyl sulfoxide, and a 1-mmol/L CFSE solution was stored at -20 ℃. The stock solution was diluted to a 5 μmol/L working solution with phosphate buffer solution (PBS). Following a 20-min incubation with the CFSE working solution, fluorescence of the E15 hepatocytes was confirmed by excitation using a wavelength of 488 nm. The cells were digested with 0.25% trypsin, counted with trypan blue staining and diluted to 2 × 10^7 cells/0.5 mL.

Orthotopic liver transplantation of fluorescently-labeled embryonic hepatocytes: The rats were anesthetized with 0.5 mL/100 g chloral hydrate and immobilized on a surgical table. A 1.5-cm vertical incision on the right side of the abdomen was made under the xiphoid process to expose the liver. Using a 1-mL syringe, 0.5 mL of the labeled E15 hepatocyte suspension was slowly injected into the liver parenchyma. The abdomen was closed, and the rats were placed at ≥ 26 ℃ overnight.

Serum assay: Blood was taken from the abdominal aorta, and the following indicators were analyzed: total protein (TP), ALB, total bilirubin (TBil), alanine aminotransferase (ALT), and aspartate aminotransferase (AST). The levels of collagen type Ⅲ, AFP and ET-1 were determined by radioimmunoassays. SPSS13.0 software was used for statistical analysis using a completely randomized single-factor F test.

Histopathology: The rat livers were fixed in formalin for 48 h, paraffin embedded and sectioned into 4-μm thick slices for hematoxylin and eosin (HE) and van gieson (VG) staining.

Immunohistochemistry: Immunohistochemical staining of α-SMA, ET-1. Marker expression was examined using the two-step immunoperoxidase method. Briefly, after tissue sections were deparaffinized and rehydrated, sections were heated in a microwave for 10 min to enhance antigen retrieval. Slides were then incubated for 10 min with 3% H_2O_2 to inactivate endogenous peroxidase activity. Primary antibodies (rabbit anti-human/mouse/rat α-SMA polyclonal antibody, 1:50; goat anti-human/mouse/rat ET-1 polyclonal antibody, 1:50) were applied and incubated overnight at 4 ℃. The appropriate secondary antibody (biotinylated goat anti-rabbit IgG, 1:200; anti-goat IgG antibody, 1:200) was applied for 40 min, and 3,3'-diaminobenzidine was used as a chromogen. Negative controls were performed for each antibody using PBS instead of the primary antibody.

Immunohistochemical staining analysis: Immunohistochemical staining of paraffin-embedded liver sections was analyzed with a Leica Q500 IW Imaging Worksta-

STAP: Stellate activation-associated protein; SMA: Smooth muscle actin; ET: Endothelin.

tion. The average optical density was calculated in image analysis. For quantitative analyses, several fields were selected in each slice using a micro-camera (Magnification: 10 × 10), and the images were transferred to a computer. The position of positive staining was first observed under low magnification, and the optical density values were measured using a high power (Magnification: 10 × 20). Five high-power fields of each specimen were randomly selected, and their average optical density value was calculated. SPSS13.0 software was used for the statistical analysis following a completely randomized single-factor *F* test.

Western blotting: Liver tissue samples and cells were lysed in ice-cold RIPA buffer supplemented with protease inhibitors. Whole cell lysates were obtained by subsequent centrifugation at 14 000 r/min for 10 min at 4 ℃. Protein concentrations were determined using the Bradford protein assay with bovine serum albumin as a standard. Twenty-five micrograms of protein extracts were separated using 10% sodium dodecyl sulfate-polyacrylamide gel electrophoresis and were transferred to a nitrocellulose membrane. Membranes were blocked with a 7.5% solution of nonfat dry milk dissolved in a Tris-HCl-buffered solution (TBS, pH 7.5) and were then probed with a primary antibody (rabbit anti-human/mouse/rat α-SMA polyclonal antibody, 1:50; goat anti-human/mouse/rat ET-1 polyclonal antibody, 1:50). Membranes were subsequently washed with TBST (TBS, 0.1% Tween 20) and exposed for 45 min at room temperature to the appropriate secondary antibody (anti-goat IgG antibody, 1:5000; anti-rabbit IgG antibody, 1:5000). Staining was detected using chemiluminescence followed by autoradiographic and densitometric analyses. Experiments were performed at least 3 times, and similar results were obtained for each replicate.

Real-time PCR: RNA from liver tissue was extracted using TRIzol. First-strand cDNA was reversely transcribed (RT) from 1 μg of total RNA using Oligo (dT) 15 primers and a M-MLV reverse transcriptase. The primers were designed based on gene sequence data from GenBank. Primer sequences used for real-time PCR are shown in Table 1. Real-time PCR was performed using an ABI Prism 7900HT Sequence Detection System (SDS). Triplicate reactions of each sample were performed in a 96-well plate using SDS instrumentation for 40 cycles. Real-time PCR amplifications were carried out using 2 μL cDNA, 12 μL 2 × SYBR Green PCR Master Mix, 0.3 μL primers (forward/reverse, 15 pmol/μL), and 10.4 μL H_2O for a final reaction volume of 25 μL. Real-time PCR cycling parameters were 50 ℃ for 2 min, 95 ℃ for 10 min, followed by 40 cycles of 95 ℃ for 15 s, 60 ℃ for 1 min, 95 ℃ for 15 s, 60 ℃ for 15 s and 95 ℃ for 15 s.

Data were analyzed using SDS2.2 software. The relative quantities of the target genes were normalized against the expression of β-actin[24]. The following formulas were used for RT-PCR data analysis: △Ct = Ct value of the target gene - Ct value of the normalization gene (the reference gene); quantity of the experimental group = 2-△Ct of the experimental group; quantity of the control group = 2-△Ct of the control group; quantity (relative expression levels) = quantity of the experimental group /quantity of the control group. After the expression of each gene in the normal control group was normalized to 1, the relative 2-ΔΔCt values for each gene in the untreated cirrhotic and the cell transplantation groups were calculated.

RESULTS

In vitro culture and identification of isolated cells

The primary fetal hepatocytes became adherent approximately 5 h into the culture period, and spheres formed on day 2 (Figure 1A). Spheres had a round or oval homogeneous morphology, and round or oval nuclei. Microscopic analysis revealed that the adherent cells grew in a monolayer and had a clear cell boundary (Figure 1B). Cells were round or polygonal and were arranged in neat rows. In addition, the cells had abundant cytoplasm and round nuclei. However, a small number of fibroblasts were observed within the cultures. Following a few days in culture, approximately half of the clones gradually grew into sheets and merged with one another or gradually differentiated (Figure 1C). In a 25-mm^2 flask, the peak number of cell colonies (> 4000 colonies) appeared on day 2 into the culture period. Most cells isolated from the 50% Percoll sample were not adherent, and a few gradually died over the course of the culture period.

Immunohistochemical staining revealed that most liver stem cell-specific markers, including c-kit (Figure 2A), c-Met (Figure 2B), Nestin (Figure 2C), AFP (Figure 2D), ALB (Figure 2E) and CK19 (Figure 2F), were expressed in the cell colonies on day 2 of culture.

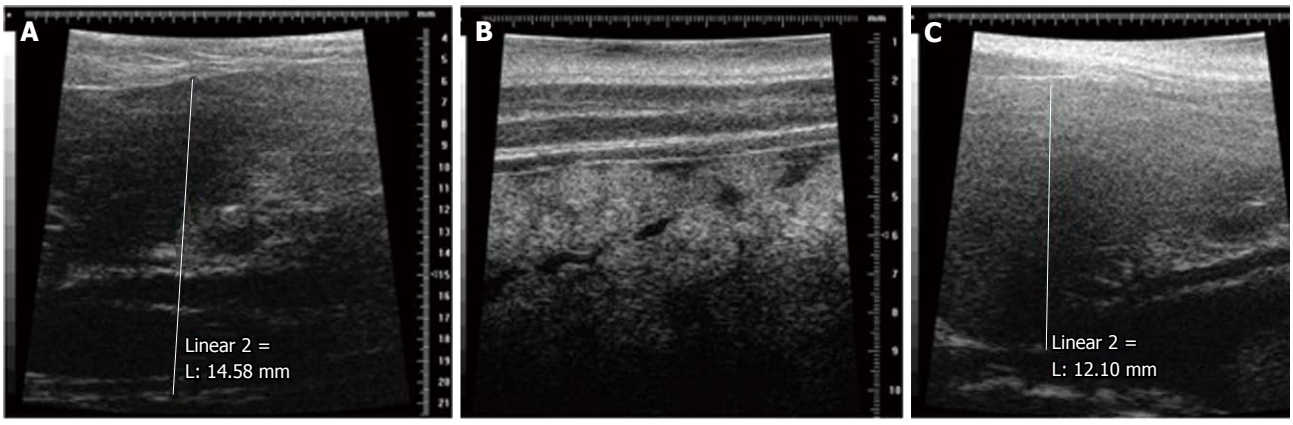

Figure 3 Parameters of ultrasound examination. A: Livers exhibit a smooth capsule, sharp edges, clear vascular texture and uniform echoes in the normal control group; B: Livers from rats of the untreated cirrhotic group exhibit uneven surfaces, blunt edges, unclear vascular texture and serrated and enhanced echoes with uneven distribution; C: In the transplantation group, rat livers exhibit a smooth capsule, smooth edges, clear vascular texture and even echo patterns.

Ultrasound examination

As shown in Figure 3A, ultrasound examination revealed that the livers of normal control rats had a smooth capsule, sharp edges, clear vascular texture and a uniform echo. In rats of the untreated cirrhotic group, however, livers had an uneven surface, blunt edges, unclear vascular texture, and serrated and enhanced echoes with uneven distributions (Figure 3B). No specific liver parenchymal lesions were observed in the untreated cirrhotic rats. Compared with the normal control group, the portal and hepatic veins in the untreated cirrhotic group were significantly widened ($P < 0.01$), and both PVV and HVV were significantly decreased ($P < 0.01$). Visible signs of ascites were observed in the untreated cirrhotic group. Ultrasound examination, therefore, revealed that livers of untreated cirrhotic rats were characterized by cirrhosis, portal hypertension, and the presence of ascites.

In the cell transplantation group, rat livers had a smooth capsule, smooth edges, clear vascular texture and even echo patterns (Figure 3C). Compared with the normal control group, the portal and hepatic veins were not obviously enlarged ($P > 0.05$, Table 2). The portal and hepatic veins were significantly narrower than those of rats in the untreated cirrhotic group ($P < 0.01$). PVV and HVV were decreased compared with the velocity in the normal control group ($P = 0.03$ and $P < 0.01$, respectively), but being higher than those observed in the untreated cirrhotic group (both $P < 0.01$). Findings and

statistical results for each parameter of the ultrasound examination before and after liver transplantation (paired *t* test, $P < 0.01$) are shown in Table 3.

Pathological changes in rats with hepatic cirrhosis

The livers of normal control rats were dark red, elastic with a smooth surface, sharp edges and a soft texture (Figure 4A). However, the livers of rats in the untreated cirrhotic group had a hard texture, a brown or gray-brown appearance, diffuse surface nodules of variable sizes, blunt edges, uneven surfaces and were adhered to the adjacent organs (Figures 4B-E). The livers of rats in

	PⅢ (μg/L)	ET-1 (pg/mL)	AFP (ng/mL)
Normal control group	48.096 ± 5.010	45.459 ± 12.626	12.150 ± 11.430
Untreated cirrhotic group	92.954 ± 4.481[b]	132.192 ± 8.906[b]	12.099 ± 8.529
Transplantation group	54.023 ± 4.535[b,d]	42.383 ± 11.701[d]	61.315 ± 20.973[b,d]

[b]$P < 0.01$ *vs* the normal control group; [d]$P < 0.01$ *vs* the untreated cirrhotic group. ET: Endothelin; AFP: α-fetoprotein.

the transplantation group had a partially red appearance, soft texture, elasticity, sharp edges and smooth facets, similar to the normal control livers (Figures 4F-I).

Tracking E15 hepatocytes

Under fluorescence microscopy, E15 hepatocytes labeled *in vitro* with CFSE showed strong green fluorescence (Figure 5A). CFSE-labeled cells were transplanted into cirrhotic rat livers, and the livers were removed 2 wk after the transplantation. Scattered green fluorescent markers were observed in frozen tissue sections from these livers (Figure 5B); however, no fluorescent cells were observed in sections from the normal control or untreated cirrhotic rats (Figure 5C). These results suggest that embryonic hepatocytes labeled with CFSE *in vitro* are able to survive in the livers of cirrhotic rats.

Effects of hepatocyte transplantation on serum indicators

As shown in Table 4, ALT, AST and TBil levels in rats in the untreated cirrhotic group were much higher than in the normal control and cell transplantation groups. ALT and AST levels in the cell transplantation group were also slightly higher than in the normal control group ($P < 0.01$); however, no statistical differences in TBil levels were observed between the cell transplantation and normal control groups ($P > 0.05$). The TP and ALB levels of the model rats were lower than those in the cell transplantation group, which were also lower than the TP and ALB levels in the control group ($P < 0.01$).

PⅢ and ET-1 levels of rats in the untreated cirrhotic group were much higher than in the normal control or cell transplantation groups ($P < 0.01$, Table 5). PⅢ levels in rats with transplanted cells were higher than those observed in normal control rats ($P < 0.01$); however, no statistical difference in ET-1 levels was observed between the cell transplantation and normal control groups ($P > 0.05$). AFP levels in the cell transplantation group were much higher than in the control and untreated cirrhotic groups ($P < 0.01$); no statistical difference in AFP levels were observed between the control and untreated cirrhotic groups ($P > 0.05$).

Effects of hepatocyte transplantation on histopathology

Results of HE staining revealed that normal control rats exhibited typical liver lobules and orderly hepatic cords (Figure 6A). In contrast, livers from cirrhotic rats exhibited swollen hepatocytes, severe diffuse hydropic degeneration, and fatty degeneration. Some necrotic hepatocytes and pyknotic or dissolute nuclei were observed in the cirrhotic livers. The following abnormalities were also noted in the cirrhotic livers: remarkable expansions of the hepatic sinus and central vein; disorganization of the hepatic cord; apparent focal lymphocyte infiltration in the portal area; hyperplasia of the bile duct epithelia; brown pigmentation; diffuse hyperplasia of interstitial

cells; noticeable fibrosis with septation; and formation of pseudo-lobules (Figures 6B-E). In the cell transplantation group, no pseudo-lobules or disorganized hepatic cords were detected, and the hepatocytes were similar to those in normal control rats. Although a small number of cells had vacuoles, most hepatocytes of the transplantation group had abundant cytoplasm (Figures 6F-I).

Depositions of collagen fibers were examined in VG-stained rat liver tissues. In the normal control group, rats had normal hepatic lobules. Hepatocytes were radially arranged around the central vein and no hyperplasia of the fibrous tissue was observed (Figure 7A). In the cirrhotic rats, the hepatic lobule was destroyed, and pseudo-lobules were surrounded by fibrous tissues (Figures 7B-E). The cell transplantation group exhibited noticeably less hyperplasia of the collagen fibers when compared with the untreated cirrhotic group (Figures 7F-I).

Immunohistochemical analysis

α-SMA expression was only observed in the vascular wall of normal rats; no significant expression was observed at other sites (Figure 8A). In untreated cirrhotic rats, α-SMA was primarily expressed in the periportal areas, fibrous septa, pseudo-lobules and hyperplastic fibers (Figure 8B). α-SMA expression in the cell transplantation group was observed in the periportal vascular wall while it was rarely detected in the periportal areas or fibrous septa (Figure 8C). The optical density (OD) values of α-SMA in the untreated cirrhotic group were much higher than in normal control or cell transplantation groups ($P < 0.01$, Table 6). No statistical difference was observed in the α-SMA OD values between the cell transplantation and normal control groups ($P > 0.05$).

Weak ET-1 expression was detected in a small number of sinusoid endothelial cells of the normal control rats (Figure 8D). In contrast, clear expression was ob-

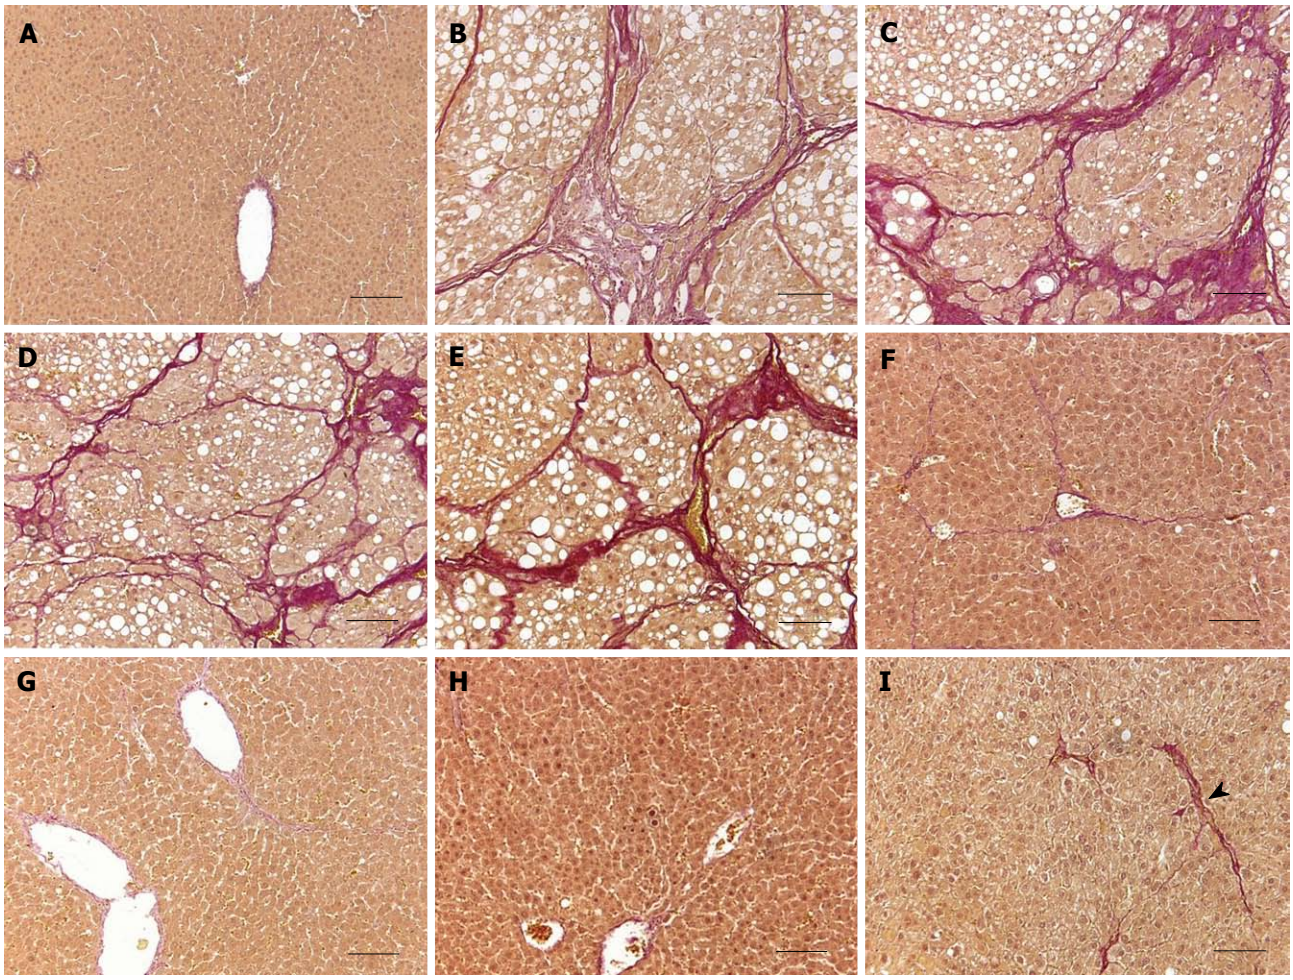

Figure 7 Van gieson staining of tissue slices from rat livers in each group. A: No hyperplasia of the fibrous tissue was observed in the normal control group; B-E: Pseudo-lobules were surrounded by fibrous tissues in livers from the untreated cirrhotic group; F-I: A few collagen fibers (arrow) were observed in livers from the transplantation group. Scale bars: 20 μm.

Table 7 Optical density values of Western blotting protein bands (mean ± SD, *n* = 3)

	α-SMA	ET-1
Normal control group	0.457 ± 0.055	0.593 ± 0.006
Untreated cirrhotic group	0.929 ± 0.036[b]	1.034 ± 0.112[b]
Transplantation group	0.502 ± 0.066[d]	0.607 ± 0.012[d]

[b]$P < 0.01$ *vs* the normal control group; [d]$P < 0.01$ *vs* the untreated cirrhotic group. SMA: Smooth muscle actin; ET: Endothelin.

served in the pseudo-lobules (Figure 8E) and fibrous septa (Figure 8F) of the untreated cirrhotic rats. In the cell transplantation group, ET-1 expression was only observed in the sinusoid endothelial cells (Figure 8G). The OD values of the untreated cirrhotic group were much higher than those of the normal control and cell transplantation groups ($P < 0.01$, Table 6). There was no significant difference in these values between the cell transplantation and control groups ($P > 0.05$).

Western blotting analysis

α-SMA and ET-1 expression levels in normal rat livers were extremely low (Figure 9). α-SMA and ET-1 protein was more highly expressed in the liver tissues of the untreated cirrhotic group than in the normal group. Additionally, the expression of α-SMA and ET-1 in rats treated with cell transplantation was significantly lower than that of the untreated cirrhotic group ($P < 0.01$). There was no statistically significant difference between the cell transplantation group and the control group ($P > 0.05$). The Western blotting optical density ratios are shown in Table 7.

Real-time PCR

After the expression of each gene in the normal control group was normalized to 1, the relative $2^{-\Delta\Delta Ct}$ value of each gene in the untreated cirrhotic and cell transplantation groups was calculated. Compared with the control group, the expression levels of STAP, c-myb, α-SMA and ET-1 were increased in the untreated cirrhotic group ($P < 0.01$). However, the expression levels of these mRNAs in rats of the cell transplantation group were significantly reduced when compared with the untreated cirrhotic group ($P < 0.01$) (Table 8). There was no statistically significant difference between the cell transplantation and

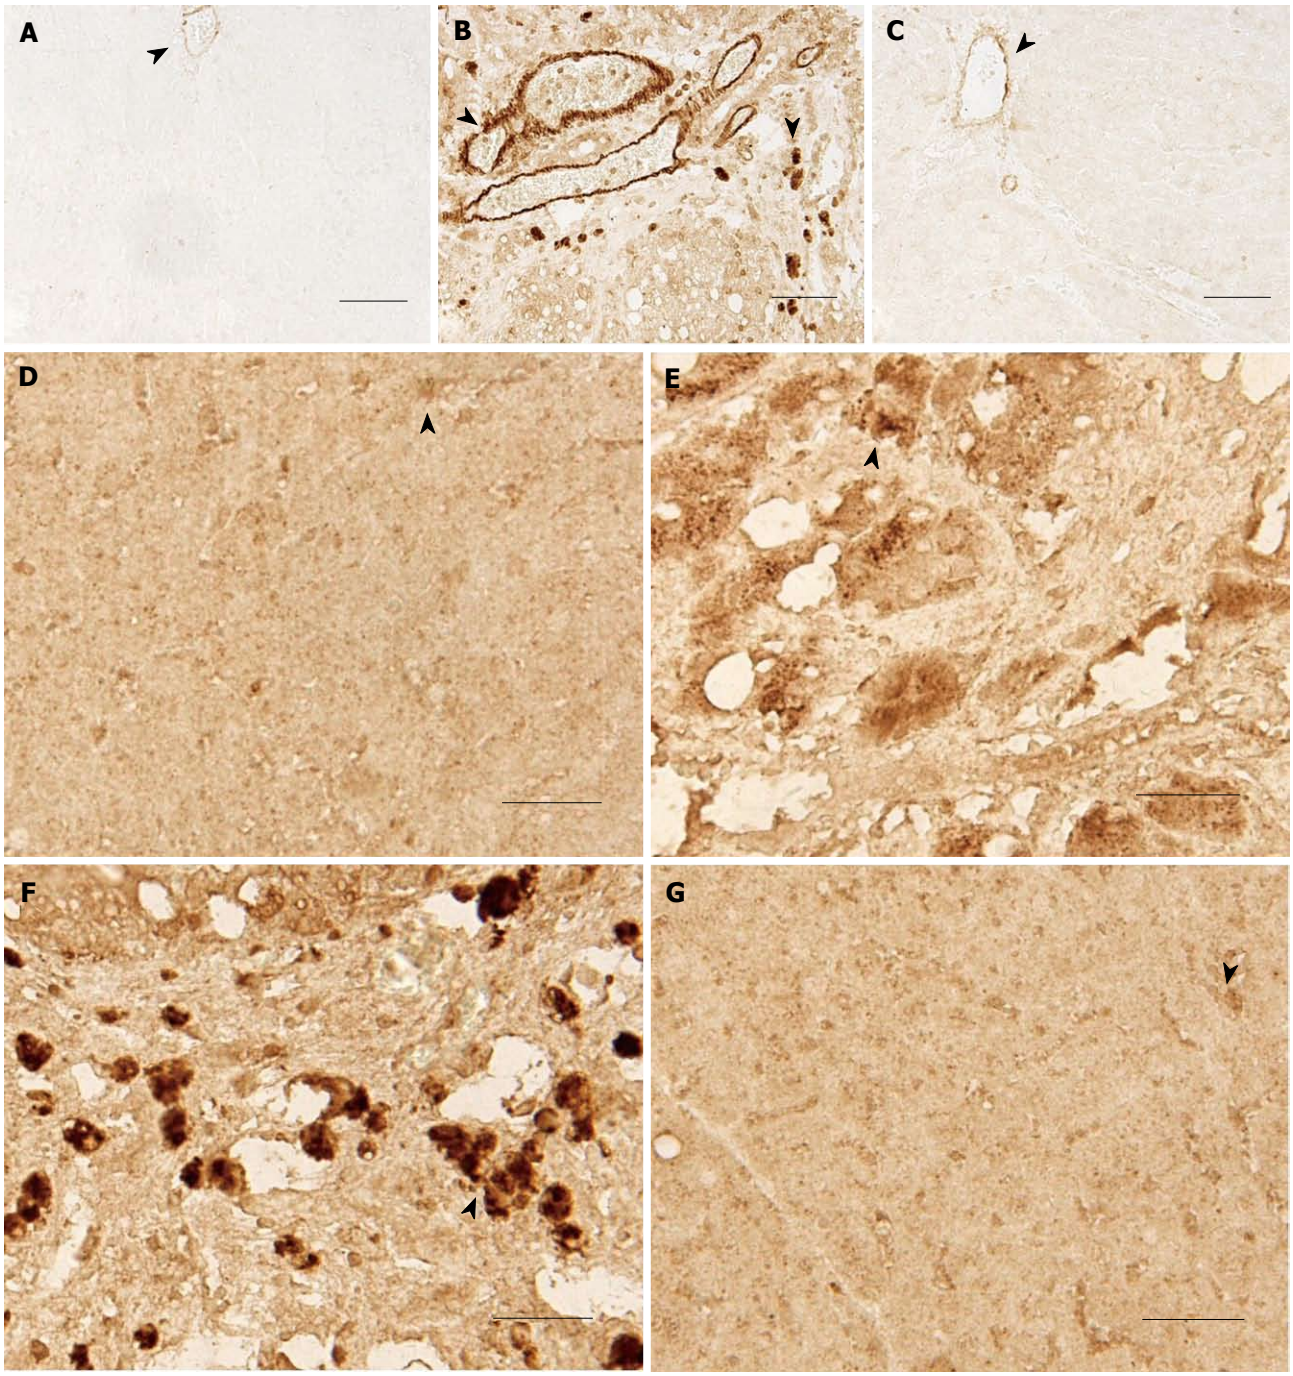

Figure 8 Immunohistochemical staining of rat livers in each group. A: α smooth muscle actin (α-SMA) expression (arrow) was only observed in the vascular wall of the normal group; B: α-SMA (arrow) was highly expressed in the periportal areas and fibrous septa of livers from the untreated cirrhotic group; C: The cell transplantation group exhibited noticeably weaker α-SMA (arrow) expression than the untreated cirrhotic group; D: Weak endothelin-1 (ET-1) (arrow) expression was detected in a few sinusoid endothelial cells of livers from the normal control group; E: Clear ET-1 expression (arrow) was observed in the pseudo-lobules of livers from the untreated cirrhotic group; F: Clear ET-1 (arrow) expression in the fibrous septa of livers from the untreated cirrhotic group; G: In the cell transplantation group, ET-1 (arrow) expression was only observed in the sinusoid endothelial cells. Scale bars: 20 μm.

control groups ($P > 0.05$).

DISCUSSION

There is no precise or unified definition for hepatic stem cells. In 1956, Farber *et al*[25] observed hepatic oval cells with a diameter of approximately 10 μm. These cells were shown to be able to differentiate into either hepatocytes or bile duct cells and were considered as liver stem cells[8,26,27]. It is well known that hepatic stem cells have unlimited proliferative capacity and the potential to differentiate into hepatocytes.

The morphology, phenotype and molecular expression profile of hepatic stem cells change dynamically in their degree of differentiation[28]. Due to the lack of specific markers, hepatic stem cells are principally identified

Table 8 Effects of embryonic hepatocyte transplantation in rats on different mRNA expression (mean ± SD, *n* = 9)

	STAP	c-myb	α-SMA	ET-1

using their differentiation potentials. Hepatic stem cells with bi-potentiality can differentiate into hepatocytes and biliary duct epithelial cells and can be identified using antibodies for specific hepatocyte and biliary epithelial cell markers. Pack *et al*[29] reported that ALB specifically marks mature hepatocytes and that CK19 specifically marks bile duct epithelial cells[30]. Although AFP can be expressed in both embryonic hepatocytes and hepatic oval cells, AFP synthesis ceases upon differentiation and maturation of hepatocytes[31]. c-Met and Nestin are stem cell markers, and c-kit is a common epitope for hepatic and blood stem cells[32-35].

In this study, E15 hepatocytes were cultured *in vitro* and grew in a similar manner as stem cells, exhibiting colony-like growth with clear boundaries for each clone. Molecular characterization revealed that c-kit, c-Met, Nestin, AFP, ALB and CK19 were expressed in the majority of colony cells, suggesting that the majority of rat E15 hepatocytes were undifferentiated and bipotential. Because embryonic hepatocytes have a higher proliferative capacity, multiple differentiation potentials, and low immunogenicity, there is greater clinical value for embryonic hepatocytes than for mature hepatocytes in the treatment of liver injury due to chronic cirrhosis.

The use of CCl_4 and alcohol to induce and model cirrhosis has a high success rate, which is the reason why this technique is chosen for this study. Following the completion of this protocol, ultrasound examination and HE and VG staining of paraffin-embedded specimens revealed pathological changes indicative of hepatic cirrhosis. In addition, serum biochemical indicators were also abnormal, suggesting that hepatic cirrhosis was effectively induced.

Two weeks after E15 hepatocytes were transplanted into the cirrhotic rats, serum levels of ALT, TBil, type-Ⅲ procollagen and ET-1 were significantly reduced. However, serum ALB and TP were significantly increased, indicating that embryonic liver hepatocyte transplantation significantly improved the hepatic function of cirrhotic rats. This conclusion is particularly exemplified by the observed normalization of total bilirubin levels in treated cirrhotic rats. Serum AFP levels in the cell transplantation group were significantly higher than in the untreated cirrhotic group, suggesting that the biological activities of transplanted embryonic hepatocytes induced liver regeneration in cirrhotic rats. There was no significant difference in the ultrasound results between the cell transplantation and normal control groups; neither high portal vein pressure nor ascites were observed. Pathological results revealed that collagen fiber hyperplasia was significantly reduced in rats treated with liver cell transplantation. A small number of collagen fibers around the lobules were observed in treated livers, and the majority of hepatocytes in the lobules were morphologically normal. All these results demonstrate that rat embryonic hepatocyte transplantation significantly improves liver morphology and function in rats with hepatic cirrhosis. These cells also effectively inhibit hepatic necrosis and fibrosis and promote normal hepatocyte proliferation and function.

CCl_4 is a hepatotoxic compound that damages the liver *via* lipid peroxidation[36,37] and leads to intracellular calcium overload, resulting in fatty degeneration of hepatocytes. Continuous administration of CCl_4 in rats leads to hepatic necrosis. Moreover, CCl_4 may cause hepatocyte damage *via* its metabolism into CCl_3 radicals by cytochrome P450, resulting in the oxidation of unsaturated fatty acids and the production of lipid peroxides[38]. Lipid peroxidation can directly activate hepatic stellate cells (HSCs) and facilitate hepatocyte conversion to myofibroblasts. The latter cell type subsequently synthesizes extracellular matrix (ECM) proteins, leading to liver fibrosis[39].

The metabolites of alcohol, such as acetaldehyde, lactic acid, and reactive oxygen species (ROS), can stimulate oxidative stress and cytokine-mediated damage. ROS generated by alcohol metabolism in hepatocytes is also known to activate HSCs and to result in the production of large amounts of collagen[40,41]. Alcohol-induced hepatocyte apoptotic bodies can be phagocytosed by HSCs and Kupffer cells, resulting in HSC activation and ECM synthesis.

The combination of CCl_4 and alcohol induced hepat-

ic cirrhosis in rats in the current study. Although these two agents induced cirrhogenesis *via* distinct mechanisms, they ultimately converged on the key step of HSC activation. Under normal circumstances, HSCs are in a resting state. Following liver damage, however, HSCs are activated and transformed into myofibroblast-like cells, a transition characterized by the loss of cytoplasmic lipid droplets, morphological changes, and the expression of α-SMA and many cytokines and their receptors. These myofibroblast-like cells can proliferate and synthesize a variety of ECM proteins, primarily type- I and type-Ⅲ collagens. HSC activation plays an essential role in liver fibrosis and can cause excessive accumulations of ECM proteins in the liver, resulting in liver fibrosis and cirrhosis. In 2001, Kawada *et al*[42] described a novel protein in rat HSCs that is highly associated with HSC activation, namely STAP [also referred to as cytoglobin/STAP (Cygb/STAP)]. STAP is a cytoplasmic protein in HSCs and myofibroblasts, and both protein and mRNA levels are significantly up-regulated during HSC activation[42,43]. Kang *et al*[44] used the increased expression of STAP as an indicator of cirrhosis in the rat model of cirrhosis.

Our results demonstrate that STAP mRNA expression in the untreated cirrhotic rats was significantly higher than in control rats, indicating the HSC activation and the development of hepatic cirrhosis in untreated cirrhotic rats. CCl_4 and other pathogenic factors can lead to lipid peroxidation, the up-regulation of STAP-related signaling pathways, and HSC activation. Due to the peroxidative activities of STAP on hydrogen peroxide and lipid peroxides, increased expression of this gene can lower the peroxide levels and prevent hepatic fibrosis[42]. In the present study, STAP mRNA levels were much lower in the transplantation group than in the untreated cirrhotic group and were comparable to the normal control group. This result suggests that HSCs in the cell transplantation group were in a resting state and that STAP-related signaling pathways were inactive. Alternatively, transplanted embryonic hepatocytes may selectively induce activated HSCs to undergo apoptosis or inactivate HSCs. Therefore, cell transplantation treatment maintains HSCs in a resting state[45] and reverses hepatic cirrhosis in rats.

There are no definitive reports with respect to upstream regulators of STAP. *In vitro* experiments found that α-SMA can induce increased expression of STAP, but STAP is not regulated by IFN-γ, TGF-β, PDGF/BB, cAMP or cGME[42]. In the initial stages of HSC activation, the transcription factor c-myb is up-regulated. c-myb is a proto-oncogene, and its expression is growth-dependent; it is expressed at low levels in quiescent cells, and its expression is rapidly increased in exponentially dividing cells. c-myb can interact with α-SMA promoter regulatory elements and alter α-SMA expression. α-SMA is a microfilament protein with contractile properties and is widely distributed in muscle cells. It is also the cytoskeletal marker of HSC activation, and its increased expression may up-regulate STAP expression. In the present study, mRNA levels of c-myb, α-SMA and STAP were significantly increased in the untreated cirrhotic group but were much lower in the cell transplantation group. However, there was no significant difference between the normal control and the cell transplantation group. Similar results were observed in α-SMA protein expression levels. These findings suggest that the observed successful treatment of cirrhosis with embryonic hepatocyte transplantation is related to the activity of STAP-related signaling.

ET is the most powerful vasoconstrictor peptide in humans; it is also a damage-inducible factor produced during ischemia and hypoxia[46]. The occurrence and development of many chronic liver diseases, such as hepatic cirrhosis, are related to ET plasma and tissue levels. ET-1 is the most important member of the ET family and is one of the primary inducers of portal hypertension[47]. ET-1 catalyzes the phosphorylation of amino acid residues in many kinases through the G-protein complex-phospholipase C-protein kinase C signaling pathway. ET-1 thereby regulates gene expression and promotes HSC mitosis and the synthesis of collagen and matrix proteins[48]. After ET-1 binds to its receptor, endothelin receptor, it activates voltage-dependent calcium channels, promoting calcium influx and leading to vasoconstriction. HSC is considered one of the main sources of ET-1, which is involved in increased portal vein pressure and plays an important role in the regulation of blood flow in the liver. In the normal liver, ET-1 is primarily expressed in liver sinusoid endothelial cells; upon liver injury, however, ET-1 is primarily expressed in activated HSCs.

Contraction of the portal vein and sinusoid as a result of EF-1-induced HSC activation may be a significant event in cirrhogenesis, resulting in increased portal vein obstruction following liver fibrosis[49]. In the current study, serum and liver ET-1 levels were significantly higher in the untreated cirrhotic group when compared with the normal control and cell transplantation groups. Ultrasound results demonstrated that the untreated cirrhotic rats had a wider portal vein and reduced PVV. Rats in the cell transplantation group showed significant remission, suggesting that treatment of hepatic cirrhosis with embryonic hepatocytes is able to reduce ET-1 expression and modify various parameters of this pathway. The reduction in the portal vein pressure of the cell transplantation-treated cirrhotic group may indicate a remission of the portal hypertension caused by cirrhosis.

Significant therapeutic effects were observed in the treatment of hepatic cirrhosis using embryonic hepatocyte transplantation in rats. Transplanted embryonic hepatocytes significantly reduce c-myb, α-SMA and STAP expression, all of which are involved in HSC activation. This treatment also down-regulates the expression of ET-1, a vasoactive substance.

COMMENTS

Background

Hepatic cirrhosis is a terminal illness that can only be cured by a liver trans-

plant. Stem cells are capable of indefinite self-renewal and are able to generate other cell types *via* differentiation. Stem cell transplantation is the most promising therapy for hepatic cirrhosis. Embryonic hepatocytes are stem cells that have the capacity to proliferate and to differentiate into hepatocytes. These cells have a more promising clinical potential than adult hepatocytes for the treatment of liver injury due to chronic cirrhosis.

Research frontiers

Stem cell transplantation for the treatment of hepatic cirrhosis is far from application. The identification of the most effective stem cells and probe into their mechanisms of action have recently become a popular research topic.

Innovations and breakthroughs

The authors confirm the efficacy of embryonic hepatocyte transplantation for hepatic cirrhosis in rats by demonstrating reduced expression level of stellate activation-associated protein (STAP), α smooth muscle actin and endothelin-1. In addition, they initially revealed the mechanism of this therapy, which may be of significance for the treatment of hepatic cirrhosis.

Applications

Although it is far from clinical application, it is possible that embryonic hepatocyte transplantation will become a curative treatment for hepatic cirrhosis and other severe liver diseases. This study has laid a foundation for further experimental researches and clinical studies, and provided useful data for the treatment of cirrhosis.

Terminology

STAP is a protein expressed in hepatic stellate cells. Hepatocyte damage leads to increased STAP expression; therefore, STAP can be used as an indicator of cirrhosis in the rat cirrhosis model.

Peer review

This is a well-performed and comprehensive study. The authors show the effectiveness of embryonic stem cells to treat cirrhosis. Furthermore, the mechanism by which this protective effect is mediated has been elucidated.

Abstract

AIM: To investigate the relationship between donor liver cold preservation, lung surfactant (LS) changes and acute lung injury (ALI) after liver transplantation.

METHODS: Liver transplantation models were established using male Wistar rats. Donor livers were preserved in University of Wisconsin solution at 4 ℃ for different lengths of time. The effect of ammonium pyrrolidinedithiocarbamate (PDTC) on ALI was also detected. All samples were harvested after 3 h reperfusion. The severity of ALI was evaluated by lung weight/body weight ratio, lung histopathological score, serum nitric oxide (NO) and endothelin (ET)-1 levels, lung tumor necrosis factor (TNF)-α and interleukin (IL)-1β levels. Lung surfactants (LSs) were determined by micellar electrokinetic capillary chromatography.

RESULTS: With extended donor liver cold preservation time (CPT), lung histopathological scores, serum ET-1 levels, lung weight/body weight ratio and the level of TNF-α and IL-1β in lung were increased significantly in the 180-min group compared with the sham group (3.16 ± 0.28 *vs* 1.12 ± 0.21, $P < 0.001$; 343.59 ± 53.97 *vs* 141.53 ± 48.48, $P < 0.001$; 0.00687 ± 0.00037 *vs* 0.00557 ± 0.00056, $P < 0.001$; 17.5 ± 3.0 *vs* 1.3 ± 0.3, $P < 0.001$; 10.8 ± 2.3 *vs* 1.8 ± 0.4, $P < 0.001$), but serum NO levels decreased remarkably (74.67 ± 10.01 *vs* 24.97 ± 3.18, $P < 0.001$). The expression of lung phosphatidylcholine (PC), phosphatidylethanolamine (PE), phosphatidylinositol (PI) and phosphatidylserine (PS) increased when CPT was < 120 min, and decreased when CPT was > 180 min (PC: 1318.89 ± 54.79 *vs* 1011.18 ± 59.99, $P < 0.001$; PE: 1504.45 ± 119.96 *vs* 1340.80 ± 76.39, $P = 0.0019$; PI: 201.23 ± 34.82 *vs* 185.88 ± 17.04, $P = 0.2265$; PS: 300.43 ± 32.95 *vs* 286.55 ± 55.55, $P = 0.5054$). All these ALI-associated indexes could be partially reversed by PDTC treatment.

CONCLUSION: Prolonged CPT could induce or inhibit the expression of LSs at the compensation or decompensation stage, and some antioxidants (e.g., PDTC) may reverse the pathological process partially.

Liver cold preservation induce lung surfactant changes and acute lung injury in rat liver transplantation. *World J Gastroenterol* 2012; 18(4): 323-330 Available from: URL: http://www.wjgnet.com/1007-9327/full/v18/i4/323.htm DOI: http://dx.doi.org/10.3748/wjg.v18.i4.323

INTRODUCTION

Acute lung injury (ALI) is a common complication of liver transplantation, which may develop into its severest form, acute respiratory distress syndrome (ARDS), and play a pivotal role in the death of patients post-transplantation[1]. It has been reported that the incidence of lung complications after liver transplantation is 60%-80%; the morbidity rate of ARDS is 4.5%-18%, and the case-fatality rate is 50%-70%[2,3]. Thus, prevention of the complications is important in reducing in-hospital mortality after liver transplantation, and investigation of the etiological factors of liver-transplantation-related ALI is therefore of great importance.

Lung surfactant (LS) is synthesized primarily by alveolar type Ⅱ cells and is stored in lamellar bodies. In response to some stimuli, LS is secreted to supply the surface-active monolayer. LS is a complex mix of phospholipids, neutral lipids and proteins that lines the gas/liquid interface. LS is essential for normal breathing and the severity of ALI correlates with surfactant dysfunction and abnormalities in surfactant composition[4].

In our clinical practice, we have observed that ALI often occurs in the patients transplanted with long-persevered donor livers. Therefore, we raised a hypothesis that prolonged donor liver cold preservation time (CPT) might induce lung damage. Therefore, we conducted the present study to investigate the change of LS in liver-transplantation-induced ALI along with changes in donor liver CPT, aiming at uncovering the association between prolonged CPT and ALI.

MATERIALS AND METHODS

Experimental design

Male Wistar rats (n = 110) were used as donors and recipients to establish orthotopic liver transplantation models. The rats were randomly divided into six groups (n = 10 in each group, n = 10 for donor in liver transplantation groups). Donor livers from each group were preserved in 4 ℃ University of Wisconsin solution respectively for 0 min (sham operation), 45 min, 90 min, 120 min, 180 min, and 180 min plus intravenous injection of ammonium pyrrolidinedithiocarbamate (PDTC) at a dosage of 100 mg/kg immediately after the onset of liver reperfusion. All recipients were sacrificed at 180 min after liver transplantation.

Animal preparation and sample collection

A total of 110 adult male Wistar rats (272 g ± 31 g; Tongji Medical Center, Central China University of Science and Technology) were used as donors and recipients. Prior to the experiment, the rats were fasted for 12 h and allowed free access to water. Liver harvesting and liver transplantation were performed under anesthesia with intraperitoneal injection of ketamine hydrochloride (80 mg/kg) and by using the method described by Kamada *et al*[5] and Hori *et al*[6]. Protocols for animal care and experimental management were approved by the ethics committee.

Blood samples were collected from the suprahepatic vena cava to determine the serum levels of nitric oxide (NO) and endothelin (ET)-1. Body weight and lung weight were measured and part of left lower lobe of lung was fixed with polyoxymethylene for histological examination. Lung tissue (200 mg) was harvested for the extraction of lung phospholipids.

Lung histopathological assessment

Left lower lobe of lung was harvested, fixed in 10% formalin, and embedded in paraffin. Tissue sections (4 μm) were stained with hematoxylin and eosin for light microscopy, and evaluated blindly by an independent consultant pathologist. Damage to the lung tissue was graded by the pathologist on a scale of 1 (no injury) to 4 (worst), as described previously[7].

Serum ET-1 measurement

Serum ET-1 was quantified with a radioimmunoassay kit (Radioimmunity Institute of PLA General Hospital, China) by Wizard gamma counter (PerkinElmer, United States) according to the manufacturer's recommendations.

Serum NO analysis

Serum NO was measured by an NO assay kit (Nanjing Jiancheng Bioengineering Institute, Nanjing, China) according to the manufacturer's protocol. The absorbance of the reaction mixture was read at 550 nm in a BioTek ELX 808 microplate reader (Bio-Tek Instruments, Winooski, Vermont, United States).

Lung weight/body weight ratio

All recipients' body weight and lung weight were measured by electronic balance.

Measurement of tumor necrosis factor (TNF)-α and interleukin (IL)-1β in lung by immunohistochemistry

Histological sections (4 μm) of lung were cut on a rotary microtome and stained to detect intragraft expression of TNF-α and IL-1β. Paraffin sections were spread on a slide, and rabbit anti-rat TNF-α, IL-1β polyclone antibodies (diluted 1:200, Santa Cruz Biotechnology, Santa Cruz, CA, United States) were used to detect the intragraft expression of TNF-α, IL-1β respectively. Biotin-labeled goat anti-rabbit secondary antibody (Santa Cruz Biotechnology), horseradish-peroxidase-labeled anti-

biotin, and 3,3-diaminobenzidine were used to visualize positive expression. We counted 10 randomly chosen fields per section using a light microscope at high power (400 × magnification; Leica Q550CW, Germany) and the results were expressed as absorbance units (*A*).

Lung phospholipid extraction

Fresh lung tissue (200 mg) was homogenized with 2 mL PBS on ice, and 1 mL tissue homogenate was dissolved in 2 mL chloroform/methanol (2:1, v/v). After thermal agitation and 30 min standing at room temperature, the solution was centrifuged at 2500 rpm at 4 ℃ for 5 min. The supernatant was transferred to a freezing tube. The above procedures were repeated, and then all the supernatants obtained were evaporated and frozen at -80 ℃.

Lung phospholipid analysis

Chemicals and reagents used were of analytical reagent grade. Phospholipid standard solutions (Sigma, United States) included: phosphatidylcholine (PC), phosphatidylethanolaraine (PE), phosphatidylinositol (PI), and phosphatidylserine (PS). Micellar electrokinetic capillary chromatography (MECC) was performed in an Agilent G1600AX Capillary Electrophoresis (Agilent, Santa Clara, CA, United States). The electrophoresis buffer for MECC was composed of 35 mmol/L sodium deoxycholate, 6 mmol/L disodium tetraborate, 10 mmol/L disodium hydrogen phosphate, and 30% 1-propanol. The buffer pH value was adjusted to 8.5 with 1 mol/L HCl. MECC was conducted at a temperature of 40 ℃ and a voltage of 18 kV. The total length of capillary was 570 mm and the detection region was 500 mm away from the injection end. Vacuura injection was performed at 50 mbr for 5 s, and ultraviolet detection was performed at 200 nm[8].

Statistical analysis

All data were expressed as mean ± SEM, and analyzed with one-way ANOVA and Student's *t* test. All the statistical analyses were carried out using SPSS version 13.0. $P < 0.05$ was considered to represent statistical significance.

RESULTS

General condition of the animals

The duration of donor operation was 45.6 ± 13.8 min, the time for donor liver preparation was 20.3 ± 6.7 min, and warm ischemia was avoided. The receptor operation took 26.7 ± 5.5 min, and anhepatic phase lasted for 16.1 ± 2.5 min. No significant difference was seen in portal clamping time among groups. No animal died before sample harvest.

Lung histopathological investigation

The representative lung injuries in different groups are shown in Figure 1. Lung microscopic examination revealed alveolar, perivascular and interstitial edema, neutrophil infiltration, atelectasis, disruption of alveolar and bronchiolar epithelial cells, and local hemorrhage in severe cases with prolonged CPT. Consistent with these histopathological observations, the lung injury scores in the 180-min group were significantly higher than those in the sham group and 45-min group (3.16 ± 0.28 *vs* 1.12 ± 0.21, $P < 0.001$; 3.16 ± 0.28 *vs* 2.05 ± 0.24, $P < 0.001$), and were also higher than those in PDTC group although the difference was not significant (3.16 ± 0.28 *vs* 2.95 ± 0.16, $P = 0.054$).

Serum NO and ET-1 assaying

The experiment results showed that with donor liver CPT prolonged, the serum NO level in the 180-min group were significantly lower than those in the sham group and 45-min group (24.97 ± 3.18 *vs* 74.67 ± 10.01, $P < 0.001$; 24.97 ± 3.18 *vs* 69.05 ± 2.74, $P < 0.001$) and the decline could not be reversed by PDTC (24.97 ± 3.18 *vs* 7.67 ± 3.79, $P < 0.001$; Figure 2A).

With longer liver CPT, serum ET-1 levels increased significantly in the 180-min group compared with the sham group (343.59 ± 53.97 *vs* 141.53 ± 48.48, $P < 0.001$). There was a significant difference between each of the operation groups and the control group ($P < 0.05$). The expression of ET-1 was inhibited significantly by PDTC (343.59 ± 53.97 *vs* 217.80 ± 11.32, $P < 0.001$; Figure 2B).

Lung weight/body weight ratio

Lung weight/body weight ratio increased with prolonged CPT. It peaked in the 180-min group compared with the sham group (0.00687 ± 0.00037 *vs* 0.00557 ± 0.00056, $P < 0.001$), but greatly decreased after PDTC was used 0.00687 ± 0.00037 *vs* 0.00576 ± 0.00016, $P = 0.001$; Figure 2C).

Lung TNF-α and IL-1β measurement

Figure 3 shows a significant increase in TNF-α and IL-1β in lung with prolonged CPT, which peaked in the 180-min group compared with the sham group (TNF-α: 17.5 ± 3.0 *vs* 1.3 ± 0.3, $P < 0.001$; IL-1β: 10.8 ± 2.3 *vs* 1.8 ± 0.4, $P < 0.001$). After administration of PDTC, TNF-α and IL-1β production was significantly attenuated (TNF-α: 17.5 ± 3.0 *vs* 9.8 ± 2.3, $P < 0.001$; IL-1β: 10.8 ± 2.3 *vs* 7.1 ± 2.0, $P = 0.0012$). We suggest that the prolonged CPT induced some inflammatory factors expressed in lung.

Lung phospholipid composition determination

The area under curve (AUC) represents the composition of lung phospholipids (Figures 4 and 5). With the extension of CPT, PC levels increased significantly, reaching a maximum in the 120-min group compared with the sham group (1318.89 ± 54.79 *vs* 406.79 ± 56.49, $P < 0.001$), and then declined in notably the 180-min group (1318.89 ± 54.79 *vs* 1011.18 ± 59.99, $P < 0.001$). No significant difference was observed between the 180-min group and PDTC group (1011.18 ± 59.99 *vs* 1062.58 ± 78.49, $P = 0.1173$).

PE changed similarly with PC, reaching a maximum in the 120-min group compared with the sham group

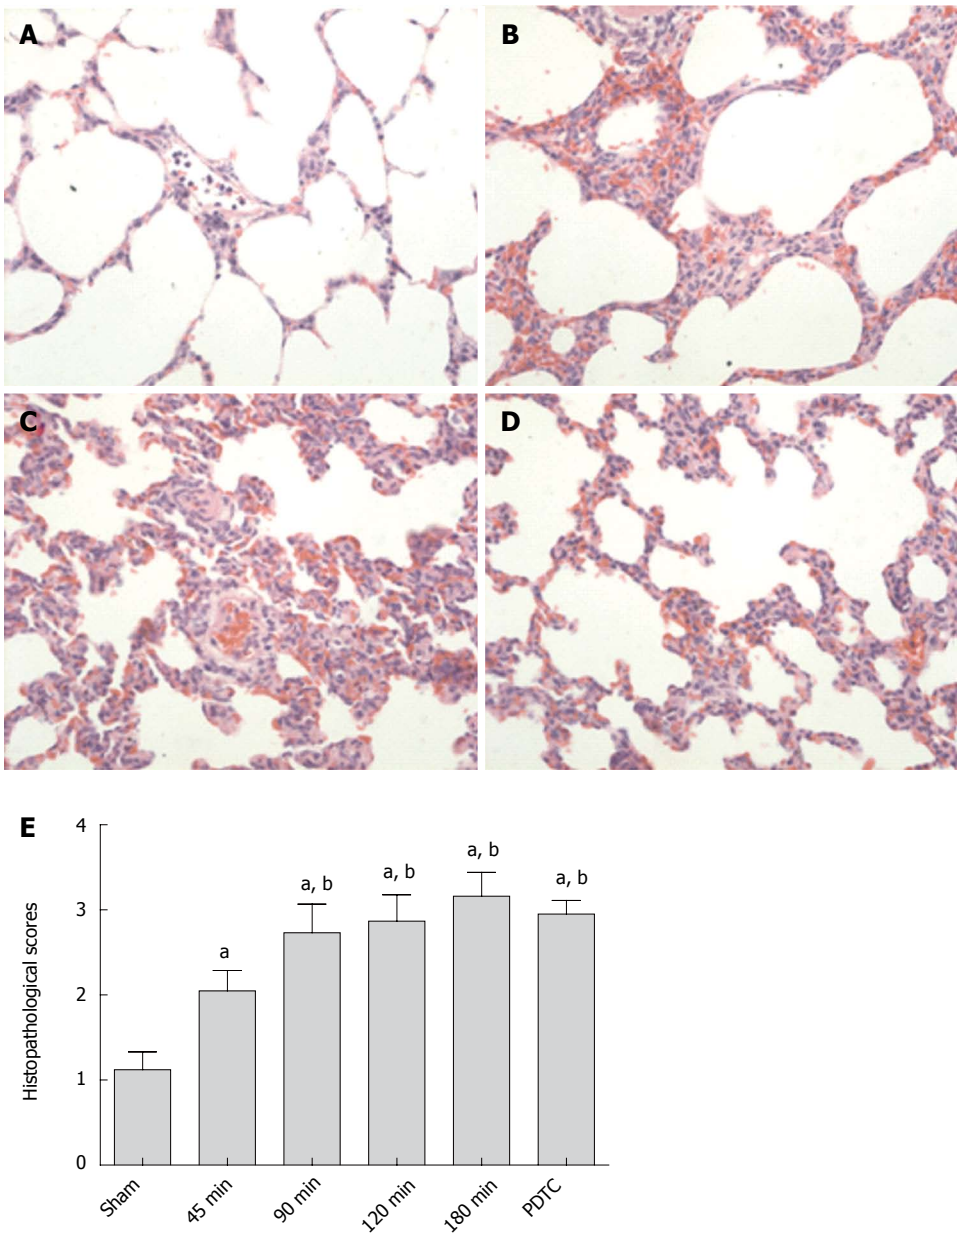

Figure 1 Representative lung tissue sections and histopathological scores. A: Sham group; B: 90-min group; C: 180-min group; D: PDTC group. Alveolar, perivascular and interstitial edema, neutrophil infiltration, atelectasis, disruption of alveolar and bronchiolar epithelial cells, and local hemorrhage aggravated with prolonged CPT; E: Lung histopathological scores in different groups. The scores in the CPT groups were significantly higher than that in the sham group, but lower than in the PDTC group. $^{a}P < 0.05$ *vs* sham group; $^{b}P < 0.05$ *vs* 45-min group. PDTC: Pyrrolidinedithiocarbamate; CPT: Cold preservation time.

(1504.45 ± 119.96 *vs* 430.38 ± 57.91, $P < 0.001$), and decreased significantly in the 180-min group (1504.45 ± 119.96 *vs* 1340.80 ± 76.39, $P = 0.0019$). PE in the PDTC group decreased significantly compared with the 180-min group (1340.80 ± 76.39 *vs* 1222.18 ± 100.48, $P = 0.0082$).

PI kept rising gradually, and reached a peak in the 120-min group compared with the sham group (201.23 ± 34.82 *vs* 55.12 ± 10.14, $P < 0.001$), but no significant difference was found between the 120-min, 180-min and PDTC groups (201.23 ± 34.82 *vs* 185.88 ± 17.04, $P = 0.2265$; 185.88 ± 17.04 *vs* 190.10 ± 41.75, $P = 0.7707$).

PS reached a maximum in the 120-min group compared with the sham group (300.43 ± 32.95 *vs* 51.29 ± 13.89, $P < 0.001$), and decreased in the 180-min group (300.43 ± 32.95 *vs* 286.55 ± 55.55, $P = 0.5054$), but dropped significantly in the PDTC group (286.55 ± 55.55 *vs* 132.60 ± 40.27, $P < 0.001$).

DISCUSSION

The incidence of ALI post-liver transplantation has been reported to be 60%-80%[3]. Despite intense research and diverse therapeutic trials, there is no effective prevention or treatment for ALI at present[1]. Recent studies have shown that the pathogenesis of ALI involves disorders of oxidants/antioxidants, inflammation/anti-inflammation, and upregulation of inflammatory factors[9,10]. It has been suggested that the antioxidant PDTC can inhibit some oxidants and inflammatory damage[1].

In our study, levels of serum NO and ET-1 were used

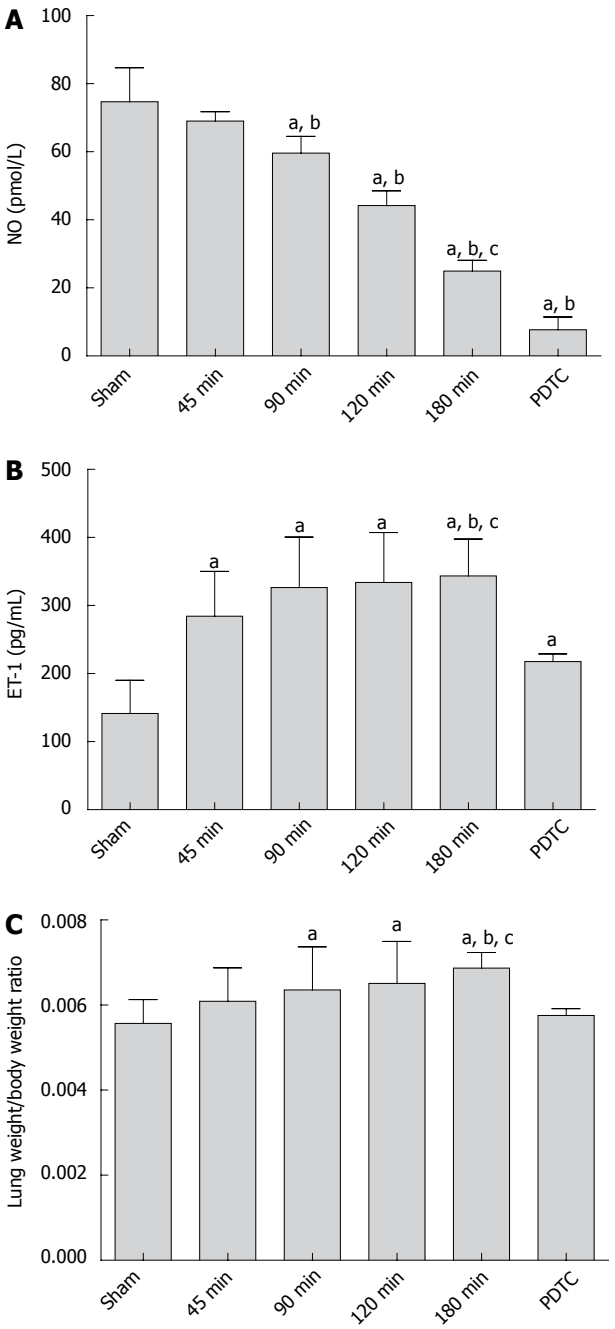

Figure 2 Serum NO, ET-1 level and lung weight/body weight ratio. A: NO levels in different groups. With CPT prolonged, NO level decreased significantly, and became even lower with PDTC injection post-reperfusion; B: ET-1 level in different groups. With CPT prolonged, ET-1 level increased significantly compared with the sham group. The PDTC group had a significantly lower ET-1 level than 180-min group; C: Lung weight/body weight ratios in different groups. The ratios increased compared with the sham group. Significant difference was observed between the 180-min group and PDTC group. $^{a}P < 0.05$ *vs* sham group; $^{b}P < 0.05$ *vs* 45-min group; $^{c}P < 0.05$ *vs* PDTC group. to evaluate the severity of ALI. NO and ET-1 are secreted by endothelial cells and are two important vasoactive substances that regulate mini-circulation. NO can expand blood vessels, prevent platelet aggregation, and therefore improve microcirculation. After liver transplantation, the implanted graft liberates high amounts of arginase and causes L-arginine deficiency. L-arginine is the substrate of NO synthesis reaction. Its depletion influences NO synthesis after liver transplantation[11]. This might be the reason why serum NO level drops after liver transplantation. An increase in NO level by L-arginine could attenuate LS depletion, and therefore, ameliorate postoperative pulmonary dysfunction[12]. PDTC could inhibits cytokine-induced NO production[13], as our study showed.

ET-1, as the most powerful vasoactive substance, can cause microcirculation disturbance and induce pulmonary injury[14]. The slowdown of liver blood flow can concen-

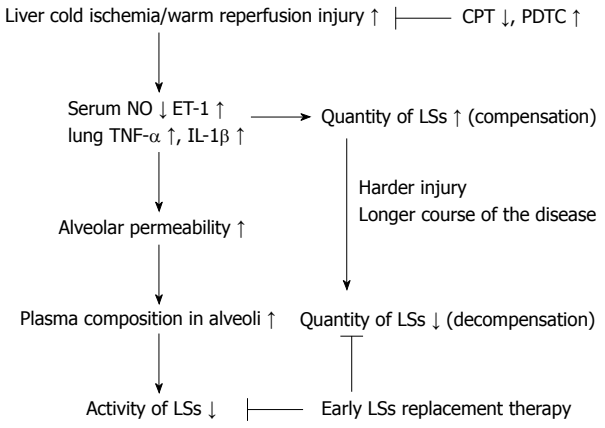

Figure 6 A schematic diagram for the mechanism of lung surfactants in liver-transplantation-related acute lung injury. With prolonged CPT of donor liver, the cold ischemia/warm reperfusion injury increased, inducing an imbalance of serum NO/ET-1 levels and production of TNF-α and IL-1β in lungs. Consequently, alveolar permeability increased, and the plasma composition in the alveoli inactivated the lung surfactants (LSs). In the early stage of ALI, LSs increased in compensation, but in the decompensation stage, the level of LSs decreased, and ALI was aggravated. Shorter CPT or using PDTC may reduce ALI, and surfactant replacement therapy at an earlier stage may be useful in the treatment of ALI. PDTC: Pyrrolidinedithiocarbamate; CPT: Cold preservation time; TNF: Tumor necrosis factor; IL: Interleukin; ALI: Acute lung injury; NO: Nitric oxide; ET: Endothelin.

trate ET-1 in the serum and liver. We observed that the balance between NO and ET-1 was disrupted after liver transplantation.

Natural lung surfactants (LSs) are a mixture of phospholipids and specific proteins, and are produced by type Ⅱ alveolar epithelial cells, stored in Golgi bodies and secreted into the alveolar space. They are important in maintaining alveolar expansion during breathing and physiological gas exchange. The pathological condition of ALI is often characterized with metabolic anomalies of LSs and disrupted lung function[15].

We found that with prolonged CPT of donor liver, that cold ischemia/warm reperfusion injury increased. The imbalanced levels of NO and ET-1 induced capillary endothelial dysfunction. Together with TNF-α and IL-1β produced in the lungs, the permeability of the air-blood barrier increases, just as shown by lung weight/body weight ratio and lung histopathological scores. Then, a variety of plasma compositions, such as serum, serum proteins, hemoglobin and proteases migrate into the alveolar space and inactivate LSs[16]. At the same time, ET-1 and some inflammatory factors, such as TNF-α and IL-1β, stimulate the production of cAMP, which can induce type Ⅱ alveolar epithelial cells to secrete LSs[17]. Because of the anti-inflammatory properties of LSs[18], an increase in their concentration in the lungs indicates a strong compensatory ability in the defense against ALI[19]. Our study showed that, when CPT was < 2 h, the expression of LSs increased with longer CPT, however, when CPT was 3 h, more severe injury of type Ⅱ alveolar epithelial cells inhibited secretion of LSs. This agrees with the results of Shu *et al*[20].

In contrast, the change in LSs after ALI is time-dependent, with early increases and late decreases. Therefore, surfactant replacement therapy should be administered at an early stage of ALI, the compensation stage, to alleviate injury[21]. If applied in the decompensation stage, the therapy may not provide satisfactory effects. This may be the reason why surfactant therapy has only limited success in ARDS[22,23]. Furthermore, as an antioxidant, PDTC can relieve cold ischemia/warm reperfusion injury of donor liver, and partly reverse the disturbance. Thus, shortening CPT or using PDTC may be useful for alleviation of ALI post-liver transplantation. A proposed scheme of the mechanism is given in Figure 6, summarizing how LS affects liver-transplantation-associated ALI.

COMMENTS

Background

Acute lung injury (ALI) and its severe subset acute respiratory distress syndrome (ARDS) have relatively high morbidity and mortality in post-liver transplantation patients. The pathogenesis and prevention of liver-transplantation-related ALI are not very clear. Lung surfactants (LSs) are a complicated mixture of approximately 90% lipids and 10% proteins. They are produced by type Ⅱ alveolar epithelial cells and secreted into the alveolar space to maintain normal respiratory mechanics by reducing alveolar surface tension to near-zero values.

Research frontiers

Recent studies have shown that the pathogenesis of ALI involves disorders of oxidants/antioxidants, inflammation/anti-inflammation, and upregulation of inflammatory factors. Many antioxidants can inhibit some oxidants and inflammatory damage. The severity of ALI correlates with abnormalities in surfactant composition. Supplementing exogenous surfactant to newborns suffering from respiratory distress syndrome has a satisfactory therapeutic effect. Surfactant therapy has also been used in ALI/ARDS, but with only limited success.

Innovations and breakthroughs

We observed that ALI often occurred in patients transplanted with long-preserved donor livers. Therefore, we raised a hypothesis that cold preservation/warm reperfusion injury of donor liver may induce ALI after liver transplantation. To validate the hypothesis, we transplanted donor liver after different cold preservation times in rats. Prolonged cold preservation time had a positive correlation with the severity of ALI, and could induce or inhibit the expression of LSs in different time phases, and some antioxidants (e.g., ammonium pyrrolidinedithiocarbamate) may reverse the pathological process partially.

Applications

Shorter cold preservation time or some antioxidants may reduce liver-transplantation-related ALI, and surfactant replacement therapy should be useful in the early stage of ALI to achieve better results.

Terminology

Cold ischemia/warm reperfusion injury, different from warm ischemia/reperfusion injury, is a characteristic injury in organ transplantation. It depends on the length of cold storage. Liver is one of the organs that are sensitive to ischemia/reperfusion injury. Emerging evidence suggests that the early stage of the injury can be regarded as part of the immune response to injury stress and sinusoidal endothelial cells are the targets of cold ischemia, whereas hepatocytes appear to be relatively unscathed.

Peer review

This study suggests that liver transplantation in rats and the length of cold ischemia induce surfactant changes and ALI. The study was well designed and conducted.

Abstract

AIM: To examine the effects of nitroglycerine on portal vein haemodynamics and oxidative stress in patients with portal hypertension.

METHODS: Thirty healthy controls and 39 patients with clinically verified portal hypertension and increased vascular resistance participated in the study. Liver diameters, portal diameters and portal flow velocities were recorded using color flow imaging/pulsed Doppler detection. Cross-section area, portal flow and index of vascular resistance were calculated. In collected blood samples, superoxide anion radical (O_2^-), hydrogen peroxide (H_2O_2), index of lipid peroxidation (measured as TBARS) and nitric oxide (NO) as a marker of endothelial response (measured as nitrite-NO_2^-) were determined. Time-dependent analysis was performed at basal state and in 10th and 15th min after nitroglycerine (sublingual 0.5 mg) administration.

RESULTS: Oxidative stress parameters changed significantly during the study. H_2O_2 decreased at the end of study, probably *via* O_2^- mediated disassembling in Haber Weiss and Fenton reaction; O_2^- increased significantly probably due to increased diameter and tension and decreased shear rate level. Consequently O_2^- and H_2O_2 degradation products, like hydroxyl radical, initiated lipid peroxidation. Increased blood flow was to some extent lower in patients than in controls due to double paradoxes, flow velocity decreased, shear rate decreased significantly indicating non Newtonian characteristics of portal blood flow.

CONCLUSION: This pilot study could be a starting point for further investigation and possible implementation of some antioxidants in the treatment of portal hypertension.

Key words: Portal hypertension; Endothelium; Nitroglycerine; Oxidative stress; Portal vein haemodynamics

Nitroglycerine effects on portal vein mechanics and oxidative stress in portal hypertension. *World J Gastroenterol* 2012; 18(4): 331-339 Available from: URL: http://www.wjgnet.com/1007-9327/full/v18/i4/331.htm DOI: http://dx.doi.org/10.3748/wjg.v18.i4.331

INTRODUCTION

Oxidative stress is a condition in which the delicate balance that exists between prooxidant (free radicals) production and their subsequent amelioration *via* the antioxidant defense system (ADS) becomes skewed in favor of free radical expression[1]. An increasing body of evidence suggests that oxidative stress is involved in the pathogenesis of many cardiovascular diseases, including hypertension, hypercholesterolaemia, atherosclerosis, diabetes and heart failure[2-5]. The existence of an interference of increased oxidative stress with the vasodilatating properties of veins is now a well known fact. The term endothelium dysfunction is usually used to refer to an impairment of endothelium-dependent vasorelaxation caused by a loss of nitric oxide (NO) bioactivity in the vessel wall, which is, in part, induced by accelerated NO degradation by reactive oxygen species (ROS)[2-8]. Endothelial function is most commonly assessed as a vasodilatatory response to various pharmacological agonists or mechanical stimuli that induce endothelium-dependent or endothelium-independent vasodilatation[9]. One such agonist is nitroglycerine (GTN)[9]. The aim of our study was to determine how sublingual administration of GTN might be used for the evaluation of portal endothelium-independent vasodilatation through estimating parameters of portal vascular mechanics and oxidative stress in patients suffering from portal hypertension. We hypothesized that the endothelium independent vasodilatation of the portal vein induced by sublingual GTN administration would lead to increased oxidative stress and significant changes in portal haemodynamics. The precise mechanism of increased oxidative stress is to be determined; we favor the importance of Haber-Weiss and Fenton's mechanism. Also, increased blood flow through the portal vein and reduced shear rate may be involved in the previously mentioned process of enhanced oxidative stress. Indeed, portal blood flow is known to be affected by factors and circumstances of chronic liver diseases, and its changes evolved from basic haemodynamic laws[10-15].

MATERIALS AND METHODS

Patients

This research was performed with a group of 39 patients with chronic liver disease and 30 healthy controls. Patients with chronic liver disease were recruited from the Department of Gastroenterology, Internal Clinic, Clinical Centre Kragujevac, while controls were recruited from the medical staff. The only obligatory inclusion criterion for the participants of the experimental group referred to the existence of previously clinically confirmed serious chronic liver disease (by ultrasonographical assessments, patient's anamnesis and biochemical parameters). Thirty eight patients had previously confirmed hepatic cirrhosis and one patient was recruited with clinical diagnosis of Hepatitis B. Patients were defined as preascitic if they had never been diagnosed with ascites according to clinical and ultrasonographical examinations. None of the subjects took any medication known to affect vascular tonus or blood flow. Written informed consent was obtained from all patients and the study protocol was approved by the local Ethics Committee prior to the onset of the study. The investigation was conducted in accordance with the principles outlined in the Declaration of Helsinki (Last updated in 2005) and principles of Good Clinical Practice (GCP).

Protocol

The examinations were performed in a quiet, air-conditioned, temperature controlled room (22-24 ℃). The antecubital vein was cannulated by using a 19-gauge polyethylene catheter for taking blood samples. Blood samples were taken at rest and in the 10th and 15th min after endothelium-independent vasodilatation induced by sublingual GTN administration (0.3 mg). Parameters of portal vascular mechanics were recorded in the 10th and 15th min after endothelium-independent vasodilatation by using a Doppler 2D machine. All ultrasonographical measurements were performed by 3 independent physicians and mean value was used for the final calculations.

Biochemical assays

Blood samples were taken from the antecubital veins into a Vacutainer test tube containing sodium citrate anticoagulant. Blood was centrifuged to separate plasma and red blood cells (RBCs). Biochemical parameters were measured spectrophotometrically.

Nitrite determination

Nitric oxide was assessed as nitrite and quantified by a spectrophotometric method using Griess reagent. 0.5 mL of perfusate was precipitated with 200 μL of 30% sulfosalicylic acid, vortexed for 30 min and centrifuged at 3000 × *g*. Equal volumes of the extracted plasma and Griess's reagent, containing 1% sulfanilamide in 5% phosphoric acid/0.1% napthalene ethylenediamine-dihydrochloride was added and incubated for 10 min in the dark and read at 543 nmol/L. The nitrite levels were calculated by using sodium nitrite as a standard[16].

Superoxide determination

The level of superoxide anion radical (O_2) was measured using Nitro Blue Tetrazolium (NBT) reaction in TRIS-buffer with plasma and read at 530 nm. Bidistilled water

was used as a blank probe[17].

Hydrogen peroxide determination

The level of hydrogen peroxide (H_2O_2) was measured using Phenol Red reaction in TRIS-buffer with plasma and read at 230 nm. Bidistilled water was used as a blank probe[18].

Index of lipid peroxidation (thiobarbituric acid reactive substances)

The degree of lipid peroxidation in coronary venous effluent was estimated by measuring of thiobarbituric acid reactive substances (TBARS) using 1% thiobarbituric acid (TBA) in 0.05 NaOH incubated with plasma TCA extracts (using 28% Trichloracetic acid-TCA) at 100 ℃ for 15 min and read at 530 nm. Bidistilled water solution was used as a blank probe[19].

Calculations

The following haemodynamic and biomechanical parameters were calculated: (1) Portal flow-blood flow rate (l/min) through portal vein; (2) Shear rate-the velocity gradient between the moving planes, $\Delta V/\Delta X$ (s^{-1}); (3) Portal cross sectional area-area normal to flow direction (cm^2); (4) Resistance index-relative maximal velocity gradient; (5) Inlet length-point where a constant flow regime is established (cm); (6) Expected (ideal) portal vein flow ratio-ideal flow ratio with regard to Poiseuille's equation; (7) Pressure ratio-estimated pressure changes derived from Poiseuille`s equation; and (8) Portal vein flow ratio-experimentally obtained value quotient flow.

The portal flow (Q) was calculated by using equation 1.1a, where D is portal diameter and V_{mean} is average blood flow velocity:

$$Q = \frac{D^2\pi}{4} V_{mean} \qquad (1.1a)$$

It is of interest to emphasize that portal blood flow calculated by equation 1.1a has to be in concordance with theoretical consideration of venous blood return and modified Poiseuille's law (equation 1.1b and 1.1c). MCP is mean circulatory pressure, RAP is right atrial pressure, R_v and R_a are vein and arterial resistance, η is viscosity, ΔP is pressure difference, P is pressure, L is length, E is incremental elastic modulus, h is wall thickness.

$$Q = \frac{MCP - RAP}{Rv + \frac{Ra}{19}} \qquad (1.1b)$$

$$Q = \frac{R_v^4\pi}{8\eta}\frac{\Delta P}{L}\frac{1}{(1-\frac{R_v P}{Eh})^4} \qquad (1.1c)$$

Shear rate (Sr) was calculated according to equation 1.2, where Q is portal flow and r is portal radius:

$$Sr = \frac{4Q}{r^3\pi} \qquad (1.2)$$

Portal cross sectional area (CSA) was calculated with regard to equation 1.3, where D is portal diameter:

$$CSA = \frac{D^2\pi}{4} \qquad (1.3)$$

RI represent portal resistance index and it was estimated by using maximal and minimal blood flow velocity (V_{max} and V_{min}) according to the formula 1.4:

$$RI = \frac{V_{max} - V_{min}}{V_{max}} \qquad (1.4)$$

The inlet length (L) was taken as:

$$L = 4,2\frac{V_{mean}D^2}{4} \qquad (1.5)$$

Expected (ideal) portal vein flow ratio (F_{ideal}) with regard to Poiseuille's equation was calculated by using equation 1.6. We made the assumption that α is 1. α is ratio of the viscosity, D_t is diameter in 10th or 15th min of test and D_0 represents initial diameter.

$$F_{ideal} = \frac{D_t^4}{D_0^4}\alpha \qquad (1.6)$$

Pressure ratio (ΔP_{ratio}) was calculated according to equation 1.7. Q_t is portal blood flow in the 10th or 15th min of test, Q_0 is basal portal flow, while D_t and D_0 are portal vein diameters in the same time intervals apparently.

$$\Delta P_{ratio} = \frac{Q_t D_0^4}{Q_0 D_t^4} \qquad (1.7)$$

We used equation 1.8 to approximately assess portal vein pressure difference between 10th min of the test and basal pressure with regard to Bernoulli's rule. In the following equation V_{mean0} and V_{meant} are the initial and 10th or 15th min mean blood flow velocity. ρ is the density of blood with assumption that it's value is 1060 kg/m^3.

$$\Delta P = \frac{1}{2}\rho(V_{meant}^2 - V_{mean0}^2) \qquad (1.8)$$

Portal vein flow ratio (F) was calculated with regard to experimentally obtained portal vein flow values:

$$Q_{10}/Q_0 \text{ and } Q_{15}/Q_0 \qquad (1.9)$$

Statistical analysis

Descriptive data were expressed as means ± SEM. The significance of difference between the two groups was assessed by Student's *t*-test, while differences between parameters in different time measurements were assessed by analysis of variance test with repeated measures and paired samples *t*-test as post-hoc. Statistical analysis of interobserver agreement for quantitative variables (D, V_{max}, V_{min}) was performed using the intraclass correlation coefficient. Results were interpreted as poor (< 0.04), regular (0.41-0.75) or excellent (> 0.76). *P* values < 0.05 were considered significant. All statistical analysis was performed using the SPSS (version 15).

RESULTS

Subjects' characteristics and portal vein parameters

Demographic and clinical characteristics of the study population are presented in Table 1.

Investigated haemodynamic and biomechanical parameters of patients and controls before and after GTN administration are summarized in Table 2.

Groups significantly differed in the majority of investigated parameters in all three times of measurement.

Following GTN administration, the majority of portal vein vascular mechanic and hemodynamic parameters reached a maximum after 10 min in both groups and then slightly changed in the opposite direction during the last 5 min of the performed test. Figure 1 illustrates the effects of GTN administration on mean portal flow.

Vasodilatation after GTN administration was associated with a significant difference between obtained and ideal portal flow rate ratio in patients both in 10th and 15th min of the test. However, there was no significant difference in F between the controls and patients.

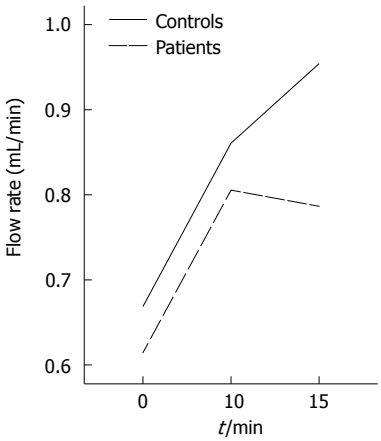

Figure 1 Portal blood flow rate in controls (full line) and patients (dotted line).

In the 15th min of the test, the decrease of the pressure ratio in controls resulted in significant differences in its values between controls and patients and this phenomenon is in concordance with the decrease in hydrodynamic pressure in controls but still significantly higher hydrodynamic pressure in controls. Bernoulli's equation was used with regard to significantly shorter portal vein (about 8 cm) when compared to the inlet length and therefore flat velocity profile. Shear rate observation could be of interest with regard to study of the boundary level and served to assess flow velocity profile. During our study velocity profile was flat, with a very thin boundary level. Table 3 shows data (diameter, maximal and minimal blood flow velocity) measured by three independent observers. Interobserver agreement evaluated by the intraclass correlation coefficient showed excellent and regular results for the quantitative variables as shown in Table 3.

Oxidative stress parameters

The dynamics of oxidative stress parameters in patients and controls can be seen in Figures 2A-D. At rest, significant differences between patients and controls were observed in levels of O_2^- (12.88 ± 2.24 nmol/mL *vs* 6.57 ± 1.07 nmol/mL, $P < 0.05$) and NO (4.85 ± 1.01 nmol/mL *vs* 15.06 ± 1.11 nmol/mL, $P < 0.01$). The same situation was observed 10 min after GTN administration, while in 15th min of the test patients experienced a significant rise in the level of the index of lipid peroxidation (2.37 ± 0.47 μmol/L *vs* 1.26 ± 0.08 μmol/L, $P < 0.05$), so groups now differed in three oxidative stress parameters.

GTN administration induced a significant rise in NO levels only in controls (NO levels were increased in the 10th min), but their NO levels returned to the basal values 15 min after GTN administration. The responses of O_2^- and TBARS to GTN administration were similar: 10 min after GTN administration levels of O_2^- and TBARS were elevated in both groups. In the 15th min of the test, controls' O_2^- and TBARS levels decreased to the levels similar to that in rest, while patients experienced further increases in the level of the index of lipid peroxidation and their

Interobserver agreement for quantitative parameters (portal vein diameter, maximal and minimal blood flow velocity) calculated from the comparison of data from all three observers. D: Portal diameter; IA: Interobserver agreement.

O_2^- levels remained elevated. Hydrogen peroxide did not change significantly throughout the study.

DISCUSSION

Haemodynamics

Endothelium-independent vasodilatation observed after GTN administration was caused by smooth muscle relaxation of the portal vein. Portal vein diameter rose significantly throughout the study and concomitantly statistically significant enhancement in portal blood flow (15th min) appear to be in concordance with equation 1.1b. With regard to equation 1.1b it is clear that small changes in vein resistance lead to huge blood flow changes, whereas the influence of arterial resistance is dampened due to high value of capacitance. However, there was no statistically significant difference in portal flow rate between the groups in the first ten minutes of the test, moreover flow rate was higher in controls compared to patients. In controls portal flow rate rose continuously compared to a decreasing pattern in patients after the 10th min of the test. One possible explanation for the lower flow rate in patients *vs* controls is increased incremental elastic modulus (with regard to equation 1.1c) and consequent leftward shift of the pressure-volume curve. However, in patients we could expect a parallel shift of the pressure-volume curve. The latter does not imply changes in compliance. It is of interest to emphasize hyperdynamic circulation in

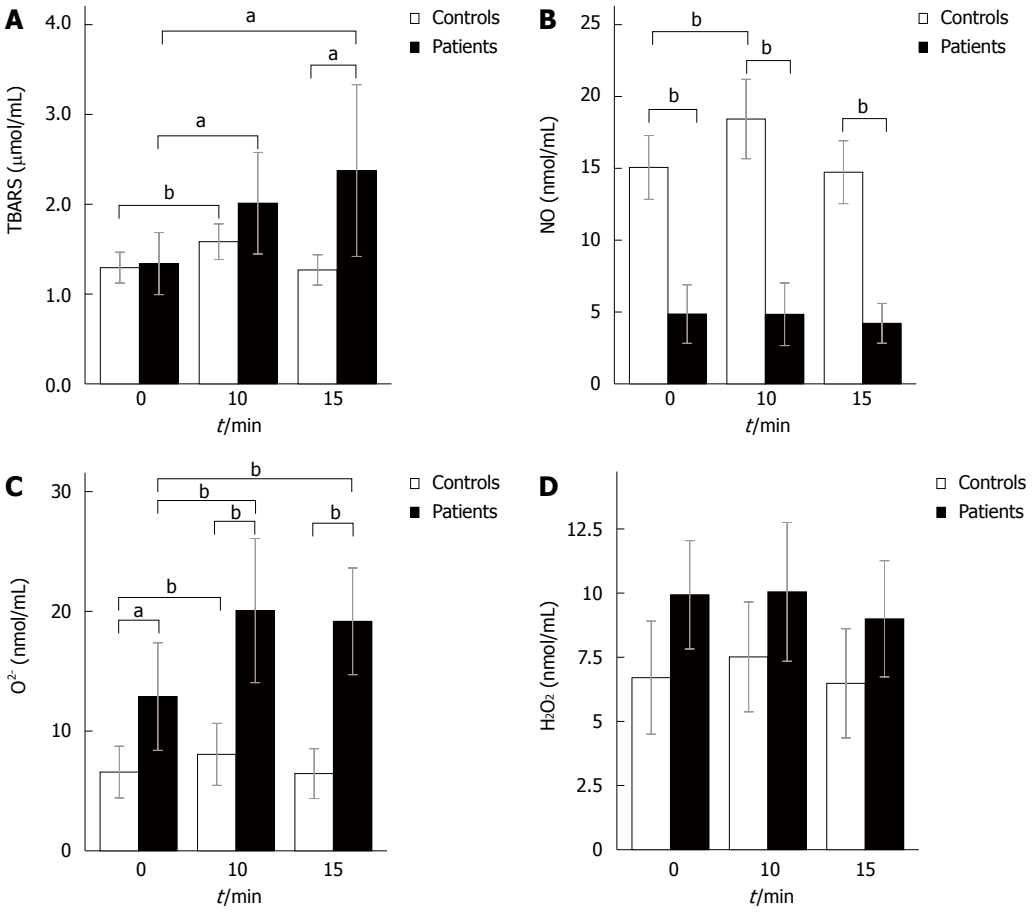

Figure 2 Thiobarbituric acid reactive substances, nitric oxide, O_2^- and H_2O_2 levels after nitroglycerine administration: measured at the beginning of the test, in the 10th and the 15th min of the test (results are expressed as mean ± SE of the mean; $^aP < 0.05$, $^bP < 0.01$). A: Thiobarbituric acid reactive substances levels (TBARS); B: Nitric oxide (NO) levels; C: O_2^- levels; D: H_2O_2 levels.

patients with liver cirrhosis. During the first 10 min, average blood flow velocity decreases simultaneously in both groups due to higher increases in portal cross-sectional area compared to flow rate. Our study disclosed significantly reduced mean blood flow velocity during the first 10 min of the test due to discrepancies between blood flow and CSA. Table 2 shows that blood flow velocity parameters were significantly higher in controls than in patients.

A similar pattern was obtained by using ideal and measured portal blood flow values. The ideal (expected) value was calculated by using equation 1.6 with regard to assumption of the equality of blood viscosity during the study. If the assumption about the equality viscosity is true, then $\alpha = 1$. Nevertheless, a significantly reduced shear rate in patients after GTN administration (49.85 ± 3.07 *vs* 66.50 ± 3.91) led to a nonlinear correlation with shear stress, so α might be different in comparision to the ideal value. In the 10th min of the test, expected (ideal) flow ratio rose up to 2.32 in patients and 2.54 in controls, while at the same time obtained flow ratio (F) was 1.34 *vs* 1.45 and both these differences were not statistically significant between groups. At the same time ideal flow ratio was significantly higher in both groups compared to the experimentally obtained flow ratio. However, ideal flow ratio was significantly higher in controls *vs* patients in the 15th min of test. High compliance does not reflect good elastic properties of vein, as one could presume, it rather reflects a change in geometry[20]. At low pressure the vein's cross section is ellipsoidal and every rise in pressure causes the vein to become more circular, without change in diameter, but with a great increase in cross-sectional area the vein becomes fully rounded and concomitantly the flow velocity decreases due to an inverse relationship with CSA. At higher steady state pressure, every further rise in pressure causes changes in diameter.

This concept is very similar to the observations made in our study. Table 2 shows a significant difference between the diameter in patients *vs* controls after GTN administration. This is, together with mentioned changes in viscoelastic properties (increased elastic modulus) and observed low shear rate in patients, a possible explanation for the proposed "double paradoxes"[21], phenomenon seen in cirrhotic patients, due to obviously increased intrahepatic resistance as a consequence of elevated vasoconstrictor levels. At the same time increased systemic vasodilatation dampened responses to endogenous vasoconstrictors, and the overall effect was markedly increased systemic blood flow. Under physiological conditions vein capacitance does not allow any apparent de-

cline in venous system pressure[22]. However, we assumed that under physiological conditions, increased flow rate (volume overload) due to GTN administration means the portal vein wall is still working in less steep part of the tension-volume curve which further leads to a significant hydrodynamic pressure drop in the control group (15th min). The net effect is lower resistance to pressure changes than we could expect, reflecting the inherently limited distensibility of the portal vein. On the contrary, in some liver diseases increased sinusoidal resistance is responsible for the parallel and leftward shift of the pressure-volume curve. The result of this phenomenon could be a significantly lower hydrodynamic pressure difference in patients *vs* controls and observed significant difference between the groups in 15th min of test with regard to pressure ratio. Indeed, it is obvious that the lower initial velocity in patients led to a significant difference in hydrodynamic pressure during the whole test.

The most interesting observation is lower pressure ratio in controls *vs* patients in the 15th min of the test, which suggested proposed mechanism of geometry and biomechanical changes in portal vein wall. Shear stress is in good linear correlation to the shear rate (equation 1.2) only in Newtonian fluid. The very low shear rate in patients, observed in our study (66.50 ± 24.14 1/s in basal conditions), rules out linear correspondence between these parameters. At low shear rates the apparent viscosity (η) increases markedly. Shear rate measured in the 10th min of the test was significantly lower than the basal value in both groups, while in controls shear rate was significantly higher compared to patients. Below a value of 2001/s the fluid behaviour is non Newtonian[23]. The significance of this observation was stated above in discussion about blood flow discrepancy (double paradoxes). Using the inlet length value, given previously in Table 2, the parabolic velocity profile would not be expected to show complete development, already held flat profile. The reason is a much shorter portal vein (usually 8 cm) compared to inlet length. We used equation 1.8 to approximately assess portal vein pressure difference between the beginning of the test and the 10th min of the test with regard to Bernoulli's rule and Poiseuille's equation. Bernoulli's equation was used, as we mentioned above, due to greater unsheared region in the flat velocity profile and it could at least be useful for explaining pressure change.

Oxidative stress

Increased oxidative stress is a well-known condition in many diseases. Oxidative stress is defined as the tissue damage resulting from an imbalance between an excessive generation of oxidant compounds and insufficient anti-oxidant defence mechanisms[1]. Different cellular enzymes, including xanthine oxidase, cyclooxygenases, lipoxygenase, have been identified as cellular source of ROS.

NO: Nitric oxide, as we expected, did not change significantly in patients in our study. Controls had significantly higher levels of NO at rest, and GTN administration induced its significant increase, observed in the 10th min of the test. NO excessive synthesis might be possible due to mechanisms of flow mediated vasodilatation *via* opening of stretch-activated calcium channels and further intracellular calcium accumulation, which in turn stimulate NO production[24,25]. Increased NO synthesis is also expected in liver cirrhosis environment conditions. However, several mechanisms counteracted the flow-mediated increase in NO synthesis in patients: decreased shear stress induced NO synthesis inhibition; superoxide mediated peroxynitrite formation (superoxide was dramatically higher in patients verus controls). We propose that in portal hypertension, high pressure (P) mediated an exponentially decreased reaction rate constant (K_2) of the ion channel, and altered gating properties of the channel[26]. This mechanism may be explained according to equation 2.0:

$$\frac{k_2}{k_1} = e^{-\frac{P\Delta V}{RT}} \qquad (2.0)$$

K_2 represents the reaction rate constant at pressure P, k_1 is the channel activation constant in basal condition, T is temperature. However, the pressure ratio is similar in both groups, so it is more likely to presume that increased peroxynitrite formation and extensive synthesis of asymmetric dimethyl arginine (ADMA), a potent NOS inhibitor[27], are involved in maintaining the same values of NO in patients. ADMA is downregulated and very much depends on the activity of the enzyme dimethyldiamino-hydrolase (DDHA) which transforms ADMA into citrulline. Increased oxidative stress should be able to reduce the availability of NO, so counteracting excessive NO production in liver cirrhosis. The present data demonstrate that excessive NO synthesis seen in patients with liver cirrhosis might be significantly modified by several described mechanisms.

H_2O_2: Hydrogen peroxide is created in the reaction of superoxide anion and hydrogen cation but this reaction is too slow (K2 < 1.0 $M^{-1}S^{-1}$, $t_{1/2}$ = 1 min) despite the high redox potential (0.89 V). Almost certainly the Fenton and Haber-Weiss reactions are essential for H_2O_2 disassembling. The total redox potential of Haber Weiss and Fenton reaction is 0.78 V, very close to redox potential of synthesis reaction (0.89 V), indicating equilibrium between these opposite reactions (probability that hydrogen peroxide will change it's value in this case is zero, see later) and giving a possible explanation for unexpected lack of changes in hydrogen peroxide values throughout the performed study. Haber-Weiss and Fenton reactions can be deleterious, giving rise to the formation of the highly reactive hydroxyl radical ($OH^{\cdot}$), which induces lipid peroxidation. The concentrations of hydrogen peroxide and superoxide prior to test were in approximately equimolar equilibrium (in controls $O_2^{\cdot-}$: 12.88 nmol/mL and H_2O_2: 9.93 nmol/mL; in patients

O_2^-: 6.57 nmol/mL and H_2O_2: 6.70 nmol/mL). The possibility (P) of some reaction and it's correlation to the redox potentials difference ($\Delta U \approx \varphi_1 - \varphi_2$) is theoretically determined by using equation 2.1:

$$P = e^{-\frac{\Delta U}{RT}} \qquad (2.1)$$

O_2^-: Superoxide basal value was markedly higher in the patients compared to controls, and this observation suggests increased oxidative stress in patients with chronic liver disease. Significantly higher initial nitric oxide levels in controls compared to patients may be due to a "mirror pattern" with superoxide. Taken overall, these findings suggest that superoxide is a good indicator of oxidative stress in patients with chronic liver disease.

Superoxide is produced in accordance to Hund's rule so the probability of it's formation is higher than the probability of reduction with two electrons. The redox potential of superoxide generation is 0.16 V. Superoxide was significantly higher in patients compared to controls during the entire test. There is the possibility, albeit not undisputed, that one major contributing factor is the diameter, as the larger diameter in patients *vs* controls created greater circumferential wall stress according to Laplace's law. Increased oxygen consumption, promoted by increased tension, leads to increased superoxide production. However, there are doubts about whether superoxide levels are in better correlation with shear stress and Voigt's model[28] compared to Laplace's law.

TBARS: Oxidative stress could firstly be evidenced by an increase in TBARS concentration. TBARS continuously increased significantly (compared to basal value) in patients during the test. Basal values did not differ between the groups, but a significant difference was revealed after GTN administration. Indeed, we assumed that increased production of superoxide interferes with increased lipid peroxidation and TBARS concentration.

In conclusion, our study showed that endothelium-independent vasodilatation leads to a significant increase in blood flow and significant decline of mean blood flow velocity and shear rate in participants with chronic liver disease. Increased blood flow was to some extent lower than expected, probably due to increased liver sinusoidal resistance and mentioned double paradoxes. We proved, as a consequence of decreased shear rate far below the critical value, non Newtonian behaviour of portal vein blood flow. Tentative changes in O_2^- and H_2O_2 levels revealed the crucial role of ROS as trigger factors of lipid peroxidation. The preceding findings are in coherence with our assumption of O_2^- and H_2O_2 mediated lipid peroxidation *via* Haber Weiss and Fenton reactions.

Our study could be of great clinical importance, especially regarding the role of oxidative stress in portal vein haemodynamics. This pilot study could be a starting point for further investigation and possible implementation of some antioxidants in the treatment of portal hypertension.

COMMENTS

Background

Oxidative stress is a condition in which the delicate balance that exists between prooxidant (free radicals) production and their subsequent amelioration *via* the antioxidant defense system becomes skewed in favor of free radical expression. The existence of an interference of increased oxidative stress with the vasodilative properties of veins is now a well known fact, resulting in endothelial dysfunction i.e., a loss of nitric oxide (NO) bioactivity in the vessel wall. We hypothesized that the endothelium independent vasodilatation of the portal vein induced by sublingual nitroglycerine administration would lead to increased oxidative stress and significant changes in portal hemodynamics.

Research frontiers

Nitroglycerine is one of the most often used drugs in the treatment of vascular diseases. In some previous studies it was shown that nitroglycerine-induced vasodilation is impaired in some vascular diseases which points to the possible use of that drug in the diagnosis of different vascular diseases.

Innovations and breakthroughs

In previous investigations, application of nitroglycerine in order to test brachial artery reactivity showed that patients suffering from coronary artery disease exhibit loss of endothelium-independent (induced by nitroglycerine) as well as endothelium-dependent vasodilation (induced by short-term artery occlusion) compared to controls. Taking into consideration hyperdynamic portal vein circulation in patients suffering from portal hypertension it seems that some basic vascular mechanisms can correlate with other vascular diseases such as coronary artery disease. In concordance with that, the aim of our study was to determine how sublingual administration of nitroglycerine might be used for the evaluation of portal endothelium-independent vasodilatation through estimating parameters of portal vascular mechanics with special interest in oxidative stress in patients suffering from portal hypertension.

Applications

The study results suggest that nitroglycerine-induced vasodilation could be used as a potential new diagnostic test for evaluation of severity in portal hypertension.

Terminology

Portal hypertension: Increase in blood pressure in the veins of the portal system caused by obstruction in the liver (often associated with alcoholic cirrhosis), causing enlargement of the spleen and collateral veins associated with regional hyperdynamic circulation; Nitroglycerine: Commonly used drug for treatment of vascular diseases, basically coronary artery disease, which acts by inducing endothelium-independent vasodilation; Oxidative stress: A condition in which the delicate balance that exists between prooxidant (free radicals) production and their subsequent amelioration *via* the antioxidant defense system becomes skewed in favor of free radical expression.

Abstract

AIM: To investigate whether α-fetoprotein (AFP) and vascular endothelial growth factor receptor (VEGFR)-1 correlate with early recurrence of hepatoma/hepatocellular carcinoma (HCC).

METHODS: From 2000 to 2005, 114 consecutive patients with HCC underwent primary curative hepatectomy. The mean age was 60.7 (8.7) years and 94 patients were male. The median follow-up period was 71.2 mo (range: 43-100 mo). Immediately prior to commencing laparotomy, 5 mL bone marrow was aspirated from the sternum and collected in citrate-coated test tubes. The initial 2 mL of bone marrow aspirate was discarded in each case. AFP mRNA and VEGFR-1 mRNA in the bone marrow and peripheral blood (BM- and PH-AFP mRNA and BM- and PH-VEGFR-1 mRNA, respectively) were measured by real-time quantitative reverse transcription polymerase chain reaction. As normal controls, VEGFR-1 mRNA in the bone marrow and peripheral blood was also measured in 11 living liver donors. These data were evaluated for any correlation with early recurrence, comparing clinical and pathological outcomes.

RESULTS: The cut-off value of the BM-AFP mRNA and PH-AFP mRNA level in patients with HCC was set at 1.92×10^{-7} and zero, respectively, based on data from the controls. A total of 34 (29.8%) and six (5.4%) patients were positive for BM-AFP mRNA and PH-AFP mRNA, respectively. The BM-VEGFR-1 mRNA levels in all HCC patients were higher than those in the normal controls, and this was the case also for PH-VEGFR-1mRNA. The 25-percentile values for the BM- and PH-VEGFR-1 mRNA in HCC patients were used as the cut-off values for assigning the patients into two groups based on these transcript levels. The High group for BM- VEGFR-1 mRNA contained 81 (71.1%) HCC cases and the Low group was assigned 33 (28.9%) patients. These numbers for PH-VEGFR-1mRNA were 78 (75.0%) and 26 (25.0%), respectively. HCC recurred in 80 patients; in the remnant liver in 48 cases, in the remnant liver and remote tissue in 20, and in the remote tissue alone in 12. BM-AFP mRNA-positive cases showed a significantly higher rate of early recurrence (within 1 year of surgical treatment) compared with BM-AFP mRNA-negative patients (P = 0.0091). Patients were classified into four groups according to the level/status of their BM-VEGFR-1 and BM-AFP mRNA as follows: group A (n = 23), BM-VEGFR-1/BM-AFP mRNA = low/negative; group B (n = 57) high/negative; group C (n = 10) low/positive; group D (n = 24), high/positive. This classification was found to correlate with a recurrence of this

disease within 1 year (P = 0.0228). The disease-free survival curve of group A was significantly better than that of groups B, C or D (P = 0.0437, P = 0.0325, P = 0.0225). No other classification (i.e., PH-VEGF-R1/BM-AFP, BM-VEGF-R1/PH-AFP, and PH-VEGF-R1/PH-AFP mRNA) showed such a correlation.

CONCLUSION: The evaluation of BM-AFP and BM-VEGFR-1 mRNA in patients with HCC may be a valuable predictor of disease recurrence following curative resection.

INTRODUCTION

Various factors are thought to contribute to hepatocellular carcinoma (HCC) recurrence, which commonly results in death, including multicentric carcinogenesis in the remnant liver due to an underlying hepatitis-B-virus- or hepatitis-C-virus-induced liver cirrhosis[1], hematogenic spread, or micrometastasis of HCC cells prior to surgery or during hepatectomy by manipulation of the liver[2]. Recently, using various molecular biological markers, the detection of malignant cells in the systemic circulation and bone marrow has become possible and the presence of these cells has been found to correlate with the clinical outcome[3-8]. We have also reported from our laboratory that the detection of HCC cells in the bone marrow by real-time reverse-transcriptase polymerase chain reaction (RT-PCR) analysis of α-fetoprotein (AFP) mRNA before curative hepatectomy correlates with HCC recurrence and patient survival outcomes. Although early recurrence within 1 year of curative resection for HCC is one of the most important factors affecting the prognosis and clinical outcomes[9,10], the relationship between early recurrence and disseminated cancer cells has not yet been evaluated.

It has been recently hypothesized that metastasis is dependent on both isolated cancer cells and the host response. Kaplan *et al*[11] have reported that bone-marrow-derived hematopoietic progenitor cells that express vascular endothelial growth factor receptor (VEGFR)-1 migrate to tumor-specific pre-metastatic sites and form cellular clusters before the arrival of tumor cells both *in vitro* and *in vivo*. Moreover, it has been reported that the simultaneous presence of isolated tumor cells and VEGFR-1 expression at pre-metastatic sites is clinically significant for disease progression in gastric cancer[12]. With regard to HCC however, there has been no study to date of the association between isolated cancer cells and the expression of VEGFR-1.

In our present study, we examined whether the expression of AFP mRNA and VEGFR-1 in the bone marrow and peripheral blood, detected by sensitive real-time quantitative RT-PCR, could predict early recurrence in consecutive HCC patients who had undergone a curative hepatic resection.

MATERIALS AND METHODS

Ethics

This study was approved by the Institutional Review Board of the Hokkaido University, School of Advanced Medicine. Informed consent was obtained from each patient in accordance with the Ethics Committee Guidelines at our institution.

From July 2000 to June 2005, 114 consecutive patients underwent primary curative hepatectomy at the First Department of Surgery, Hokkaido University Hospital. The mean age was 60.7 (8.7) years and 94 patients were male. The Child-Pugh staging was A in 110 patients and B in four. Patients were discharged from the hospital at an average of 17.5 (7.1) d after surgery. They were followed up at 3-mo intervals by computed tomography (CT), magnetic resonance imaging (MRI), ultrasonography (US) and laboratory tests for AFP, lens culinaris agglutinin-reactive fraction of AFP (AFP-L3), and protein induced by vitamin K absence or antagonist-Ⅱ (PIVKA-Ⅱ). The median follow-up period was 71.2 mo (range: 43 mo-100 mo).

As normal controls, VEGFR-1 mRNA in the bone marrow and peripheral blood was also measured in 11 living liver donors. The cut-off value for AFP mRNA/glyceraldehyde-3-phosphate dehydrogenase (GAPDH) in the bone marrow and peripheral blood was set as described in our previous study[13].

Sample collections

Immediately prior to commencing the laparotomy, 5 mL bone marrow was aspirated from the sternum and collected in citrate-coated test tubes. The initial 2 mL of the bone marrow aspirate was discarded in each case.

RNA isolation and reverse transcription

Bone marrow samples were prepared for the measurement of total RNA using a Blood RNA extraction kit (QIAGEN, Hilden, Germany) according to the manufacturer's protocol with minor modifications. Briefly, 5 mL bone marrow cells were mixed with 25 mL Reagent buffer erythrocyte lysis (EL). They were then cooled on

ice for 15 min, centrifuged, and the cell pellets were collected. The pellets were suspended in 1.35 mL buffer and applied to the reagent columns, and then washed twice with reagent buffer containing ethanol. Total RNA was eluted with RNase-free water. These bone marrow RNA samples were stored at -80 ℃ until use. cDNA was generated from 1 μg total RNA using Moloney murine leukemia virus reverse transcriptase (SuperScript Ⅱ, Life Technologies, Carlsbad, CA, United States), plus 20 pmol/L each dNTP and 10 pmol/L oligo dT primers in a 20-μL final reaction volume at 42 ℃ for 1 h. This was followed by heating at 99 ℃ for 5 min.

Real-time quantitative RT-PCR

A LightCycler PCR and detection system (Roche Diagnostics, Mannheim, Germany) was used for amplification. Online quantification real-time RT-PCR was then performed in glass capillaries according to the manufacturer's protocol. The cDNA was amplified in a 20-μL PCR reaction mixture containing each dNTP (with dUTP instead of dTTP), 1 × PCR buffer, specific primers, and magnesium chloride.

For the detection of AFP, two adjacent oligonucleotide probes were used: the LightCycler Red 640 fluorophore, hAFP-LCR; (5'-CTTGCACACAAAAGCCCACTCCA-3') and a fluorophore labeled at the 3'-end with fluorescein, hAFP-FITC; (5'-TCGATCCCACTTTTCCAAGTT-3') (Nihon Gene Research Laboratories, Sendai, Japan). The sense and antisense primers (kindly supplied by Dr. Hiroaki Nagano at Osaka University) used for the amplification of AFP were as follows: 5'-TGCAGCCAAAGTGAAGAGGGAAGA-3') (hAFP-s) and 5'-CATAGCGAGCAGCCCAAAGAAGAA-3' (hAFP-As). The RT-PCR amplification was carried out for one cycle of 95 ℃ for 10 min, followed by 35 cycles of 95 ℃ for 10 s, 62 ℃ for 15 s, and 72 ℃ for 15 s. The final cycle was followed by a 10-min extension step at 40 ℃.

For the detection of VEGFR-1, two adjacent oligonucleotide probes were used: hVEGFR-1-LCR; 5'-TTCCGTGTCCCCACTGCCAA-3' and hVEGFR-1-FITC; 5'-GGGAAGCTCACTGGCATGGC-3'. The sense and antisense primers for the amplification of VEGFR-1 were as follows: 5'-TCATGAATGTTTCCCTGCAA-3' (h VEGFR-1-S) and 5'-GGAGGTATGGTGCTTCCTGA-3' (h VEGFR-1-As). These primers were designed using sequences described in a previous report[14]. RT-PCR amplification was carried out for one cycle of 95 ℃ for 10 min, followed by 35 cycles of 95 ℃ for 10 s, 60 ℃ for 10 s, and 72 ℃ for 16 s. The final cycle was followed by a 10-min extension step at 40 ℃.

For the detection of GAPDH as an internal control, two adjacent oligonucleotide probes were used: hGAPDH-LCR; 5'-TTCCGTGTCCCCACTGCCAA-3' and hGAPDH-FITC; 5'-GGGAAGCTCACTGGCATGGC-3'. The sense and antisense primers for the amplification of GAPDH were as follows: 5'-GCCTCCTGCACCACCAACTG-3' (hGAPDH-S) and 5'-CGACGCCTGCTTCACCACCTTCT-3' (hGAPDH-As). The RT-PCR amplification was carried out for one cycle of 95 ℃ for 10 min, followed by 35 cycles of 95 ℃ for 10 s, 60 ℃ for 10 s and 72 ℃ for 16 s. The final cycle was followed by a 10-min extension step at 40 ℃.

Quantification analysis

Quantification data were analyzed using the LightCycler analysis software (Roche Diagnostics, Mannheim, Germany) in accordance with the manufacturer's instructions. In this analysis, the background fluorescence was removed by setting a noise band. The crossing point for the calculation of amplified PCR products was set by the intersection of the best-fit line through the log-linear lesion and the noise band. The standard curve was a plot of the "crossing point" versus the copy number of DNA fragments inserted into the cloning vector.

Statistical analysis

Cumulative survival and disease-free survival (DFS) rates were computed according to the Kaplan-Meier method and compared between groups using the Breslow-Gehan-Wilcoxon test. The Cox proportional hazards model was used for multivariate analysis. Statistical analyses using standard tests (χ^2, *t* test) were performed where appropriate. Significance was defined as $P < 0.05$. Statistical analyses were performed using StatView 5.0 Windows (SAS Institute Inc., Cary, NY, United States).

RESULTS

Analysis of AFP mRNA levels in bone marrow

The mean AFP mRNA/GAPDH ratio in the bone marrow (BM-AFP mRNA) of HCC patients, as determined by real-time quantitative RT-PCR, was 3469.27 × 10^{-7} (range: 0-348 526.19 × 10^{-7}). The cut-off value of the BM-AFP mRNA level was set at 1.92 × 10^{-7} (with reference to a previous report)[13]. The HCC patients were then divided into two groups according to this cut-off value. Accordingly, 80 patients (70.2%) were found to be negative for BM-AFP mRNA and 34 patients (29.8%), assigned to the "High" group, were positive for this transcript.

Expression of AFP mRNA in peripheral blood

No AFP mRNA was detectable in the peripheral blood of the control patients, therefore, the cut-off value for AFP mRNA/GAPDH in the peripheral blood (PH-AFP mRNA) was set at zero. Accordingly, six patients (5.4%) were found to be positive and 105 (94.6%) were negative for AFP mRNA. Due to some sampling loss, peripheral blood samples were unavailable for three patients.

Expression of VEGFR-1 mRNA in bone marrow

The mean VEGFR-1 mRNA/GAPDH in the bone marrow (BM-VEGFR-1 mRNA) of normal controls, again determined by real-time quantitative RT-PCR measurements, was 0.1497 × 10^{-3} (range: 0.0212 × 10^{-3} to 0.3213 × 10^{-3}). The mean BM-VEGFR-1 mRNA level in the HCC patients was 3.8474 × 10^{-3} (range: 0.3481 × 10^{-3} to

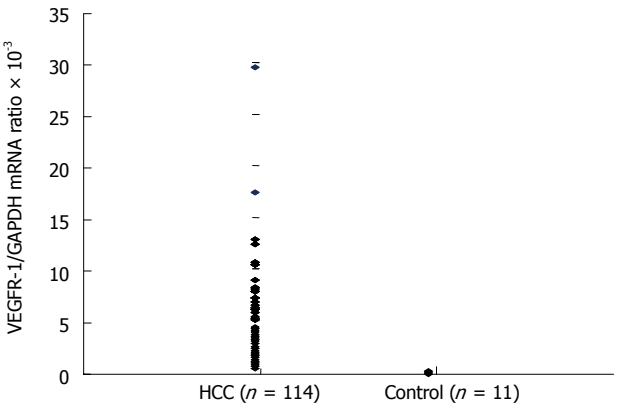

Figure 1 Expression of vascular endothelial growth factor receptor-1 mRNA in bone marrow detected by real-time quantitative reverse transcription polymerase chain reaction. The mean VEGFR-1/GAPDH mRNA ratio in the bone marrow (BM-VEGFR-1 mRNA) of normal controls was 0.1497 × 10^{-3} (range: 0.0212 × 10^{-3}-0.3213 × 10^{-3}). The mean BM-VEGFR-1 mRNA level in HCC patients was measured at 3.8474 × 10^{-3} (range: 0.3481 × 10^{-3}-29.5885 × 10^{-3}). HCC: Hepatocellular carcinoma; VEGFR: Vascular endothelial growth factor receptor; BM: Bone marrow; GAPDH: Glyceraldehyde-3-phosphate dehydrogenase.

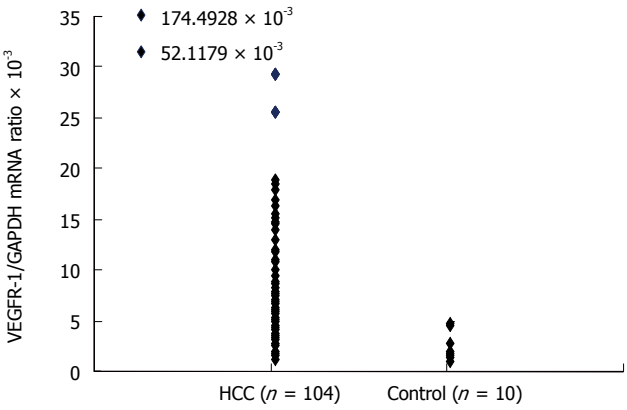

Figure 2 Expression of vascular endothelial growth factor receptor-1 mRNA in peripheral blood detected by real-time quantitative real-time quantitative reverse transcription polymerase chain reaction. The mean VEGFR-1/GAPDH mRNA ratio in the peripheral blood (PH-VEGFR-1 mRNA) of normal controls was 2.4944 × 10^{-3} (range: 1.0730 × 10^{-3}-4.6958 × 10^{-3}). The mean PH-VEGFR-1 mRNA level in HCC patients was 9.1285 × 10^{-3} (range: 1.2774 × 10^{-3}-174.4928 × 10^{-3}). HCC: Hepatocellular carcinoma; VEGFR: Vascular endothelial growth factor receptor; PH: Peripheral blood; GAPDH: Glyceraldehyde-3-phosphate dehydrogenase.

29.5885 × 10^{-3}). The mean BM-VEGFR-1 mRNA level of all HCC patients was higher than that of the normal controls (Figure 1). The HCC patients were then divided into two groups ("High" and "Low") according to their BM-VEGFR-1 mRNA level; the cut-off value was 1.5664 × 10^{-3}, which was the 25th percentile value of the BM-VEGFR-1 mRNA levels in the HCC cohort. The number of patients in the High group was 81 (71.1%) and 33 (28.9%) were assigned to the Low group.

Expression of VEGFR-1 mRNA in peripheral blood

The mean VEGFR-1 mRNA/GAPDH ratio in the peripheral blood (PH-VEGFR-1 mRNA) of the normal controls was 2.4944 × 10^{-3} (range: 1.0730 × 10^{-3} to 4.6958 × 10^{-3}). The mean PH-VEGFR-1 mRNA level in the HCC patients was 9.1285 × 10^{-3} (range: 1.2774 × 10^{-3} to 174.4928 × 10^{-3}). The PH-VEGFR-1 mRNA level of almost all HCC patients was higher than that of the normal controls (Figure 2). The HCC patients were divided into high and low groups according to their PH-VEGFR-1 mRNA level. The cut-off value was 4.0238 × 10^{-3}, which was in the 25th percentile of the PH-VEGFR-1 mRNA level of HCC patients. The number of patients in the high group was 78 (75.0%) with 26 (25.0%) placed in the Low group. Peripheral blood samples were available for 104 patients only.

Clinical significance of the BM- and PH-VEGFR-1, and BM- and PH-AFP mRNA levels

The status of the BM-AFP mRNA levels was correlated with microscopically detectable portal invasion, whereas that of PH-AFP mRNA was found to correlate with the serum AFP and AFP-L3 levels, the number of tumors, microscopic portal invasion, and microscopic intrahepatic metastasis (Table 1). The number of tumors, serum albumin level, and a noncancerous liver were significantly correlated with the BM-VEGFR-1 mRNA level (Table 2).

Patient outcomes

Mortality: By the end of our study, 42 of the HCC patients under analysis had died; 35 from HCC, three from liver failure and four from another malignant disease. The 1-, 2- and 3-year patient survival rates for this cohort were determined to be 92.1%, 85.9% and 78.7%, respectively.

HCC recurrence: HCC recurred in 80 patients (70.2%); in the remnant liver in 48 cases (60%), in the remnant liver and remote tissue in 20 (25%), and in the remote tissue alone in 12 (15%). The 1-, 2- and 3-year DFS rates were 67.5%, 49.8% and 34.4%, respectively. We found a significant tendency for patients who were positive for BM-AFP mRNA to experience recurrence within 1 year of their surgery compared with patients who were negative for this transcript (Table 3).

HCC classification according to VEGFR-1 and AFP mRNA status

Patients were classified into four groups according to the level/status of their BM-VEGFR-1 and BM-AFP mRNA as follows: group A (n = 23), BM-VEGFR-1/BM-AFP mRNA = low/negative; group B (n = 57) high/negative; group C (n = 10) low/positive; group D (n = 24), high/positive. This classification was correlated with disease recurrence within or more than 1 year after surgery. Significantly, in the groups in which patients were negative for BM-AFP mRNA, only three patients (13.0%) experienced recurrence in group A, whereas 17 (29.0%) in group B experienced recurrence within 1 year of surgery (Table 3). Classification of the HCC cases in the current study cohort by their PH-VEGFR-1 and BM-AFP (P = 0.1024), BM-VEGFR-1 and PH-AFP (P = 0.2100), and

BM: Bone marrow; PH: Peripheral blood; AFP: α-fetoprotein; HBsAg: Hepatitis B surface antigen; HCV: Anti-hepatitis C virus antibody; AR: Patients who underwent anatomical resection; ICGR15: Indocyanine green retention rate at 15 min; vp: Microscopic tumor thrombus in the portal vein; vv: Microscopic tumor thrombus in the hepatic vein; im: Microscopic intrahepatic metastasis.

PH-VEGFR-1 and PH-AFP ($P = 0.2138$) mRNA status showed no such correlation. The DFS curve of group A was significantly better than that of group B, C or D ($P = 0.0437$, $P = 0.0325$, $P = 0.0225$, respectively; Figure 3).

Univariate analysis further revealed that age, hepatitis B surface antigen (HBsAg), albumin, AFP, AFPL3, PIVKA-Ⅱ, the number of tumors, tumor size, portal vein invasion, hepatic vein invasion, intrahepatic metastasis, BM-AFP mRNA and classification by BM-VEGFR-1/BM-AFP mRNA are important risk factors for HCC early recurrence (Table 3). Multivariate analysis revealed that albumin ≤ 4.0 mg/dL and positive portal vein invasion were independent risk factors for recurrence within 1 year of surgery. Although BM-AFP mRNA positivity was not a significant factor by multivariate analysis, it was still found to be an important factor in predicting an early recurrence in HCC cases ($P = 0.0761$, Table 4).

DISCUSSION

In our current study, we found a significant tendency for HCC patients who were positive for BM-AFP mRNA to experience disease recurrence within 1 year of surgery. Patients with low BM-VEGFR-1 mRNA and who were negative for BM-AFP mRNA experienced early recurrence in 3/23 cases, whereas in 57 cases with high BM-VEGFR-1 and BM-AFP mRNA, 17 recurrences were observed. Hence, BM-AFP mRNA positivity is an important predictor of early HCC recurrence after curative hepatectomy due to hematogenic spread. BM-VEGFR-1 mRNA was also found to be associated with early HCC recurrence.

The time between hepatectomy and recurrence of metachronous *de novo* tumors is longer than that of intrahepatic metastases[15], therefore, early recurrence of these

lesions (within 1 year) is thought to be dependent on hematogenic spread. By real-time quantitative RT-PCR, we found in our current analyses that, although the AFP/GAPDH mRNA ratios in the liver tissues were generally constant among normal control subjects, they were markedly different among HCC patients. This indicated highly variable AFP synthesis activity among individual HCC cells. It has been shown that high AFP mRNA levels reflect the presence of HCC cells[13]. In our present study, the 1-year survival and DFS rates of HCC patients who were positive for AFP mRNA were 86.5% and 54.5%, respectively. Hence, we analyzed the relationship between early recurrence and the preoperative status of the BM- and PH-AFP, and the BM- and PH-VEGFR-1 mRNA.

Although we found in our present experiments that the BM-AFP mRNA status significantly correlates with early HCC recurrence, the BM-VEGFR-1, PH-VEGFR-1 and PH-AFP mRNA levels did not correlate with this outcome. However, classifying the HCC cases in our cohort using the BM-VEGFR-1/BM-AFP mRNA levels showed a correlation with early recurrence (P = 0.0228). Based on these findings, we speculate that the preoperative presence of cancer cells in the bone marrow is an important and essential driver of early HCC recurrence due to hematogenic spread, although we did not detect any changes in the AFP or VEGFR1 mRNA levels in the bone marrow and peripheral blood after surgical intervention in recurrent cases. The importance of the coexistence of disseminated cancer cells and VEGFR-1-positive hematopoietic bone marrow progenitor cells was further supported by the improved DFS curve of HCC patients that were negative for BM-AFP mRNA, and that showed low BM-VEGFR-1 transcript levels as compared with the other three patient groups. On the other hand, we surmised that the relationship between BM-VEGFR-1 mRNA and hematogenic spread in HCC

BM: Bone marrow; PH: Peripheral blood; AFP: α-fetoprotein; HBsAg: Hepatitis B surface antigen; VEGFR: Vascular endothelial growth factor receptor; HCV: Anti-hepatitis C virus antibody; ICGR15: Indocyanine green retention rate at 15 min; vp: Microscopic tumor thrombus in the portal vein; vv: Microscopic tumor thrombus in the hepatic vein; im: Microscopic intrahepatic metastasis.

during hematogenic recurrence was not stronger than that in gastric cancer, because it has been reported in a clinically relevant and widely used preclinical study model that blockade of VEGFR-1 activity does not affect the formation of spontaneous metastases[16].

In our present study, the BM-VEGFR-1 mRNA level

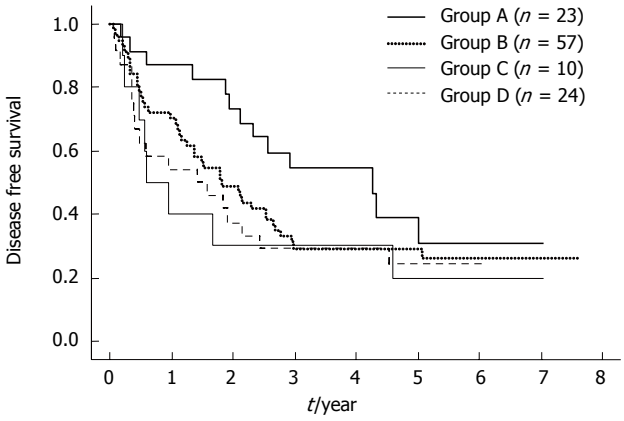

Figure 3 Patients were classified into four groups according to the level/status of their bone marrow-vascular endothelial growth factor receptor-1 and bone marrow-α-fetoprotein mRNA as follows: group A (*n* = 23), bone marrow-vascular endothelial growth factor receptor-1/bone marrow-α-fetoprotein mRNA = low/negative; group B (*n* = 57) high/negative; group C (*n* = 10) low/positive; group D (*n* = 24), high/positive. The disease-free survival (DFS) curve of group A was significantly better than that of groups B, C or D (*P* = 0.0437, *P* = 0.0325, *P* = 0.0225).

of all HCC patients was higher than that in the normal controls, and the PH-VEGFR-1 mRNA levels of almost all of these patients were also higher than in the normal controls. Direct evidence for the role of the chemokine stromal-cell derived factor-1 [SDF-1, also known as chemokine CXC ligand (CXCL)12] in regulating the mobilization of proangiogenic bone marrow cells *in vivo* has been demonstrated by plasma elevation of SDF-1, which stimulates the mobilization of chemokine CXC receptor (CXCR) 4^+ bone marrow cells, including hematopoietic stem cells and endothelial progenitor cells[17,18]. SDF-1 not only promotes revascularization by engaging with CXCR4 expressed on vascular cells but also supports the mobilization of proangiogenic $CXCR4^+$ $VEGFR1^+$ hematopoietic cells[19]. In contrast, Li *et al*[20] have reported a much higher expression level of the CXCL12-CXCR4 axis in HCC specimens than in adjacent, cirrhotic, adenocarcinoma or normal liver tissues. Hence, we speculate that VEGFR-1-positive hematopoietic bone marrow progenitor cells might be regulated and recruited by a mechanism similar to the SDF-1-CXCR4 pathway in most HCC patients. On the basis of our current data and the results of these earlier reports, we further predict that, in almost all patients with HCC, a pre-metastatic niche might have already been initiated by VEGFR-1-positive hematopoietic bone marrow progenitor cells. The levels of BM- and PH-VEGFR-1 mRNA were not found to correlate with early recurrence in each of the HCC patients, although BM-AFP mRNA positivity was significantly associated with early recurrence. These findings thus indicate that the initiation of a pre-metastatic niche be recognized as a first but essential step in the development of metastasis that requires the presence of disseminated cancer cells. This hypothesis is supported by our finding that patients negative for BM-AFP mRNA and with low levels of BM-VEGFR-1 mRNA show the lowest rate of recurrence among all of the groups analyzed.

Table 4 Multivariate analyses of variables that are predictive of early hepatocellular carcinoma recurrence after curative hepatectomy

	P value	Risk ratio	95% CI
Age ≤ 60 yr	0.0899	3.147	0.836-11.838

It has been shown in several previous studies that the detection of micrometastases from solid tumors in bone marrow samples can be an important prognostic indicator with high specificity[3-7,11]. The release of carcinoma cells from the bone marrow into the peripheral blood can be induced by cytokine treatment[21]. Hence, the bone marrow might function as an important reservoir and a source of disseminated cancer cells that can subsequently spread into other organs. Moreover, the bone marrow itself may become altered in response to chemokines produced by the primary tumor and thereby enhance the metastatic capabilities of tumor cells that reside within it[22]. It has been reported that VEGFR-1-positive cells promote tumor adherence and growth[11]. VEGFR signaling is a crucial inducer of angiogenesis, enables primary tumor growth, and probably releases micrometastases from dormancy[23]. In our current study, only the classification by BM-VEGFR-1 and BM-AFP mRNA was correlated with early recurrence. Hence, the coexistence of bone-marrow-derived hematopoietic progenitor cells that express VEGFR-1 in the bone marrow, and not in the peripheral blood, might be advantageous for various cancer cells in the bone marrow in terms of metastasis.

In conclusion, the evaluation of BM-AFP mRNA and BM-VEGFR-1 mRNA in patients with HCC shows great promise as a predictor of recurrence in curatively resected HCC.

COMMENTS

Background

α-fetoprotein (AFP) mRNA, which represents disseminate cancer cells, is related to recurrence of hepatocellular carcinoma (HCC). Bone-marrow-derived hematopoietic progenitor cells that express vascular endothelial growth factor receptor (VEGFR)-1 home to tumor-specific pre-metastatic sites and form cellular clusters before the arrival of tumor cells.

Research frontiers

It has been reported that simultaneous presence of isolated tumor cells and VEGFR-1 expression at pre-metastatic sites is clinically significant for disease progression in gastric cancer. With regard to HCC, there has been no study about the association between the presence of isolated cancer cells and the expression of VEGFR-1. In the present study, we tried to determine whether expression of AFP mRNA and VEGFR-1 in bone marrow and peripheral blood detected by real-time quantitative reverse transcriptase polymerase chain reaction (RT-PCR) could predict early recurrence in consecutive patients after curative hepatic resection.

Innovations and breakthroughs

There was a significant tendency for patients who were positive for AFP mRNA in bone marrow to experience recurrence within 1 year after surgery compared to those negative for AFP mRNA in bone marrow. The VEGFR-1 mRNA level in bone marrow in all HCC patients was higher than that of normal controls. It was supposed that this initiation of pre-metastatic niche represented by the high level of VEGFR-1mRNA might be recognized as only the first step and as a necessary condition for development of metastasis, and required the subsequent presence of disseminated cancer cells represented by AFP mRNA.

Applications

The evaluation of AFP mRNA and VEGFR-1 mRNA in bone marrow in patients with HCC could be very important for the prediction of recurrence of curatively resected HCC.

Peer review

This study found that the expression of AFP and VEGFR-1 mRNA in bone marrow detected by real-time quantitative RT-PCR predicted early recurrence in consecutive patients after curative hepatic resection. This finding is very important to elucidate the mechanism of metastasis and recurrence by hematogenic spread of HCC cells.

Abstract

AIM: To investigate the inhibitory effect of hepatitis B virus (HBV) preS2 antibody (preS2Ab) against HBV infection and HBV-associated hepatic carcinogenesis.

METHODS: An adenoviral vector carrying the full-length light and heavy chains of the HBV preS2Ab gene, Ad315-preS2Ab, was constructed. Enzyme linked immunosorbent assay (ELISA) and Western blotting analyses were used to determine the preS2Ab expression levels *in vitro*. Immunofluorescent techniques were used to examine the binding affinity between the expressed HBV preS2Ab and HBV-positive liver cells. ELISAs were also used to determine hepatitis B surface antigen (HBsAg) levels to assess the inhibitory effect of the preS2Ab against HBV infection in L02 cells. The inhibitory effect of preS2Ab against hepatic carcinogenesis was studied with diethylnitrosamine (DEN)-induced hepatocellular carcinomas (HCCs) in HBV transgenic mice.

RESULTS: The expression of HBV preS2Ab increased with increases in the multiplicity of infection (MOI) of Ad315-preS2Ab in L02 cells, with 350.87 ± 17.37 μg/L of preS2Ab when the MOI was 100 plaque forming units (pfu)/cell. The expressed preS2Abs could recognize liver cells from HBV transgenic mice. ELISA results showed that L02 cells expressing preS2Ab produced less HBsAg after treatment with the serum of HBV patients than parental L02 cells expressing no preS2Ab. HBV transgenic mice treated with Ad315-preS2Ab had fewer and smaller cancerous nodes after induction with DEN than mice treated with a blank Ad315 vector or untreated mice. Additionally, the administration of Ad315-preS2Ab could alleviate hepatic cirrhosis and decrease the serum levels of alanine transaminase and aspartate transaminase.

CONCLUSION: Adenovirus-mediated HBV preS2Ab expression could inhibit HBV infection in L02 cells, and then inhibit DEN-induced hepatocellular carcinogenesis and protect hepatic function in HBV transgenic mice.

INTRODUCTION

Hepatitis B virus (HBV)-associated hepatocellular carcinoma (HCC) poses a severe threat to human health, and HBV is an important cause of the high HCC incidence in China. The available treatments for recurrent HBV infections in patients include immunization and antiviral therapies. For these therapies, hepatitis B immunoglobulin is administered, which has been proven effective for preventing maternal-infant vertical transmission and HBV recurrence after liver transplantation. However, the immunoglobulin is limited and expensive. Additionally, it has an unsatisfactory neutralization effect and may carry pathogens. Immunoprophylaxis of HBV infection with genetically engineered monoclonal antibodies that are specific to HBV envelope antigens is a promising approach in the clinic. HBV encodes an outer membrane protein, preS2, which binds to polyalbumin and helps the HBV gain entry into liver cells *via* albumin receptors. Blocking preS2 with its antibody may prevent or minimize HBV infection. However, full-length antibodies with large molecular weights have low permeability, and small-molecule antibodies, including Fab, scFv, and dsFv, have relatively low affinity and specificity for antigens.

To overcome these limitations, we have constructed an adenoviral vector carrying the full-length light and heavy chains of the human HBV preS2 antibody (*preS2Ab*) gene and tested its efficacy in the prevention and treatment of HBV-associated HCC. *preS2Ab* gene therapy has the advantages of lower production costs and longer expression durations. The adenoviral vector system can express the humanized HBV preS2Ab with high and stable efficiency, so this system may provide a novel approach for HBV gene therapy and may decrease the incidence of HCC.

MATERIALS AND METHODS

Materials

Nucleic acid synthesis in this study was performed by Shanghai Shenergy Biocolor Bioscience and Technology Company (Shanghai, China). HEK293 and L02 cell lines were purchased from ATCC (Manassas, United States). HBV transgenic Imprinting Control Region (ICR) mice were provided by the Shanghai SLAC Laboratory Animal Center, Chinese Academy of Sciences, (Shanghai, China). Antibodies were purchased from Santa Cruz Biotechnology (Santa Cruz, CA, United States). Plasmids were purchased from Microbix Biosystems (Ontario, Canada). The Lipofectamine 2000 reagent is a product of Invitrogen (United States). Restriction endonucleases were from New England Biolabs (Ozyme, France). The enzyme linked immunosorbent assay (ELISA) kit was from R and D Systems (Minneapolis, MN, United States), and diethylnitrosamine (DEN) was from Sigma Chemical Co. (St. Louis, MO, United States).

Construction of adenoviral vector carrying the hepatitis B virus preS2Ab gene

The variable and constant regions of the humanized light and heavy chains of the HBV *preS2Ab* gene were synthesized. A *Bam*HI site was introduced upstream of the heavy chain, and an *Xba*I site was introduced downstream. An *EcoRI* site was introduced upstream of the light chain, and a *SalI* site was introduced downstream. Other restriction sites in the encoding sequence were abolished by same-sense mutations. Next, the light and heavy chains of the *preS2Ab* gene were cloned into the corresponding restriction enzyme sites of pDC315 adenoviral shuttle plasmid. The light and heavy chains were bridged by an internal ribosome entry site (IRES) to yield pDC315-preS2Ab. The pDC315-preS2Ab plasmid was co-transfected with pBHGE3 into HEK293 cells using the Lipofectamine 2000 reagent. Twelve days after transfection, a recombinant adenoviral vector carrying the humanized HBV *preS2Ab* gene, *Ad315-preS2Ab*, was obtained. *Ad315-preS2Ab* was then amplified in HEK293 cells and purified by cesium chloride gradient centrifugation. The recombinant virus titer was determined by TCID50 analysis.

In vitro expression and identification of Ad315-preS2Ab

L02 cells were cultured in 6-well plates for 24 h and then subjected to serum-deprived medium. Ad315-preS2Ab was added for infection according to the multiplicity of infection (MOI) gradient. After 2 h, the cells were cultured with serum-containing medium for 72 h, and the supernatants and cells were collected. ELISA was used to determine the antibody levels in the supernatants; optical density (OD) values (*A* value) were read at 450 nm, and a standard concentration curve was plotted to calculate the antibody levels in the supernatants. The antibody content in the cell lysate solution was determined by Western blotting analysis.

Liver samples from an HBV transgenic ICR mouse and a normal ICR mouse were obtained and made into single-cell suspensions. Cell smears were prepared for immunofluorescent examination using the supernatant of L02 cells infected with Ad315-preS2Ab [MOI = 100 plaque forming units (pfu)/cell] as the primary antibody and FITC-labeled goat anti-human IgG as the secondary antibody. Immunofluorescent labeling was observed under a fluorescence microscope, and photos were taken to assess the binding affinity of the expressed antibody.

Inhibitory effects of Ad315-preS2Ab against hepatitis B virus infection

L02 cells were cultured in 6-well plates for 24 h and then subjected to serum-deprived medium. Ad315-preS2Ab was added for infection at an MOI of 50 pfu/cell, and after 2 h, the cells were cultured with serum-containing medium for 72 h. Sera from HBV patients with HBsAg (+), HBeAg (+) and anti-HBc (+) were collected and

added to L02 cells infected with either Ad315-preS2Ab or the Ad315 blank vector for 7 d. ELISAs were used to determine the HBsAg levels in the supernatants.

Preventive effect of Ad315-preS2Ab against hepatic carcinogenesis

A total of 24 HBV transgenic ICR mice, aged 4 to 6 wk, were evenly divided into 4 groups. Animals in the Ad315-preS2Ab group and Ad315 blank vector group were given the corresponding adenovirus particles *via* tail vein injections; each mouse was injected with 2×10^8 pfu adenoviruses every other day for a total of 5 injections. The total amount for each animal was 1×10^9 pfu. Mice in the non-virus control group and the blank control group were given the same volume of normal saline. DEN was intraperitoneally injected (1 mg/kg, once a week for 4 wk) into animals in the Ad315-preS2Ab, Ad315 vector and non-virus groups one week after the initial injection of adenovirus or normal saline. Mice in the blank control group were not treated with DEN. The animals were sacrificed after 8 mo, and the liver tissues were sectioned at 0.5 cm intervals to observe the diameters of the cancerous nodes. Serial pathological sections were also subjected to hematoxylin/eosin (HE) staining, and all cancerous nodes under a microscope within 5 medium power fields were counted and represented as the mean ± SD.

Protective effects of Ad315-preS2Ab on hepatic function

Sera samples were collected when animals were sacrificed. Hepatic enzyme levels in the sera, including alanine transaminase (ALT) and aspartate transaminase (AST), were measured using an automated biochemical analyzer (SIEMENS ADVIA 2400, Siemens Healthcare Diagnostics, IL, United States).

Statistical analysis

All data are presented as the mean ± SD. Statistical significance was calculated using unpaired Student's *t*-tests. A $P < 0.05$ was considered significant. All analyses were performed using SPSS version 13.0 (SPSS Inc., United States).

RESULTS

Efficient expression of the preS2Ab mediated by Ad315-preS2Ab

TCID50 analysis showed that the titer of Ad315-preS2Ab was 2.1×10^{10} pfu/mL after amplification in HEK293 cells. L02 cells were infected with Ad315-preS2Ab with MOI = 1, 5, 10, 50, and 100 pfu/cell. Seventy-two hours after infection, ELISA and Western blotting results showed that the expression of preS2Ab in cell supernatants or lysates increased with increases in MOI (Figures 1A and B), with a final antibody concentration of 350.87 ± 17.37 ng/mL at an MOI of 100 pfu/cell. The preS2Ab from the supernatant of L02 cells infected with Ad315-preS2Ab (MOI = 100 pfu/cell) recognized liver cells from HBV transgenic ICR mice, as shown by strong immunofluorescent reactions. Liver cells from normal ICR mice demonstrated a lack of immunofluorescent labeling (Figure 1C).

Ad315-preS2Ab-mediated expression of preS2Ab inhibited hepatitis B virus infection

ELISA results showed that, compared with the Ad315 blank vector, Ad315-preS2Ab-mediated preS2Ab expression effectively decreased HBsAg levels in the supernatants of L02 cells treated with the serum of HBV patients. This finding indicated that the preS2Ab could inhibit HBV infection and replication (Figure 2).

Ad315-preS2Ab effectively inhibited diethylnitrosamine -induced hepatic carcinogenesis in HBV transgenic mice

The Ad315 blank vector group and the non-virus group each had one mouse death during the experiment, so the data from 5 mice in each group were analyzed. In the blank control group, there were no cancerous nodes. Slight fibroblastic proliferation and inflammatory cell infiltration were noticed; however, severe hepatic cirrhosis with fibrous septa and pseudolobule formation and cancerous nodes of different numbers and various sizes were found in the non-virus control group after DEN induction. In contrast, only slight-to-moderate hepatic cirrhosis was found in the Ad315-preS2Ab group, and the cancerous nodes were both fewer in number and smaller than those in the non-virus control group (Figure 3).

Ad315-preS2Ab effectively protected hepatic function in hepatitis B virus transgenic mice

To investigate whether the adenovirus Ad315-preS2Ab could protect hepatic function in HBV transgenic mice, the ALT and AST levels in sera were measured to assess hepatic function. Quantitative results for the liver enzyme assays showed that the DEN-treated HBV transgenic mice had higher levels of ALT and AST in sera than the ICR mice that were not treated with DEN. The Ad315 blank vector did not decrease enzyme levels, but 1×10^9 pfu of Ad315-preS2Ab resulted in an obvious decrease of ALT ($P = 0.0141$) and AST ($P = 0.0243$) compared with the DEN-treated control group (Table 1).

DISCUSSION

Globally, there are approximately 300 million HBV carriers. Therefore, it is of great importance to prevent and treat both HBV infection and the subsequent hepatic carcinogenesis. HBV infection is closely associated with the viral proteins. The HBV envelope proteins consist mainly of preS1, preS2 and HBsAg antigens, which can induce production of the corresponding antibodies[1-3]. The HBV preS2 protein is found mainly on tubulose particles and Dane particles, and it is a component of the HBV outer capsid antigen. The preS2 protein possesses stronger antigenicity than the HBsAg; moreover, it also possesses strong antigenic determinants for T and B cells

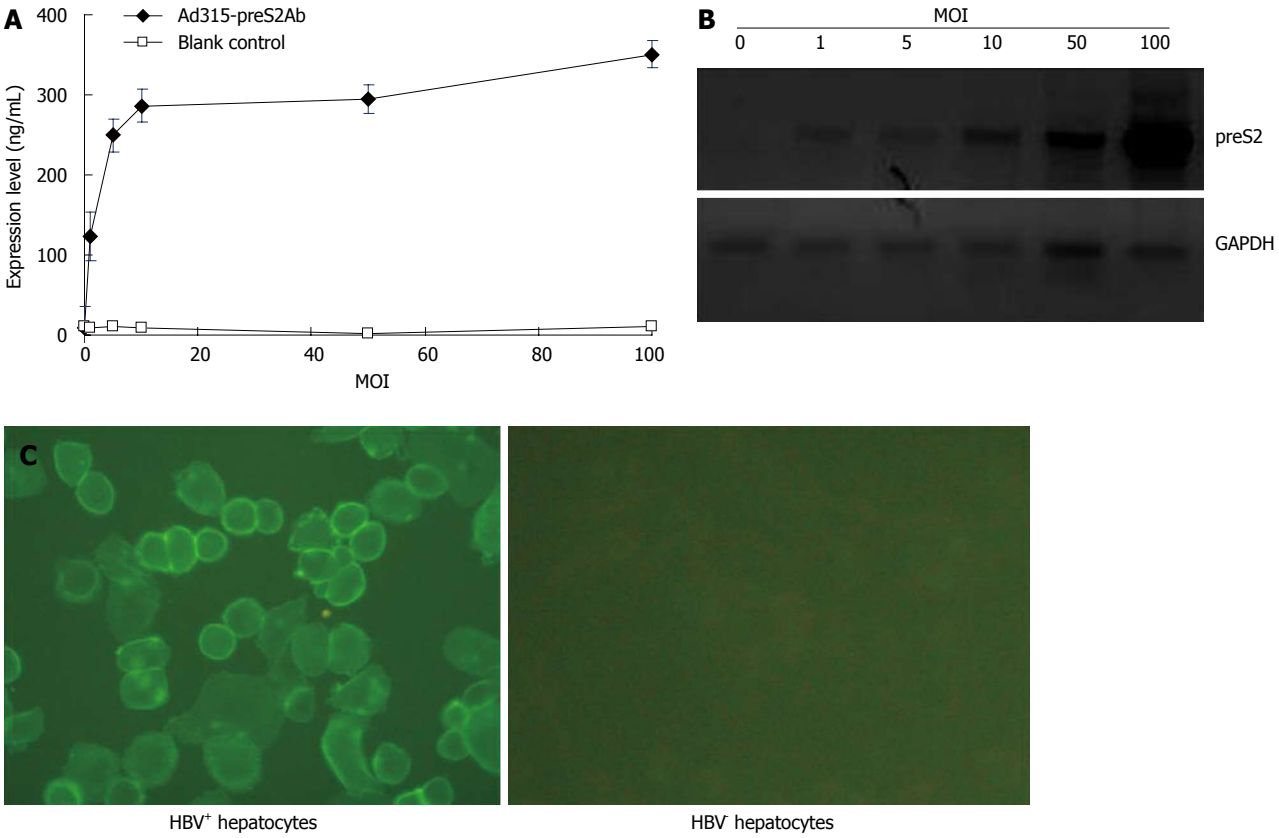

Figure 1 Expression and identification of the Ad315-preS2Ab-mediated preS2Ab. A: ELISA results show that the expression levels of the preS2Ab increase in the supernatants of Ad315-preS2Ab-infected L02 cells with increases in MOI; B: Western blotting shows that the expression of preS2Ab is high at an MOI of 100 pfu/cell. GAPDH is used as the loading control; C: The expressed preS2Ab in the supernatant of Ad315-preS2Ab-infected L02 cells recognizes liver cells from HBV transgenic Imprinting Control Region (ICR) mice as shown by a strong immunofluorescent reaction (left). Liver cells of normal ICR mice do not show labeling (right) (× 200). ELISA: Enzyme linked immunosorbent assay; HBV: Hepatitis B virus; GAPDH: Glyceraldehyde-3-phosphate dehydrogenase; MOI: Multiplicity of infection.

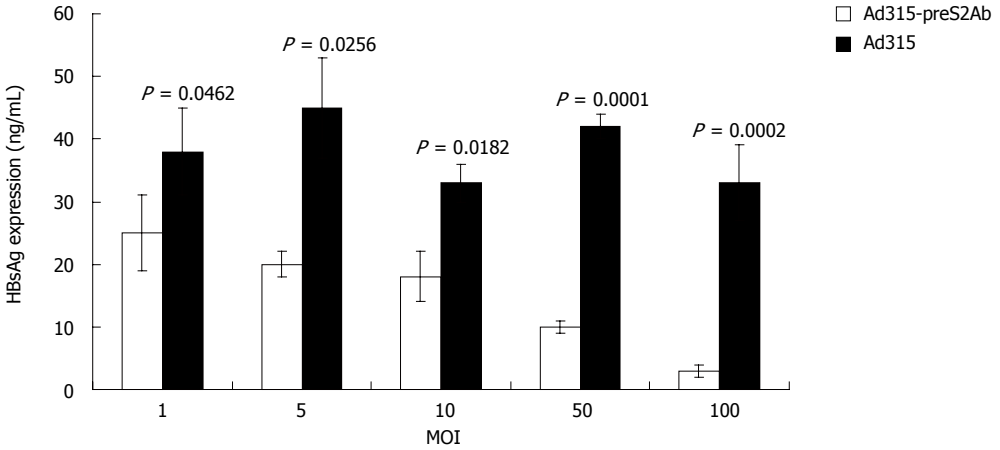

Figure 2 Inhibitory effects of the Ad315-preS2Ab-mediated preS2Ab against hepatitis B virus infection. ELISA results show HBsAg secretion in the supernatants of L02 cells infected with Ad315-preS2Ab. The inhibition of HBV infections increases with increasing Ad315-preS2Ab MOIs, as shown by decreases in HBsAg ($P < 0.05$). Cells infected with the Ad315 blank vector show no inhibitory effects against HBV infection. ELISA: Enzyme linked immunosorbent assay; HBV: Hepatitis B virus; HBsAg: Hepatitis B surface antigen; MOI: Multiplicity of infection.

and plays important roles in virus infection, assembly, replication and stimulation of the immune reaction[4,5]. preS2 protein has binding sites for polymerized human serum albumin (pHSA), which possesses determinants for binding with liver cell receptors. Therefore, HBV can enter liver cells by binding to pHSA; this ability is an important reason for the hepatotropism of HBV[6]. It has been found that the strong antigenicity of preS2 can induce immune responses during HBV infection and cause production of the preS2Ab. This antibody can help eliminate HBV and prevent the virus from entering normal liver cells[7]. Therefore, using an antibody against

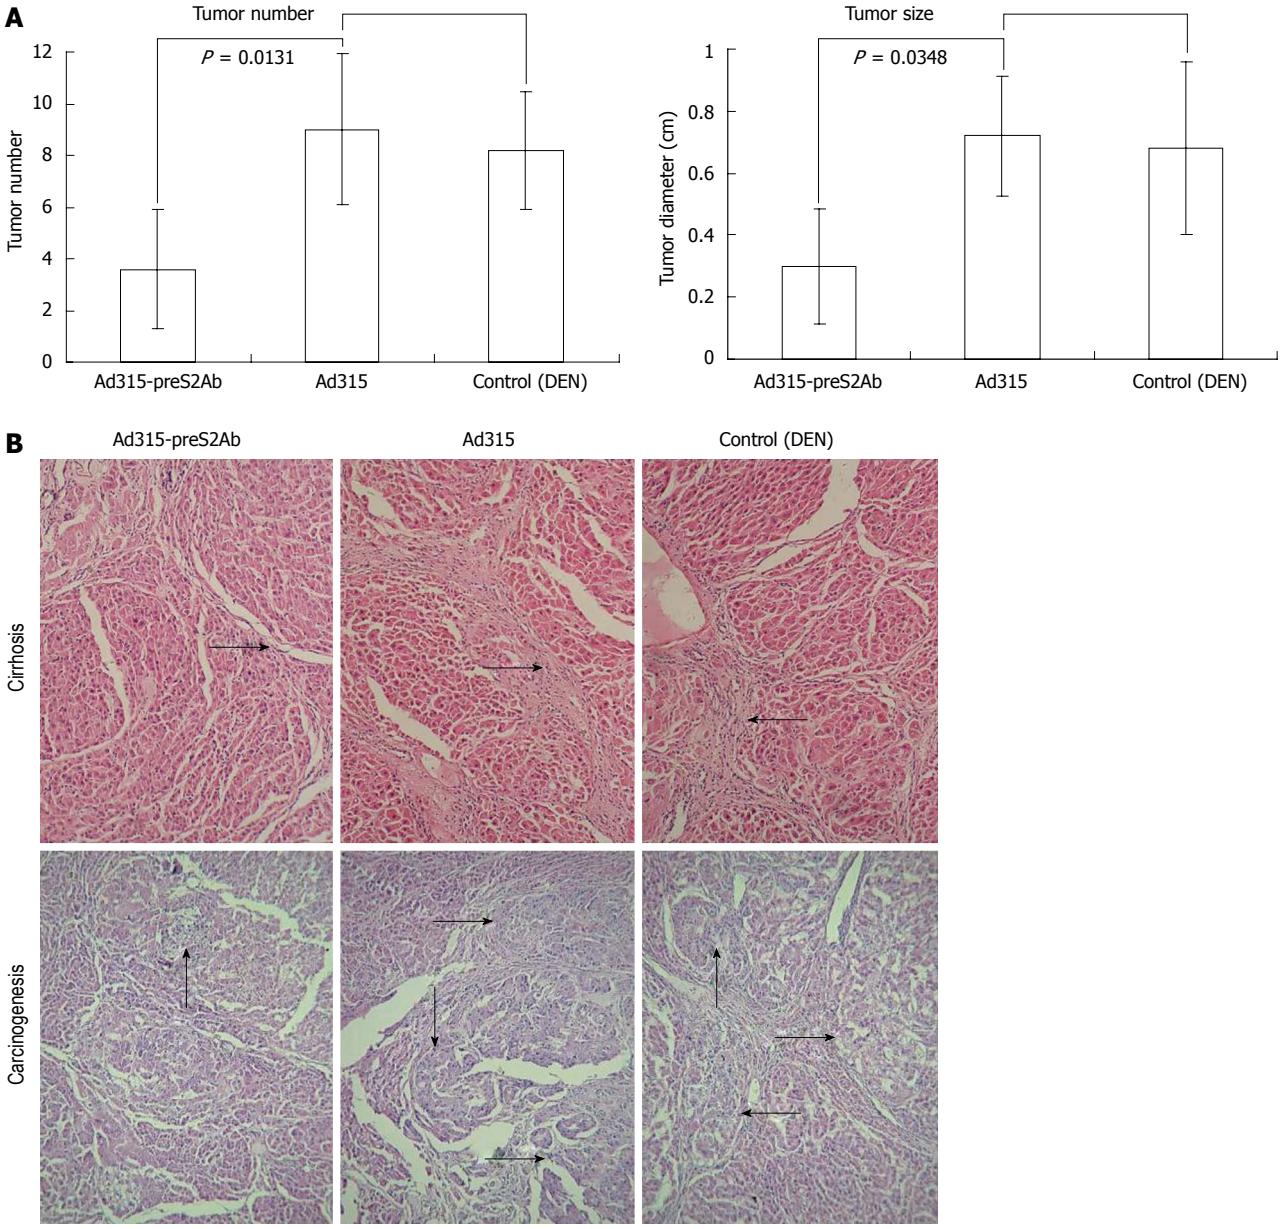

Figure 3 Ad315-preS2Ab effectively inhibited diethylnitrosamine-induced hepatic cirrhosis and carcinogenesis in hepatitis B virus transgenic mice. A: Ad315-preS2Ab-mediated preS2Ab expression demonstrates significant inhibitory effects against diethylnitrosamine-induced hepatic cirrhosis and carcinogenesis in HBV transgenic mice, as shown by significantly fewer (left panel) and smaller cancerous nodes (right panel) ($P < 0.05$); B: Pathological findings show that animals in the Ad315-preS2Ab group have a lesser degree of cirrhosis (upper panel, HE, × 100; arrows: proliferated fibrous septa) as well as fewer and smaller cancerous nodes (lower panel, HE, ×100; arrows: cancerous nodes) compared with the two control groups. HBV: Hepatitis B virus; HE: Hematoxylin and eosin. DEN: Diethylnitrosamine.

Table 1 Serum levels of alanine transaminase and aspartate transaminase in hepatitis B virus transgenic mice

Index	Non-virus control (IU/L)	Blank control (DEN) (IU/L)	Ad315 (IU/L)	Ad315-preS2Ab (IU/L)
Alanine transaminase	47.2 ± 9.4	300.8 ± 76.4	316.4 ± 41.1	167.2 ± 57.4[a]
Aspartate transaminase	118.6 ± 29.5	465.6 ± 156.4	477.4 ± 76.9	239.0 ± 94.7[b]

Data are expressed as the mean ± SD for 5 serum samples in every group. [a]$P = 0.0141$ and [b]$P = 0.0243$ when comparing the treatment samples to the alanine transaminase and aspartate transaminase levels of the diethylnitrosamine -treated blank control group. DEN: Diethylnitrosamine.

the HBV protein to block HBV infection and replication is an important strategy for preventing and treating HBV infection and hepatocellular carcinogenesis.

Hepatitis B immunoglobulin has been shown to be effective in preventing maternal-infant vertical transmission and HBV recurrence after liver transplantation; however, the immunoglobulin has limited sources and is expensive and nonspecific. Additionally, it has an unsatisfactory neutralization effect and may carry pathogens. Artificially-expressed HBsAg antibodies and gene therapy can overcome these shortcomings, indicating a bright future for HBV prevention and treatment. Presently, the best-studied genetically-engineered antibodies

are the small molecular antibodies, which mainly include Fab, ScFv, dsFv and single-domain antibodies. These small antibodies have the advantages of low molecular weight, high permeability, and easy construction and expression[8,9]. However, their low molecular weights also result in a short half-life period *in vivo*, making it difficult for them to reach effective concentrations in the blood. This limitation greatly restricts their clinical applications. Moreover, small molecular antibodies have no Fc segment, which is known to play important roles in the therapeutic effects of antibodies. Currently, there are a dozen monoclonal antibodies which have been used in clinical settings, and even more have been tested in clinical trials[10-12].

To overcome these barriers, we constructed an adenoviral vector carrying the full-length humanized HBV *preS2Ab* gene and examined its expression and inhibitory effects on HBV infection. We also examined the effects of the antibody on the carcinogenesis of HBV-positive liver cells. There are many advantages to gene therapy with adenoviral vectors. The adenoviral particles are stable, and the virus genome rarely undergoes rearrangement, so the inserted genes are kept unchanged after continuous passage of the virus. In addition, the virus genome is easily manageable, and adenovirus can be produced on a large scale. Moreover, adenovirus vectors can infect both dividing and non-dividing cells, and they can be used to transfect pulmonary cells, liver cells, bone cells, blood vessels, muscle cells, and central nervous system cells. Finally, these vectors can be used to achieve high expression of exogenous genes[13-16]. For these reasons, adenoviral vectors have been increasingly used for gene therapy. Additionally, related studies have yielded impressive achievements in China and in other parts of the world. The adenoviral vector constructed by Kim *et al*[17] permanently improved hyperlipidemia in mice, with the induced protein expression lasting for 2.5 years. In a rat hemophilia model, the adenoviral vector constructed by Reddy *et al*[18] continuously expressed factor Ⅷ for more than 9 mo. These findings demonstrate the advantages of adenoviral vectors and indicate a bright future for adenoviral vectors in gene therapy.

In the present study, we successfully constructed an Ad315-preS2Ab vector carrying the full-length *preS2Ab* genes and used this vector to infect L02 liver cells. The production of the *preS2Ab* increased with increases in the MOI of the Ad315-preS2Ab. The expressed preS2Ab recognized liver cells from HBV transgenic ICR mice, as shown by strong immunofluorescent reactions, demonstrating that the Ad315-preS2Ab-mediated preS2Ab possesses a satisfactory binding affinity for the corresponding antigen. We also found that the Ad315-preS2Ab-mediated preS2Ab could efficiently decrease the level of HBsAg in L02 cells infected with the sera of HBV patients, indicating that the expressed *preS2Ab* can inhibit HBV infection and replication. Our *in vivo* study showed that the administration of Ad315-preS2Ab could alleviate hepatic cirrhosis and decrease the number and size of cancerous nodes induced by DEN in HBV transgenic ICR mice, suggesting that Ad315-preS2Ab has an inhibitory effect against hepatocellular carcinogenesis. Our *in vivo* experiment also demonstrated that Ad315-preS2Ab can decrease ALT and AST levels in mouse sera and protect hepatic function in HBV transgenic mice.

In this study, we attempted to establish a complete antibody gene therapy expression system for the prevention and treatment of HBV infection and HBV-associated hepatocellular carcinogenesis. This study will pave the way for gene therapies for HBV infection and HCC.

COMMENTS

Background

Hepatitis B virus (HBV)-associated hepatocellular carcinoma (HCC) remains a severe threat to human health. Genetically engineered monoclonal antibodies that are specific to HBV envelope antigens are a promising approach for the treatment of recurrent HBV infection. However, full-length antibodies with large molecular weights have low permeability, and small-molecule antibodies have relatively low affinity and specificity for antigens, which affects the efficacy of these antibodies in the clinic.

Research frontiers

An adenoviral vector carrying the HBV preS2 antibody genes can express the humanized HBV preS2 antibody with high and stable efficiency to overcome the limitations of antibody permeability, affinity and specificity.

Innovations and breakthroughs

By encoding the full-length preS2 antibody genes, the Ad315-preS2Ab adenovirus efficiently expressed the HBV preS2 antibody in L02 liver cells, inhibiting HBV infection and replication. Administration of Ad315-preS2Ab could protect hepatic function, alleviate hepatic cirrhosis and suppress hepatocellular carcinogenesis in diethylnitrosamine-treated HBV transgenic mice.

Applications

The preS2 antibody gene therapy may provide a novel approach for inhibiting HBV infection and decreasing the incidence of HCC.

Terminology

HBV encodes an outer membrane protein, preS2, which binds to polyalbumin and helps HBV gain entry into liver cells *via* albumin receptors. This study demonstrates that the adenovirus-expressed preS2 antibody can block preS2, which then prevents or minimizes HBV infection to inhibit HBV-associated hepatocellular carcinogenesis.

Peer review

This is an interesting paper describing the inhibition of HBV infection and subsequent carcinogenesis using a vector carrying the anti-HBV Ab gene.

Abstract

AIM: To further investigate the important role of store-operated calcium channels (SOCs) in rat hepatocytes and to explore the effects of SOC blockers on hepatic ischemia-reperfusion injury (HIRI).

METHODS: Using freshly isolated hepatocytes from a rat model of HIRI (and controls), we measured cytosolic free Ca^{2+} concentration (by calcium imaging), net Ca^{2+} fluxes (by a non-invasive micro-test technique), the SOC current (I_{SOC}; by whole-cell patch-clamp recording), and taurocholate secretion [by high-performance liquid chromatography and 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide assays].

RESULTS: Ca^{2+} oscillations and net Ca^{2+} fluxes mediated by Ca^{2+} entry *via* SOCs were observed in rat hepatocytes. I_{SOC} was significantly higher in HIRI groups than in controls (57.0 ± 7.5 pA *vs* 31.6 ± 2.7 pA, $P < 0.05$) and was inhibited by La^{3+}. Taurocholate secretion by hepatocytes into culture supernatant was distinctly lower in HIRI hepatocytes than in controls, an effect reversed by SOC blockers.

CONCLUSION: SOCs are pivotal in HIRI. SOC blockers protected against HIRI and assisted the recovery of secretory function in hepatocytes. Thus, they are likely to become a novel class of effective drugs for prevention or therapy of HIRI patients in the future.

Key words: Hepatocyte; Hepatic ischemia-reperfusion injury; Store-operated calcium channel; Non-invasive micro-test technique

INTRODUCTION

Hepatic ischemia-reperfusion injury (HIRI) can occur in the liver in response to a wide variety of clinical and operative situations, including hemorrhagic shock, severe hepatic trauma, major hepatic resection/biliary tract operation with temporary clamping of hepatoduodenal ligament, and liver transplantation. HIRI can lead to liver dysfunction (or even loss of function) and thus represents a major therapeutic challenge.

The pathogenesis of HIRI is multifactorial, involv-

ing hepatocellular Ca^{2+} overload[1-5], release of excessive oxygen-derived free radicals[6,7], inflammatory cytokines[8], Kupffer cell activation[9,10], impairment of microvessels[11], apoptosis and nuclear factor kappa B[12]. Ca^{2+} are an important second messenger, and variation of intracellular Ca^{2+} concentration ($[Ca^{2+}]_i$) has been shown to play an important role in regulating a variety of physiological processes in both excitable and non-excitable cells. $[Ca^{2+}]_i$ is a key factor in HIRI because it is integral to the activation of calcium-dependent phospholipases, nucleases and proteases, as well as oxidative phosphorylation. $[Ca^{2+}]_i$ may be increased by the release of Ca^{2+} from the endoplasmic reticulum (ER) (or sarcoplasmic reticulum) or by the stimulation of Ca^{2+} entry from the extracellular space through calcium channels that are voltage-dependent (VDCC), receptor-operated or store-operated[13,14]. Hepatocytes are not known to express VDCC[15-18] but do express store-operated calcium channels (SOCs)[19-21]. The concept of a "store-operated calcium current" was proposed in 1986[22] and has been developed more fully during the past 20 years, including the identification of putative SOC proteins[14]. However, whether SOCs are the dominant Ca^{2+} channel in hepatocytes is uncertain. Studies have found that hepatocellular Ca^{2+} overload plays a crucial role in HIRI, although the exact mechanism of this overload remains unknown, as does the role of SOCs. Thus, no effective drugs currently exist for the prevention or therapy of HIRI.

In the present study, we aim to (1) further verify the importance of SOCs in rat hepatocytes, (2) explore the effects of SOCs in HIRI, and (3) investigate the potential use of SOC blockers for protecting against HIRI.

MATERIALS AND METHODS

Animals and materials

Male Sprague-Dawley rats weighing 180-200 g were obtained from the Beijing Laboratory Animal Research Center (Beijing, China). RPMI 1640 medium, penicillin, streptomycin, Fluo-4-acetoxymethyl (Fluo-4/AM), and poly-D-lysine were purchased from Invitrogen (United States). Collagenase Ⅳ, 4-(2-hydroxyethyl)-1-piperazineethanesulfonic acid (HEPES), adenosine-triphosphate (ATP), CsOH, Taurocholic acid sodium salt, and SKF-96365 were obtained from Sigma (United States). Ethylene glycol tetraacetic acid (EGTA) was obtained from Solarbio (Beijing, China). Vasopressin, noradrenalin, thapsigargin (TG), and 2-aminoethoxydiphenyl borate (2-APB) were obtained from Merck KcaA (Darmstadt, Germany). Methanol and acetonitrile were of chromatographic grade; all other reagents were of reagent grade.

Fresh isolation of rat hepatocytes

Rat hepatocytes were enzymatically isolated using a modification of the method originally reported by Seglen[23]. Briefly, rats were anesthetized with chloral hydrate (320 mg/kg body weight) and heparinized (1.5 U/g body weight) *via* intraperitoneal injection. A midline laparotomy was performed, and portal vein and the inferior vena cava were cannulated. The liver was initially perfused for 10 min at a constant flow rate of 25-30 mL/min with a modified oxygenated Ca^{2+}-/Mg^{2+}-free Hanks solution containing (in mmol/L) NaCl, 120; KCl, 5; Na_2HPO_4, 0.2; KH_2PO_4, 0.2; $NaHCO_3$, 25; EGTA, 0.5; and glucose, 5 (pH 7.4), followed by perfusion with Type Ⅳ collagenase (0.2 g/L) in RPMI 1640 medium for 10 min. The solution was gassed with 100% O_2 and warmed to 37 ℃. After the perfusions, the three large cephalad lobes of the liver were excised and minced in a Ca^{2+}-/Mg^{2+}-free Hanks solution at 0 ℃, before being filtered through a 74-μm nylon mesh and washed three times by centrifugation at 50 × *g* for 2 min. The isolated hepatocytes (1×10^5/mL; 85%-95% viability assessed by trypan blue exclusion) were incubated in RPMI 1640 medium containing 10% fetal bovine serum, penicillin (100 U/mL), and streptomycin (100 μg/mL) at 37 ℃ in a 95% air-5% CO_2 incubator for 1 h.

Rat model of hepatic ischemia-reperfusion injury

The rat model of HIRI was established according to our previously reported procedure[10]. Briefly, under anesthesia and heparinization (as above), a midline laparotomy was performed in each rat, and an atraumatic clip was used to interrupt the arterial and portal venous blood supply to the three cephalad lobes. After 20 min of hepatic ischemia, the clip was removed, and the liver was reperfused for a further 40 min. Sham-operated control animals were treated in an identical manner, with the omission of vascular occlusion.

Calcium imaging

Isolated hepatocytes were seeded in 35-mm glass-bottomed dishes (MatTek, Ashland, MA, United States), pretreated with poly-D-lysine (500 μg/mL in borate buffer) for 2 h, and loaded with 6.7 μmol/L fluo-4/AM (Figure 1A) in a recording solution containing (in mmol/L) NaCl, 116; KCl, 5.4; $CaCl_2$, 1.8; $MgCl_2$, 0.8; glucose, 5.05; and HEPES, 10 (pH 7.4) for 30 min at 37 ℃, followed by three washes in PBS and a 15-min incubation to allow de-esterification of fluo-4/AM before imaging. A Lambda DG-4 high-speed wavelength switcher (Sutter Instruments, Novato, CA, United States) was used for fluo-4 excitation at 480 nm, and a cooled charge-coupled device (CCD) camera (CoolSnap FX, Roper Scientific, Princeton, NJ, United States) was used for image acquisition. Meta Fluor imaging software (Universal Imaging, Downingtown, PA, United States) was used for hardware control, image acquisition and image analysis. Typically, time-lapse recording of Ca^{2+} signals in hepatocytes was performed for a 2-min control period before and for a 10-min period after the application of the different agonists. The CCD camera was used with a sampling rate of one frame per 2 s, a typical exposure time of 50-350 ms, and a 4 × 4 binning. Quantitative measurements of changes of $[Ca^{2+}]_i$ were obtained by subtracting the average background intensity (measured in cell-free regions) from the average cellular fluo-4 fluorescence intensity values. Changes in $[Ca^{2+}]_i$ for each hepatocyte were then represented by the changes in

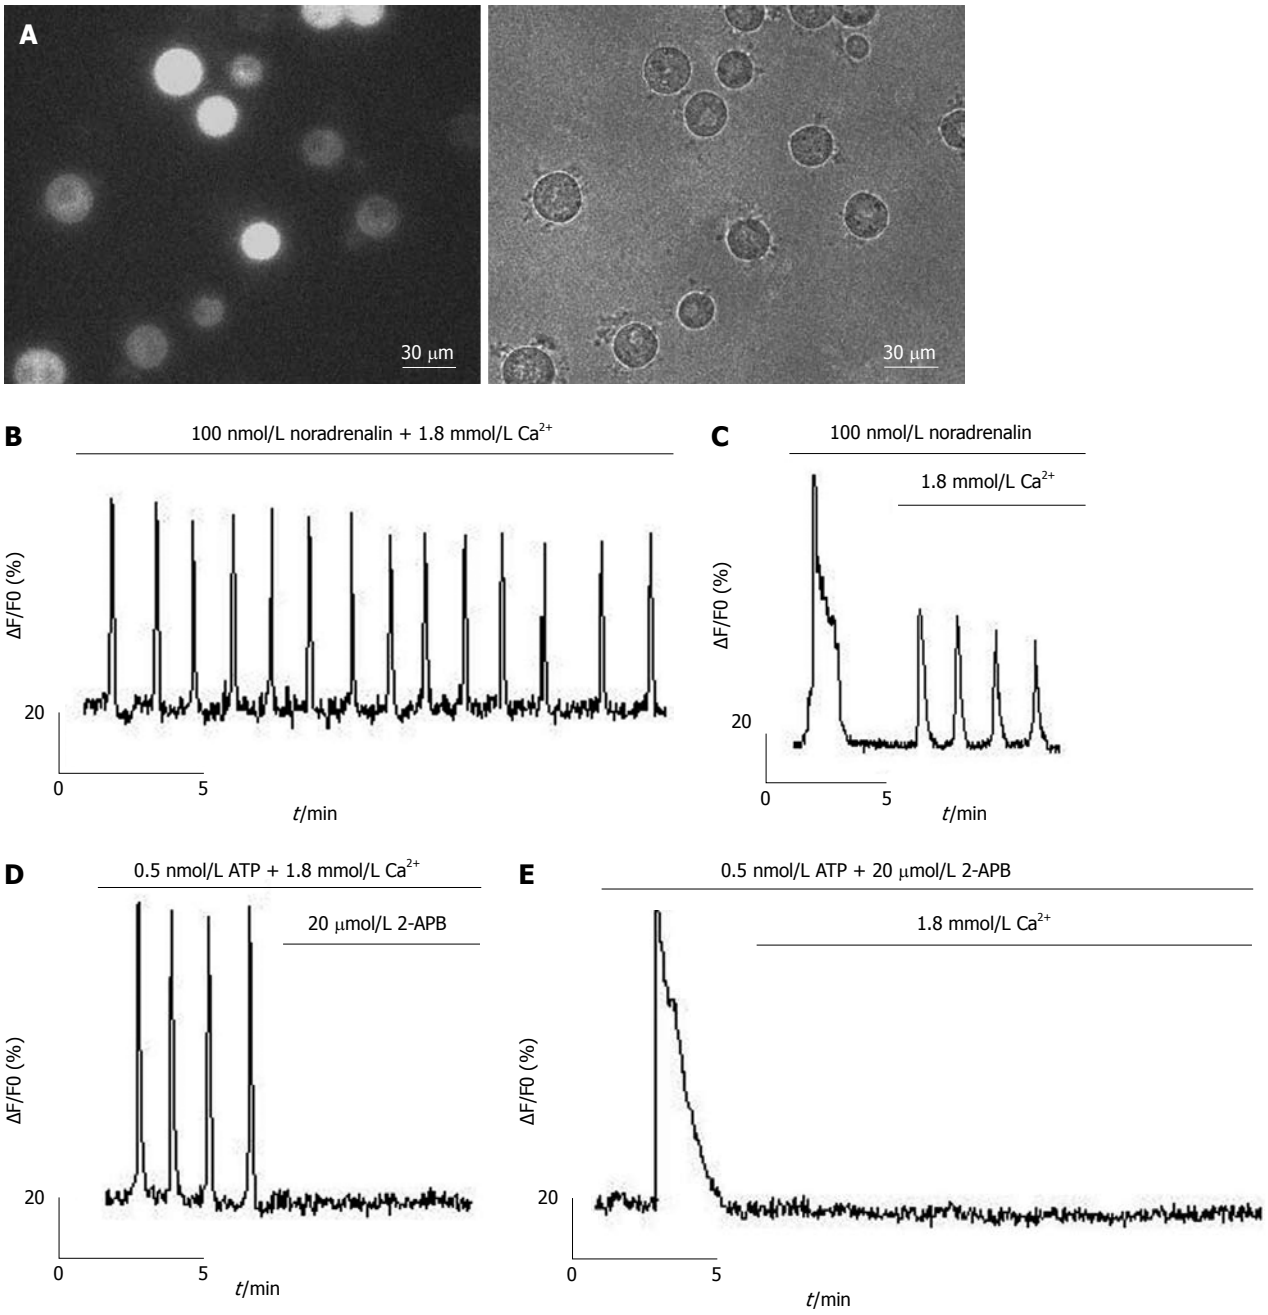

Figure 1 Agonist-induced Ca^{2+} oscillations are inhibited by blocking Ca^{2+} entry in freshly isolated rat hepatocytes. Traces show Ca^{2+} oscillations in freshly isolated rat hepatocytes, with the abscissa axis as time (min), the vertical axis as Fluo-4 fluorescence intensity (ΔF/F0), which demonstrates the changes of [Ca^{2+}]i. The number of hepatocytes measured is indicated by "*n*". A: The fluorescence image (left) and microscopic image (right) of freshly isolated hepatocytes loaded with fluo-4/acetoxymethyl. Ca^{2+} oscillations were initiated by 100 nmol/L noradrenaline in the presence (B, *n* = 27) or absence (C, *n* = 16) of extracellular Ca^{2+}. Ca^{2+} oscillations induced by 0.5 nmol/L adenosine-triphosphate were inhibited by 20 μmol/L 2-APB in the presence (D, *n* = 14) or absence (E, *n* = 11) of extracellular Ca^{2+}. 2-APB: 2-aminoethoxydiphenyl borate.

relative fluo-4 fluorescence ($\Delta F/F0$), where $F0$ was the baseline intensity obtained from the 2-min control period.

Non-invasive micro-test technique measurement

Measurements of net Ca^{2+} influx were performed using the non-invasive micro-test technique (NMT) system (BIO-IM, YoungerUnited States, Amherst, MA, United States) using our previously reported methods[24]. Briefly, isolated hepatocytes plated in a 35-mm dish (Figure 3A) were washed three times with a measuring solution containing (in mmol/L) NaCl, 136; KCl, 2.7; $CaCl_2$, 0.2; KH_2PO_4, 1.5; Na_2HPO_4, 8; and glucose, 5.05 (pH 7.4). The electrode was controlled to move with an excursion of 10 μm at a programmable frequency in the range of 0.3-0.5 Hz, chosen to minimize mixing of the bathing saline. To construct the microelectrodes, borosilicate micropipettes (2-4 μm aperture, XYPG120-2, Xuyue Sci. and Tech. Co., Ltd., Beijing, 100080, China) were silanized with tributylchlorosilane, and the tips were filled with calcium ionophore I-cocktail A (Sigma-Aldrich, St Louis, MO, United States). An Ag/AgCl wire electrode holder (XYEH01-1) was inserted in the back of the electrode to make electri-

cal contact with the electrolyte solution. Only electrodes with Nernstian slopes between 25 and 29 mV/decade were used. Ca^{2+} fluxes were calculated by Fick's law of diffusion: $J_0 = -[D \times (dC/dX)]$, where J_0 represents the net Ca^{2+} flux (in μmol per cm per s), D is the self-diffusion coefficient for Ca^{2+} (in cm^2/s), dC is the difference value of Ca^{2+} concentrations between the two positions, and dX is the 10 μm excursion over which the electrode moved in our experiments. Data and image acquisition, preliminary processing, control of the three-dimensional electrode positioner, and stepper-motor-controlled fine focus of the microscope stage were performed with imFlux® software.

Whole-cell patch-clamp recording

Whole-cell patch-clamp recording was performed at room temperature (22-25 ℃) using a computer-based patch-clamp amplifier (EPC-10, HEKA Electronics, Lambrecht/Pfalz, Germany) and PatchMaster software (HEKA Electronics, Lambrecht/Pfalz, Germany). The isolated hepatocytes were plated in 35-mm dishes and washed with a standard external solution containing (in mmol/L) NaCl, 140; CsCl, 4; $MgCl_2$, 2; $CaCl_2$, 10; glucose, 10; and HEPES, 10 (pH 7.4; adjusted with NaOH). In experiments investigating Ba^{2+} current in rat hepatocytes, the NaCl, $MgCl_2$ and $CaCl_2$ in the external solution were replaced with 30 mmol/L of NaCl and 100 mmol/L of $BaCl_2$. An automatic micropipette puller (Model P-97, Sutter Instruments, Novato, CA, United States) was used to pull the electrodes from the borosilicate glass. The pipette resistance was between 3 and 5 MΩ when filled with the pipette solution containing (in mmol/L) CsCl, 15; Cs glutamate, 135; EGTA, 10; and HEPES, 10 (pH 7.2; adjusted with CsOH). In all whole-cell patch-clamp recording experiments, recording started when the series resistance dropped to below 20 MΩ. After achieving the whole-cell configuration, voltage ramps of 50 ms duration, spanning a range from -100 mV to +100 mV, were immediately delivered from a holding potential of 0 mV every 2 s. Acquired currents were filtered at 2.9 kHz and sampled at 20 kHz. Capacitative currents were determined and compensated automatically by the EPC-10 amplifier. The voltages were corrected for a liquid-junction potential of 17 mV (estimated by JPCalc). The maximum SOC current (I_{SOC}) at -100 mV was applied for statistical analysis.

High-performance liquid chromatography analysis

High-performance liquid chromatography (HPLC) analysis was performed using LC-10A apparatus (Shimizu, Japan) with an Agilent Extend C18 column (416 × 150 mm, 5 μm). To create a fine chromatographic separation of taurocholate, a 60:20 (v/v) mixture of mobile phases A (methanol and acetonitrile 1:1) and B (5 mmol/L KH_2PO_4; pH 3.0) was employed. A constant flow rate of 0.8 mL/min was used for the quantitative determination of the standard solutions and test samples, with a column temperature of 30 ℃, sample size of 10 μL, and detection wavelength of 210 nm. Freshly isolated hepatocytes were plated at 5×10^5/mL in 35-mm dishes at 37 ℃ in a 95% air-5% CO_2 incubator and treated with 100 μmol/L 2-APB, 100 μmol/L La^{3+} or 10 μmol/L SKF-96365 for 12 h. The culture solution was collected and centrifuged at 500 rpm for 3 min. The supernatant was stored frozen at -20 ℃. Supernatant (0.5 mL) was mixed intensively with 0.5 mL of absolute ethyl alcohol, incubated in a 60 ℃ water bath for 3 min, then centrifuged at 3000 rpm for 10 min. Supernatant (0.3 mL) was run through Sep-PAK columns, washed with 10 mL of pure water, and eluted with 3 mL of methanol. This eluent was placed in a water bath (70 ℃), blown dry with nitrogen, and mixed with 3 mL of mobile phase.

3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide assay

The method of Mosmann[25] for the 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay was used with modifications for functional studies on cell survival/injury. Freshly isolated rat hepatocytes in 1640 medium were plated at 5×10^4 cells per well in 96-well microtiter plates. After 3 h, various SOC antagonists were added, or 0.025% (v/v) dimethylsulfoxide (DMSO) vehicle was used as control. Cells were cultured after drug exposure for 12 h at 37 ℃ in a 95% air-5% CO_2 incubator, which is sufficient time for evidence of drug-induced cell death, increased cell survival or dampened cell injury to become apparent, as quantified by the generation of the formazan product from the MTT substrate. The number of hepatocytes per microtiter well was proportional to the absorbance of the solubilized formazan. After addition of MTT (5 mg/mL, 20 μL) and incubation for 4 h, the medium was discarded. MTT formazan crystals were then resolubilized with 150 μL DMSO per well and mixed on a microshaker for 10 min. The plate was then read immediately on a scanning multiwell spectrophotometer (Termo Multiscan MK3, Finland) at 490 nm.

Statistical analysis

IGOR Pro 5.01 software (Wavemetrics, Portland, OR, United States) was used to conduct an analysis of whole-cell patch-clamp recording data. All current traces were corrected for leak currents. Mageflux (www.xuyue.net/mageflux) was used to process the data of the NMT. All results are expressed as mean ± SD. Statistical significance of differences between test samples and controls was determined using the Student's *t*-test. *P* values less than 0.05 were considered statistically significant differences.

RESULTS

Ca^{2+} entry mediates Ca^{2+} oscillations in freshly isolated rat hepatocytes

Using calcium imaging, we investigated the relationship between Ca^{2+} entry and Ca^{2+} oscillations in hepatocytes under physiological conditions, with Ca^{2+} oscillations induced by noradrenaline in freshly isolated hepatocytes (Figure 1B). We found that Ca^{2+} oscillations were dependent on Ca^{2+} entry through the plasma membrane (Figure

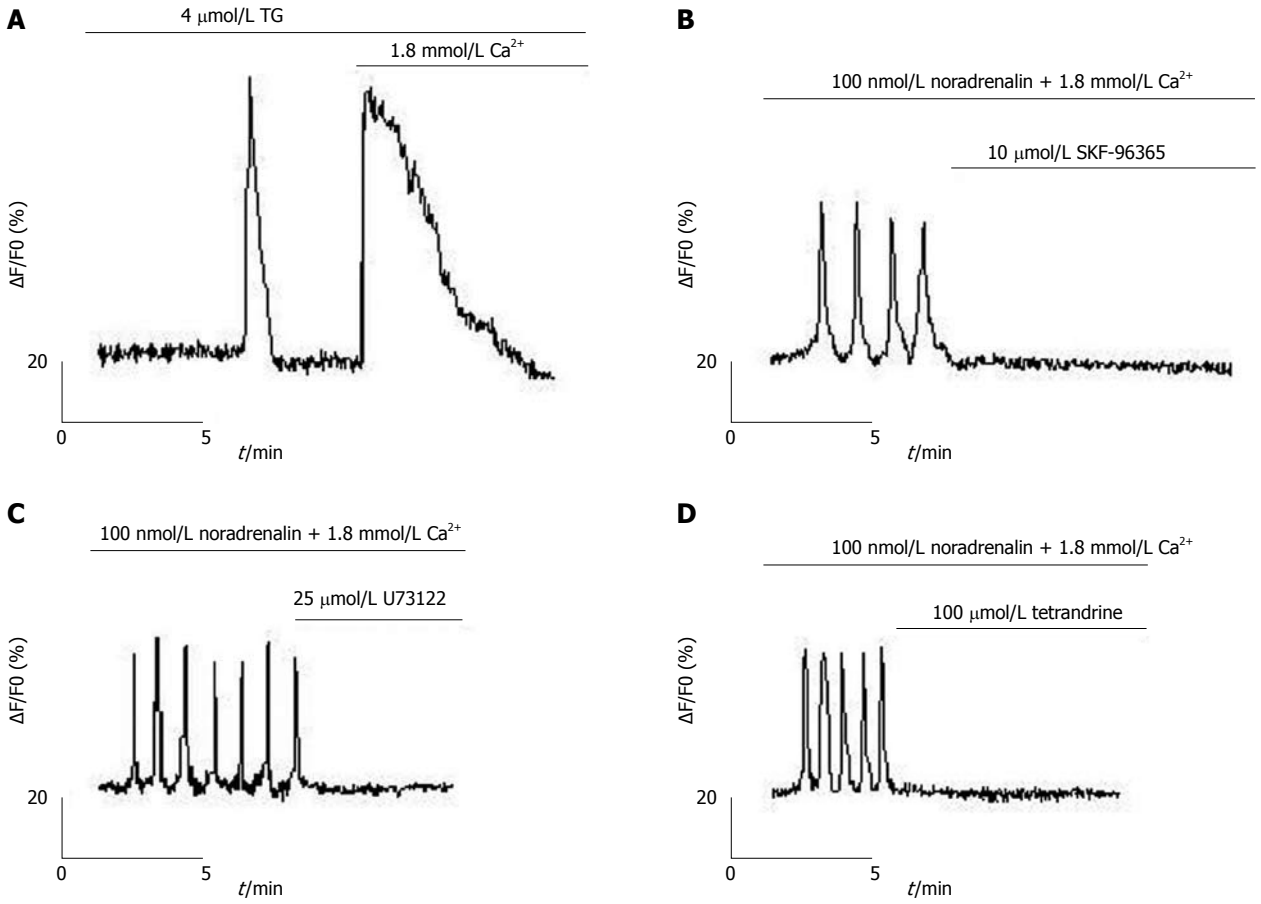

Figure 2 Store-operated calcium channel blockers inhibit Ca^{2+} oscillations of freshly isolated hepatocytes. A: Ca^{2+} stores were depleted with 4 μmol/L thapsigargin (TG), causing two peaks, the first being Ca^{2+} released from endoplasmic reticulum (ER), and the second peak being Ca^{2+} entry through the plasma membrane (n = 16); B: 10 μmol/L SKF-96365 inhibited Ca^{2+} oscillations (n = 12); C: 25 μmol/L U73122 inhibited Ca^{2+} oscillations (n = 10); D: 100 μmol/L tetrandrine inhibited Ca^{2+} oscillations (n = 10).

1C). Ca^{2+} oscillations induced by ATP (activator of phospholipase C) were inhibited by 2-APB[26] (an inhibitor of SOCs, Figure 1D), which inhibited entry of extracellular Ca^{2+} but not release of Ca^{2+} from ER (Figure 1E).

SOCs mediate Ca^{2+} entry in freshly isolated hepatocytes

TG, an inhibitor of sarcoplasmic/endoplasmic reticulum Ca^{2+} pump (SERCA)[27], was used to passively eliminate hepatocyte ER calcium stores, evoking two peaks (one for the release of Ca^{2+} from the ER and the other for the subsequent Ca^{2+} entry through the plasma membrane; Figure 2A). Ca^{2+} oscillations in freshly isolated rat hepatocytes could be inhibited by 2-APB (Figures 1D and E). Moreover, Ca^{2+} oscillations could also be inhibited by the SOC inhibitor, SKF-96365[28,29] (Figure 2B), the phospholipase C (PLC) inhibitor, U73122[27], and the phospholipase A2 inhibitor, tetrandrine[30,31] (Figures 2C and D).

Ca^{2+} influx in hepatocytes measured by NMT

Using NMT, maximum net Ca^{2+} flux values of 1163 ± 279 nmol cm^{-2} s^{-1} were recorded in freshly isolated hepatocytes (n = 10; Figure 3B). Nifedipine (an inhibitor of VDCCs; 10 μmoL/L) had no effect on net Ca^{2+} fluxes (1108 ± 298 nmol cm^{-2} s^{-1}) (n = 15; Figure 3C). The SOC blockers, SKF-96365, La^{3+} and 2-APB (all at 100 μmol/L), reduced net Ca^{2+} flux to 738 ± 195, 452 ± 136, and 84 ± 37 nmol cm^{-2} s^{-1}, respectively (Figures 3D, E and F). These effects of SOC blockers on net Ca^{2+} fluxes were statistically significant (Figure 3G).

Whole-cell patch-clamp recordings of I_{SOC} in freshly isolated rat hepatocytes

IP_3 (10 μmol/L) and EGTA (10 mmol/L) induced currents in hepatocytes (Figures 4A and C), with a reverse potential of approximately +40 mV. The current-voltage relationship revealed that the currents were inwardly rectifying (Figures 4A, B and C). To further characterize the recorded currents, we substituted Ca^{2+} for Ba^{2+} in the external solution. The Ba^{2+} current (79 ± 7 pA) was significantly greater than the Ca^{2+} current (32 ± 1 pA, t = 5.683, P = 0.002), but much more transient, dropping to a lower level after less than 2 min (Figures 4D and E). The SOC inhibitor, 2-APB (100 mmol/L), inhibited the current induced by 10 mmol/L EGTA (Figure 4F). An inhibitor of non-selective cation channels, A9C (10 μmol/L), did not influence current magnitude (Figure 4G).

SOCs are involved in hepatocellular Ca^{2+} overload in HIRI

Hepatocellular Ca^{2+} overload is thought to play a cru-

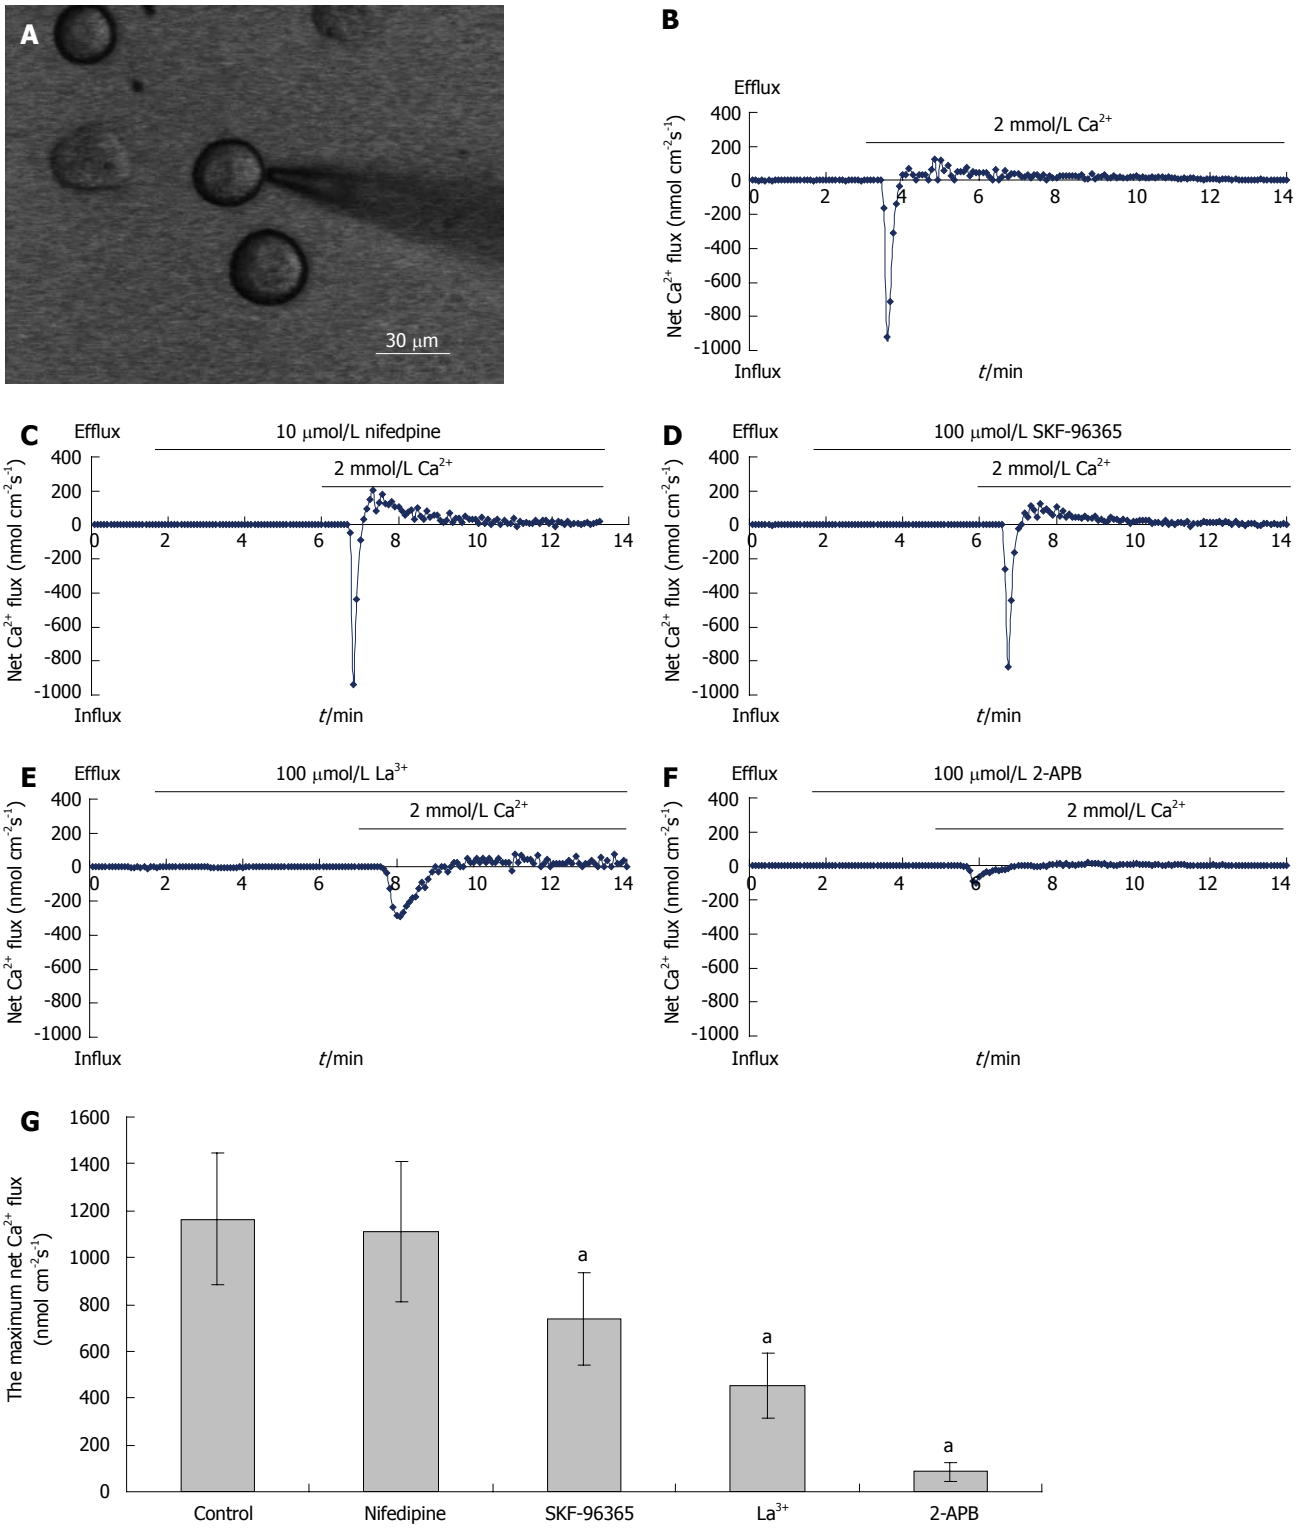

Figure 3 Ca^{2+} flux in freshly isolated hepatocytes. cial role in HIRI. To explore the effects of SOCs on the pathogenesis of HIRI, SOC currents induced by 10 mmol/L EGTA in hepatocytes were recorded in the HIRI and control groups (Figures 5A, B and C). The results showed that the SOC currents were significantly increased (from 31.6 ± 2.7 pA in controls to 57.0 ± 7.5 pA in HIRI hepatocytes; $t = 2.682$, $P = 0.036$; Figure 5D). In HIRI hepatocytes, the fully developed inward currents were rapidly reduced by 100 μmol/L La^{3+} (Figures 5E and F).

Evaluation of SOC blocker cytotoxicity

To explore the influence of SOC blockers on cell survival,

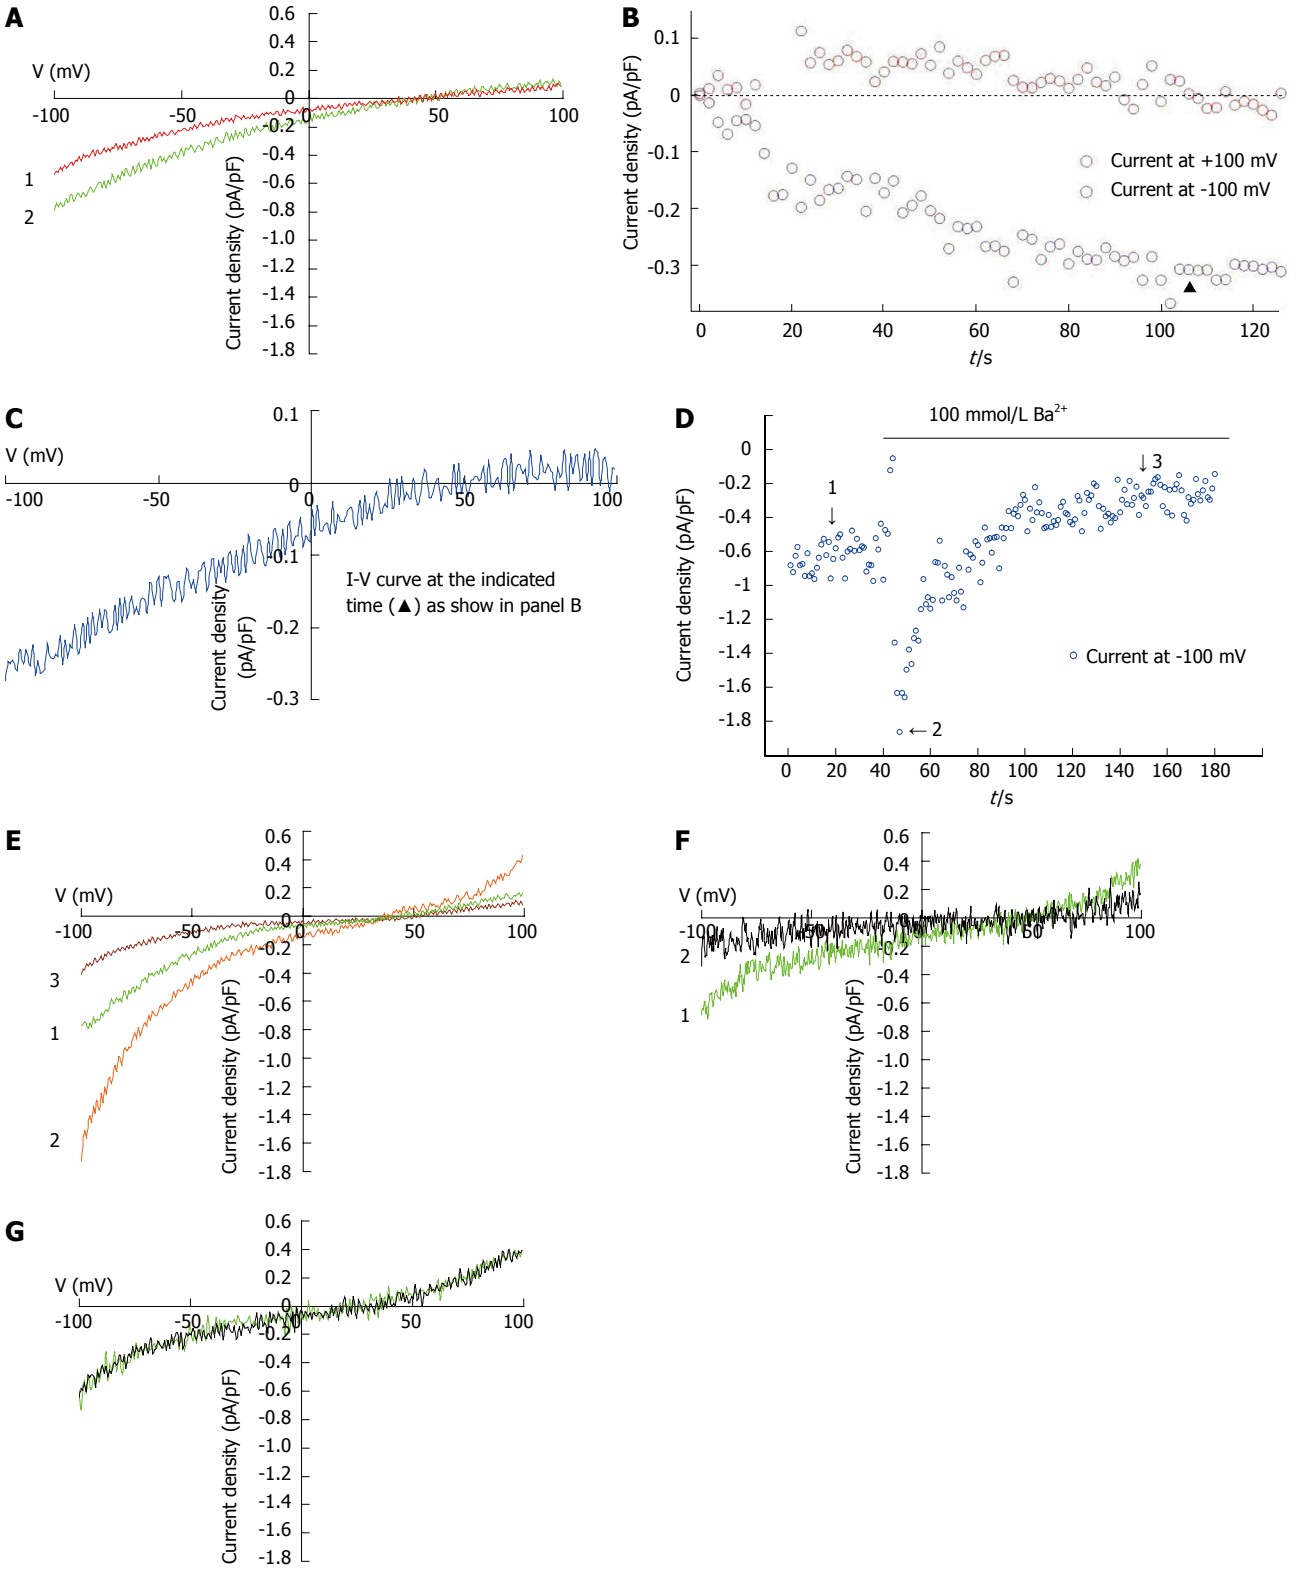

Figure 4 Store-operated calcium currents in freshly isolated hepatocytes. A: I-V curves of I_{SOC} induced by 10 μmol/L IP_3 and 10 mmol/L ethylene glycol tetraacetic acid (EGTA) in hepatocytes, recorded with the voltage ramps from -100 mV to +100 mV, showing the beginning of whole-cell patch-clamp recording (red) and reaching peak current (green) (n = 14); B: Time course of I_{SOC} development, taken at holding potentials of -100 mV and +100 mV for inward and outward currents, respectively; C: I-V curves of I_{SOC} obtained by subtraction of baseline from peak current (the red and green sections of the trace, respectively, as described in A), at the time marked "▲" in B; D: Currents induced by 10 mmol/L EGTA following replacement of Ca^{2+} with Ba^{2+} in the external solution (n = 6); E: I-V curves at the three time points indicated by the arrows in panel D: 1, SOC was fully activated by 10 mmol/L EGTA in the pipette solution, 2, 3, The amplitude of I_{SOC} at -100 mV as a function of time when the external solution was replaced by a solution containing 100 mmol/L Ba^{2+} and no Ca^{2+} or Mg^{2+} for the period indicated in D (n = 6); F: Currents stimulated by 10 mmol/L EGTA. The green trace shows the instantaneous current density-voltage relationship in the range of -100 mV to +100 mV obtained in response to a voltage ramp at the time when inward current was fully developed. The black trace was obtained in response to the presence of 100 μmol/L 2-APB (n = 6); G: Effect of 10 μmol/L A9C on current induced by 10 mmol/L EGTA. The green trace shows the instantaneous current density-voltage relationship in the range of -100 mV to 100 mV obtained in response to a voltage ramp at the time when inward current is fully developed. The black trace was obtained in the presence of 10 μmol/L A9C (n = 5).

HIRI: Hepatic ischemia-reperfusion injury.

we performed an MTT assay. No significant differences ($P > 0.05$) in cell survival rate (compared with normal hepatocytes) were observed after exposure to the DMSO vehicle or either of the two SOC inhibitors (Figure 6A). In addition, there was a similar survival rate in HIRI hepatocytes compared with hepatocytes pretreated with 0.025% (v/v) DMSO or 100 μmol/L La^{3+}. However, the average optical absorbance value in hepatocytes pretreated with 100 μmol/L 2-APB (0.79 ± 0.05) was higher than in untreated HIRI hepatocytes (0.69 ± 0.04), $P = 0.027$, $t = 4.047$ (Figure 6B). Compared with normal hepatocytes, HIRI hepatocytes incurred cell damage ($P = 0.029$, $t = 2.882$; Figure 6C).

HIRI hepatocytes recover their secretory function in the presence of SOC inhibitors

To explore the influence of SOCs on the secretory function of hepatocytes, taurocholate secretion by hepatocytes was investigated using HPLC analysis. Taurocholate concentration in the culture supernatant of normal hepatocytes was 38.58 ± 7.35 μg/mL (n = 6), notably higher than in hepatocytes treated with 100 μmol/L 2-APB (28.85 ± 8.18 μg/mL; $P < 0.05$, n = 6), 100 μmol/L La^{3+} (27.76 ± 9.86 μg/mL; $P < 0.05$, n = 6) or in HIRI hepatocytes (19.9 ± 3.8 μg/mL; $P < 0.05$, n = 6) (Figure 7). Interestingly, 100 μmol/L2-APB, 100 μmol/L La^{3+} and 10 μmol/L SKF-96365 could reverse the taurocholate level

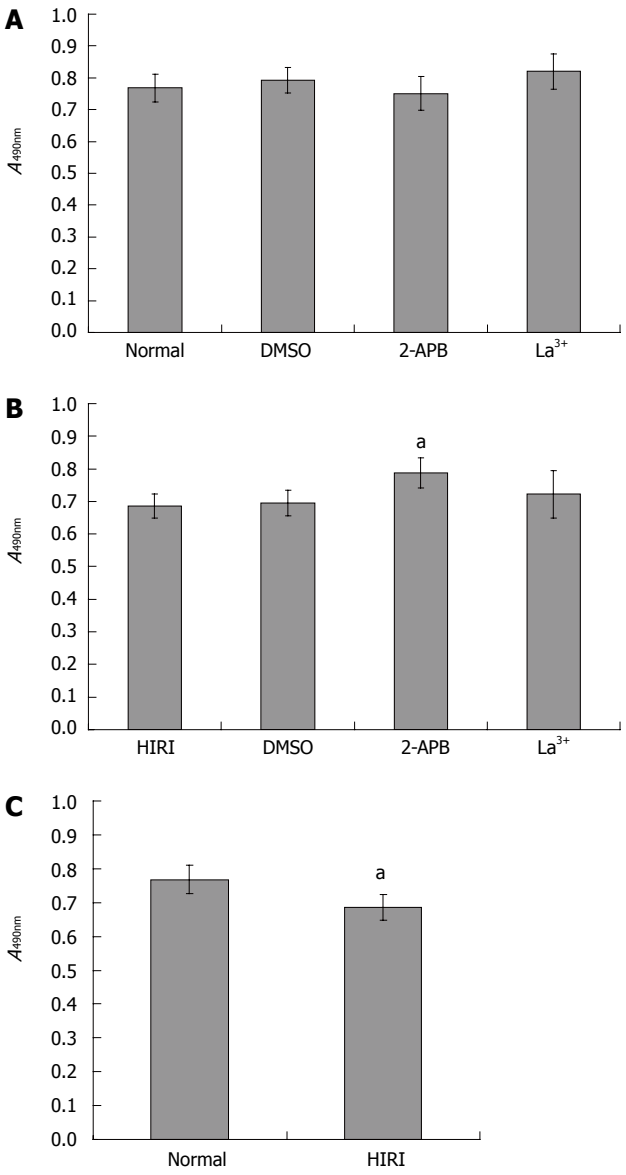

Figure 6 Effects of store-operated calcium channel blockers on cell survival or injuries of normal and hepatic ischemia-reperfusion injuried hepatocytes. A: MTT assay of normal hepatocytes alone or co-cultivated with 0.025% (v/v) DMSO, 100 μmol/L 2-APB, or 100 μmol/L La^{3+} (n = 4), the cell survival rate is not significantly different (P > 0.05); B: MTT assay of HIRI hepatocytes alone or cocultivated with 0.025% (v/v) DMSO, 100 μmol/L 2-APB or 100 μmol/L La^{3+} (n = 4), the average optical absorbance value in hepatocytes pretreated with 100 μmol/L 2-APB (0.79 ± 0.05) was higher than in untreated hepatocytes (0.69 ± 0.04), ^{a}P = 0.027; C: Compared with normal hepatocytes, HIRI hepatocytes incurred cell damage (n = 4), ^{a}P = 0.029. HIRI: Hepatic ischemia-reperfusion injury; 2-APB: 2-aminoethoxydiphenyl borate; DMSO: Dimethylsulfoxide; MTT: 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide.

to 27.42 ± 4.74, 26.58 ± 6.67 and 25.52 ± 7.30 μg/mL, respectively, in HIRI hepatocytes, $P < 0.05$, $n = 6$.

DISCUSSION

Ca^{2+} is an important second messenger, and intracellular Ca^{2+} has been shown to play an important role in regulating a variety of physiological processes in both excitable and non-excitable cells. Intracellular Ca^{2+} homoeostasis and signaling are achieved by the complex interplay of Ca^{2+} fluxes among the cytosol, the intracellular stores and the extracellular environment[32]. SOCs are a family of Ca^{2+}-permeable ion channels expressed by most cells. The signal for the activation of SOCs is a decrease in the Ca^{2+} concentration in the ER. Stimulation of a diverse range of plasma membrane receptors converges on and activates phosphatidylinositol 4,5-bisphosphate (PIP_2) hydrolysis by PLC, which results in the generation of diacylglycerol and inositol 1,4,5-trisphosphate (IP_3) and the subsequent activation of (1) Ca^{2+} release from the ER *via* IP_3 receptors and (2) Ca^{2+} influx across the plasma membrane[33]; Stromal interaction molecule 1 (STIM1, identified as the ER Ca^{2+} sensor) and Orai1 (a pore-forming subunit of SOCs) have both been shown to be necessary for SOC function[33,34]. However, the role of SOCs during physiological activation of primary cells has not been extensively investigated, and there is little information on the roles of STIM and Orai proteins in primary cells. Our previous study found that functional interactions among STIM1, Orai1 and TRPC1 (transient receptor potential canonical 1) contribute to activating I_{SOC} in human liver cells[35], but whether SOCs are the dominant Ca^{2+} channels in hepatocytes is still uncertain, and the nature of the Ca^{2+} influx mechanism following hormone activation of hepatocytes is controversial. For this purpose, we aimed to investigate the relationship between Ca^{2+} entry and Ca^{2+} oscillations in hepatocytes under physiological conditions and found that Ca^{2+} oscillations could be induced with noradrenaline, vasopressin or ATP, each of which stimulates PLC and activates both Ca^{2+} influx and intracellular Ca^{2+} release.

NMT is a novel non-invasive technology for obtaining dynamic information on specific ionic/molecular activities on material surfaces. This technique incorporates various temporal and spatial resolution domains from other traditional methods, and its three-dimensional measurement capability enables us to observe the physiological characteristics of biological phenomena that would be difficult or even impossible with other techniques[36]. To date, Ca^{2+}, H^+, K^+, Cl^-, NO^-, Mg^{2+}, Cd^{2+}, Al^{3+}, and O_2 have been detected as sensors for ionic/molecular species. Our previous study found that NMT was a powerful tool for ion channel research, allowing us to demonstrate the existence of TRPC1-dependent Ca^{2+} channels in HL-7702 cells[24]. In the present study, we used NMT to investigate net Ca^{2+} fluxes in freshly isolated hepatocytes and showed that SOC inhibitors (2-APB, SKF-96365 and La^{3+}), but not a VDCC inhibitor (nifedipine), blocked net Ca^{2+} fluxes, suggesting that these Ca^{2+} movements are mediated in rat hepatocytes by SOCs and not by VDCC.

To further explore the importance of SOCs in rat hepatocytes, we used calcium imaging and whole-cell patch-clamp recording techniques to separately measure the cytoplasmic-free Ca^{2+} concentrations and the SOC-mediated currents in rat hepatocytes. An increase in cytoplasmic free Ca^{2+} could be induced by TG-mediated passive depletion of ER calcium stores and subsequent Ca^{2+} entry through the plasma membrane. The Ca^{2+} oscillations could be antagonized by inhibitors of SOCs

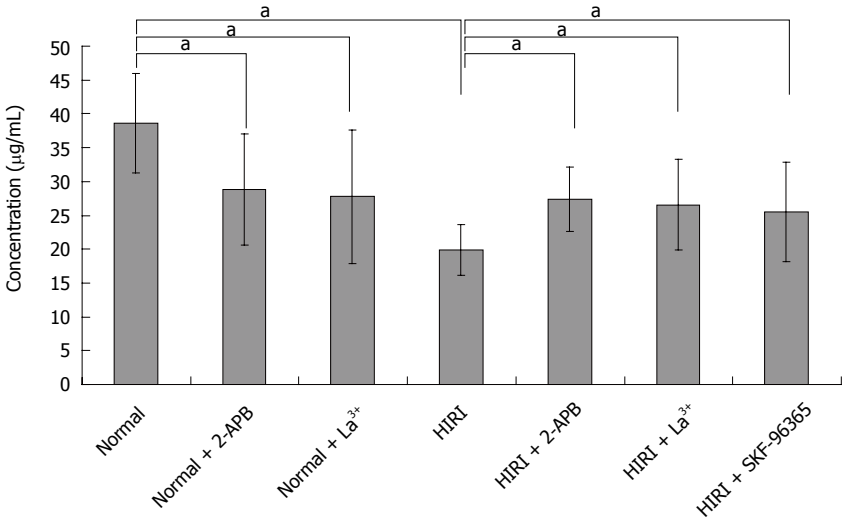

Figure 7 Taurocholate measurements in hepatic ischemia-reperfusion injuried hepatocytes. Bar graph of taurocholate secreted by hepatocytes is distinctly higher in the supernatant of cultured normal hepatocytes (38.58 ± 7.35 μg/mL, n = 6) than for cells after exposure to 100 μmol/L 2-APB (28.85 ± 8.18 μg/mL, $^aP < 0.05$, n = 6), 100 μmol/L La^{3+} (27.76 ± 9.86 μg/mL, $^aP < 0.05$, n = 6) or HIRI hepatocytes (19.92 ± 3.75 μg/mL, $^aP < 0.05$, n = 6). Whereas 100 μmol/L 2-APB, 100 μmol/L La^{3+} and 10 μmol/L SKF-96365 could respectively reverse the taurocholate level to 27.42 ± 4.74, 26.58 ± 6.67 and 25.52 ± 7.30 μg/mL in HIRI hepatocytes, $^aP < 0.05$, n = 6. HIRI: Hepatic ischemia-reperfusion injury; 2-APB: 2-aminoethoxydiphenyl borate.

(2-APB, SKF-96365), PLC (U73122) and phospholipase A_2 (tetrandrine). Tetrandrine, commonly used to inhibit activation of phospholipase A_2 by receptors, is a potent blocker of I_{SOC} in H4IIE cells. We recorded prominent inwardly rectifying currents that could be inhibited by 2-APB. A transient increase in inward current was observed when 100 mmol/L Ba^{2+} was applied to the bath (Figure 4D) which had similar amplitude and time-course properties to those of inward currents activated by IP_3- or TG-mediated depletion of intracellular Ca^{2+} stores. Such changes in the presence of Ba^{2+} have previously been shown for I_{SOC} in H4IIE liver cells[37]. These results are consistent with the properties of SOCs and, thus, strongly implicate the importance of SOCs in rat hepatocytes.

HIRI can occur during hemorrhagic shock or hepatic surgery, including trauma, tumor resection and transplantation. For the purpose of exploring the mechanism of HIRI in hepatocytes and searching for novel and clinically effective therapies, the investigation was based on validating the effects of SOCs on the pathogenesis of HIRI. A rat model of HIRI described previously by Yoshiyuki Yabe[38] that closely reflects the clinical condition was modified and established[10]. In these hepatocytes, SOC currents were significantly increased relative to controls, suggesting that SOCs could be involved in hepatocellular Ca^{2+} overload in HIRI.

The main function of hepatocytes is to synthesize and secrete bile acid; hence, we measured taurocholate secretion as an indicator of the ability of SOC inhibitors to protect and restore hepatocyte function. Taurocholate secretion in normal hepatocytes was significantly reduced in the presence of 100 μmol/L 2-APB and 100 μmol/L La^{3+}, consistent with results from previous experiments[39]. Taurocholate secretion was also reduced in HIRI hepatocytes compared with normal cells. In these cells, non-toxic concentrations (as assessed by MTT assay) of 2-APB (100 μmol/L) or La^{3+} (100 μmol/L) actually reversed this suppression of taurocholate secretion, suggesting that inhibition of SOCs may have beneficial effects on HIRI hepatocyte health and function. Indeed, a concentration of 100 μmol/L 2-APB is in agreement with a previous report[40] that found that 2-APB is (1) effective in preventing HIRI *in vivo* when administered *via* the portal vein before ischemia and (2) able to attenuate HIRI when administered following an ischemic event. Thus, 2-APB could be a potential therapy for HIRI and offers a reduced side-effect profile compared with La^{3+}, a nonspecific blocker of SOCs that also inhibits other types of Ca^{2+} channels on hepatocytes, which is consistent with previous findings by Nathanson *et al*[41]. Concerns about the safety of lanthanides have not yet been completely resolved, and drugs with greater specificity for SOCs are required if a blocker of SOCs is to be considered a viable therapeutic target for HIRI.

The physiological process of bile secretion has been studied extensively. It is believed that natural bile acids exist in the plasma which are taken up actively and concentrated, then secreted, at the biliary pole of the hepatocyte. The mechanisms whereby SOC inhibitors reversed the restraint of taurocholate secretion during HIRI in hepatocytes were determined by regulating the process of hepatic secretion, which is closely related to cytosolic Ca^{2+}. Hepatocytes, as classic epithelial cells, are highly polarized, with transport directed from the sinusoidal or basolateral domain of the cell to the canalicular or apical domain in the physiological process of bile secretion. There is evidence that taurolithocholate and lithocholate increase the cytosolic Ca^{2+} concentration and, meanwhile, inhibit bile secretion[42].

HIRI that occurs in liver surgery, which can be caused by hepatic vascular clamping during partial hepatectomy or liver transplantation, frequently results in cellular dam-

age and organ dysfunction. Although considerable investigation has provided insight into these processes of HIRI in the liver, the exact mechanisms remain only partially elucidated. Intracellular signaling pathways that have been identified as participating in the complex pathophysiological process correlating with cell necrosis and apoptosis involve: the release of multiple bioactive substances, such as cytokines, platelet activating factor (PAF), and free radicals; Ca^{2+}-mediated intracellular Ca^{2+} overload; sinusoidal endothelial cells; Kupffer cells; and cholangiocytes. Among the significant factors is cytosolic Ca^{2+}[43]. Considering that the increase of cytosolic Ca^{2+} appears in the earlier period of intracellular cascade of HIRI[44], the SOC blockers may be effective protective therapies for this clinical problem.

In our experimental results, we found that the sequence of taurocholate secretion seems to be: normal hepatocytes > normal hepatocytes + inhibitors of SOCs > HIRI hepatocytes + inhibitors of SOCs > HIRI hepatocytes. It is known that cellular secretion can not take place without the participation of Ca^{2+}; accordingly, combined with the observation above, we classified the influential factors of cellular secretion roughly into two parts: SOCs and some unknown factors related to Ca^{2+} overload. Owing to blockage of Ca^{2+} influx induced by SOCs, taurocholate secretion was decreased in both normal and HIRI hepatocytes, which is consistent with earlier published papers by other researchers. However, there are unknown factors other than the inhibition of the Ca^{2+} channels that could induce Ca^{2+} overload; thus, it is reasonable that the secretion of HIRI hepatocytes pretreated with 2-APB was lower than normal hepatocytes. We concluded that HIRI hepatocytes recover part of their secretory function in the presence of SOC blockers.

Taken together, our results confirm the important role of SOCs in rat hepatocytes and point toward the effects of SOCs on HIRI. SOC inhibitors could protect against HIRI and are helpful in the recovery of secretory function in hepatocytes. We conclude that SOCs play a vital role in the pathogenesis of HIRI and that SOC blockers could represent a novel class of drugs for the prevention or therapy of HIRI.

COMMENTS

Background

Hepatic ischemia-reperfusion injury (HIRI) can occur in the liver in a wide variety of clinical and operative situations. The pathogenesis of HIRI is multifactorial, such as in hepatocellular Ca^{2+} overload. Variation of $[Ca^{2+}]_i$ has been shown to play a significant role. $[Ca^{2+}]_i$ may be increased by releasing Ca^{2+} from the endoplasmic reticulum (ER) or the sarcoplasmic reticulum (SR), or by stimulating Ca^{2+} entry from the extracellular space through calcium channels. The concept of a "store-operated calcium current" was proposed in 1986, and store-operated calcium channels (SOCs) may play an important role in HIRI.

Research frontiers

SOCs have been verified as Ca^{2+} channels in that the amount of Ca^{2+} in the stores controls the extent of Ca^{2+} influx in non-excitable cells. However, the role of SOCs in rat hepatocytes has not been elucidated. In this study, the authors have further confirmed the important role of SOCs in rat hepatocytes and the pivotal role of SOCs in HIRI. SOC blockers assisted the recovery of secretory function in HIRI hepatocytes.

Innovations and breakthroughs

This is the first study that has used multiple experimental techniques to investigate the important role of SOCs in rat hepatocytes from various perspectives, particularly with regard to pathogenesis of HIRI on the cellular electrophysiological level and on the clinical research level.

Applications

Cytoplasmic Ca^{2+} overload could result in injury of liver cells. By understanding the role of SOCs in HIRI, this research will contribute to clarifying the exact mechanism of hepatocellular Ca^{2+} overload. This study might indicate a novel class of effective drugs targeted at Ca^{2+} channels in hepatocytes for the prevention or therapy of HIRI.

Terminology

SOCs are a family of Ca^{2+}-permeable ion channels expressed by most cells. The signal for the activation of SOCs is a decrease in the $[Ca^{2+}]_i$ in the ER Ca^{2+} store, and this is believed to be an essential and ubiquitous component of Ca^{2+}-signaling pathways. Stimulation of a diverse range of plasma membrane receptors converges on and activates phosphatidylinositol 4,5-bisphosphate hydrolysis by phospholipase C and results in the generation of diacylglycerol and IP_3, which induces the subsequent activation of Ca^{2+} release from the ER *via* IP_3 receptors and Ca^{2+} influx across the plasma membrane. STIM1, identified as the ER Ca^{2+} sensor, and Orai1, as a pore-forming subunit of SOCs, have both been shown to be necessary for SOC function.

Peer review

This is a well conducted study with a clear objective and the data reflects the quality of the work by these investigators. Significance of the data from the study complies with the background objectives. All sections including Materials and Methods, Results, Discussion and References conform well to the style of the journal.
